Although the bearing in Figure 20 (top) is classified as a radial ball bearing, it has considerable thrust or axial-load capacity. The thrust capacity  $T$  can be increased by extending the races to sections  $ff$  so that the groove in the outer race is deeper on the left side and the groove in the inner race is deeper on the right side; some angular-contact bearings are made like this. If all of the load on a bearing is axial, an axial-thrust bearing can be used. This is simply two grooved washers with balls between them.

Ball bearings of the three basic types—radial, angular-contact, and thrust—are manufactured with either a single or a double row of balls. Radial bearings are also made with seals that retain the grease applied at the factory and exclude dirt and contaminants. Neither of the basic bearings has much tolerance for axial misalignment; in Figure 20 (top), for example, if the axes of the inner and outer races are not collinear within about plus or minus a quarter of a degree or less, then an additional load will be placed on the balls. Self-aligning bearings have especially designed outer races, and they permit axial misalignment up to about plus or minus two degrees or more without loading the balls.

Special types of ball bearings are made for specific industrial applications. A number of special ball bearings, for example, are made to satisfy the particular needs of the automobile manufacturers. Among these are bearings designed especially for front-wheel service, where the heavy radial and thrust loads imposed when turning corners may alternate or combine with the shock loads generated when driving over rough roads. These bearings are of the angular-contact type and are used in pairs, the larger of each pair being on the inside of the wheel hub. For ease of assembly and removal of the wheels, the outer races are press-fitted in the wheel hubs, while the inner races are separable, and easy push fits on the front axle. The correct running adjustment is obtained by means of a nut fitting a thread on the end of the axle that

is screwed in against the smaller (outside) inner race until the balls and races are in firm angular contact.

**Roller bearings.** These bearings have rollers instead of balls between the races. The rollers may be cylindrical, tapered, or spherical. Cylindrical roller bearings have rollers with a length to diameter ratio of about one and run in cylindrical races, one of which may have retaining shoulders; they cannot carry a thrust load. Needle bearings have long, small-diameter rollers and may be installed with or without retainers and with or without races. When no races are used, the surfaces on which the needles roll must be hardened.

Needle bearings cannot carry thrust loads, but they have the highest radial load capacity, for a given radial space, of all roller bearings. Since unguided needles have a tendency to skew, needle bearings without retainers are particularly suitable for oscillating loads and where space is limited, such as for the wrist-pin bearings in automobile pistons, and in universal joints.

Tapered roller bearings (Figure 20 [centre]) have rollers and races that are truncated cones with elements that would intersect at a common apex if extended; this is the basic requirement for pure rolling contact between conical surfaces. These bearings have a high load capacity and when used in opposed pairs can carry thrust loads in either direction. The races are separable and are axially positioned during assembly to preload the bearing or to provide axial looseness to permit free thermal expansion.

Tapered roller bearings are available with different cone angles and with one, two, or four rows of rollers. They are widely used in rolling mills, transmissions, worm and spiral bevel gear speed reducers, and machine tool spindles. In tapered-roller thrust bearings the rollers are arranged like the spokes of a wheel between two flat washers with tapered grooves.

Spherical roller bearings have either convex or concave rollers in both single and double rows. Some of the rollers are basically cylindrical rollers with curved instead of straight elements, while some are tapered with curved elements. All these bearings have a self-aligning ability obtained by grinding either the outer or inner race spherical. The most commonly used type of spherical roller bearing is the double-row bearing with convex rollers.

**Linear-motion rolling bearings.** If the cage of a cylindrical roller bearing were cut and stretched out flat, it would form a self-contained pack (cartridge) of rollers that could be inserted between flat surfaces, or "ways," on adjacent machine parts to reduce the friction of relative linear motion; linear-motion rolling bearings of the ladder type are constructed in a similar way. Since the cartridge moves relative to both the fixed and moving ways—as can be demonstrated by rolling a pencil between the palm of one's hand and a table—the distance that the moving body can move is limited by the extent of the rolling surfaces on both ways and the length of the cartridge. This disadvantage can be overcome by using a "recirculating" ball or roller bearing, which, when attached to either the fixed or moving body, rolls on the ways attached to the other body and permits a movement limited only by the length of the ways.

Ball bearings that permit both rotary and linear motion are available. One such bearing is used on the spindle of a machine tool that oscillates as it reciprocates. The balls are held loosely in holes in a cage in the form of a brass sleeve that is thinner than the diameter of the balls; this permits the balls to protrude and contact the spindle on the inside of the cage and the housing or a special sleeve on the outside.

**Service life.** At ordinary ambient temperatures and under a nonvarying load that causes no permanent deformation, a machine component can be expected to carry the load for an unlimited period; a statically loaded machine component is assumed to have an infinite life.

When subjected to a dynamic (fluctuating) load the service life of a machine part depends on the nature and magnitude of the repetitive load; in such a case, life is the number of times that the load cycle can be repeated before the part fails (becomes unserviceable). For some materials and certain types of loads there is a limiting

Endurance  
limit

stress (load per unit area) known as the endurance limit or fatigue limit; if the maximum stress is less than the endurance limit, the life of the part is assumed to be infinite. Since there is a practical limit to the number of times a test specimen can be loaded, it is customary to assume that the maximum stress a test specimen can carry without failure for 10,000,000 repetitions is the endurance limit.

For some nonferrous materials and for parts subjected to certain types of loads, there is no endurance limit; the life of all parts is limited and depends on the magnitude of the maximum load imposed during the cycle. The higher the load the less the number of load repetitions that can be tolerated; rolling bearings are in this category.

Ball and roller bearings become unserviceable when the load-carrying surfaces develop pits. This pitting, or spalling, is initiated by subsurface cracks caused by the high surface-contact pressures between the rolling elements and the races. Under a repetitive load the cracks spread to the surface and eventually, aided by the lubricant that gets squeezed into the crack, a flake of metal is peeled off. The ultimate fatigue failure of a rolling bearing is unavoidable, but the life of the bearing or number of revolutions that the bearing can make before flaking begins depends on the load.

No material is more uniform in composition nor more carefully heat-treated and hardened than the steel used for rolling bearings. Few other machine components are manufactured to higher standards of accuracy and finish; in some bearings the difference between ball diameters is maintained at less than 0.00005 inch (0.0013 millimetre). In spite of this, rolling bearings that are apparently identical and operate under identical conditions may have substantially different lives. In this respect they have a mortality curve and a life expectancy like human beings.

**Sliding-contact bearings.** These bearings, also known as plain bearings to distinguish them from ball and roller bearings, can be designed to carry either radial or thrust loads on shafting and to control linear motion between adjacent machine parts. On journal, or sleeve, bearings the inner member, or shaft, is the journal, while the outer member, or sleeve, is the bearing; journal bearings can carry radial loads only and are the most commonly used type of sliding bearing.

When the load is light and the motion intermittent or slow, a journal bearing may be run without a lubricant; with some bearing materials no lubricant is necessary. In most cases, however, a solid or fluid lubricant is used. The type of lubrication that these lubricants provide may be a dry film, a fully developed fluid film that separates the sliding surfaces completely, or boundary lubrication with some contact between the sliding surfaces.

**History.** Although it has been known for centuries that oil or grease reduces the friction between sliding surfaces, the two ways in which a fully developed fluid film can be established in a bearing were not discovered until the latter part of the 19th century. One of the exhibits at the Paris exposition in 1878 was a large metallic block mounted on four legs having flat feet resting on a steel plate. Oil was pumped down each leg to the feet, and sufficient pressure was built up to raise the block on a film of oil. The friction between the feet and the plate was so low that the heavy block could be easily pushed around. This was probably the first recorded example of a hydrostatic or externally pressurized bearing, but its significance was not immediately appreciated by engineers.

One of the most spectacular hydrostatic bearings was installed in the late 1930s to support the 500-ton (450,000-kilogram) Hale telescope in the observatory on Palomar Mountain, in California. To rotate the telescope on these bearings at the speed necessary to follow the stars requires only a small clock motor.

Oil film  
without  
pumping

The discovery of the conditions under which a fully developed oil film can be established in a bearing without an external pumping system was more or less accidental. In the 1880s, while testing railroad journal bearings, it was discovered that with a copious supply of oil the friction was surprisingly low and that extraordinarily high maximum pressures were built up in the oil film.

These phenomena were later studied, and, by making some simplifying assumptions, it was mathematically proved that these results were explainable on the basis of hydrodynamic action in a wedge-shaped fluid film.

In Figure 20 (bottom) the plate *AB* is moving to the left under a fixed plate having the profile *CD* and separated from it by a tapered fluid film. Because of the taper, a pressure is developed in the fluid film that depends on the viscosity (internal friction) of the fluid, the velocity of the plate, and the geometry of the bearing. Bearings in which a fully developed oil film is created within the bearing in this way are known as hydrodynamic bearings. Film thicknesses are in the range of 0.0005–0.001 inch (0.013–0.025 millimetre).

At standstill the shaft in a journal bearing rests on the bottom of the bearing. When the shaft starts rotating it climbs the wall of the bearing, and if the speed is sufficiently high a tapered wedge of pressurized fluid will form and push the shaft to the other side of the bearing, where it will float on a hydrodynamic film.

In 1896 it was accidentally discovered in the United States that a journal bearing could be adequately lubricated with air. An experimental rotor was found to operate on a film of air at speeds above 250 revolutions per minute, with practically no friction. On the basis of these experiments, it was concluded that the hydrodynamic principle could be used on thrust bearings for heavy machinery, which at that time were very unsatisfactory, and in 1910 a United States patent was issued on a tilting-pad thrust bearing in which the stationary element was an assemblage of several flat pie-shaped segments, or shoes, arranged in a circle and contacting a ring-shaped rotating element. The shoes were supported on fixed pivots and could tilt automatically to provide the tapered oil film. Because of the oil film, the new thrust bearing had lower friction losses and could tolerate higher unit pressures than the existing thrust bearings in which both the rotating and stationary members were flat surfaces and the bearing operated in a state of boundary lubrication.

When a fully developed oil film exists in a sliding bearing there is no metal-to-metal contact, and the bearing material does not affect the performance of the bearing. Bearings do start and stop, however, and some may have to operate with boundary lubrication or no lubricant at all for short periods. Under such conditions the bearing material is important; in practice, the selection of a suitable material is a necessary step in the design of all sliding bearings. The greatest contribution to the development of improved bearing materials was made by Isaac Babbitt, who in 1839 obtained a United States patent for a railroad journal box lined with a special alloy that was largely tin with small amounts of antimony, copper, and lead. Babbitt, or "white," metal, as it is called, has served since its invention as a standard of excellence for all bearing materials.

There are two main types of babbitt metal in common use; one is largely tin, like the original, while the other is largely lead, and all babbitts have characteristics that make them particularly suitable for bearings. They deform readily in response to shaft and bearing deflections and without surface damage to either shaft or bearing. They have a favourable embeddability characteristic; *i.e.*, dirt particles that enter the bearing tend to become embedded in the soft babbitt and do not cut grooves in the shaft or the bearing. Babbitt metals operate satisfactorily with unhardened steel journals, while materials with lower deformability and embeddability characteristics require harder shafts; they also have less tendency than other materials to adhere or weld to the shaft in the absence of a lubricant. The latter characteristic, which is known as compatibility, is usually high for materials with a low coefficient of friction.

Babbitt  
metal

**Journal bearings.** There are five principal ways in which journal bearings differ from one another that can be used as bases for classification. Journal bearings differ in structure, in material, in the type of lubricant used, in the method of introducing the lubricant, and in the nature of the lubrication that exists. The only element common to all journal bearings is the journal, which is usually

steel because steel is cheap, readily available, and stiffer than any other common material.

The simplest journal bearing is a block with a hole in it that provides a free fit for a pin or shaft. To facilitate replacement for wear, a separate bushing (sleeve) can be press-fitted in the block. Many standard sizes of sleeve bearings are commercially available.

Clearance adjustment and takeup for wear can also be obtained with a bearing that is split on a plane through the shaft axis and held together with bolts. Wear is taken up by removing shims (thin metallic sheets) or some of the metal between the two halves. In automobile crankshaft bearings, for example, split replaceable bushings are used. When the load on a bearing is always in the same direction, a partial bearing that envelops only about 120 degrees of the shaft can be used. Such bearings are used for supporting the axles on railroad cars.

The tilting or pivoted-pad principle can be applied to journal bearings as well as to thrust bearings. The bearing consists of a number of concave segments pivoted at their centres that tilt to form wedge-shaped oil films that tend to force the shaft toward the centre of the bearing. Freedom of the pads to tip both longitudinally and circumferentially produces a self-aligning effect.

As a rule, bodies in sliding contact wear least when they are of different materials. Bronze and steel wear well together, and for this reason the majority of commercially available sleeve bearing bushings are bronze, of many different compositions. Bronze can tolerate higher pressures than babbit metal and it can be easily cast and machined.

Aluminum bearings have a high load-carrying capacity, good thermal conductivity, excellent corrosion resistance, and low cost. They are being used extensively in internal-combustion engines and aircraft accessory drives. The journals should be relatively hard and have a good surface finish.

Silver bearings, with an overlay of lead, were used on almost all of the aircraft engines developed during World War II. They can carry higher loads without seizure than can any other material.

Cast iron is one of the oldest and cheapest bearing materials, and it is still used where loads are light and speeds low. When factory machines are driven by belts from long lineshafts or countershafts, practically all of these shafts are supported on cast-iron bearings.

When bearings are inaccessible or periodic lubrication would be inconvenient, porous-metal, self-lubricating bearings can be used. The material in these bearings is usually bronze, but porous iron and aluminum bearings are also available. The manufacturing process creates voids or pores that take up from 10 to 35 percent of the total volume and are filled by submerging the bearings in oil. These bearings are simple in construction, cheap and easy to manufacture, and have proved their worth in home appliances, small motors, business machines, and farm machinery.

Self-lubrication can also be obtained with plastic bearings, which also provide freedom from corrosion, availability in easily molded shapes, and quiet operation. Among the many different compositions available, nylon is probably the most commonly used for the small, lightly loaded bushings used in office machines and instruments. Teflon, one of the most slippery materials known, is constantly extending its field of usefulness, particularly as a thin film deposited on hard metals.

Wooden bearings are still used in a surprisingly large number of cases. For propeller-shaft bearings on ships, lignum vitae is exceptionally well suited. This wood is 33 percent heavier than water and has a high resin content, which makes it practically self-lubricating. It is also non-contaminating and can be used for the bearings of food-processing machinery. Rubber is another material that has found wide application in propeller-shaft and pump bearings in which water is used as a lubricant and also as a coolant.

Lubricants are used in a bearing to reduce friction and wear and to carry off heat; the three functions are not independent, since the greater the reduction in friction

the smaller the quantity of heat that must be removed and the lower the wear. Practically speaking, the prevention of wear and the extension of the life of the bearing are of prime importance (see also LUBRICATION).

**Thrust bearings.** When loads are light and speeds low, the simplest and cheapest type of thrust bearing consists of a collar on the shaft rubbing on a stationary washer that may have radial grooves to improve the distribution of the lubricant. Since a state of boundary lubrication is probable, the washer material is important and may be any of the materials used for journal bearings. For heavier loads multiple collars have been used, but exceptional manufacturing precision is necessary to ensure equal sharing of the load by each collar.

For carrying heavy thrust loads, either a hydrodynamic or a hydrostatic oil film is necessary in a bearing. As previously noted, a hydrodynamic film can be developed in a tilting-pad bearing. Because each pad adjusts to provide an optimum oil-film taper, these bearings can carry high loads over a wide speed range. A similar effect is obtained by supporting the pads on nests of coiled springs. Such bearings have been built with diameters of six feet (two metres) to support hydroelectric generators.

A hydrodynamic film can also be developed in a tapered-land thrust bearing and in a step thrust bearing. The tapered-land bearing is made by cutting radial grooves in a thick washer and machining tapered lands in the spaces between the grooves. The step bearing, which was first described in 1918, contains steps on the stationary member that produce a sudden reduction in the film thickness rather than a gradual one. The calculated load-carrying capacity of these bearings is slightly greater than that of a tilting-pad or tapered-land bearing.

An external pumping system is necessary to develop a hydrostatic oil film in a thrust bearing. These bearings are particularly useful in cases where reliability is important and a substantial oil film must be maintained at all speeds from zero up. On these bearings there are recesses or pockets of constant depth in either the rotating or the stationary member to which oil from a constant-displacement pump is delivered through orifices.

**Gas bearings.** Although feasibility of using air as a lubricant was suggested as early as 1854, and an air-lubricated journal bearing was constructed in 1896, engineers did not begin to show a serious interest in gas bearings until about 1949. This interest was stimulated by the shortcomings of oil-lubricated bearings for very-low-temperature (cryogenic) and high-temperature missile applications. In addition, since oil may disintegrate in a radioactive atmosphere while gases do not, gas bearings are well suited for applications in nuclear power plants. Although helium, hydrogen, and nitrogen have been used in gas bearings, air is the most commonly used lubricant.

Like liquid-lubricated bearings, air bearings may operate on a self-induced aerodynamic film or on an aerostatic film generated by an external pump; they may be designed as journal bearings or thrust bearings. At low speeds the self-induced aerodynamic film in a journal bearing breaks down, while at high speeds the journal may become unstable and whirl around with a planetary motion in the bearing. In order to avoid metallic contact between the journal and the bearing in either case, "pressure-jacking" is used. This involves pumping high-pressure air into the bearing through holes in the bearing wall. If the jacking air is fed to the bearing continuously, the bearing is essentially an aerostatic bearing—a "hybrid" bearing—in which a substantial part of its load-carrying capacity is generated by aerodynamic action.

Because air has a much lower viscosity than oil, in order to develop a load-supporting film in an aerodynamic journal bearing, the clearance between the shaft and the bearing must usually be less than in an oil-lubricated bearing. Since air film thicknesses of 0.0005 inch (0.013 millimetre) are common, precise manufacturing and finishing techniques are required if such microscopic thicknesses are to be realized in practice. Although air bearings are usually tailor-made for the machine on which they are used, some air bearings are now available as standard, off-the-shelf components.

Air bearings

Wooden bearings

The friction in a properly functioning gas bearing is negligible; small hybrid bearings have been operated at speeds in excess of 500,000 revolutions per minute without overheating. If air is the gas, its ready availability is obviously an asset, and the possibility of contamination, which is always present when oil or grease is used, is eliminated. In addition to the applications previously mentioned, gas bearings are used in gyroscopes, instruments, high-speed drilling and grinding machines, dental drills, and refrigerators. Compared with oil-lubricated bearings the load-carrying capacity of aerodynamic bearings is low; it can be greatly increased by supplying high-pressure gas to the bearing.

Jewel bearings

**Other types of bearings.** Jewel bearings are used in instruments, clocks, watches, and other devices in which the only loads are friction and the weights of the moving parts. Usually the rotating element is a shaft with a flat end, spherical end, or conical end, while the fixed element or jewel may be in the form of a ring (a ringstone) that carries shafts in a hole, or a flat plate (an endstone) that carries end thrust from shafts with a spherical end, or a thick plate with a conical or V-shaped notch that is a receptacle for the conical end of a shaft.

The shafts or pivots in jewel bearings must be highly polished, free from surface scratches, and wear resistant, especially those with conical tips. Common materials are high-carbon steel, stainless steel, and Monel metal (a trademarked alloy consisting principally of nickel and copper). The commonest jewel materials are sapphire and borosilicate glass. When meters and instruments are subjected to vibration and shock, the jewels are mounted on shock-absorbing springs or silicone rubber cushions. Jewels are available with many special shapes and properties; in all cases minimum friction is the primary objective.

Bearings that rely on the forces created by magnetic, electrostatic, and electrodynamic fields to float the moving member in a bearing have many advantages; they eliminate friction and wear and the need for lubricants, and can operate in a vacuum and at extreme temperatures.

Liquid metals such as sodium and mercury are particularly useful as lubricants in high-temperature bearings. Their load-carrying capacity is usually poor, however, because of their relatively low viscosity. Recent developments indicate that by using superconducting magnets to create strong magnetic fields in electrically conducting fluids, the load-carrying capacity of liquid metal bearings can be greatly increased. These magnet-stiffened, liquid-metal bearings are known as magnetohydrodynamic (MHD) bearings.

Bearings in helicopters

A bearing that permits oscillations of up to 30 degrees without sliding or rolling contact has been developed for helicopter rotor hubs. It consists of alternate sleeves of steel and rubber bonded together to provide a cylindrical bearing that is extremely stiff in a radial direction but offers little resistance to being twisted within the 30-degree range. These bearings have operated successfully for long periods without lubrication or maintenance.

Improvements in the performance of aircraft jet engines are, to a large extent, attributable to the ability of rolling bearings to operate at higher and higher speeds. Research has shown that bearings with hollow balls can operate successfully at higher speeds and have longer useful lives than conventional bearings. Hollow balls, being lighter than solid balls, create lower centrifugal forces and stress on the outer race.

Another promising development is a hybrid arrangement with a ball bearing whose inner race forms a fluid-film bearing with the shaft. Because of the fluid film the inner race rotates at a slower speed than the shaft, reducing the relative speed in the ball bearing and increasing the fatigue life.

**Comparison of bearings.** All sliding and rolling bearings have their own particular advantages and disadvantages. The most important advantage of rolling bearings over sliding bearings is their availability as standardized off-the-shelf units covering a wide range of sizes and with known load-carrying capacities and life expectancies.

They require more radial space but less axial space than journal bearings, and the dimensions of the shaft and housing to which they are fitted must be kept within close limits. In addition, if properly sealed, there is practically no leakage of lubricant, and the starting friction is less than on hydrodynamic or aerodynamic bearings but greater than on externally pressurized bearings.

Rolling bearings are noisier than sliding bearings, particularly at high speeds, and they are usually more expensive than off-the-shelf sleeve bearings and bushings. All rolling bearings have a finite life, while the life of a full-film sliding bearing has no bounds.

In some applications, the superiority of one type of bearing over the other may be clearcut, but in other cases either type may be satisfactory, and the selection will depend on the designer's preferences.

Electric motors have bearings of both types; fractional horsepower motors usually have sleeve bearings made from a rolled strip in large quantities. From about 1 to 500 horsepower, ball and roller bearings are usually preferred, while above 500 horsepower, sleeve bearings are popular. Grease-lubricated ball bearings are preferred when motors must be started and stopped in cold weather.

In automotive engines sliding bearings are used for crankshafts, connecting rods, and wrist pins. These are low-cost, mass-produced sleeve bearings that have been improved from year to year and function successfully when well supplied with a lubricant. Ball and roller bearings are found in the front wheels, rear axle, and transmission. In the suspension systems of automobiles there are many joints in which the relative motion between the connected parts is small and can be easily taken care of with a flexible rubber connection. These bearings require no lubricant, since there is no relative sliding and nothing to wear.

As previously noted, the starting friction in a hydrodynamic bearing is higher than a rolling bearing. Since the gas turbine in a jet engine must start easily in low temperatures, rolling bearings are commonly used. These bearings are subjected to heavy thrust loads and also to high radial loads caused by gyroscopic effects during manoeuvring. Since they are replaced at regular intervals, the required life is comparatively short.

Jet engine bearings

#### SHAFTS

**Solid shafts.** As a machine component a shaft is commonly a cylindrical bar that supports and rotates with devices for receiving and delivering rotary motion and torque. The crankshaft of a reciprocating engine receives its rotary motion from each of the cranks, via the pistons and connecting rods (the slider-crank mechanisms), and delivers it by means of couplings, gears, chains, or belts to the transmission, camshaft, pumps, and other devices. The camshaft, driven by a gear or chain from the crankshaft, has only one receiver or input, but each cam on the shaft delivers rotary motion to the valve-actuating mechanisms.

An axle is usually defined as a stationary cylindrical member on which wheels and pulleys can rotate, but the rotating shafts that drive the rear wheels of an automobile are also called axles, no doubt a carryover from horse-and-buggy days. It is common practice to speak of short shafts on machines as spindles, especially tool-carrying or work-carrying shafts on machine tools.

In the days when all machines in a shop were driven by one large electric motor or a prime mover, it was necessary to have long lineshafts running the length of the shop and supplying power, by belts, to shorter countershafts, jackshafts, or headshafts. These lineshafts were assembled from separate lengths of shafting clamped together by rigid couplings. Although it is usually more convenient to drive each machine with a separate electric motor, and the present-day trend is in this direction, there are still some situations in which a group drive is more economical.

A single-throw crankshaft that could be used in a single-cylinder reciprocating engine or pump is shown in Figure 21. The journals *A* and *B* rotate in the main

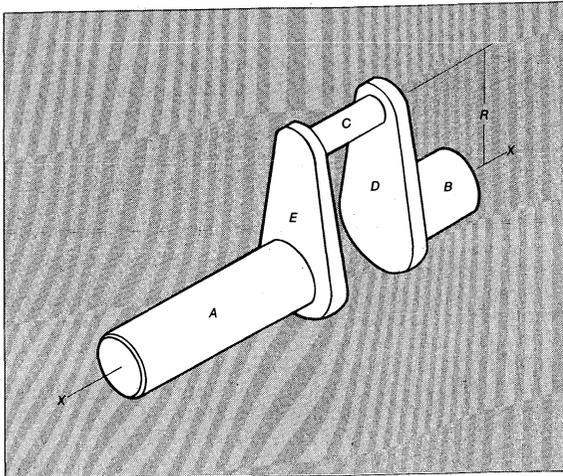

Figure 21: Single-throw crankshaft (see text).

bearings, *C* is the crankpin that fits in a bearing on the end of the connecting rod and moves on a circle of radius *R* about the main bearings, while *D* and *E* are the cheeks or webs. The throw *R* is one half the stroke of the piston, which is connected, by the wrist pin, to the other end of the connecting rod and guided so as to move on a straight path passing through the axis *XX*. On a multiple-cylinder engine the crankshaft has multiple throws—eight for a straight eight and four for a V-8—arranged in a suitable angular relationship.

**Stresses and strains.** In operation, shafts are subjected to a shearing stress, whose magnitude depends on the torque and the dimensions of the cross section. This stress is a measure of the resistance that the shaft material offers to the applied torque. All shafts that transmit a torque are subjected to torsional shearing stresses.

In addition to the shearing stresses, twisted shafts are also subjected to shearing distortions. The distorted state is usually defined by the angle of twist per unit length; *i.e.*, the rotation of one cross section of a shaft relative to another cross section at a unit distance from it.

Shafts that carry gears and pulleys are bent as well as twisted, and the magnitude of the bending stresses, which are tensile on the convex side of the bend and compressive on the concave side, will depend on the load, the distance between the bearings, and the dimensions of the shaft cross section.

The combination of bending and twisting produces a state of stress in the shaft that is more complex than the state of pure shear produced by torsion alone or the state of tension-compression produced by bending alone.

To the designer of shafts it is important to know if the shaft is likely to fail because of an excessive normal stress or an excessive shearing stress. If a piece of chalk is twisted, it will invariably rupture on a plane at about 45 degrees to the axis, not on a plane perpendicular to the axis. This is because the maximum tensile stresses act on this plane, and chalk is weak in tension. Steel shafting is usually designed so that the maximum shearing stress produced by bending and torsion is less than a specified maximum.

Shafts with circular cross sections are easier to produce in the steel mill, easier to machine, and easier to support in bearings than shafts with other cross sections; there is seldom any need for using noncircular shapes. In addition, the strength and stiffness, both in bending and torsion, are more easily calculated for circular shafts. Lastly, for a given amount of material the circular shaft has the smallest maximum shearing stress for a given torque, and the highest torsional rigidity.

The shearing stress in a circular shaft is highest at the surface and drops off to zero at the axis. This means that most of the torque is carried by the material on and near the surface.

**Critical speeds.** In the same way that a violin string vibrates when stroked with a bow, a cylindrical shaft suspended between two bearings has a natural frequency

of lateral vibration. If the speed of revolution of the shaft coincides with the natural frequency, the shaft will experience a whirling critical speed and become noisy. These speeds are more likely to occur with long, flexible shafts than with short, stiff ones. The natural frequency of a shaft can be raised by increasing its stiffness.

If a slender rod is fixed to the ceiling at one end and supports a heavy disk at the other end, the disk will oscillate back and forth around the rod axis like a torsion pendulum if given an initial twist and let go. The frequency of the oscillations will depend on the torsional stiffness of the rod and the weight of the disk; the stiffer the rod and the lighter the disk the higher the frequency. Similar torsional oscillations can occur in the crankshafts of reciprocating engines, particularly those with many crank throws and a heavy flywheel. Each crank throw and part of the associated connecting rod acts like a small flywheel, and for the crankshaft as a whole, there are a number of ways or modes in which these small flywheels can oscillate back and forth around the shaft axis in opposition to one another and to the main flywheel. For each of these modes there corresponds a natural frequency of oscillation.

When the engine is operating the torques delivered to the crankshaft by the connecting rods fluctuate, and if the crankshaft speed is such that these fluctuating impulses are delivered at a speed corresponding to one of the natural torsional frequencies of the shaft, torsional oscillations will be superimposed on the rotary motion of the shafts. Such speeds are known as torsional critical speeds, and they can cause shaft failures. A number of devices to control the oscillations of crankshafts have been invented.

**Flexible shafts.** A flexible shaft consists of a number of superimposed tightly wound right- and left-hand layers of helically wound wires wrapped about a single centre wire or mandrel. The shaft is connected to the source of power and the driven member by special fittings attached to the ends of the shaft. Flexible casings of metallic or nonmetallic materials, which guide and protect the shaft and retain the lubricant, are also available. Compared with solid shafts, flexible shafts can be bent to much smaller radii without being overstressed.

For transmitting power around corners and for considerable distances flexible shafts are usually cheaper and more convenient than belts, chains, or gears. Most speedometers on automobiles are driven by flexible shafts running from the transmission to the dashboard. When a valve, a switch, or other control device is in a hard-to-reach location, it can be operated by a flexible shaft from a more convenient position. For portable tools such as sanders, grinders, and drilling machines, flexible shafts are practically indispensable.

#### SHAFT ACCESSORIES

**Keys, splines, and pins.** When power is being transmitted from a machine member such as a coupling, a clutch, a gear, a flywheel, or a pulley to the shaft on which it is mounted, means must be provided for preventing relative motion between the shaft and the member. On helical and bevel gears, relative movement along the shaft caused by the thrust (axial) loads is prevented by a step in the shaft or by having the gear contact the bearing directly or through a tubular spacer. When axial loads are incidental and of small magnitude, the members are kept from sliding along the shaft by means of a set screw. The primary purpose of keys, splines, and pins is to prevent relative rotary movement.

A commonly used type of key has a square cross section (Figure 22A) and is sunk half in the shaft and half in the hub of the other member. If the key is made of steel (which is commonly the case) of the same strength as the shaft and has a width and depth equal to one fourth of the shaft diameter (this proportion is closely approximated in practice) then it will have the same torque capacity as the solid shaft if its length is 1.57 times that of the shaft diameter. Another common type of key has a rectangular cross section with a depth to width ratio of 0.75. Both of these keys may either be straight or tapered in depth. The

Torsional

keys

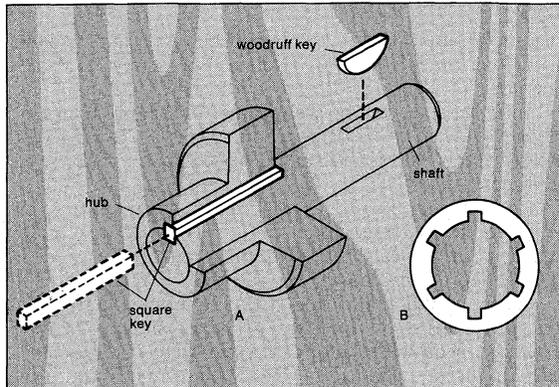

Figure 22: (A) Shaft keys. (B) Internal spline.

straight keys fit snugly on the sides of the keyways only, the tapered keys on all sides. Gib-head keys are tapered keys with a projection on one end to facilitate removal.

Woodruff keys (Figure 22A) are widely used on machine tools and motor vehicles. The key is a segment of a disk and fits in a keyway in the shaft that is cut with a special milling cutter. Though the extra depth of these keys weakens the shaft considerably, it prevents any tendency of the key to rotate or move axially. Woodruff keys are particularly suitable for tapering shaft ends.

Because they weaken the shaft less, keys with straight or tapered circular cross sections are sometimes used in place of square and rectangular keys, but the keyways, half in the shaft and half in the hub, must be cut with a drill after assembly, and interchangeability of parts is practically impossible. When a large gear blank is made by shrinking a high-strength rim on a cheaper cast centre, circular keys, snugly fitted, are frequently used to ensure a permanent connection.

Splines (Figure 22B) are permanent keys integral with the shaft, fitting in keyways cut in the hub. The dimensions of splined fittings are standardized for both permanent (press) fits and sliding fits. The teeth have either straight or involute profiles; the latter are stronger, more easily measured, and have a self-centring action when twisted.

Tapered circular pins can be used to restrain shaft-mounted members from both axial and rotary movement. The pin fits snugly in a reamed tapered hole that is perpendicular to the shaft axis and either radial or tangential to the shaft surface. A number of straight pins that grip by deforming elastically or plastically when driven into straight holes are commercially available.

All the keys and pins that have been described are standard driving devices. In some cases they are inadequate, and unorthodox means must be employed. For driving small gears in which there is no room between the bore and the roots of the teeth for a longitudinal keyway, a transverse radial slot on the end of the gear can be made to fit a radial protuberance on the shaft. For transmitting moderate loads, a cheap and effective connection can be made by forming a series of longitudinal serrations on the shaft with a knurling tool and pressing the shaft into the hole in the driven member. If the shaft is hard enough relative to the member, it will cut grooves in the hole and provide, in effect, a press-fitted splined connection. Press and shrink fits are also used, and they can provide surprisingly firm connections, but the dimensions of the connected members must be closely controlled.

**Fluid seals.** When a reciprocating or rotating shaft extends from a bearing or a housing (enclosure) containing a fluid, such as a pump, a gearbox, or a hydraulic transmission, the shaft must be free to move relative to the housing, and at the same time leakage of fluids and entry of contaminants at the shaft-housing interface must be restricted. The purpose of a seal is to restrict the leakage with the least possible restraint on the relative motion.

There are four basically different types of seals: shaft seals, face seals, labyrinth seals, and hydrodynamic seals. The sealing element in shaft seals acts directly on the surface of the shaft. One of the oldest shaft seals is the

stuffing box and gland; it was used by James Watt on his steam engine and, with modern compression packings, is still used for sealing acids, ammonia, water, oil, gasoline, steam, gas, and air. The stuffing box, which is an annular (ringlike) space between the surface of the shaft and an enlarged opening in the housing, is filled with a ropelike packing. The gland has a tubular member with a cross section that fits the stuffing box and can be moved axially to reduce the length of the stuffing box and create a pressure on the packing. A common type of packing consists of twisted strands of asbestos or cotton lubricated with oil and graphite. A wide variety of fabric, metallic, and plastic packings is available.

**Shaft and face seals.** The radial lip seal is probably the most commonly used oil or shaft seal. Figure 23A shows a cross section of a bonded-type seal in which the elasto-

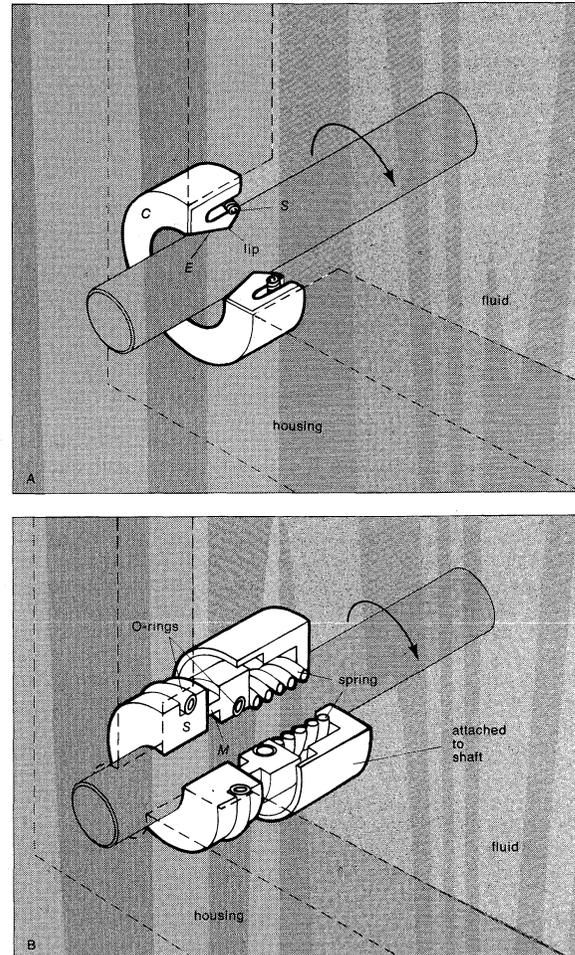

Figure 23: (A) Shaft (lip) seal; (B) face seal (see text).

mer sealing element *E* is bonded to the metallic case *C*, which is pressed into the housing. The initial interference pressure between the lip of the sealing element and the shaft is augmented by the helically wound garter spring *S* and pressure from the fluid in the housing.

When properly designed and installed, the lip rides on a film of lubricant about 0.0001 inch (0.0025 millimetre) thick. If the film gets too thick, fluid leaks, while if too thin the lip gets hot and the seal may fail. Although the finish on the shaft is important, some laboratory tests indicate that too smooth a finish may be undesirable, as it may retard development of an oil film. Leather, synthetic rubber, and silicones are among the materials used for lip seals.

In the face seal (Figure 23B) the sealing is done on the radial face where the rotating element *M*, attached to the shaft, contacts the stationary element *S*, attached to the housing. The element *M*, which may be carbon-graphite, and the element *S*, which may be steel, have precision-finished contacting surfaces and are spring-loaded against

O-ring seals

one another. The O-rings are flexible rings with a circular cross section and provide static sealing. O-ring materials include neoprene, butyl, fluorinated silicones, and natural rubber; they are widely used for static seals and sometimes also for dynamic applications. Face seals are expensive, precision components and must be handled and installed with care. They have been used under pressures up to 3,000 pounds per square inch (200 kilograms per square centimetre) and at speeds up to 50,000 feet (15,000 metres) per minute; their leakage rate is exceptionally low.

*Labyrinth and hydrodynamic seals.* The labyrinth seal provides a series of annular spaces between disks attached to the shaft and matching grooves in the stationary member; this arrangement merely limits leakage by restricting the annular clearance between the disks and the grooves. These seals are used in large steam and gas turbines, where the friction and wear of a contact seal is less tolerable than a small loss in efficiency caused by leakage. A labyrinth seal consisting of a row of tapered rings fixed in the housing and a plain shaft has proven effective for sealing gas. The rings are tapered to an edge thickness of about 0.010 inch (0.25 millimetre) at the shaft surface. When assembled there is some interference and the edges of the rings are worn off when the shaft rotates.

The hydrodynamic seal consists of a housing with a smooth bore and a helically grooved rotating shaft. If the radial clearance between the shaft and the bore is sufficiently small, a pumping action tending to move the oil along the shaft will be created. A similar pumping effect can be obtained with a plain shaft and a helix cut in the housing.

Hydrodynamic seals have some limitations; they do not seal when the shaft is stationary, they are usually restricted to unidirectional applications, and close radial clearance between the elements is required. By themselves, neither the lip nor the hydrodynamic seal is ideal, but by utilizing the best features of each, a more reliable sealing mechanism has been developed.

In the United States, the automotive industry is probably the largest user of seals. Dissatisfied with the performance of lip seals, one of the largest automobile manufacturers has developed a seal in which the lip and hydrodynamic methods of sealing are combined. This seal is basically a lip-type seal in which a circumferential static ridge and a series of helical grooves are molded in the elastomer element. Seals with right- and left-hand helices have been developed for bidirectional rotation.

*Modern developments.* Man's urge to travel faster, fly higher, and explore outer space has created a need for seals with capabilities of a high order. Since World War II, with the advent of nuclear power plants, space vehicles, and supersonic aircraft, the temperature levels at which seals must operate have risen from about 200° F (90° C) to about 900° F (500° C). In addition, operating speeds have increased and ambient pressures have dropped below atmospheric.

There has been considerable recent development in seal technology, and a variety of high-performance seals is available for applications involving gas, liquid metals, and all of the common fluids. One of these is a face seal with spiral grooves to produce a hydrodynamic effect; it has been used to seal liquid sodium.

With the introduction of automobile warranties, car manufacturers became increasingly concerned with oil seal performance. Car owners are seldom aware of oil seals until one leaks, and although the seals themselves may be inexpensive, labour costs for replacement are high. If seal leakage leads to engine, transmission, or rear axle failure—which can easily happen—the costs are much higher.

Successful application of seals requires that the seal be properly designed, carefully manufactured, and correctly applied. Unfortunately, there is no seal technology to which a designer can turn to learn the science and art of seal design. The importance of the problem has been recognized; in 1967 research in sealing was being carried out in over 100 laboratories throughout the world, and the volume of literature had increased tenfold since 1947.

## SCREWS

**Screw fasteners.** Screws have been used as fasteners for a long time. Medieval jewelers used screws to fasten bracelets, and taps and dies for cutting internal and external threads, respectively, were in use in the 14th century. A book written in the 16th century has a drawing of a tapered screw with a flat, slotted head that is apparently a wood screw.

As indicated in the section on simple machines, a screw acts with a wedging action and consists of a circular cylinder (or truncated cone) with a helical groove in it. When used for fastening, all screws are provided with means for applying a torque (twisting moment) to them; this may consist of a square or hexagonal head for a wrench, a head with a slot or a cross-shaped recess for a screwdriver, a cylindrical head with a recess fitting a special wrench, or a slot or recess on one end fitting a screwdriver or special wrench and no head.

Screws with screwdriver slots have heads of several shapes, such as flat, oval, round, and fillister (cylindrical with a round top). Wood screws are tapered, and self-tapping screws have tapered ends and a variety of special points. The latter are usually hardened and cut or form a mating internal thread when screwed into the proper size hole.

Screws with hexagonal heads are usually known as cap screws. Screws with other types of heads are also known as cap screws in the larger sizes and as machine screws in the smaller sizes. All of these screws are used to clamp machine parts together when one of the parts has an internal thread. If neither part is threaded a bolt must be used; this consists of a screw with a hexagonal head, a nut (hexagonal ring with an internal thread), and usually a washer (flat ring). A stud has threads on both ends and no means for turning. It is permanently screwed into one member and clamps by means of a nut on the other end. All of these fasteners stretch when tightened, and the tensile load created in this way clamps the members together.

Set screws differ in form and function from the other types of screws. They are hardened and have cup, cone, oval, flat, and dog (cylindrical) ends or points. They are usually headless and are frequently used as substitutes for keys or in conjunction with keys in shaft-mounted members. The set screw fits in a threaded radial hole in the hub, and the point is tightened down into a hole, a flat, or a dimple in the shaft or key. Set screws are stressed in compression, and in action they create a helical wedge between the connected parts.

*Standard thread forms.* Until 1841 there was no standard for the form and size of the helical groove in threaded fasteners; there was little likelihood that a screw made by one manufacturer would fit a nut or a tapped hole made by another manufacturer. Interchangeability of screw threads requires standardization of the form of the groove and the dimensions of the groove as a function of the diameter of the blank in which the groove is cut. Since 1841 several forms have been proposed and adopted; these forms are all referred to a longitudinal plane passing through the axis of the screw (an axial plane).

Over the years, but especially during the world wars, the non-interchangeability between British and United States screw threads was inconvenient. To remedy this, a Unified Screw Thread Standard was recommended by the International Organization for Standardization and accepted by Canada, the United Kingdom, and the United States in an accord signed at Washington, D.C., on November 18, 1948. The form of the Unified Screw Thread for an external thread is shown in Figure 24. Unified and United States threads have substantially the same thread form.

In Figure 24 the distance between the crests of adjacent threads is given by the pitch  $p$ , which in terms of the number of threads per inch  $N$  can be expressed as  $p = 1/N$ . This is a measure of the size of a thread, and to create a standard it is necessary to correlate the pitch  $p$  (or  $N$ ) and the diameters of the various screws in a series. Of the 11 standard Unified Screw Thread series the coarse, fine, and extra fine series are the most commonly

Unified Screw Thread

Research in sealing methods

## Thread chasings

In chasing, a tool is moved at a controlled rate parallel to the axis of the rotating workpiece and fed in radially at the end of each pass until the thread is the proper depth. On an engine lathe the tool has only one cutting point, and its longitudinal movement is controlled by the lead screw that is driven by gears from the spindle. Thread chasing can also be done with a multiple-point tool that looks like a comb.

Thread milling can be done with a single disk-type milling cutter shaped on its periphery to the profile of the thread to be cut and rotating about its own axis as it moves parallel to the axis of the workpiece under the control of a lead screw; it can also be done with a cutter that is essentially a stack of single cutters, or with a hob, which has cutting edges arranged on a helix. Thread milling is usually done on special machines. Thread grinding is done in much the same way as thread milling; the milling cutter is replaced by a disk-type grinding wheel that reproduces its peripheral shape on the workpiece.

Thread rolling is done with dies that are either flat plates or rolls with grooves in them to match the thread being formed. When flat dies are used, one die is fixed and the other reciprocates longitudinally at a fixed distance above it. The grooves on the opposed faces of the dies are straight and inclined to the long sides at an angle equal to the lead angle of the screw. The screw blank, which is fed in at the starting end as the moving die starts its forward stroke, rolls along the stationary die and, being wedged between the dies, is impressed with the thread form. When two roll dies are used, one is mounted on a fixed spindle and the other, connected to it by gears, is mounted on a movable slide. The workpiece rests on a stationary blade between the rolls and is impressed with the thread form when the movable roll is advanced. The rolling process improves the strength of the part on account of the cold deformation of the workpiece. Compared with cut threads, rolled threads can be up to 50 percent stronger under repetitive loads.

When large numbers are required, the threads on machine screws, and cap screws and bolts in the smaller sizes, are rolled. The production rate is higher and the cost lower than for any other method. It is probable that more screws are produced by rolling than by any other method. Although rolling is usually restricted to V-shaped threads, the successful rolling of Acme threads has been reported.

## SPRINGS

A spring is a load-sensitive, energy-storing device the chief characteristics of which are an ability to tolerate large deflections without failure and to recover its initial size and shape when loads are removed. Although most springs are mechanical and derive their effectiveness from the flexibility inherent in metallic elements, hydraulic springs and air springs are also obtainable.

Springs are used for a variety of purposes, such as supplying the motive power in clocks and watches, cushioning transport vehicles, measuring weights, restraining machine elements, making resilient connections, launching and retarding missiles and vehicles, mitigating the transmission of periodic disturbing forces from unbalanced rotating machines to the supporting structure, and providing shock protection for delicate instruments during shipment.

**Mechanical springs.** *Elasticity and Hooke's law.* If a solid body recovers its original size and shape after being deformed, it is said to be elastic. Most mechanical elements used in machine construction are practically elastic up to a limiting load that depends on the dimensions of the element and the material from which the element is made. In order to eliminate the dimensional effect and obtain a measure of elastic capability that depends only on the material, the stress concept is utilized. The elastic limit stress is the load at which a straight bar of the material with a circular cross section of one square inch would cease to be elastic when pulled in a tensile-testing machine. Thus, if a specimen with a cross-sectional area of 0.5 square inch becomes inelastic at a load of 15,000 pounds, the elastic limit would be  $15,000/0.5 = 30,000$

pounds per square inch (2,100 kilograms per square centimetre). This is an average value for low-carbon steel.

If the deflection of an elastic body is proportional to the load, the body is said to be linearly elastic and to satisfy Hooke's law. This means that if the load is doubled the deflection is doubled. The relation between load and deflection for two linearly elastic bodies is shown in Figure 25A. Under the same load  $P$ , the deflection of body 1 is  $\Delta_1$ , which is less than half the deflection of body 2; body 1 is obviously stiffer than body 2. The stiffness  $K$  of a linearly elastic body is the ratio of the load to the corresponding deflection and is commonly expressed in pounds per inch or kilograms per centimetre.

The stiffness of a body when loaded in a given manner depends on its dimensions and configuration, and on an important property of the material known as the modulus of elasticity. The modulus of elasticity in tension, designated by  $E$ , is very close to 30,000,000 pounds per square inch (2,100,000 kilograms per square centimetre) for all steels, and it represents the stress required to stretch a steel bar to twice its original length, if such a large elongation were possible. The modulus of elasticity in compression is usually assumed to be the same as in tension. Like the elastic limit, the modulus of elasticity is strictly a material property; it is a measure of the stiffness of a material and influences the stiffness or spring rate of all mechanical springs that are stressed in tension or compression.

*Stiffness and energy.* In order to deflect a linearly elastic spring, a gradually increasing force must be applied. By definition, work is average force times distance. In the case of a spring, the work done during a deflection is stored in the spring as elastic energy, which can be recovered when the load is relaxed. The energy stored in a spring can be used to cushion shocks or to actuate mechanisms. In Figure 25A the energy stored in body 1 is  $P\Delta_1/2$ , while the energy stored in body 2,  $P\Delta_2/2$ , is much greater because body 2 is more flexible. The stiffness  $K$  is a measure of the flexibility and is given by the slope of the line in the Figure.

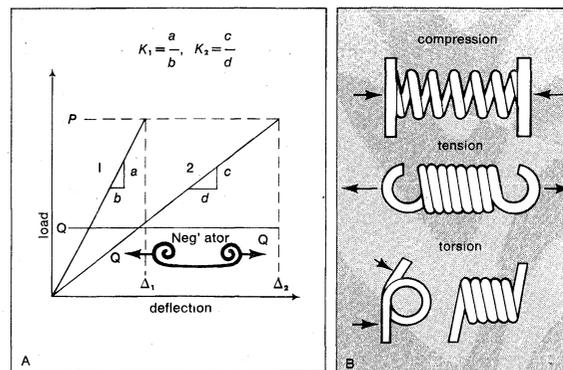

Figure 25: (A) Spring characteristics. (B) Helical springs (see text).

Under load, all mechanical springs have either tensile, compressive, or shear stresses, or combinations of these stresses. In most cases the stresses are produced by simple pull or push loads, bending, or torsion.

*Common types.* The helical spring (Figure 25B) is probably the most commonly used of all springs. It can be designed to carry pull or push loads or a torque. In the latter case, the torque produces a bending stress in the wire. Among the applications of springs of this type are hinges, engine starters, and handles. Helical tension and compression springs have innumerable uses, among which are measuring weights in spring balances, restoring moving machine elements to their initial positions, and closing valves on engines; they are also used for automobile suspension systems, for gun recoil mechanisms, and for shock-modifying mounts.

The torsion-bar spring is favoured by some automobile manufacturers for wheel suspensions. It consists of a long steel bar fixed at one end and supported but free to rotate

## Uses of springs

## Helical springs

at the other end. It is twisted by a load applied by a crank at the free end. The leaf spring is used mainly for vehicle suspension, and in its simplest form is a cantilever beam of uniform rectangular cross section loaded at the free end. Since the bending stress is proportional to the bending moment, which is equal to the product of the load and the distance to the cross section, the stress is a maximum at the fixed end and zero at the load. This means that the material is being inefficiently used in a beam of uniform width. To obtain a uniform stress along the beam it should be in the form of a triangular plate of uniform thickness with the apex at the free end. In practice, the triangular plate is replaced by a stack of narrow plates of uniform width and varying length. The leaf spring in Figure 26A can be treated as two cantilevers, each supporting half the load, or  $P/2$ .

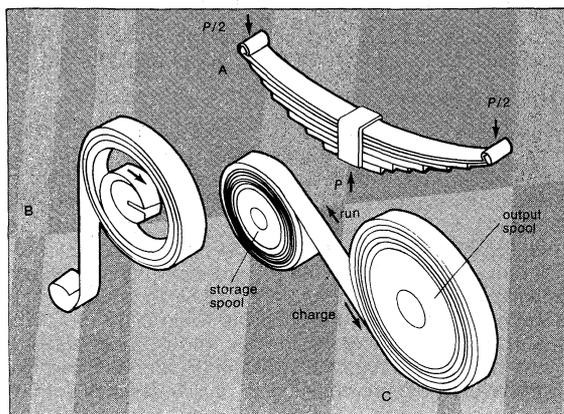

Figure 26: Types of springs. (A) Leaf spring; (B) spiral spring; (C) Neg'ator motor.

The spiral spring (Figure 26B) is made from flat strip or wire; as a mainspring or hairspring it provides a compact source of energy in clocks and watches. It is also used on typewriters, parking meters, and wind-up toys.

**The Neg'ator.** A spring of unusual interest and usefulness and having characteristics totally unlike those of other springs was introduced in 1949. It is called the Neg'ator, or constant-force spring, and consists of a strip of flat spring material that has been given a curvature by continuous heavy forming so that in its relaxed or unstressed condition it is in the form of a tightly wound spiral. When mounted for free rotation the material resists withdrawal from the coil with a force ( $Q$ ) that remains essentially constant regardless of the extension as shown in Figure 25A. In this form the Neg'ator is widely used as a long-deflection spring for retracting, constant-force tensioning, and counterbalancing.

Figure 26C shows a Neg'ator motor. The coil is mounted on, but not usually fixed to, the smaller storage spool, which can rotate freely. The other end of the coil is fixed to the larger output spool. To charge the motor, the output spool is rotated and the spring withdrawn from the storage spool. When fully charged, most of the spring is wound on the output spool. Because of the difference in the diameters of the spools, the spring will return to the storage spool when released and create a torque on the output spool that is essentially constant through 50 to 60 revolutions or more. Neg'ator spring motors are used extensively in movie cameras, clocks, phonographs, slide projectors, retracting steel tape rules, and in counterbalancing movable lighting fixtures and venetian blinds.

**Recapitulation.** Most mechanical springs are made from high-strength steel. Since the stiffness depends on the modulus of elasticity and this property is practically the same for all grades of steel, this stiffness of a steel spring cannot be increased by making it stronger or harder. Increasing the strength only increases the maximum load that the spring can carry. Since the modulus of elasticity of phosphor bronze wire is approximately half that of steel, a significant reduction in stiffness can be obtained by switching from steel to phosphor bronze.

Summarizing, the essential characteristics of mechanical

springs are strength and flexibility, whereas in structures, strength and rigidity are the usual requirements. Control of these two properties in a spring or a structure to satisfy diverse requirements is possible only because of the fortunate circumstance that the stress and the deflection that a given load produces in an elastic body are not affected in the same degree by changes in the dimensions of the body. The strength of a torsion bar, for example, depends only on the area of the cross section, while the stiffness depends on both the area and the length. If the area is sufficient to carry the load, the stiffness can be adjusted by varying the length. The stress in a loaded helical spring depends on the wire diameter and the coil diameter; the stiffness can be altered by changing the number of coils, which has no effect on the stress.

**Air and hydraulic springs.** An air spring is basically a column of air confined within a rubber-and-fabric container that may take the form of a bellows. The spring action results from the compression and expansion of the air. Air springs provide means for control of load capacity, height, and spring rate; they are used in aircraft landing gear, shock and vibration isolators, seat suspensions, and for suspension systems for machines and vehicles. When used on buses, air springs can keep the vehicle at a constant standing height regardless of load. Hydraulic or liquid springs are comparatively small, thick-walled, hydraulic cylinders in which the spring effect is produced by applying a load to the fluid in the cylinder through a comparatively small piston entering at the centre of one end of the cylinder. The piston movement, which represents the spring deflection, results from the compression of the fluid and the deformation (bulging) of the cylinder. Some special oils, under a given pressure, have twice the percentage of volume reduction of water.

A helical spring and a hydraulic spring of the same energy capacity are approximately equal in weight; the hydraulic spring, however, is much smaller. Hydraulic springs are particularly suited for applications in which high load capacities and stiffnesses are required. They are widely used in punch and die assemblies in machine tools and as recoil springs and buffers in gun systems.

HARTENBERG and JACQUES DENAVIT, *Kinematic Synthesis of Linkages* (1964), an up-to-date textbook containing original material on geometric and algebraic methods for the design of planar (two-dimensional) and spatial (three-dimensional) linkage mechanisms; PAUL H. BLACK and O. EUGENE ADAMS, JR., *Machine Design*, 3rd ed. (1968); RICHARD M. PHELAN, *Fundamentals of Mechanical Design*, 3rd ed. (1970); SAMUEL J. BERARD, EVERETT O. WATERS, and CHARLES W. PHELPS, *Principles of Machine Design* (1955), three textbooks containing information on all the machine components; DUDLEY D. FULLER, *Theory and Practice of Lubrication for Engineers* (1956), covers the analysis and design of sliding (fluid film) bearings and bearing materials.

(A.Co.)

## Machine Tools

Machine tools are stationary power-driven machines for shaping or forming parts made of metal or other materials. The shaping is accomplished in four general ways: (1) by cutting excess material from the part in the form of chips; (2) by shearing the material; (3) by squeezing metallic parts to the desired shape; and (4) by application of electricity, ultrasound, or the corrosive action of chemicals. The fourth category covers recently developed machine tools and processes for machining ultrahard metals not machinable by older methods.

Neg'ator  
motors

Machine tools that form parts by removal of metal chips include lathes, shapers and planers, drilling machines, milling machines, grinders, and power saws. Cold forming of metal parts such as cooking utensils, automobile bodies, and similar items is done on punch presses, while hot forming of white-hot blanks in appropriately shaped dies is done on forging presses.

#### Tolerances

Modern machine tools cut or form parts to tolerances of plus or minus one ten-thousandth of an inch (0.0025 millimetre). In special applications parts are produced to within plus or minus two millionths of an inch (0.00005 millimetre) with precision lapping machines. Because of the precise dimensional requirements of the parts and the heavy cutting forces exerted on the cutting tool, machine tools combine weight and rigidity with delicate accuracy.

Machine tools process parts for all production machinery, service machinery, and consumer products and make other machine tools.

#### HISTORY

Before the Industrial Revolution of the 18th century, hand tools were used to cut and shape materials for the production of goods such as cooking utensils, wagons, ships, furniture, and other products. After the advent of the steam engine, material goods were produced by power-driven machines that could only be manufactured by machine tools. Machine tools capable of producing dimensionally accurate parts in large quantities and jigs and fixtures for holding the work and guiding the tool were indispensable in permitting mass production and the interchangeability of parts to become realities in the course of the 19th century.

The earliest steam engines suffered from inaccurate boring of their large cast cylinders by machines powered by water wheels and originally designed to bore cannon. During the following half century the basic machine tools, with all the fundamental features required for machining heavy metal parts, were designed and developed. Some of them were adaptations of earlier woodworking machines; thus the metal lathe derived from wood cutting lathes in use in France as early as the 16th century. In 1774 John Wilkinson of England built a precision machine for boring engine cylinders. In 1797 Henry Maudslay, also of England and one of the great inventive geniuses of his day, designed and built a screw-cutting engine lathe. The outstanding feature of Maudslay's lathe was a lead screw for driving the carriage, geared to the spindle of the lathe, which made it possible to advance the tool at a constant rate of speed, thus guaranteeing accurate screw threads. By 1800 Maudslay had equipped his lathe with 28 change gears for cutting threads of various pitches by controlling the ratio of the lead-screw speed and the spindle speed.

The shaper was invented by James Nasmyth, who had worked in Henry Maudslay's shop in London. In Nasmyth's machine a workpiece could be clamped horizontally to a table and worked on by a cutter with a reciprocating motion that could plane small surfaces, cut keyways, or machine other straight-line surfaces. A few years later (1839), Nasmyth invented the steam hammer for forging heavy pieces. Another disciple of Maudslay, Joseph Whitworth, invented or improved a great number of machine tools and came to dominate the field; at the International Exhibition of 1862 his firm's exhibits took up a quarter of all the space devoted to machine tools.

Considerable efforts were made by Britain to keep its lead in machine-tool development by prohibiting exports, but the attempt was foredoomed by industrial development elsewhere. British tools were imported to continental Europe and to the U.S. despite the prohibition, and new tools developed outside Britain. Notable was the milling machine produced by Eli Whitney of the U.S. about 1818 and used by Simeon North to manufacture firearms. The first fully universal milling machine was built in 1862 by J.R. Brown of the U.S. and used to cut helical flutes in twist drills. The turret lathe, developed in the U.S. in the middle of the 19th century, was made fully automatic for some purposes, such as making screws, presaging momentous developments in the 20th century. Various gear-cut-

ting machines reached their developmental climax in a gear shaper designed in 1896 by F.W. Fellows, an American, that could turn out rapidly almost any type of gear.

The production of artificial abrasives in the late 19th century opened up a whole new field, that of grinding machines. C.H. Norton of Massachusetts dramatically illustrated the potential of the grinding machine by making one that could grind an automobile crankshaft in 15 minutes, a process that had previously required five hours of turning, filing, and hardening.

By the end of the 19th century a complete revolution had taken place in the working and shaping of metals, creating the basis for a mass-production, industrialized society. The 20th century has witnessed the introduction of numerous refinements, such as multiple-point cutters for milling machines, the development of automated operations governed by electronic and fluid-control systems, and "chipless" techniques, such as electrochemical and ultrasonic machining. Yet even in the 1970s the basic machine tools remain largely the legacy of the 19th century.

#### MACHINE-TOOL CHARACTERISTICS

All machine tools must provide work-holding and tool-holding devices and means for accurately controlling the depth of cut. Relative motion between the cutting edge of the tool and the work is called the cutting speed, while the feed motion brings uncut material into contact with the tool. Means must be provided for varying all of these.

Because an overheated tool may lose cutting ability, it is important to control temperature. The amount of heat developed depends on the shearing force and the cutting speed, but because shearing force varies with the material being cut and tool material varies in its tolerance for high temperatures, the optimum cutting speed depends both on the material being cut and the cutting-tool material. It is also influenced by the rigidity of the machine, the shape of the workpiece, and the depth of cut.

Optimum  
cutting  
speed

#### CUTTING TOOLS

Metal-cutting tools are classified as single point or multiple point. A single-point cutting tool is shown in Figure 1 (left) performing a turning operation on a rotating cylindrical workpiece. Such tools are also used for increasing the size of holes, or boring. Turning and boring are performed on lathes and boring mills.

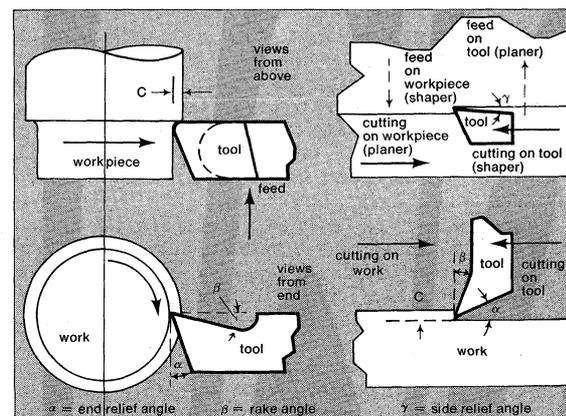

Figure 1: Single-point cutting tools. (Left) Lathe tool; (right) planer and shaper tool. Depth of cut is indicated by C.

Figure 1 (right) represents two types of operation: either the tool moving on a straight path against the stationary work, as on a shaper, or the work moving against the stationary tool, as on a planer.

Multiple-point cutting tools have two or more cutting edges and include milling cutters, drills, and broaches (Figure 2). Relief or clearance angles must be provided to prevent the tool surface below the cutting edge from rubbing against the workpiece.

Rake angles are often provided on cutting tools to cause a wedging action in the formation of chips and to reduce friction and heat.

hammer

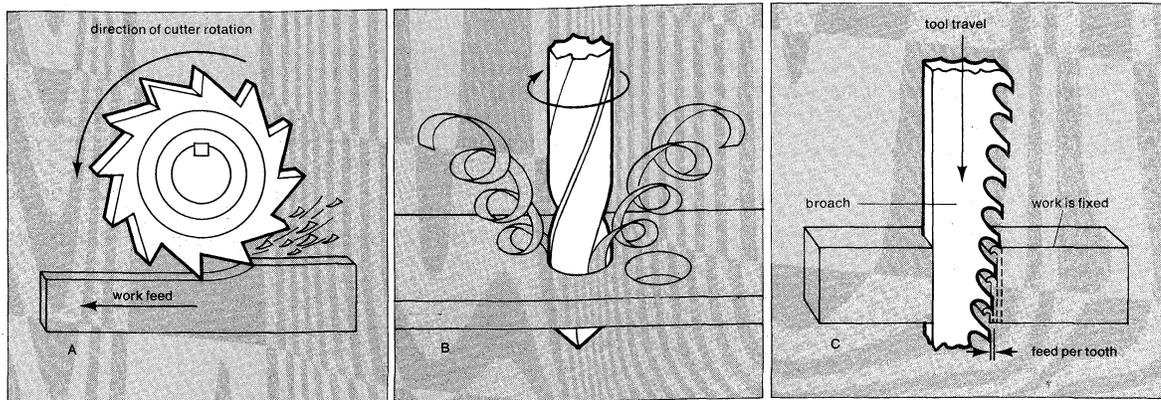

Figure 2: Multiple-point cutting tools. (A) Milling with plain milling cutter. (B) Machining with twist drill. (C) Action of broaching tool.

**Tool materials.** In order to remove chips from a workpiece, a cutting tool must be harder than the workpiece and maintain a cutting edge at the temperature produced by the friction of the cutting action.

**Carbon steel.** Steel with a carbon content ranging from 1 to 1.2 percent was the earliest material used. Tools made of this carbon steel are comparatively inexpensive but tend to lose cutting ability at temperatures around 400° F (205° C).

**High-speed steel.** The introduction of high-speed steel about 1900 permitted operation of tools at twice or three times the speeds allowable with carbon steel, thus doubling or trebling the capacities of the world's machine shops. One of the commonest types of high-speed steel contains 18 percent tungsten, 4 percent chromium, 1 percent vanadium, and only 0.5 to 0.8 percent carbon.

**Cast alloys.** A number of cast-alloy cutting-tool materials have been developed; these nonferrous alloys contain cobalt, chromium, and tungsten and are particularly effective in penetrating the hard skin on cast iron and retaining their cutting ability even when red hot.

**Cemented tungsten carbide.** This material was first used for metal cutting in Germany in 1926. Its principal ingredient is finely divided tungsten carbide held in a binder of cobalt; its hardness approaches that of a diamond. Tungsten carbide tools can be operated at cutting speeds many times higher than those used for high-speed steel.

**Oxides.** Ceramic or oxide tool tips are the latest development in cutting-tool materials. They consist primarily of fine aluminum oxide grains, bonded together.

**Diamonds.** Diamonds have been used for many years for truing grinding wheels, for wire-drawing dies, and as cutting tools. For cutting applications they are used largely for taking light finishing cuts at high speed on hard or abrasive materials and for finish-boring bronze and babbit-metal bearings.

**Cutting fluids.** On many machine-tool operations, cutting fluids or coolants are used to modify the harmful effects of friction and high temperatures. In general, the major functions of a coolant are to lubricate and cool. In cutting a screw thread, either on a lathe or with a tap, the lubricating function is most important; on production-grinding operations, the cooling function predominates. Water is an excellent cooling medium but corrodes ferrous materials. Lard oil has excellent lubricating qualities but tends to become rancid with time. Sulfurized mineral

oil is one of the most popular coolants. The sulfur tends to prevent chips from the work from welding to the tip of the tool. For sawing and grinding operations, soluble oil, which is an oily emulsion freely miscible in water, is commonly used.

#### BASIC MACHINE TOOLS

Hundreds of varieties of metal machine tools, ranging in size from small machines mounted on workbenches to huge production machines weighing several hundred tons, are used in modern industry. They still retain the basic characteristics of their 19th- and early 20th-century ancestors and are still classed as one of the following: (1) turning machines (lathes and boring mills), (2) shapers and planers, (3) drilling machines, (4) milling machines, (5) grinding machines, (6) power saws, and (7) presses.

**Turning machines.** The engine lathe, as the horizontal metal-turning machine is commonly called, is the most important of all the machine tools (Figure 3). It is usually considered the father of all other machine tools. Many of the fundamental mechanical elements of the engine lathe are incorporated in the design of the other machine tools.

The engine lathe is a basic machine tool that can be used for a wide variety of turning, facing, and drilling operations. It utilizes a single-point cutting tool for turning and boring operations (Figure 4). Turning operations involve

The engine lathe

Cutting at red heat

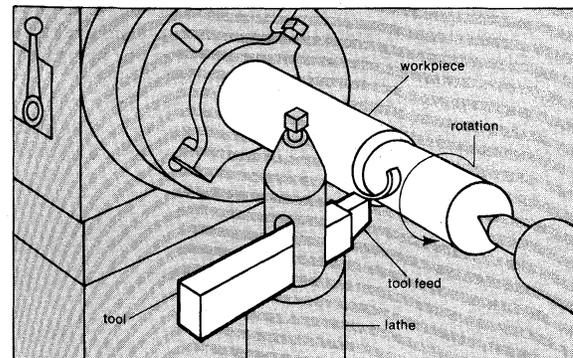

Figure 4: Turning of steel shaft mounted between centres.

cutting excess metal, in the form of chips, from the external diameter of a workpiece and include turning straight or tapered cylindrical shapes, grooves, shoulders, and

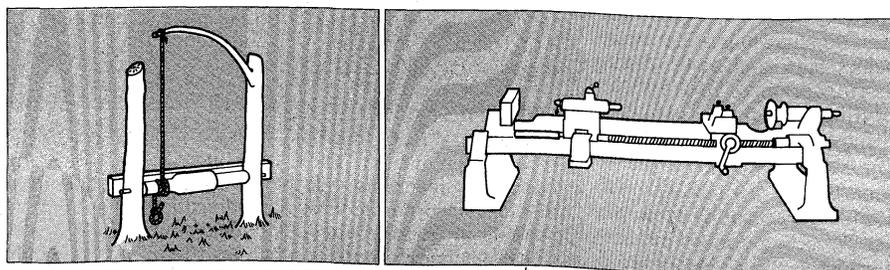

Figure 3: (Left) Primitive lathe. (Right) Maudslay's lathe of 1797.

screw threads and facing flat surfaces on the ends of cylindrical parts. Internal cylindrical operations performed on the engine lathe include most of the common hole-machining operations such as drilling, boring, reaming, counterboring, countersinking, and threading with a single-point tool or a tap (Figure 5).

Adapted from W.J. McCarthy and R.E. Smith, *Machine Tool Technology*

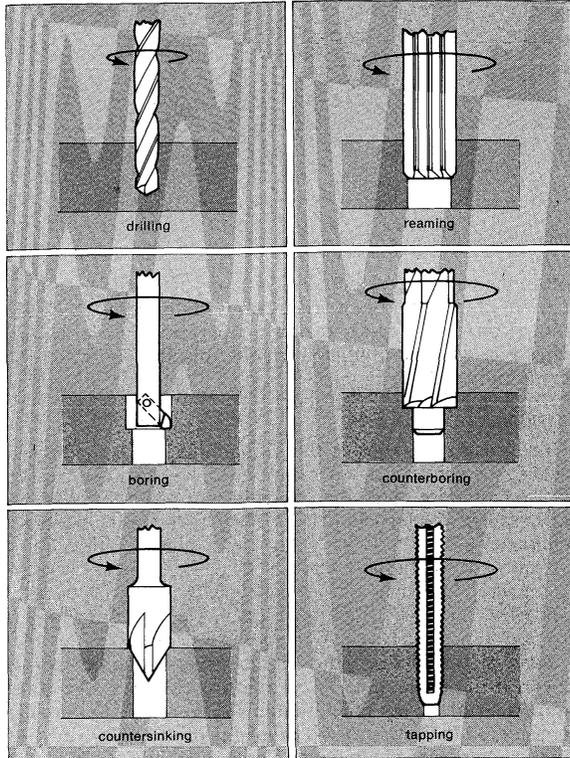

Figure 5: Common hole-machining operations.

Boring involves enlarging and finishing a hole that has been cored or drilled. Bored holes are more accurate in roundness, concentricity, and parallelism than drilled holes. A hole is bored with a single-point cutting tool that feeds along the inside of the workpiece. Boring mills have circular horizontal tables that rotate about a vertical axis, and they are designed for boring and turning operations on parts that are too large to be mounted on a lathe.

**Shapers and planers.** Shaping and planing operations involve the machining of flat surfaces, grooves, shoulders, T-slots, and angular surfaces (Figure 6) with single-point

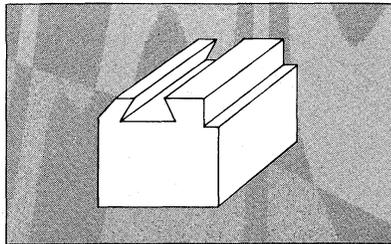

Figure 6: Surface shapes cut on shaper, planer, or milling machines.

tools. The largest shapers have a 36-inch cutting stroke and can machine parts up to 36 inches long. The cutting tool on the shaper reciprocates back and forth, cutting on the forward stroke, with the workpiece feeding automatically toward the tool during each return stroke.

Planing machines perform the same operations as shapers but can machine longer workpieces. Some planers have a capacity to machine parts up to 50 feet in length. The workpiece is mounted on a reciprocating table that moves the workpiece under a cutting tool. This tool, which remains stationary during the cutting stroke, feeds into the workpiece automatically after each cutting stroke.

**Drilling machines.** Drilling machines, also called drill presses, cut holes in metal with a twist drill (Figure 2). They also utilize a variety of other cutting tools for performing the following basic hole-machining operations: (1) reaming, (2) boring, (3) counterboring, (4) countersinking, and (5) tapping internal threads with the use of a tapping attachment (Figure 5).

**Milling machines.** A milling machine cuts metal as the workpiece is fed against a rotating cutting tool called a milling cutter (Figures 2 and 7). Cutters of many shapes

Tapping

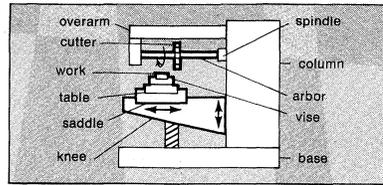

Figure 7: Horizontal knee-and-column milling machine.

and sizes are available for a wide variety of milling operations. Milling machines cut flat surfaces, grooves, shoulders, inclined surfaces, dovetails, and T-slots. Various form-tooth cutters are used for cutting concave forms, convex grooves, rounding corners, and for cutting gear teeth.

Milling machines are available in a variety of designs, which can be classified under the following general classifications: (1) standard knee-and-column machines, including the horizontal type (Figure 7) and the vertical type, (2) bed-type or manufacturing machines, and (3) special machines designed for special milling jobs.

**Grinding machines.** Grinding machines remove small chips from metal parts that are brought into contact with a rotating abrasive wheel called a grinding wheel (see also ABRASIVES), or an abrasive belt. Grinding is the most accurate of all of the basic machining processes. Modern grinding machines grind hard or soft parts to tolerances of plus or minus 0.0001 inch (0.0025 millimetre).

The common types of grinding machines include (1) plain cylindrical, (2) internal cylindrical, (3) centreless (Figure 8), (4) surface (Figure 8), (5) off-hand, (6) special, and (7) abrasive-belt.

**Power saws.** Metal-cutting power saws are of three basic types: (1) power hacksaws, (2) band saws, (3) circular disc saws. Vertical band saws are used for cutting shapes in metal plate, internal and external contours, and for angular cuts.

**Presses.** This large class of machines includes equipment used for forming metal parts through application of the following processes: shearing, blanking, forming, drawing, bending, forging, coining, upsetting, flanging, squeezing, and hammering. All of these processes require presses that are provided with a movable ram that is pressed against an anvil or base. Power to the movable ram may be furnished through gravity, mechanical linkages, or through hydraulic or pneumatic systems.

Appropriate die sets, with one part mounted on the movable ram and the matching part mounted on the fixed bed or platen, are an integral part of the machine. Punch presses punch out metal parts from sheet metal and form the parts to the desired shape. Dies with cavities having a variety of shapes are used on forging presses that form white-hot metal blanks to the desired shape. Power presses are also used for shearing, bending, flanging, and shaping sheet metal parts of all sizes. Power presses are made in various sizes, ranging from small presses mounted on a workbench to machines weighing more than 1,000,000 pounds (450,000 kilograms).

Dies

#### MODIFICATIONS OF BASIC MACHINES

Certain production machine tools have been designed to speed up production. These tools include features of the basic machine tools and perform the same operation, but they incorporate design modifications that make it possible to perform either complex or repetitive operational sequences more rapidly. Furthermore, after the production machine has been set up by a skilled worker

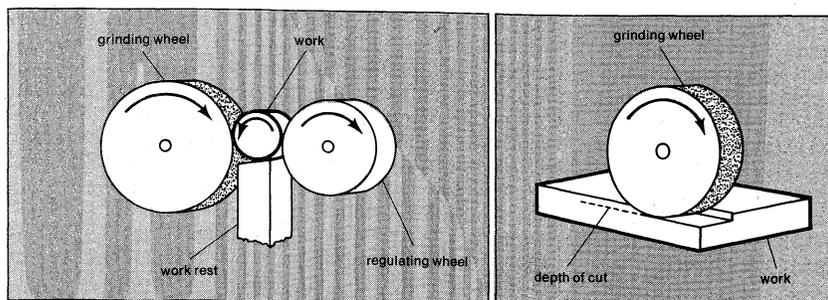

Figure 8: (Left) Centreless grinding operation. (Right) Surface grinding operation.

or machinist, a less skilled operator can produce parts accurately and rapidly. The following are examples of production machine tools that are modifications of basic machine tools: (1) turret lathes, including screw machines, (2) multiple-station machines, (3) gang drills, and (4) production milling machines.

**Turret lathes.** Horizontal turret lathes have two features that distinguish them from the engine lathe. The first is a multiple-sided main turret, which takes the place of the tailstock on the engine lathe (Figure 9). A variety of

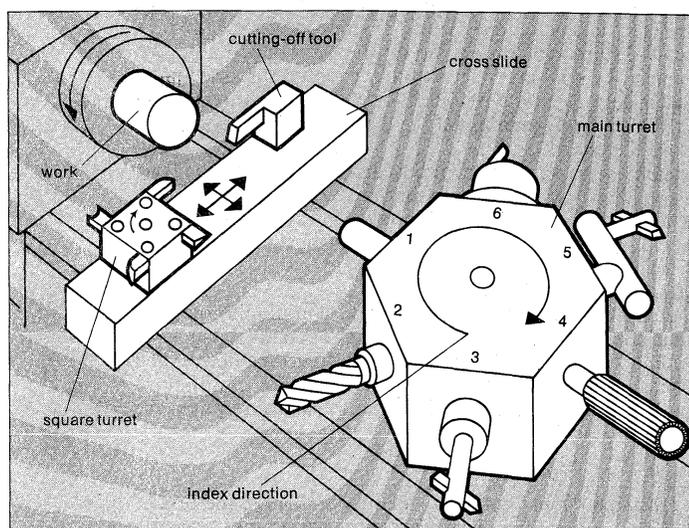

Figure 9: Horizontal turret lathe.

turning, drilling, boring, reaming, and thread-cutting tools can be fastened to the main turret, which can be rotated intermittently about its vertical axis with a hand wheel. Either a hand wheel or a power feed can be used to move the turret longitudinally against the workpiece mounted on the machine spindle.

The second distinguishing feature of the turret lathe is the square turret mounted on the cross slide. This turret also can be indexed about its vertical axis and permits the use of a variety of turning tools. A tool post or tool block can be clamped to the rear of the cross slide for mounting additional tools. The cross slide can be actuated either by hand or by power.

Turret lathes may be classified as either chucking machines or bar machines. Bar machines formerly were called screw machines, and they may be either hand controlled or automatic. A bar machine is designed for machining small threaded-type parts, bushings, and other small parts from bar stock fed through the machine spindle. Automatic bar machines produce parts automatically, including automatic replacement of bar stock into the machine spindle. A chucking machine is designed primarily for machining larger parts, such as castings, forgings, or blanks of stock that usually must be mounted in the chuck manually.

**Multiple-station machines.** Several types of multistation vertical lathes have recently been developed. These machines are essentially chucking-type turret lathes for machining threaded cylindrical parts. The machine has 12 spindles, each equipped with a chuck. Directly above

each spindle, except one, tooling is mounted on a ram. Parts are mounted in each chuck and indexed for up to 11 machining operations. At the 12th station the finished part is removed and a rough part is inserted.

**Gang drills.** A gang-drilling machine consists of several individual columns, drilling heads, and spindles mounted on a single base and utilizing a common table. Various numbers of spindles may be used, but four or six are common. These machines are designed for machining parts requiring several hole-machining operations, such as drilling, countersinking, counterboring, or tapping. The workpiece is moved from one drilling spindle to the next for sequential machining operations by one or more operators.

**Production millers.** Milling machines used for repetitive-production milling operations generally are classified as bed-type milling machines because of their design. The sliding table is mounted directly on the massive bed of the machine, without provision for table elevation or transverse table movement. Table movement is longitudinal only. The spindle head may be adjusted vertically to establish the depths of cut. Some machines are equipped with automatic controls. Thus, a semiskilled operator can load parts in fixtures at each end of the table and start the machine. One part can be unloaded and replaced while the other is being machined.

#### SPECIAL-PURPOSE MACHINES

Special-purpose machine tools are designed to perform special machining operations, usually for production purposes. Examples include gear-cutting and gear-grinding machines, broaching machines, lapping and honing machines, and boring machines.

**Gear-cutting machines.** Three basic cutting methods are used for machining gears: (1) form cutting, (2) template cutting, and (3) generating. The form-cutting method involves the use of a cutting tool that has the same form as the space between two adjacent teeth on a gear. This method is used for cutting gear teeth on a milling machine. The template-cutting method makes use of a template for guiding the single-point cutter on large bevel-gear cutting machines.

Most cut gears produced in large lots are made on machines that utilize the gear-generating principle. This principle is based on the fact that two involute gears, or a gear and rack, with the same diametral pitch mesh together properly. Therefore, a cutting tool with the shape of a gear or rack but with proper grinding may be used to cut gear teeth in a gear or rack blank. This principle is applied in the design of a number of widely used gear-cutting machines of the generating type. Some gear-generating machines cut with reciprocating strokes and are called gear shapers.

Gear-hobbing machines use a rotating, multiple-tooth cutting tool called a hob for generating teeth on spur gears, worm gears, helical gears, splines, and sprockets. More gears are cut by hobbing than by other methods. The hobbing cutter cuts continuously and produces accurate gears at high production rates.

In gear-making machines gears can be (1) entirely cut, (2) entirely ground, or (3) produced by a combination of cutting and grinding operations. Gear-grinding machines of special design are used for grinding gear teeth.

**Broaching machines.** Broaching is classified in a general way as a planing or shaping art, because the action of

The  
chucking  
machine

Hobbing

a broaching tool resembles the action of planer and shaper tools. Broaching tools of various designs are available (Figure 2). The teeth on broaching tools are equally spaced, with each successive tooth designed to feed deeper into the workpiece, thus completing the broaching operation in a single stroke. Examples of internal broaching applications include cutting keyways in the hubs of gears or pulleys, cutting square or hexagonal holes, and cutting gear teeth. External grooves can be cut in a shaft with an external broaching tool. Some broaching machines are used for pulling or pushing broaching tools through or over the workpiece.

**Lapping and honing machines.** Lapping and honing operations are classified under the basic art of grinding. Lapping involves the use of abrasive pastes or compounds impregnated in a soft cloth and rubbed against the surface of a workpiece. Lapping is done to produce a high quality surface finish or to finish to very close size limits. Dimensional tolerances of two millionths of an inch (0.00005 mm) can be achieved by either hand or machine lapping precision parts such as gages or gage blocks.

**Honing** is a low-speed surface finishing process used for removing small amounts of metal, usually less than 0.0005 inch (0.0125 mm) from ground or machined surfaces for the purpose of removing scratches or machine marks. Honing is done with bonded abrasive sticks or stones that are mounted in a honing head. For a typical honing operation, such as honing automotive engine cylinder walls, a honing machine with one or more spindles is used. The honing head rotates slowly with an oscillating motion, holding the abrasive sticks against the work surface under controlled light pressure.

**Boring machines.** Boring can be done on any type of machine equipped to hold a boring tool and a workpiece and equipped to rotate either the tool or the workpiece in proper relationship (Figure 5). Special boring machines of various designs are used for boring workpieces that are too large to be mounted on a lathe, drill press, or milling machine. Boring and turning operations are also performed on large vertical turret lathes or on larger boring mills. Standard boring machines are able to bore or turn work up to 12 feet (3.6 m) in diameter.

#### AUTOMATIC CONTROL

To be truly automatic a machine tool must be capable of producing parts repetitively without operator assistance in loading parts, starting the machine, and unloading parts. In this sense, some bar-turning machines are automatic. In practice, however, some machine tools designated as automatic are actually semi-automatic, since they require an operator to load the workpiece into the machine, press the start button, and unload the part when completed.

The tooling for automatic machines is more complex than for hand-controlled machines and usually requires a skilled worker for making the setup. After the setup, a less skilled operator can operate one or more machines simultaneously. Tracer lathes and numerically controlled machine tools are examples of machines utilizing varying degrees of automatic and semi-automatic control.

**Tracer techniques.** The tool slide on a tracer lathe is guided by a sensitive stylus, hydraulically actuated, that follows an accurate template. The template may be an accurate profile on a thin plate or a finish-turned part. Tracing mechanisms generally are accessory units that are attached to engine lathes, but some lathes are especially designed as automatic tracing lathes. Optional accessories for use on tracing lathes include automatic-indexing toolheads and one or more cross slides for operations such as facing, grooving, and chamfering.

Tracing lathes machine all common cylindrical shapes; straight, tapered shoulders; and irregular curves. Accessory tools permit facing, grooving, and chamfering operations. An unlimited combination of cutting speeds, feeds, and types of cuts may be used, including roughing cuts and finishing cuts. On machines equipped for automatic operation, changes in speed, feed, and cutting tools are automatic.

**Numerical control.** Many types of machine tools and other industrial processes are equipped for numerical con-

trol, now commonly called NC. An NC system or device is one that controls the actions of a machine or process through direct insertion of numerical data at some point, and the system must automatically interpret at least some portion of these data. Perhaps the term symbolic control would have been more appropriate, since various kinds of NC systems use data coded in the form of numbers, letters, symbols, words, or a combination of these forms.

The machining instructions necessary for machining a part by NC are derived from the part drawing and are written in coded form on a program manuscript. The following kinds of data may be included on the manuscript: (1) sequence of operations, (2) kind of operation, (3) depth of cut, (4) coordinate dimensions for the centre of the cutting tool, (5) feed rate, (6) spindle speed, (7) tool number, and (8) other miscellaneous operations.

The coded information is then punched into a ribbon of one-inch wide machine-control tape with a tape-punching machine similar to a typewriter. The tape, usually made of paper or plastic, is inserted into the NC system, which is connected to the machine tool. The NC system interprets the information on the tape, thus activating relays and electrical circuits that cause the machine's servomechanisms and other controls to perform a sequence of operations automatically. On some NC systems, the coded information is inserted into the machines on punched cards or magnetic tape instead of punched tape. The tape can be stored for future use on the same machine or on others like it at any location. NC machines produce parts accurately to limits of 0.001 or 0.0001 inch (0.025 or 0.0025 mm) depending on the design of the machine and the NC system.

NC systems on machine tools can be classified under two basic types: (1) point-to-point and (2) continuous-path. Point-to-point systems, commonly used on machines that perform hole-machining and straight-line milling operations, are relatively simple to program and do not require the aid of a computer.

Continuous-path NC systems are commonly used on machines that perform contouring operations, such as milling machines, lathes, flame-cutting machines, and drafting machines. Program preparation for continuous-path machines is more complex and usually requires the aid of an electronic computer.

#### CHIPLESS METHODS OF REMOVING METAL

**Plasma arc machining.** Called PAM, this is a method of cutting metal with a plasma-arc, or tungsten inert-gas-arc, torch. The torch produces a high velocity jet of high-temperature ionized gas (plasma) that cuts by melting and displacing material from the workpiece. Temperatures obtainable in the plasma zone range from 20,000° to 50,000° F (11,000° to 28,000° C). The process may be used for cutting most metals, including those that cannot be cut efficiently with an oxyacetylene torch. With heavy-duty torches, aluminum alloys up to six-inch (15 cm) thicknesses and stainless steel up to four-inch (10 cm) thicknesses have been cut by the PAM process. The process also has been used on lathes for turning large, hardened steel rolls.

**Laser-beam machining.** Known as LBM, this is a method of cutting metal or refractory materials by melting and vaporizing the material with an intense beam of light from a laser (see LASER AND MASER). The beam of light is used to produce small-diameter holes that can be spaced along a layout line to cut materials. Applications of LBM are limited to cutting or drilling thin metals and refractory materials that cannot be cut more economically by other methods.

**Electrical-discharge machining.** This technique, called EDM, involves the direction of high-frequency electrical spark discharges from a graphite or soft metal tool, which serves as an electrode, to disintegrate electrically conductive materials such as hardened steel or carbide. The electrode and workpiece are immersed in a dielectric liquid, and a feed mechanism maintains a spark gap of from 0.0005 to 0.020 inch (0.013 to 0.5 mm) between the electrode and the workpiece. As spark discharges melt or vaporize small particles of the workpiece, the particles

Symbolic control

Abrasive sticks

Cutting holes with lasers

are flushed away, and the electrode advances. The process is used for machining dies, molds, holes, slots, and cavities of almost any desired shape.

**Electrochemical machining.** In electrochemical machining (ECM) metal is dissolved from a workpiece at a controlled rate with direct current in an electrolytic cell. The workpiece serves as the anode and is separated by a gap of 0.001 to 0.030 inch (0.025 to 0.75 mm) from the tool, which serves as the cathode. The process is essentially a deplating process. The electrolyte, usually a saline solution, is pumped under pressure through the servocontrolled tool gap, thus flushing away dissolved waste removed from the workpiece. The process is used for machining odd-shaped parts and deep holes in hard metals.

**Chemical machining.** This nonelectrical process, called CHM, removes metal from selected or overall areas by controlled chemical action. Masking tape is used to protect areas not to be removed. The method is related to the process used for making metal-printing and engraving plates. Two types of chemical machining processes include: (1) chemical blanking, which is used for blanking thin metal parts and (2) chemical milling, which is used for removing metal from selective or overall areas of metal parts.

**Ultrasonic machining.** In USM, material is removed from a workpiece with particles of abrasive that vibrate at high frequency in a water slurry circulating through a narrow gap between a vibrating tool and a workpiece. The tool, shaped like the cavity to be produced, oscillates up and down about 0.0005 to 0.0025 inch (0.013 to 0.062 mm) at 19,000 to 25,000 hertz (cycles per second). The tool vibrates the abrasive grains against the surface of the workpiece, thus removing material. USM is used primarily for cutting hard, brittle materials that may be conductors of electricity or insulators. It also is used for machining hardened steels, carbide, and semiconductors.

**Electron-beam machining.** This technique, EBM, is used for cutting fine holes and slots in any material, enclosed in a vacuum, with the use of a focussed beam of high-velocity electrons. The kinetic energy of the electrons, upon striking the workpiece, changes to heat that vaporizes minute particles of the material. The vacuum prevents the electrons from scattering, due to collisions with gas molecules. EBM is used for cutting holes as small as 0.001 inch (0.025 mm) diameter or slots as narrow as 0.001 inch in materials up to 0.250-inch (6.25 mm) thickness. Welding also can be done on very fine wire or tiny parts with an electron beam by reducing its energy level.

**BIBLIOGRAPHY.** The best sources of general information on machine tools are W.J. MCCARTHY and R.E. SMITH, *Machine Tool Technology*, 3rd ed. (1968); and E.P. DEGARMO, *Materials and Processes in Manufacturing*, 3rd ed. (1969). The most authoritative, although highly technical, source for all phases of machine tools is the AMERICAN SOCIETY FOR METALS, *Metals Handbook*, vol. 3, *Machining*, 8th ed. (1967). An excellent source on the history of machine tools is L.T.C. ROLT, *A Short History of Machine Tools* (1965). O.A. LUDWIG and W.J. MCCARTHY, *Metalwork: Technology and Practice*, 5th ed. (1969), is a good secondary school text. A comprehensive source of technical data is E. OBERG and F.D. JONES, *Machinery's Handbook: A Reference Book for the Mechanical Engineer, Draftsman, Toolmaker and Machinist*, 18th ed. (1968).

(W.J.McC.)

## Mackenzie River

Draining an area that, at 711,000 square miles (1,841,000 square kilometres), is almost as large as that of Mexico, the Mackenzie River is one of the major river systems in the drainage pattern of North America: its basin is the largest in Canada, and it is only exceeded on the continent by the Mississippi-Missouri system. From the headwaters of the Finlay River, which flows into the Peace River Reservoir west of the Rocky Mountains, the entire river system runs for 2,635 miles (4,240 kilometres) through the sparsely settled, lake-strewn Canadian north to empty into the cold waters of the Beaufort Sea in the Arctic Ocean. The Mackenzie itself is 1,060 miles (1,706 kilometres) long, according to the conventional measurement from Great Slave Lake. The river is

generally wide, mostly from one to two miles across, and in island-dotted sections, three or four miles wide. It has a strong flow. Its lake-covered triangular delta measures more than 120 miles from north to south and is about 50 miles wide along the Arctic shore.

The headwaters of the system include several large rivers, which themselves drain vast forested plains of north-eastern British Columbia and northern Alberta. These drainage basins include the Liard River (107,000 square miles), the Peace River (125,250 square miles), and the Athabasca River (62,900 square miles). Much shorter rivers flow into the system from the east, draining the low rocky hills of the ancient structural mass known as the Canadian Shield. The system also includes the huge Great Slave Lake (10,980 square miles), Great Bear Lake (12,275 square miles), and the smaller Lake Athabasca (940 square miles).

The whole basin is sparsely populated, and its resources are few and less accessible than those of southern Canada. Yet the whole region is one of the few great unspoiled areas of the world, offering a rich wildlife and spectacular scenery, as well as a somewhat harsh climatic environment.

**Exploration of the region.** Explorers and fur traders pushed westward across Canada in the late 18th century to the headwaters of rivers that flowed into Hudson Bay, seeking to tap the fur resources in the lands beyond. In 1778 one of them, Peter Pond, found Portage La Loche (Methy Portage) connecting the headwaters of Churchill River with the Clearwater River, itself one of the east-bank tributaries of the Athabasca River. In 1789 Alexander Mackenzie made his historic journey northward from the trading post of Fort Chipewyan on Lake Athabasca, exploring with a crew of 12 persons in three canoes, the full length of the mighty river now bearing his name.

Other fur traders of the North West Company followed early in the 19th century, establishing posts at several sites along the river and on its headwater tributaries. From the mid-1820s, supplies were carried in by the distinctive York boats, shallow-draft vessels with a sharply angled stern and bow. In 1884 the first steamer began to operate northward from McMurray, at the junction of the Clearwater and Athabasca rivers, to Fitzgerald on the Slave River. At this point there are 16 miles of rapids in Slave River, the only break in 1,700 miles of shallow-draft river navigation from McMurray to the Arctic Ocean. In 1886 the first steamer began operating north of Fort Smith, on the present Northwest Territories-Alberta border, taking supplies to the Mackenzie River trading posts and bringing out bales of fur. During the 1920-40 period, flat-bottomed, stern paddle-wheeled vessels operated on the Mackenzie River, but they were replaced after 1945 by small diesel tugs that could push several barges.

**The course of the river.** *The role of ice.* The Mackenzie River itself begins at the western end of Great Slave Lake, at 513 feet (156 metres) above sea level. Deep (more than 1,000 feet in some places), clear water fills the lake's eastern arm, and shallow, murky water is found in the western part. Because of its large size and extent of winter ice cover, Great Slave Lake is the last part of the Mackenzie waterway to be free of ice in the spring, with some ice remaining until mid-June in the lake's centre.

The ice on the Mackenzie River begins to break up in early to mid-May in its southern section, being preceded by breakup on the Liard River. Tributary rivers are free of ice before the Mackenzie itself, and high water and flooding are common during the breakup period, particularly when ice dams form. The ice across the lower Mackenzie River breaks up in late May; the channels in the Mackenzie River Delta are usually free of floating river ice by the end of May or early June, with the western channels being influenced by the earlier breakup of the Peel River. Sea ice usually remains offshore from the delta in the Beaufort Sea during June, particularly if prevailing winds are onshore.

*The upper course.* The head of the Mackenzie River is about six miles wide where the western end of the Great Slave Lake narrows and is filled by one large island and

Size of the system

Great Slave Lake

several small ones. The river narrows to less than a half mile in width near Fort Providence, and it is there that ice bridges are built across the river in early winter to carry truck traffic along the Mackenzie-Slave Lake Highway. Ferries are used for this crossing in summer, but all road traffic ceases during the breakup period in May. A branch road extends to Fort Simpson, and except for a winter trail that is used only occasionally, there are no through roads farther north along the Mackenzie Valley. Mills Lake is a shallow broadening of the Mackenzie River west of the village of Fort Providence. To the west the river again narrows to about a mile in width, and the current is fast at Green Island Rapids, about 12 miles east of Fort Simpson. There is, however, a seven- to ten-foot channel among the boulders in these rapids, sufficient for the flat-bottomed barges pushed by shallow-draft tugs that operate out of the southern terminal of Hay River and along the Mackenzie.

At Fort Simpson the 755-mile-long Liard joins the Mackenzie from the west from its source in the southeastern Yukon Territory. The contrast between the muddy, silt-laden water of the Liard and the clear water of the Mackenzie is very apparent in the river after the junction, as these "two rivers in one" remain separate in terms of certain physical properties for about 300 miles downstream. At Fort Simpson, as for much of its course, the Mackenzie flows between steep, gray gravel banks, 100 to 200 feet high, which obscure the adjacent lowlands from view.

The Mackenzie River Lowlands are about 250 miles wide near Fort Simpson. Although it is classed as forested, mainly with a few species of coniferous trees, such as black and white spruce, and some poplar, much of the lowland away from the tributary rivers is covered by swamps, muskegs (bogs), and lakes, as well as many open areas of grassy vegetation and low bushes. The Mackenzie Mountains rise steeply on the western side of the Mackenzie Valley to altitudes of 5,000 to 6,000 feet; since the tree line is at about 3,000 feet, the upper slopes are barren. The eastern edge of the Mackenzie Lowlands is formed by ancient hills of the Canadian Shield, which slope up to altitudes of about 1,000 feet.

The Mackenzie River Lowlands are underlain by flat-lying sedimentary rock of Cretaceous (100,000,000 years old) and Devonian (350,000,000 years old) geological ages. Little of this rock is exposed at the surface, however, because it is mantled with glacial and alluvial deposition of clays, sands, and gravels.

North of Fort Simpson the Mackenzie River is a little less than 400 feet above sea level, is a mile wide, and flows between steep banks. The mean discharge is measured at 228,000 cubic feet per second at Fort Simpson; the average flow at high water during June is above 400,000 cubic feet per second, and this seems to be equally obtained from the Liard and upper Mackenzie. The latter supplies a larger share of the river's volume during winter.

*The lower course.* North of the trading post at Wrigley, the Redstone and Keele rivers enter from the west; they have deep canyons where they break out of the Mackenzie Mountains but flow across the lowland as shallow, braided streams. These rivers and the others that drain from the Mackenzie Mountains have their peak flows in June after the snow melts in the mountains; they become shallow rivers in late summer. The Mackenzie River picks up relatively little volume within its valley lowland, as the average summer precipitation recorded at dispersed settlements is only about seven or eight inches (175 to 200 millimetres); total annual precipitation throughout the Mackenzie Valley is ten to 14 inches (250 to 350 millimetres).

At the village of Fort Norman the cold, clear water of Great Bear River enters from the east. This short river empties out of Great Bear Lake; it is navigable for shallow-draft vessels, except for a short portage around rapids about 30 miles east of its mouth. Once more, there is a distinct summer demarcation for 50 miles northward in the Mackenzie River between its silt-laden water and the clear water from the Great Bear River on the eastern bank. At Norman Wells the Mackenzie River broadens

to about four miles in width and is less than 175 feet above sea level. The mean annual discharge of the river there is 311,000 cubic feet per second but flows during June and July will usually exceed 500,000 cubic feet per second.

The Mackenzie Valley Lowland is only about 30 miles wide in this section, being broken by the treeless summits of the Franklin Mountains, which rise to a little more than 3,000 feet altitude on the east side of the river. Small lakes are not so common across the Mackenzie Valley in this area as they are on the lowland west of Great Slave Lake. Forest vegetation is scanty except in the river valleys and in areas of better drainage; most of the trees are stunted spruce.

Where Mountain River joins the Mackenzie from the west there is a fast water section known as Sans Sault Rapids; the river drops about 20 feet within a few miles. There is ample depth of water for the shallow-draft barges during July, but, despite deepening of the channel by rock blasting, shallow water is sometimes a navigation problem in late summer. South of the Indian village of Fort Good Hope, the Mackenzie narrows as it flows between 100- to 150-foot perpendicular limestone walls known as The Ramparts. North of Fort Good Hope, the Mackenzie crosses the Arctic Circle. It is slightly entrenched and meanders across its flat valley floor, its banks being two or three miles apart; low islands are numerous, and shifting sandbars are a problem for the riverboats. Where the Arctic Red River enters from the south, the Mackenzie again flows between steep rock walls, which rise about 100 to 200 feet directly from the water.

*The delta region.* At Point Separation the Mackenzie River Delta begins. From the south the 425-mile Peel River is the last major tributary to add water to the Mackenzie. The mean discharge of water into the Mackenzie Delta is estimated at 400,000 cubic feet per second, more than doubling at flood peaks. The delta covers about 4,700 square miles and is a maze of branching, intertwining channels, numerous cutoff lakes, and circular ponds. These lakes are an excellent habitat for muskrat, and the trapping of these animals became the main source of income for the Indian and Eskimo inhabitants of the delta from 1920 to 1950.

The perpetually frozen subsurface layer known as permafrost lies a few feet beneath the surface of the islands in the delta and exists in a discontinuous layer beneath the whole Mackenzie River Lowlands north of Great Slave Lake. Depending on the type of vegetation cover, the top few inches to several feet of ground above the permafrost melts during the summer months. Northern construction of airfields, roads, and pipelines has to be adapted to these permafrost conditions; houses and other buildings are usually placed on wooden piles that are sunk and frozen into the permafrost to give stability. One of the distinctive features of the town of Inuvik, built in the 1950s, is a utilidor, a linear boxlike metal container raised slightly above the surface of the ground, in which the separate sewer, water, and heating pipes are placed. Mackenzie River water-transport routes terminate at Tuktoyaktuk on the Arctic coast northeast of the delta, where cargo is transferred to other vessels of greater draft, which serve the small settlements and defensive radar stations along the western Arctic coast.

**Human exploitation.** The Mackenzie River Basin is sparsely populated. Its natural resources are few, and they are less accessible than comparable resources in southern Canada. Fur-bearing animals were the resource attraction of the 19th century; although they are still trapped throughout the forests of the river basin, particularly by the Indian population, furs now constitute a minor element in the regional economy. Muskrat, marten, beaver, lynx, and fox are the main pelts sought. The forests in the southern part of the basin have been utilized for local lumber in the Peace River area and near other small settlements. The small trees may have future value as a source of pulpwood.

Agricultural land is developed only in the south, particularly in the Peace River area. Settlers moved into the Athabasca River, Lesser Slave Lake, and Peace River

The "two rivers in one"

Rainfall in the lowlands

The permafrost region

areas in large numbers after 1920, when the farmlands of the Canadian prairies were almost all occupied. When railroad connections were established southward to Edmonton, these farms were able to produce grain, livestock, and legume seed for external markets. A few farms and many gardens produced well along the Mackenzie River before 1940, but the improved transport of recent decades has permitted most food to be imported. With July mean temperatures averaging about 60° F (16° C), and daily temperatures that reach into the 70s and sometimes 80s, climate does not prevent the growth of certain crops.

The  
role of  
oil and  
minerals

Minerals are the economic basis of some of the larger settlements in the basin. The first oil field was discovered at Norman Wells in 1921, but production did not begin until the 1930s. These wells and the small refinery at Norman Wells still produce for the industries, transport, and homes of the central and northern parts of the Mackenzie Valley. Other oil fields were discovered in the early 1970s near the Mackenzie River Delta. The largest oil fields are in the southern parts of the river basin, in northwestern Alberta and northeastern British Columbia. This oil is carried southward by pipeline to Edmonton to be distributed to refineries in southern Canada and the northern United States. An enormous reserve of petroleum lies in the Tar Sands along the Athabasca River north of McMurray; production there has been limited by a quota system.

Metallic minerals were found along the eastern edges of the basin. Valuable radium and uranium ores were produced from 1933 to 1961 at Port Radium on the eastern shores of Great Bear Lake, despite very high transportation costs. Other uranium mines came into production after 1950 at Uranium City on the north side of Lake Athabasca. High-quality gold mines, discovered after 1935, brought into existence the city of Yellowknife, the present capital of the Northwest Territories, on the north arm of Great Slave Lake. Lead-zinc deposits were developed in the 1960s at Pine Point on the south side of Great Slave Lake. When the deposits proved to be large enough, the first railroad into the Northwest Territories was built from the Peace River area along the Mackenzie Highway to Hay River and Pine Point.

The water of the Mackenzie River system was too far away from large industrial and urban markets to be used for hydroelectric power until the late 1960s. At that time the Peace River was dammed as it broke out of the Rocky Mountains and a large storage lake formed westward in the Rocky Mountain Trench. This electric power is transmitted 600 miles to Vancouver, British Columbia. Otherwise, the only developed waterpower sites are on the Snare and Talston rivers, which drop westward out of the Canadian Shield to the Mackenzie Lowlands and supply power to the mines and residents at Yellowknife and Pine Point. There is no utilization of the water of the Mackenzie River itself, except for river transportation.

The large lakes of the Mackenzie Basin are a source of lake trout and whitefish. Lake Athabasca was first exploited during the 1930s, and then Great Slave Lake was opened to commercial fishing after 1945. In the latter lake, fish are caught in both summer and winter and transported south by truck or rail to urban markets in both Canada and the United States. The catch is controlled by seasonal quotas that prevent depletion of the species. The cold water of Great Bear Lake has some fish, but they grow too slowly to withstand commercial fishing except by sports fishermen. Fish of the Mackenzie River are netted by some local residents to supplement their imported food.

**BIBLIOGRAPHY.** LESLIE ROBERTS, *The Mackenzie* (1949), is a popular account of the history and use of the river.

(J.L.Ro.)

### Mackinder, Sir Halford John

Sir Halford Mackinder introduced to political geography a view of the Earth as potentially ranged in two camps—the land power of Eurasia, the “heartland,” which had, following the decline in the military importance of navies and the opening up of Siberia, gained

Mackinder, drawing by Sir William Rothenstein, 1933. In the collection of the London School of Economics and Political Science.

ascendancy over the sea power of the “maritime lands,” including the other continents.

Mackinder was born on February 15, 1861, at Gainsborough, Lincolnshire, where his father, of Scottish descent, practiced as a doctor. He was early fascinated by the natural history of the countryside and was a voracious reader of the great Victorian travellers. In 1880 he entered Christ Church, Oxford, where he studied natural sciences with a preference for biology; he obtained first class honours in 1883 and, one year later, a second class in modern history. His political aspirations found expression in his election as president of the Oxford Union, the principal debating society at the university. After leaving Oxford he read for the bar at the Inner Temple, one of the law “colleges” in London, and qualified as a barrister in 1886. As a lecturer for the Oxford extension movement—formed to give educational opportunities to people unable to attend a university—he travelled widely through the country, particularly among the workmen of the north of England, expounding what he called the “new geography.” With this new, clear-cut concept of geography as a bridge between the natural sciences and the humanities, he soon won attention. Tall, of distinguished presence, and with a gift for generalization, he excelled in his ability to drive home the fundamental points of a theme. His *Britain and the British Seas* (1902, 2nd ed. 1930), written with assurance and style, is a recognized landmark in British geographical literature.

At that time, a group of men at the Royal Geographical Society were making strong efforts to raise the status of geography as an academic discipline in Britain and to secure for it an adequate place in the educational system. Learning of Mackinder’s success, the society invited him to address it on the new geography. He met the challenge boldly, delivering his paper on “The Scope and Methods of Geography” with great persuasiveness. In 1887 he had become reader in geography at Oxford, the first such appointment in a British university. When in 1899 the Royal Geographical Society and the university established the Oxford School of Geography, it was almost inevitable that Mackinder should be the first director. It was typical of the man that in the same year he organized and led an expedition to East Africa, where he made the first ascent of Mt. Kenya. As he commented, in the popular view, the geographer must also be “an explorer and adventurer.”

Mackinder, working also at Reading and London, continued at Oxford until 1904, when he was appointed director of the recently founded London School of Economics and Political Science, a constituent body of the University of London. There, for four years, he devoted

The “new  
geography”

Director  
of London  
School of  
Economics

his energies to its administration and to that of the university. He played a prominent part in ensuring that the university centre was established at Bloomsbury in the heart of London and not on the periphery of the metropolis. Though he continued as reader in economic geography for another 18 years, his resignation as director marked the beginning of the third phase of his career. He entered Parliament in 1910 as Unionist (Conservative) member for the Camlachie division of Glasgow. Holding strong imperialist views, his circle of friends included similarly minded men, among them the politician L.S. Amery and Lord Milner, the imperial administrator. In the House, Mackinder did not make a strong impact, perhaps because the Commons are not overfond of academics. He retained his seat at the general election of 1918, when he described his opponent as "boldly defensive of the Russian Bolsheviks," but was defeated in 1922.

"The Geographical Pivot of History"

Studying the prerequisites for a stable peace settlement during World War I, he developed a thesis in political geography that he had first outlined in a paper read to the Royal Geographical Society in 1904, "The Geographical Pivot of History." In it he argued that interior Asia and eastern Europe (the heartland) had become the strategic centre of the "World Island" as a result of the relative decline of sea power as against land power and of the economic and industrial development of southern Siberia. His extended views were set out in a short book, *Democratic Ideals and Reality*, published early in 1919 while the Paris Peace Conference was in session. The role of Britain and the United States, he considered, was to preserve a balance between the powers contending for control of the heartland. As a further stabilizing factor, he urged the creation of a tier of independent states to separate Germany and Russia, much along the lines finally imposed by the peace treaty. The book included, apart from the main theme, many farsighted observations; e.g., his insistence on the "one world" concept, the need for regional organizations of minor powers, and the warning that chaos in a defeated Germany would inevitably lead to dictatorship. The book attracted little attention in Britain but rather more in America. There was an unexpected sequel, however, for the concept of the heartland was seized upon by the German geopolitician Karl Haushofer to support his grand design for control of the World Island. Thus, during World War II there were suggestions that Mackinder, through Haushofer, had inspired Hitler. More sober evaluation disposed of this absurd notion, and, though developments have affected some of the arguments, the thesis is recognized as an important view of world strategy. In 1924, mindful of the lessons of World War I, Mackinder published his prophetic theory of the Atlantic community that became reality after World War II and assumed military form in the North Atlantic Treaty Organization (NATO). In his hypothesis—which remained largely unnoticed—Mackinder argued that the power of the Eurasian heartland could be offset by western Europe and North America, which "constitute for many purposes a single community of nations."

In 1919 Mackinder went as British high commissioner to south Russia in an attempt to unify the White Russian forces and was knighted on his return. After the close of his academic career in 1923, he served as chairman of the Imperial Shipping Committee, 1920–45, and of the Imperial Economic Committee, 1926–31. He was made a privy councillor (an honorific office) in 1926; among the other honours he received were the Patron's Medal, Royal Geographical Society, 1946, and the Charles P. Daly Medal of the American Geographical Society, 1944. He died on March 6, 1947.

**BIBLIOGRAPHY.** E.W. GILBERT, *Sir Halford Mackinder, 1861–1947* (1961), the most detailed biographical sketch yet available; H.J. MACKINDER, *The Scope and Methods of Geography and the Geographical Pivot of History* (papers of the Royal Geographical Society, reprinted 1951), detailed discussion in the introduction by E.W. GILBERT of Mackinder's contribution to the advancement of geography and the "Heartland" thesis; "Round World and the Winning of the Peace," *Foreign Affairs*, 21:595–605 (1943), a classic restatement of Mackinder's thesis; H.W. WEIGERT, V. STEFANSSON and R.E.

HARRISON (eds.), *New Compass of the World* (1949), includes a brief discussion of the geopolitics of the "Heartland" thesis; G.R. CRONE, *Modern Geographers*, rev. and enl. ed. (1970), sketch of the general background of Mackinder's work as a geographer.

(G.R.C.)

## Madagascar

Madagascar, or the Malagasy Republic (République Malgache), is an island republic off the southeast coast of Africa. Madagascar is the fourth largest island in the world, after Greenland, New Guinea, and Borneo, with a surface area of 226,444 square miles (586,486 square kilometres). Located in the southwestern Indian Ocean, it is separated from the African coast by the 500-mile-wide Mozambique Channel. The population numbers about 7,000,000. The national capital is at Tananarive.

In spite of its proximity to the continent, Madagascar's population is not related to the African peoples but rather to those of Indonesia, over 3,000 miles to the east. The Malagasy peoples do not consider themselves as Africans and have virtually no relations with neighbouring East African countries. Instead, because of the continuing bond with France that resulted from former colonial rule, the island is specially linked with French-speaking countries of West Africa; French, as well as Malagasy, has official status as a language.

Madagascar remains a geographical and historical paradox, linked in practice to Africa but in feeling identified with Indonesia, which is so far away as to have hardly any awareness of Madagascar or to maintain any substantial contemporary ties of substance with it. The Malagasy government has sought a role as a hyphen joining Africa and Asia, but this has not been expressed in any institutional form. The animal life and vegetation is equally anomalous, differing greatly from that of nearby Africa and being, in many respects, unique.

Although the coastlands have been known to Europeans for over 400 years and for much longer to Arabs, recent development has been more intense and concentrated in the central plateau, which contains the capital city of Tananarive. The road network and communications are generally better on the plateau, and the majority of its inhabitants have received some school education and are professing Christians, whereas in the coastal areas the majority follow traditional religions and have not attended school. The coastal peoples are, however, well represented in the ruling party, which arose from a coalition of forces the main strength of which lay off the plateau.

Although many small deposits of minerals and semiprecious stones are found, none has led to profitable exploitation on any large scale. The country remains overwhelmingly agricultural in production and in its exports. (For an associated physical feature see INDIAN OCEAN; for historical aspects see MADAGASCAR, HISTORY OF.)

(A.I.S.)

### THE LANDSCAPE

**The natural landscape.** *Relief features.* Madagascar consists of three large parallel longitudinal zones—the central plateau, the narrow coastal strip to the east, and the zone of low plateaus and vast plains in the west.

Situated between 2,500 and 4,500 feet above sea level, the plateau has been folded and worn down several times and is tilted to the west, where the slope is less sheer than it is to the east. Three massifs (mountain masses) are over 6,500 feet high. The Massif de Tsaratanana in the north is separated from the rest of the plateau by the ridge of Androna, whose volcanic summit at 9,436 feet (2,876 metres) is the highest point on the island. The Ankaratra Mountains in the centre comprise an enormous volcanic mass whose summit, Tsiafajavona, is 8,671 feet (2,643 metres) high. They act as a watershed separating three main river basins. Farther south, the Andringitra Mountains are a vast granite massif between the southern Betsileo and Bara districts.

The plateau slopes more regularly toward the extreme southern plain, but its boundaries to the east and west are more abrupt. To the east it descends in a sharp fault, by

The plateau

steps of 1,000 to 2,000 feet. This cliff, called the Great Cliff or Cliff of Angavo, is often impassable and is itself bordered by the Betsimisaraka Escarpment, a second and lower cliff to the east, which overhangs the coastal plain.

Behind the scarp face are the remains of ancient lakes, including one called Alaotra. To the south the two steep gradients meet and form the Mahafaly and the Androy plateaus, which overhang the sea in precipitous cliffs. Toward the west the descent is made in a series of steps. In places, however, the central plateau is bordered by an impassable escarpment, such as the Cliff of Bongolava. To the extreme north, the plateau is separated by the low belt of the Montagne de Ambre, which includes a series of volcanic craters.

The  
coasts

The eastern coast has an average width of 30 miles. It is a narrow alluvial plain that terminates at the sea in a low coastline bordered with extensive lagoons linked together by the Canal des Pangalanes, which is 400 miles long. To the south of Farafangana, the coast becomes rocky, and in the southeast there are little bays. The deep Baie d'Antongil (Bay of Antongil) is located to the northeast.

The western zone is between 60 and 125 miles wide. Its sedimentary layers slope toward the Mozambique Channel and produce a succession of hills. The inland (eastern) side of these steep hills dominates the hollows formed in the soft sediments, while the other side descends to the sea in rocky slopes.

The coastline is straight, bordered by small dunes and fringed with mangroves. The currents in the Mozambique Channel have favoured the deposit of alluvium and the growth of river deltas. On the northwestern coast there are estuaries and bays. This coast is bordered by coral reefs and volcanic islands, such as Nosy Be, which protects the Baie d'Ampasindava. (Je.D.)

*Soils.* The central plateau and the eastern coast are mainly composed of gneiss (a granite-like rock formed under heat and pressure), granite, quartz, and other crystalline formations. The gneiss decomposes into red murum (solid ironstone) and laterite (an infertile red soil with a high content of iron oxides and aluminum hydroxide) but also deeper and more fertile red earths, giving Madagascar its colloquial name of the Great Red Island. Fertile soils in the valleys support intensive cultivation. There are also northern, central, and southeastern volcanic intrusions that produce very fertile but easily erodible soils. Lac Alaotra (Lake Alaotra) is a sedimentary pocket in the central plateau, north of Imerina. The western third of the island consists entirely of sedimentary deposits that were raised up from under the sea or that underlay ancient lakes.

*Drainage.* The steep eastern face of the plateau is drained by numerous short, torrential rivers, which discharge either into the coastal lagoons or directly into the sea over waterfalls and rapids. They include the Mandrara, the Mananara, the Faraony, the Ivondro, and the Maningory. The more gently sloping western side of the plateau is crossed by longer and larger rivers, including the Onilahy, the Mangoky, the Tsiribihina-Mania, and the Betsiboka-Ikopa, which bring huge deposits of fertile sediments down into the vast plains and many-channelled estuaries; the river mouths, while not completely blocked by this sediment, are full of sandbanks.

The  
volcanic  
lakes

There are numerous lakes of volcanic origin, such as Lac Itasy. Alaotra is the last surviving lake of the eastern slope. Lac Tsimanampetsotsa, near the coast south of Tuléar, is a large body of saline water that has no outlet.

*Climate.* The hot, wet season extends from November to April and the cooler, drier season from May to October. The climate is governed by the combined effects of the southeast trade winds and the northwest monsoon (rain-bearing) winds as they blow across the central plateau. The trade winds, which blow throughout the year, are strongest from May to October. The east coast is to the windward and receives a high rate of annual precipitation, reaching about 146 inches (3,700 millimetres) at Maroantsetra on the Bay of Antongil. As the winds cross the plateau, they lose much of their humidity, causing drizzle and mists on the plateau and leaving the west dry. The monsoon, bringing rain to the northwest coast and

the plateau, is most noticeable during the hot, humid season. The wind blows obliquely onto the west coast, which receives a moderate rate of precipitation; the southwest, which is protected, remains arid. Annual rainfall drops from 92 inches (2,300 millimetres) on the northwestern island of Nosy Be to 30 inches (760 millimetres) at Maintirano and Morondava (both on the west coast) and to 13 inches (330 millimetres) at Tuléar in the southwest. The plateau receives moderate rains, with 53 inches falling annually at Tananarive and 48 inches at Fianarantsoa, about 200 miles further south.

July is the coolest month, with temperatures between about 54° and 77° F (12° and 25° C), and December the hottest month, with temperatures between 68° and 82° F (about 20° and 28° C). Temperatures are highest on the northwest coast and lowest on the plateau. The annual average temperature at Diégo-Suarez, on the extreme northern coast, is 80° F (27° C) and at Fort-Dauphin, on the extreme southeastern coast, 73° F (23° C). On the plateau, however, the annual average temperature is 64° F (18° C) at Tananarive and 65° F at Fianarantsoa.

Cyclones—turbulent windstorms that often bring torrential rain—are an important climatic feature. They form far out over the Indian Ocean, especially from December to March, and approach the eastern coast, bringing destructive floods.

*Vegetation and animal life.* Much of the island was once covered with evergreen and deciduous forest, but little now remains except on the eastern escarpment and in scattered pockets in the west. The plateau is particularly denuded and suffers seriously from erosion. The forest has been cut to clear rice fields, to obtain fuel and building materials, and to export valuable timber, such as ebony, rosewood, and sandalwood. About seven-eighths of the island is covered with prairie grasses and bamboo or small thin trees, including the travellers' tree, which holds water in its cellular trunk and produces the long banana-like leaves that are widely used for thatching. There are also screw pines, palms, and reeds on the coasts. In the arid south are thorn trees, giant cacti, dwarf baobab trees, and drought-resistant plants that are peculiar to the island.

The  
grassland  
vegetation

Because of the island's isolation, many zoologically primitive primates have survived and evolved into unique forms. Three-quarters of all known species of lemurs—nocturnal, arboreal mammals related to monkeys—are indigenous to Madagascar. Several unique hedgehog-like insectivores have evolved, and there are all sizes of chameleons. Birds are numerous and include guinea fowls, partridges, pigeons, herons, ibis, flamingoes, egrets, owls, and several kinds of birds of prey. There are about 800 species of butterfly, many moths, and a variety of spiders. The only large or dangerous animals are the crocodiles, which occupy the rivers. The snakes, including the *do*, which is 10 to 13 feet in length, are harmless.

There are few freshwater fish, but marine fish and crustaceans abound on the coasts and in the lagoons, as well as in the streams of the plateau. Certain species, such as the spiny globefish (a marine fish that inflates when disturbed) and the cofferfish, are peculiar to Madagascar.

*The landscape under human settlement.* *Rural settlement.* Despite the importance of intensive rice cultivation, the land is primarily used for pastoral purposes. Cattle are kept in all parts and are more numerous than the human population; they are fewer in the dense forest areas of the eastern escarpment. Elsewhere, pastoralism predominates, although the people also cultivate subsistence crops. On the plateau, the valley bottoms and irrigable slopes are mainly used for rice growing. The forest peoples traditionally grew hill rice, after cutting and burning the forest; this practice still continues, although it is discouraged by the government, which promotes the establishment of permanent irrigated rice fields.

The older villages of the Merina and Betsileo were often perched on hilltops and defended by huge ditches. Today, villages have been rebuilt on lower ground, and hamlets and homesteads are scattered over the landscape.

On the plateau, cattle enclosures are built of dry stone walls; the landscape is also dotted with funerary or com-

## MAP INDEX

## Political subdivisions

memorative monuments; in parts of the south and west, these take the form of wooden posts, beautifully carved.

**Urban settlement.** Madagascar, which has six main cities, has had an urban tradition since the 16th and 17th centuries. Tananarive, in the centre of the plateau, is the national capital and has a population of more than 380,000; it is six and a half times larger than the port of Tamatave in the east, which has 59,000 inhabitants. Fianarantsoa in the south of the plateau and the ports of Majunga in the northwest, Diégo-Suarez on the northern tip of the island, and Tuléar in the southwest have less than 57,000 inhabitants each. The smaller urban centre of Antsirabe (population 28,000), south of Tananarive, is mainly important as a tourist centre.

Racial or economic separation is not noticeable in the older cities such as Tananarive and Fianarantsoa, but the newer towns are often divided into socio-economic sectors. On the plateau, the cities are almost entirely composed of a particular ethnic group, but the ports are ethnically mixed.

## THE PEOPLE

**Population groups.** *Origin of the population.* Madagascar has been inhabited by man for the relatively short period of only about 2,000 years. Language and culture point unequivocally to Indonesian origins, but there is no empirical evidence of how, why, or by what route the first settlers came to the island. Studies of the winds and currents of the Indian Ocean indicate that the voyage from Indonesia could have been made. It is assumed that the original peopling of the island, however sparse, was accomplished by a single cultural group, probably as the result of a single voyage.

There is also widespread evidence from vocabulary, archaeology, and tradition of influence from Afro-Arab settlers on the coasts before AD 1000. There is slighter evidence of an Indian influence in vocabulary, but there is no trace of Hinduism in Malagasy culture and none of orthodox Islām except in later coastal settlements.

*Language.* The inhabitants of Madagascar speak Malagasy, which, written in the Latin alphabet, is a standardized version of the Merina language. Although there are numerous local dialects, they are all mutually intelligible.

French is widely spoken and is also officially recognized. It is used as a medium of instruction, as is Malagasy.

*Ethnic groups.* The population is divided into about 20 ethnic groups, the largest and most dominant of which is the Merina people, who are scattered throughout the island and number about 2,000,000. The name Merina (Imerina) is said to mean Elevated People, deriving from the fact that they lived on the plateau. There are almost 1,000,000 members of the Betsimisaraka (The Inseparable Multitude), who live generally in the east. The third most numerous group is the Betsileo (The Invincible Multitude), about 900,000 of whom inhabit the plateau around Fianarantsoa. Other important peoples are the Tsimihety (Those Who Do Not Cut Their Hair), 533,000; the Sakalava (People of the Long Valley), 434,000; the Antandroy (People of the Thorn Bush), 384,000; the Tanala (People of the Forest), 250,000; the Antaimoro (People of the Banks), 248,000; and the Bara (a name of uncertain origin), 250,000. Smaller groups are the Antanosy (People of the Island), 165,000; the Antaifasy (People of the Sand), 88,000; the Sihanaka (People of the Lake), 143,000; the Antakarana (People of the Rocks), 44,000; the Betanimena (People of the Red Soil), who are now largely absorbed by the Merina; the Bezanozano (Those with Many Braided Hair), 56,000; and the Mahafaly (the Joyful People), 117,000.

*Religious groups.* About half of the population has been converted to Christianity, and the Christian community is about equally divided between Protestantism and Roman Catholicism. There is a sizable community of Muslims in the northwest.

The rest of the people continue to practice their traditional religion, which is based upon ancestor worship. The dead are buried in tombs and are believed to reward or punish the living. There is a supreme being called Zanahary (the Creator) or Andriamanitra (the Fragrant One). There is also a belief in local spirits; a complex system of taboos constrains Malagasy life.

**Demography.** The population exceeded 6,000,000 during the 1960s and has been expanding at a rate of about 150,000 to 200,000 a year. All but about 105,000 are Malagasy. The main foreign communities are the French, 42,000; the Comorians, 34,000; the Indians, 14,000; and the Chinese, 8,000.

*Birth and mortality rates.* Births greatly outnumber deaths, and in 1970, for example, the estimated rate of registered births was 39 per thousand, while registered deaths were 14 per thousand, representing an annual rate of increase of 25 per thousand. Registration of births and deaths is, however, incomplete.

*Immigration and emigration.* Emigration of the non-Malagasy population exceeded immigration during the post-independence years from 1961 to 1965. The French, Comorian, and Chinese groups fell, while the Indian community showed a slight increase. There is no significant emigration abroad.

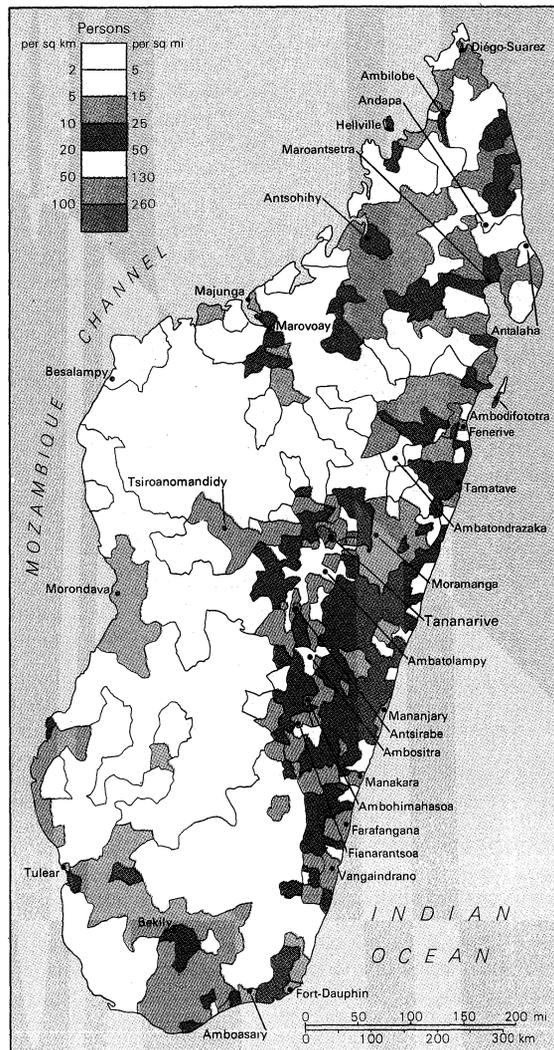

*Distribution of the population.* The eastern part of the central plateau is the region of highest population density, averaging over 130 persons per square mile (50 persons per square kilometre). The eastern forest zone and the northeast coast have densities that vary from 25 to 50 persons per square mile, while the east coast plain has the second highest density, with over 50 persons per square mile. The whole of the western two-thirds of the country is sparsely inhabited, averaging less than 25 persons per square mile.

The eastern half of the island contains almost all the major cities and towns. Tananarive alone contains approximately 5 percent of the total population; perched on two precipitous mountain ridges, the old part of the city is dominated by the palace and has an extremely picturesque, almost medieval appearance.

*Demographic trends.* In the early 1970s it seemed probable that the prevailing rapid rate of growth would continue, if not increase, throughout the decade because government policy was opposed to any form of population control. While there are large tracts of empty land, they are not easy to exploit, and the more favoured areas may quickly reach the point of acute overcrowding.

Popula-  
tion  
densities

Indonesian  
origins

Population density of Madagascar.

There is every reason to expect continued population growth in Tananarive—a growth that is likely to outstrip employment opportunities.

**THE ECONOMY**

The economic position of Madagascar has been defined by its colonial connection with France, which in the early 1970s still took nearly half of its exports and supplied more than half of its imports. Currency, banking, finance, loans, and economic planning are influenced not only by accords with France but by French personnel in government, commerce, and technical assistance. Madagascar is sheltered by this from certain risks and gains some material advantages, but the full exercise of political and economic responsibility is thereby delayed.

The regional position of Madagascar has been as anomalous as its geographical and cultural connections.

It hardly belongs to Africa yet is remote from Asia. It has close connections with the Indian Ocean island of Réunion. Otherwise, economic links with Senegal have been closer than with any nearer part of Africa, although in the last few years increasing interest and investment from South Africa have been welcomed. Despite great efforts in development and increases in production, inflation and population growth had resulted in real income per head falling slightly in the decade of the 1960s.

**The extent and distribution of resources.** *Mineral resources.* The Great Red Island disappointed those who hoped to discover precious metals in large quantities. Considerable small-scale gold mining was conducted towards the end of the 19th century, both by French and Malagasy prospectors. There is a wide variety of semiprecious stones, but deposits are not of significant economic importance. Mineral deposits include chromite, which is found north of Tananarive and near Tamatave; ilmenite (a black mineral, iron titanate), found on the southeast coast and near Fenerive; low-grade iron, found in scattered deposits in the southern half of the island; low-grade coal near Antsirabe, north of Tuléar and inland from Besalampy; nickel near Fianarantsoa; and copper north of Ampanihy and near Ambilobe. There are also smaller deposits of zircon, monazite, bauxite, lead, graphite, quartzite, gold, uranothorianite, bentonite, kaolin, and alunite. The various gems include beryl and columbite.

*Biological resources.* The eastern evergreen forest and the remnants of the deciduous forest are valuable for their timber. Except for the fish and crustaceans of the rivers and coasts, the indigenous animal life is of little economic importance. Domestic animals include the zebu (an Asiatic ox), which has great importance in Malagasy life, the fat-tailed sheep, and dogs, poultry, and pigs.

*Power resources.* Although there are many magnificent waterfalls, especially on the eastern escarpment, only about six of them have been developed. Hydroelectric power stations serve the cities of Tananarive, Tamatave, Antsirabe, and Fianarantsoa and are supplemented by thermal stations, which burn coal. There are also thermal stations serving Majunga, Tuléar, Diégo-Suarez, Ambositra, Manakara, and Morondava.

**Sources of national income.** *Agriculture, forestry, and fishing.* By far the most important crop in Madagascar is rice. Various types of both dry and wet rice are raised by irrigation in the central plateau; dry rice is also produced in the eastern forests, and wet rice in the western estuaries. Annual production surpassed 1,500,000 tons after 1965, and rice occupied almost half the total acreage devoted to crops.

Slash-and-burn techniques (the temporary clearance of land for agriculture) are used in the escarpment forest and along the east coast. In the river valleys of the west, cultivation is permanent; irrigation and rainfall are used.

Sugarcane is grown on plantations in the northwest, around Majunga, and on the east coast near Tamatave. Estimated 1970 production was 1,300,000 metric tons of cane from only 54,000 acres (22,000 hectares). Manioc is grown all over the island, producing an estimated 940,000 metric tons from 640,000 acres, and the production of potatoes and yams is estimated at 280,000 metric tons, mainly in the highland region of Ankaratra. Bananas are produced commercially on the east coast, with production reaching about 180,000 metric tons annually. Corn (maize) is grown mainly in the central plateau, in the south, and in the west. Fruits include apples, grapefruits, avocado pears, plums, grapes, litchis (the fruit of a type of soapberry tree), pineapples, guavas, pawpaws, passion fruits, and bananas. Robusta coffee is grown on the east coast and arabica coffee on the plateau. Other significant crops are beans, peanuts, *pois du cap* (Lima beans), coconuts, cloves, pepper, vanilla, cocoa, sisal, raffia, tobacco, and castor beans.

The estimated 10,000,000 head of cattle are distributed throughout the island. The large numbers of pigs, sheep, goats, chickens, ducks, geese, and turkeys are found mainly on the plateau.

Principal mineral deposits

Agricultural produce

One-fourth of an estimated 40,000,000 acres of forest is degraded (*i.e.*, regenerated after repeated burnings, with many original species lost and smaller, fewer, less valuable species becoming dominant); the rest is wet or dry tropical forest. Major reforestation has taken place since 1960, with as many as 15,000,000 trees being planted annually, mainly eucalyptus, pine, and cypress.

Fisheries are poorly developed and depend mostly on the small traditional fishing communities of the west coast; production is badly adjusted to the island's needs and to the potential market. Only the inshore waters are fished, and the distant offshore waters are neglected; inland distribution of the fish caught is poor or nonexistent, except in main towns. The bulk of the catch is composed of fresh fish, shrimps, crabs, and crayfish; some fish are also dried. There is also considerable raising of fish in the irrigated rice fields, mainly for home consumption.

**Mining and quarrying.** Mining and quarrying is little developed. The most important products are graphite, mica, monazite, quartz, garnet, and amethyst. Less valuable amounts of gold, tourmaline, citrine (a black quartz that is changed into a yellow semiprecious stone by heating), beryl, ilmenite, columbite (a black mineral, grading into tantalite), chromite, zircon, and jasper are produced. Merina jewellers polish and set semiprecious stones at small workshops in most towns of the plateau.

**Manufacturing.** There are no large or heavy industries, and there were fewer than 200 small industrial establishments during the mid-1960s. More than half of the manufacturing is located in the province of Tananarive. Products include oils, soap, sugar, cigarettes and tobacco, sisal rope and mats, bricks, processed foods, and beverages. There is also a small printing industry.

**Energy.** The installed electric capacity in the mid-1960s reached almost 36,000 kilowatts of hydroelectric power and more than 67,000 kilowatts of thermal power. Most of the hydroelectric plants are located on the plateau and in the neighbouring eastern escarpment.

**Financial services.** The Malagasy franc is the monetary unit and is equivalent to the CFA (Communauté Financière Africaine) franc, which it replaced in 1963. The Institut d'Emission Malgache (Malagasy Issuing Institute) was formed in 1962 with a capital of 500,000,000 Malagasy francs that were equally subscribed by France and by Madagascar. There are five main commercial banks; all are of French derivation and have branches both in Tananarive and Tamatave. Other provincial capitals have three or four of these banks represented, but smaller towns usually have fewer banking offices.

**Foreign trade.** More than half the value of exports derives from vegetable products, of which coffee, vanilla, sisal, raffia, rice, and *pois du cap* are the most important. Other exports include processed foods, meat and fish, tobacco and cigarettes, minerals, hides and skins, and cloves. Export earnings rose during the 1960s as exports of rice, cloves, and coffee increased; there was, however, a decrease in the production of sisal and vanilla. The most important imports are processed foods and beverages, cement, gasoline, oils, paper, manufactured textiles, and metal products, including machinery and vehicles.

Foreign trade is overdependent upon France, which receives 36 percent of Madagascar's exports and supplies 52 percent of its imports. The remaining trade is carried out mainly with the United States, the European Economic Community, Senegal, and Japan. Exports are more varied than those of other African countries, but a number of them, such as coffee, cloves, vanilla, and sisal, are endangered by world overproduction or by the manufacture of synthetic substitutes. There is virtually no trade with the countries of eastern and southern Africa.

**Management of the economy.** *The private sector.* The economy is primarily one of free capitalist enterprise, with a slowly increasing governmental participation. Despite an increasing diversification of foreign interests, most of the important businesses are French. There are less than a dozen large firms engaged in the export-import trade, banking, mining, electricity, and water supply. An intricate network of diverse smaller operations and subsidiaries is connected with these large firms.

*The public sector.* Within the limits of its means, including the foreign aid received mainly from France, the government has put its main thrust into the development of improved transportation and communications systems and of an improved agricultural sector. Producers' and consumers' cooperatives, Animation Rurale (a rural development program), and state farms pioneer new methods and try to extend and increase the commercial production of rice, cattle, coffee, oil palm, cotton, and silk. The producers' cooperatives collect and process most of the rice crop, while the national consumers' cooperative has established retail stores in most towns.

**Taxation.** Taxation is mainly indirect and is largely derived from various customs, import, and export duties. The various excise taxes are also important. Direct taxes take the form of taxes on company income, registration fees, stamp duties, and personal taxes; the latter bear heavily on the peasants.

**Trade unions and employer associations.** The unions represent a total of about 20,000 employees, most of whom hold office jobs or work in industry. The largest and most extensive trade union is the Union des Syndicats de Madagascar, followed by the Union des Travailleurs Malgaches; there are also two smaller unions.

The main employers' association is the Union des Syndicats d'Intérêt Économique de Madagascar, which represents over 2,700 enterprises. There are also more than 20 other syndicates that represent 1,000 enterprises.

**Contemporary economic policies.** The declared policy of the government is one of gradual grass roots (rural) development of a mixed economy, with increasing state participation and with strong emphasis on cooperative organization. Private and foreign capital investment receive continued encouragement as well as guarantees from the government, despite the demands of opposition parties for a policy of nationalization. The predominant reliance for aid is upon France and the European Economic Community, while lesser amounts are received from the United States and the United Nations. Nationalist China, India, Israel, Italy, and Switzerland have all provided aid for smaller projects, and there are plans for South African investment in tourist facilities.

**Problems and prospects.** Despite improved crop production, the economy seems to have been caught in an impasse since the late 1960s. Urban unemployment was increasing in the early 1970s. The population and the civil service continue to grow rapidly; at the same time there is serious inflation and a mounting trade deficit. The First Five-Year Plan of 1964 to 1969 realized less than a 2 percent growth rate for internal production, instead of the projected 5 percent per annum. The first serious austerity budget was adopted in 1970. Hopeful prospects of finding oil deposits off the east coast provide one indication of a possible solution to current economic problems. There is also a good potential for tourism; there are many unused beaches.

**Transportation.** Transport facilities are primarily on the plateau and along the east coast. Service is rudimentary on the western half of the island, although the country's best natural harbours are located there.

**Roads.** The country has about 5,300 miles (8,500 kilometres) of roads, of which only 2,000 miles are paved. Roads down the eastern escarpment and across the western coastal strip, as well as minor roads everywhere, become impassable during the wet season.

The main paved road runs south from Tananarive to Ambalavao, after which it continues part of the way to Ihoay, where the main dirt road forks southwest to Tuléar and southeast to Fort-Dauphin. A paved road runs for a short distance east from Tananarive toward Tamatave and another part of the way west to Arivonimamo. Other road connections from Tananarive to the west coast, to the entire northern half of the island, and down the eastern escarpment are poor and rapidly become impassable after rain.

**Railways.** There are about 550 miles (880 kilometres) of railway track. Two railways connect the plateau with the east coast; they run from Tananarive to Tamatave and from Fianarantsoa to Manakara. A plateau route

Foreign  
aid

Trading  
partners

from Tananarive south to Antsirabe was being connected to Fianarantsoa in the early 1970s.

*Port facilities and waterways.* The main port is Tamatave, which has a fine deepwater harbour, equipped with quay berths and directly linked to Tananarive by rail as well as by road. Majunga is second in importance but is only accessible to small ships of shallow draft; it has considerable dhow traffic with the Comoro Islands. Diégo-Suarez has one of the finest natural harbours in the world but is as yet too remote from the main centres of economic activity; it contains the French naval base, arsenal, and dry dock and also has a small commercial port. Fort-Dauphin also has a small port, and there are small wharves and minor facilities at Tuléar, Manakara, Morondava, Analalava, and Voahemmar. The coastal lagoons and swamps of the Canal des Pangalanes on the east coast, linked by artificial channels where necessary, provide a waterway 400 miles long.

*Air transport.* The island has about 50 airports. The main international airport is at Ivato, near Tananarive, and some international flights make secondary landings at Majunga. Madagascar is mainly served from abroad by Air France, but there are a few flights by South African Airways and Alitalia. Air Madagascar, the national airline, is technically assisted by Air France and mainly operates internal routes.

#### ADMINISTRATION AND SOCIAL CONDITIONS

**The structure of government.** *Constitutional framework.* Madagascar has been an autonomous republic within the French Community since 1958 and, as the Malagasy Republic, received its independence from France in 1960. The head of state is the president. Until 1972, the legislature was bicameral, and the National Assembly consisted of 107 members elected by universal suffrage for five years; the Senate had 54 members—one-third of whom were nominated by the president and council of ministers, and two-thirds of whom were elected by the representatives of provincial, municipal, and rural councils—serving six-year terms. In 1972, however, parliamentary rule was suspended and full executive powers given to the army chief of staff, which formed a cabinet composed of officers of the armed forces.

*Regional, state, and local government.* The country is divided into six provinces, each under a *chef de province* ("provincial head"), and is further subdivided into 18 prefectures, 91 subprefectures, and 692 cantons (small administrative divisions). The 36 urban and 735 rural communes are divided among the 692 cantons, with some cantons containing several communes. The cantons are further subdivided first into *quartiers* (districts) and then into villages. The *chefs de province*, prefects, and subprefects are transferable civil servants, while the *chefs de canton* ("canton heads") are administratively appointed but are usually local people. The district and village heads are locally chosen by informal elections. They are responsible for collecting taxes, maintaining order, and transmitting government instructions. The urban communes have their own budgets, and their elected councillors, in turn, elect mayors and deputy mayors. Each province also has an elected council, which exercises a degree of financial responsibility and autonomy.

*The political process.* The elections of district and village heads are conducted entirely on a local basis when circumstances require them to be held. Before 1972 municipal elections for the urban communes were nationally coordinated, as were the elections for the National Assembly and the presidency. Adult franchise is available to all mentally fit, noncriminal male and female citizens. Voting participation in the early 1970s was extremely high in and around Tananarive, where the opposition is strong; elsewhere, participation is low.

The Parti Social Démocrate (Social Democratic Party or PSD) has held power since the attainment of independence in 1960. It has a national following but is regarded as particularly representative of the coastal districts. The main opposition party, Ankoton'ny Kongresi'ny Fahaleovantenan Madagasikara (AKFM) or Parti du Congrès de l'Indépendance de Madagascar (Congress Party of the

Independence of Madagascar), is believed particularly to represent the plateau region and the Merina people. A third party is Monima (Mouvement National pour l'Indépendance de Madagascar). AFKM supports a more radical form of Socialism than does the PSD, while Monima favours the Chinese Communist position.

Much of the support for the PSD in the vast rural areas is attributed to strong administrative encouragement. Mass discontent has not been directly manifested at the ballot box but obliquely and anonymously in devastating reactions, such as the widespread burning of forests—a tactic that has harmed the previously successful reforestation program. In 1972 mass demonstrations by thousands of students and workers erupted in Tananarive and Tamatave. Pres. Philibert Tsiranana, who had led the country since independence, dissolved his government and handed power over to the army. Subsequent events seemed to presage a renewal of Merina influence in the central government and a corresponding increase in the power of Monima.

**Justice.** The former Merina state that ruled the island throughout the 19th century had an elaborate system of laws, courts, and justice. The present Malagasy legal system, however, is based upon French codes and practices, and most judges and magistrates have had French training. French citizens (both of French and Malagasy origin) have certain special rights in relation to France and the French Community. There is a supreme court, an appeal court, criminal tribunals, and tribunals of first instance; there is also a criminal code, a code of criminal procedure, and a code of civil procedure. The customary law of Imerina and other ethnic groups is taken into account by state magistrates when judging marriage, family, land, and inheritance cases.

**The armed forces.** The army, until 1972, had played no direct role in political life, although the regime in power was strengthened by the presence of French army contingents. The Malagasy Army consists of about 3,700 men, and there is an 8,000-man security force. Under a defense agreement the French also maintain armed forces in Tananarive and a naval base at Diégo-Suarez. The United States has a satellite tracking station near Tananarive. Officers of the Malagasy Army and security forces are trained in France.

**The social sector.** *Educational services.* About half of the school-age children attend classes. In the early 1970s there were over 1,000,000 students in over 6,000 primary schools, about 100,000 students in over 500 secondary schools, and more than 2,000 in teacher training colleges. The University of Madagascar had almost 4,000 students, of whom the overwhelming number were Malagasy. The level both of school attendance and of educational attainment is higher on the plateau than in the coastal areas. Protestant and Roman Catholic missions have been providing education since the 19th century, and the missions still educate a majority of the school children, although the government now maintains official schools at all levels. In the main towns there are also privately run schools, catering to those unable to enter either government or mission schools.

*Health and welfare services.* Malagasy doctors began to practice Western medicine in 1880; there is now a medical school in Tananarive. The health system includes principal and secondary hospitals, dispensaries, and medical centres. Medical personnel includes more than 600 doctors, as well as pharmacists, dentists, midwives, social assistants, visiting nurses, and health assistants.

Hospitals and specialists are mainly in the towns, apart from some rural hospitals run by Christian missions. Health insurance and other social benefits are mainly available to better paid and professional elements among the employed population.

*Housing.* Houses are typically rectangular and are usually crowned with steeply angled roofs. In the rural areas, most houses are made of either mud and wattle or woven matting supported by poles. In the eastern forest they are built of interlaced split bamboo and are thatched with palm, while in the south, overlapping wooden planks are used for the walls. In the urban areas, upper income

The role of mission schools

housing consists of two- or three-story homes surrounded by wide balconies supported by brick columns and crowned with steep tiled roofs. Lower income housing is constructed of earth blocks and thatched roofing.

The French colonial government provided housing for the more senior civil servants, and the Malagasy government has continued the practice. The government-sponsored housing authority conducts research into design, materials, and methods of production and is endeavouring to promote inexpensive urban housing, but the problem of overcrowding is expected to increase with continued urban growth. The existence of a well-established craft of house construction, however, may successfully alleviate housing pressures without resorting to the use of imported materials or relying upon foreign enterprise.

*The police.* Detachments of police are stationed at the headquarters of each province, prefecture, and subprefecture, as well as in Tananarive. They have general responsibility for keeping the peace, enforcing laws, and apprehending criminals. The whole force is under unified command and falls within the responsibility of the ministry of the interior.

*Wages and the cost of living.* The size of the labour force employed for wages varies between 150,000 and 200,000; average monthly cash wages are higher in commerce and transportation than they are in industry and agriculture. While the average annual income dropped during the 1960s to about U.S. \$95, the prices for such important commodities as rice, flour, charcoal, and meat rose sharply.

*Health conditions.* The extension of health services is largely credited for the steady population increase. Infant mortality remains high, but infant deaths from malaria, which is endemic all over the island, have been cut by half. Debilitating parasitic diseases, such as schistosomiasis, an infection of the bladder or intestines, remain serious and are hard to control since their breeding grounds are the irrigated rice fields and the streams that feed them. Venereal disease is also widespread, especially in its incipient form. Rural diet is often deficient in protein and some vitamins.

*Social and economic divisions.* Traditionally, society was divided into three castes—the nobles, the freemen, and the former slaves and their descendants. These social distinctions are no longer strict and are manifest only on ceremonial occasions, such as weddings and funerals. They do, however, form the basis of other economic and social distinctions. During the 19th century, the Merina élite conquered the island, established themselves as rulers, and adopted Protestant Christianity; in the late 1800s, some also became Roman Catholics. Under French rule in the 20th century, the Merina retained their supremacy in education, business, and the professions, while the remainder of the population retained its sense of “difference” from the dominant peoples and adopted Roman Catholicism.

A further distinction is made between the peoples of the plateau and those of the coast, who are called *cotiers*. The coastal peoples feel deprived of the education, power, and wealth that is concentrated on the plateau. Since independence, the government has been composed of *cotiers*, and a conscious effort has been made to keep the Merina elite of the plateau from power.

#### CULTURAL LIFE AND INSTITUTIONS

*The cultural milieu.* The culture is basically Indonesian. Arabic and Islāmic contributions include an intricate system of divination, or *sikidy*, and calendrical features, such as the names of the days of the week, which are particularly significant in their application to markets. The coastal areas of the west, north, and south might be expected to show African cultural elements, but, apart from some Bantu words, these are often difficult to identify conclusively.

*The state of the arts.* The conquest of the plateau peoples by the French and their assimilation of Western values has deprived them of most of their traditional institutions. Western dance and musical instruments have been adapted to Malagasy rhythms. The tube zither, the

conch, and the cone drum are of Indonesian origin, while other types of drums and animal horns suggest African influence. Folk music has been retained, but much of the singing is of Western church hymns and chants adapted to the distinctive Malagasy musical style. Social and religious life centres upon the church congregation, and the cultural emphasis on ancestral tombs is now largely expressed in Christian terms. More time, money, and care is spent on building tombs than houses. The dead are always brought back to their ancestral tombs, however long or far away they have spent their lives. Tombs are opened every few years, the corpses taken out and carried in procession with much ceremony, then replaced wrapped in new shrouds, which are still woven from locally produced silk, coloured with natural, herbal dyes.

The male peasants wear cloth trousers with tunics reaching to the knees. Women wear cloth dresses but wrap a silk cloth under one arm and over the other shoulder, even when wearing Western fashions.

Most of the coastal peoples have retained their traditional customs. Funeral practices are similar to those of the plateau, with local variations of detail. In the eastern forests men wear shorts rather than trousers, and many still wear the short tunic that is woven from raffia fibres. In the far south some older men wear a homespun silk cloth that is wrapped around the waist and between the legs, but most have adopted imported cotton clothes.

The Mahafaly have a remarkable wood-carving industry, and their tombs of coloured stones and carved wooden posts are the most beautiful on the island. The Betsileo also have a thriving wood-carving industry, making inlaid furniture of valuable hardwoods. They also produce ornamental cloths of very finely woven raffia and have become specialists in the production of coloured straw hats. Betsileo and Merina women have become experts in French-style embroidery, sewing, and dressmaking.

The Malagasy language is very rich in proverbs, and there is now an extensive written literature including poetry, legend, history, and scholarly works, as well as contemporary themes. Literary production is aided by an excellent printing industry, for which the Merina have shown a flair since learning it from the London Missionary Society in the 1820s. The peoples of the southeast still preserve their manuscripts in Arabic script with great reverence; few can be more than 200 years old, although some may be copies of much earlier manuscripts.

*Cultural institutions.* Since 1960 a number of new seasonal festivals have been promoted, including the Festival of Rice, the Festival of the Trees, the Festival of the Party, and Independence Day. The ministries of cultural affairs and of traditional arts encourage the blending of old and new cultural expressions. Towns, churches, schools, and private groups hold concerts or dances, and in the cities there are cultural associations based on the members' home districts.

The main libraries and museums, located in Tananarive, include the Bibliothèque Nationale (which has a good general collection and extensive coverage of Madagascar), the library of the Académie Malgache (containing a valuable collection of works on Madagascar), the university library, and the university museum (containing especially interesting collections from recent archaeological and ethnographic expeditions). The Organisation pour la Recherche Scientifique et Technique d'Outre Mer (a French agency) houses the main museum collection of Malagasy culture and archaeology, as well as natural science collections and a zoo composed of lemurs and other animals specific to Madagascar.

*The press and broadcasting.* There are over 200 newspapers and magazines published in Malagasy and in French. The main press publications are the *Courrier de Madagascar*, a daily; the *Bulletin d'Information*, a daily; *La Lumière* and *l'Info-Madagascar*, both weeklies; *Le Lien*, a monthly bulletin of statistics; the *Bulletin de Madagascar*, a monthly economic review; and *Revue de Madagascar*, published three times monthly.

There are four radio services. The two major services broadcast in Malagasy, and the third most important station broadcasts in French. The fourth station is an

The cult  
of the  
dead

Handi-  
crafts

Prevalent  
diseases

international service that broadcasts programs in French and English to Africa, the Far East, and Latin America. The Tananarive area has daily television service in French, organized by the French Bureau of Radiophonic Cooperation.

#### PROSPECTS FOR THE FUTURE

Madagascar desperately needs to raise its productivity. Population growth is very rapid, but no official anxiety is expressed, on the grounds that large areas of the country are underpopulated—especially the west, south, and north. It is much more likely, however, that continued population growth will lead to a massive increase of unemployed and underemployed immigrants to Tananarive and other cities. The west can be developed for ranching, but this does not require a large labour force. The growers of irrigated rice on the plateau, although they could be assisted further by technological improvements adapted to local conditions, nevertheless have a very highly developed system of mixed farming, including the raising of cattle, pigs, poultry, and fish, combined with a very hard-working tradition. It would be disastrous to disrupt this pattern by ill-considered interference. Communications need considerable improvement, and much more could be done in processing and exporting the varied temperate- and tropical-fruit crop. Tourism and offshore oil exploitation offer the most promising future possibilities. There may be a temptation to exploit the rivalry between the Soviet Union, on the one hand, and the United States, the United Kingdom, France, and South Africa, on the other, for control of the Indian Ocean—especially since the Suez Canal has been closed or partially superseded by the use of giant tankers and merchant vessels plying directly around the Cape of Good Hope. (A.I.S.)

#### BIBLIOGRAPHY

*Official publications:* MALAGASY REPUBLIC, INSTITUT NATIONAL DE LA STATISTIQUE ET DE LA RECHERCHE ECONOMIQUE, *Inventaire socio-économique de Madagascar, 1960–1963*, 2 vol. (1966), information on social and economic conditions; *Recensements urbains: Ambositra, Ambalavao, Mananjary, Manakara, Farafangana* (1966), special surveys carried out in the main cities in addition to the general census; *Recensement Industriel* (1967), a survey of industries; SERVICE DE STATISTIQUE ET DES ETUDES SOCIO-ECONOMIQUES, *Population de Madagascar au 1<sup>er</sup> janvier 1965* (1966), a detailed compendium of demographic information; *Enquête agricole* (1966), details of agricultural production by crops and regions; MADAGASCAR, SERVICE GEOGRAPHIQUE, *Madagascar et Archipel des Comores*, 1:500,000 (1947–48).

*General references:* *The Antananarivo Annual and Madagascar Magazine*, 24 vol. (1875–78, 1881–1900), a journal in English produced by members of the London Missionary Society in Madagascar, containing unique articles on history, custom, belief, fauna, and flora; *Bulletin de l'Académie Malgache* (1905– ), the main scholarly journal of Madagascar; MAURICE BLOCH, *Placing the Dead: Tombs, Ancestral Villages and Kinship Organization in Madagascar* (1971), a detailed ethnographic account of the numerically and culturally dominant Merina people; ANDRE DANDOUAU, *Manuel de géographie de Madagascar*, 10th ed. (1960), a useful general geography; HUBERT J. DESCHAMPS, *Les Migrations intérieures passées et présentes à Madagascar* (1959), the only detailed study of internal population movements, and with SUZANNE VIANES, *Les Malgaches du Sud-Est* (1959), an ethnographic account of the southeastern peoples through whom Arabic scripts and elements of Islamic belief and practice influenced Madagascar; GUILLAUME GRANDIDIER, *Bibliographie de Madagascar*, 3 vol. (1905–57), an authoritative, cumulative bibliography, and with ALFRED GRANDIDIER, *Histoire physique, naturelle et politique de Madagascar* and *Ethnographie de Madagascar* (1908–28), two works that represent the most monumental attempt to present a complete account of the natural history and culture of Madagascar and its peoples; NIGEL HESELTINE, *Madagascar* (1971), a recent general study of the land and people; *Madagascar* ("Les Guides Bleus," 1968), information on all towns and places of interest; AIDAN SOUTHALL (ed.), "Kinship, Descent, and Residence in Madagascar," *Am. Anthropol.*, 73:144–208 (1971), a comparative analysis of variations in Malagasy kinship and family structure; MARCELLE URBAIN-FAUBLEE, *L'Art Malgache* (1963), a publication devoted to Malagasy art.

(A.I.S./J.E.D.)

## Madagascar, History of

Although the Malagasy people are of mixed African and Indonesian ancestry, their language is basically Indonesian, with a few words of Bantu. The Indonesian element probably migrated to Madagascar in successive waves during the 1st millennium AD; one hypothesis is that they came by way of the African coast and reached the island after mingling with Africans. Archaeological evidence indicates that these people were living on the island in the 10th century.

**Madagascar to 1810.** After the 14th century, small groups of Muslims, coming perhaps from the eastern coast of Africa, set up trading colonies in the north; others, mingling with Africans, founded in the southeast the kingdoms of Zafi-Raminia and Antemoro. The settlement of the Indonesian Merina (or Hova) in the central-plateau region probably occurred at the same time.

*Early European contacts.* Madagascar is mentioned in the writings of Marco Polo, but the first European known to have visited the island is Diogo Dias, a Portuguese navigator, in 1500. It was called the Isle of St. Lawrence by the Portuguese, who frequently raided Madagascar during the 16th century, attempting to destroy the Muslim settlements. Other European nations also moved in; in 1643 the French established Fort-Dauphin in the southeast and maintained it until 1674. One of their governors, Étienne de Flacourt, wrote the first substantial description of the island. In the late 17th and early 18th centuries, Madagascar was frequented by European pirates (among them Capt. William Kidd) who preyed upon shipping in the Indian Ocean.

In the 18th century, the Mascareigne Islands to the east were colonized by the French with the help of Malagasy slaves. Two attempts at fortified settlements failed, one at Fort-Dauphin by the comte de Modave, the other at Antongil Bay by Baron Benyowski; however, French trading settlements prospered, notably at Tamatave.

*The kingdoms.* In Madagascar as on the African mainland, new states arose between 1500 and 1800, and many of them engaged in the traffic in slaves and firearms with the Europeans. The traditional clan organization of the Malagasy gave way to a number of autocratic kingdoms. In the 17th century, the southern Sakalava state spread northward into the sparsely populated plains of the far west. Antemoro chieftains founded kingdoms in the interior, among the Tanala and the Betsileo peoples. In the 18th century, the short-lived Betsimisaraka kingdom was founded on the east coast by Ratsimilaho, a half-English Malagasy.

The Merina kingdom was founded toward the end of the 16th century in the swampy Ikopa Valley in the centre of the island. Tananarive became its capital. In the 18th century, Merina was divided among four warring kings. One of them, Andrianampoinimerina, who reigned 1787–1810, reunited the kingdom about 1797. He gave it uniform laws and administration, and sold slaves to the French on the coast, using the guns he got in return to conquer his neighbours, the Betsileo. Under Andrianampoinimerina, Merina society was divided into a ruling noble class (*Andriana*), a class of freemen (*Hova*), and a slave group (*Andero*). The name Hova was sometimes used for all Merinas. At his death, he left to his son Radama a single political ambition: "The sea will be the boundary of my rice field" (*i.e.*, of his kingdom).

**The kingdom of Madagascar.** *Formation of the kingdom (1810–61).* Radama I (1810–28) allied himself with Sir Robert Farquhar, the British governor of the nearby island of Mauritius. In order to prevent reoccupation of the east coast by the French, Farquhar supported Radama's annexation of the area by supplying him with weapons and advisers and giving him the title "king of Madagascar." At the same time, Radama agreed to cooperate with Britain's new campaign to end the slave trade. In 1817 he took Tamatave. From then on, he launched yearly expeditions against the coastal populations. In this way, he conquered almost the entire east coast, the northern part of the island, and most of the two large Sakalava kingdoms. Only the south and a part of the west remained

Merina  
expansion

independent. The French retained no more than the small island of Sainte-Marie. In addition, Radama invited in European workmen; the London Missionary Society spread Christianity and influenced the adoption of a Latin alphabet for the Malagasy language. Radama died prematurely in 1828; he was succeeded by his wife, Ranaivalona I, who reversed his policy of Europeanization. Under the influence of traditional beliefs, she expelled Christian missionaries and persecuted Malagasy converts. A very few Europeans, notably the Frenchman Jean Laborde, maintained external trade and local manufacture, but eventually they also were expelled. The British and French launched an expedition against Ranaivalona, but were repulsed at Tamatave in 1845. By the end of her reign (1861), Madagascar was isolated from European influence. She made several unsuccessful attempts to subdue the island's independent areas.

*Outside influences (1861–95).* Ranaivalona died in 1861. Her son, Radama II, readmitted the foreigners; English Protestants and French Roman Catholics vied for supremacy; businessmen obtained excessive concessions. This policy led to Radama's overthrow by the Merina oligarchy (1863). The head of the army, Rainilaiarivony, a Hova, became prime minister and remained in power by marrying three queens in succession: Rasoherina, Ranaivalona II, and Ranaivalona III. He embarked on a program of modernization; in 1869 he caused Protestantism to be adopted and suppressed the Malagasy religion. European-style ministries were created and governors set up in the provinces. Villages were supervised by former soldiers. Education was declared obligatory under the direction of the Christian missions. A code of laws was worked out that combined ancient customs with Western innovations, such as monogamy. After 1880, France revived its claims to Madagascar. The French had installations at Nosy Be, and began to extend their influence over the Sakalava. In 1883 the first "Franco-Merina" War broke out, terminating in 1885 with an ambiguous treaty: France was given the right to maintain a settlement at Diégo-Suarez, and a resident at Tananarive, but the prime minister temporarily managed to avoid the institution of a protectorate. The succeeding period was marked by disorder and internal strife. In 1890 the British recognized Madagascar as a French protectorate, removing the last barrier to France's control over the island. When Rainilaiarivony refused to submit, France decided to use force. In January 1895, French troops landed at Majunga. The opposing Merina forces were not well armed and were poorly organized. Moreover, the Merina were not supported by their subject peoples; some of the Sakalava even assisted in the French offensive. Once they had worked their way out of the swamps of the coastal areas, the invaders formed a mobile column which, on September 30, 1895, after the only significant battle of the war, occupied Tananarive. The prime minister was exiled. The queen signed a treaty recognizing the protectorate and was maintained on the throne as a figurehead.

**The French period.** *The colonial period (1896–1945).* The occupation soon extended to the entire part of the island conquered by the Merina. But in Imerina itself, armed bands (the Menalamba, or "red togas") resisted modernization and French rule. The French Parliament voted the annexation of the island on August 6, 1896, and sent Gen. J.S. Gallieni first as military commander, then as governor general. Slavery was abolished. Gallieni established military posts in Merina that gradually put down the insurrection; he subdued the oligarchy by putting two hostile ministers to death and sent the queen into exile on February 27, 1897. In 1898 the old Merina kingdom was pacified; Gallieni then undertook the difficult task of subjugating the independent peoples. Two insurrections, in the northwest (1898) and in the southeast (1904), were quickly put down. When he left the island in 1905, unification had been achieved and the organization of the government had a solid base. The Merina governors had been replaced by French administrators with leaders taken from local peoples. The teaching of French in the schools was made compulsory.

Customs duties favoured French products, though Malagasy enterprise was also encouraged. The Tamatave-Tananarive railroad was begun, roads were built, and a modern health service was inaugurated.

The economic development of the island continued under Gallieni's successors. The railroad and its branch lines were completed in 1913. A second line, the Fianarantsoa-Manakara, was finished in 1935. Automobile roads increased after 1920, airlines after 1936. The seaports were built up and equipped, as were the cities. Loans, contracted in France, supplemented the resources of the colony.

Exports were confined to agricultural products and raw material for industry. Rice, manioc, rubber, raffia, meat, and graphite predominated at first. Between World Wars I and II, coffee, vanilla, cloves, and tobacco, introduced by the Europeans and then taken up by native planters, became more important. Cultivation of these products was sustained by subsidies during the depression of the 1930s. Three-quarters of all trade was with France. From 1900 to 1940 the population rose from 2,500,000 to 4,000,000; internal migrations populated the far west. Material aspects of life became westernized, especially in the cities. Half the population became Christianized.

Political progress lagged, however. In 1915 a nationalist secret society, the vvs (Vy Vato Sakelika), was outlawed by the government. In 1920 a teacher, Jean Ralaimongo, launched a campaign in the press to give the Malagasy French citizenship (they were classed as "subjects") and to make Madagascar a French *département*. When France failed to respond to the demand for assimilation, the emancipation movement turned toward nationalism. Still weak, it suspended all activity during World War II. In 1940 Madagascar, though hesitant at first, rallied to the Vichy government. Then came a blockade, occupation by the British and South Africans (1942), and finally a return to Free France. But these events, added to the unfavourable economic situation, increased nationalist sentiment among the Malagasy.

*The French Union (1946–1958).* In the elections of 1945, two Malagasy nationalists were elected to the French parliament. The constitution of 1946, creating the French Union, made Madagascar an Overseas Territory of the French Republic, with representatives to the Paris assemblies and a local assembly at Tananarive. Six provincial assemblies were created later. The political struggle irrupted in violence on March 30, 1947, with an insurrection in eastern Madagascar. The leaders of the MDRM (Mouvement Démocratique de la Rénovation Malgache), including the three deputies, were outlawed. More than 11,000 lives were lost before the revolt was ended.

A period of political inactivity followed. In 1954, when the ministry of Pierre Mendès-France was in power in France, the nationalist movement was revived. After the "Overseas Territories Law" of 1956 gave Madagascar an executive elected by the local assembly, Vice Premier Philibert Tsiranana founded the PSD (Parti Social Démocrate), which, though most of its members were non-Merina from the coastal areas, offered to cooperate with the Merina in a spirit of unity.

In 1958 the government of French President Charles de Gaulle agreed to let the overseas territories decide their own fate. In a referendum on September 28, Madagascar voted for autonomy within the French Community 77 percent to 22 percent; the opposing votes were mainly Merina. On October 14, 1958, the autonomous Malagasy Republic was proclaimed; Tsiranana headed the provisional government.

**The Malagasy Republic.** The opposition regrouped under the name of AKFM (Ankoton'ny Kongresy ny Fahaleovantena Malagasy), which included the Protestant Merina dissidents and Communists. Tananarive was this party's stronghold; it also had some support in the provinces but, owing to the electoral system established by the PSD, held only three seats in the legislature.

The PSD also settled the provincial question: local assemblies continued in existence but executive power in the provinces was vested in a minister delegated by the central government. Tsiranana was elected president of

Malagasy  
nationalism

The  
French  
invasion

the republic. He obtained independence for the republic on June 26, 1960, but maintained military, financial, and cultural ties with France. Madagascar was admitted to the United Nations, and on July 19 Tsiranana brought the three former MDRM deputies back from France, and two of them entered his government.

The PSD remained in power through the first decade of independence. Successive development plans, inspired, according to Tsiranana, by a "grass roots socialism," aimed at improving the lot of the peasantry. The increase in agricultural production through fertilizers has permitted a rise in population from 5,500,000 to 7,000,000 with no adverse effects on the economy.

In foreign policy, the bond with France remained strong, and close relations were established with the United States, West Germany, Taiwan, South Africa, and other anti-Communist powers. Measures were taken to halt an influx of immigrants from India. In the Organization of African Unity, Madagascar plays a conservative role. In 1971, the poor state of Tsiranana's health made him yield to pressure to modify the government, and a rebellion in the south was quashed without difficulty.

CHAUVET, *Gallieni pacificateur* (1949); and VIRGINIA THOMPSON and RICHARD ADLOFF, *The Malagasy Republic, Madagascar Today* (1965).

(H.J.D.)

## Madhya Pradesh

Madhya Pradesh, with an area of 171,220 square miles (443,459 square kilometres), is the largest of the states of the Republic of India, but, with a population of about 41,651,000 at the time of the 1971 census, is only the sixth most populous. As its name implies—*madhya* means central and *pradesh* means region—it is situated in the heart of India. It has no coastline and no international frontier. The state capital is Bhopāl.

When India became independent in 1947, the British Indian Central Provinces, together with Berār, were grouped together to form Madhya Pradesh. Boundary changes followed: the old Central Indian Agency (divided after independence into Madhya Bhārat and Vindhya Pradesh) was added to Madhya Pradesh, and eight Marathi-speaking districts were detached from it and joined to Bombay (later Mahārāshtra) state. The present boundaries of the state were defined in 1956. Madhya Pradesh is bordered by the states of Rājasthān to the northwest, Uttar Pradesh to the north, Bihār to the northeast, Orissa to the east, Andhra Pradesh and Mahārāshtra to the south, and Gujarāt to the west. (For historical background, see INDIAN SUBCONTINENT, HISTORY OF THE.)

**History.** The history of Madhya Pradesh extends to the remote past. Several remains of prehistoric cultures, including rock paintings and stone and metal implements, have been found in various parts of the state.

One of the earliest states that existed in the territory of the present Madhya Pradesh was Avanti, which had Ujjain as its capital. This was part of the Mauryan Empire (4th-3rd century BC); it was later known as Mālwa and was situated in the western part of the state.

Among the various dynasties that ruled part or the whole of Madhya Pradesh between the 2nd century BC and the 16th century AD were the Śuṅgas (185 to 73 BC), who ruled in eastern Mālwa; the Andhras (Śātavāhanas; 1st century BC-3rd century AD); the Kṣātrapas (2nd-4th century AD), and the Nāgas (2nd-4th century AD). The whole of Madhya Pradesh lying north of the Narmada

River formed part of the Gupta Empire (4th-5th century AD) and was the scene of a power struggle against the Huns (a nomadic, pastoral people) in this area. Yaśodharman was an important Mālwa 6th century king who wrested power from the Huns and established his rule. Mālwa was annexed by the emperor of northern India, Harṣa, during the first part of the 7th century.

The 10th century was a period of confusion: of the various dynasties, the Kalacuris ruled over the Narmada Valley and some other regions; their contemporaries were the Paramāras at Dhār in what is now the western region, the Kacchwāhās at Gwalior in the north, and the Candellas at Khajurāho, about 100 miles southeast of Jhānsi. Later the Tomaras ruled at Gwalior and the tribal Gonds ruled over several districts.

The Muslim invasion of the area took place in the 11th century, and Gwalior was conquered. The Hindu domains there were incorporated into the Delhi sultanate in 1231 by the sultan Iltutmish. Later the Khaljī sultans of Delhi overran Mālwa, which was subsequently annexed into the Mughal Empire by Akbar (1556 to 1605), the greatest of the Mughal emperors. Marāthā power extended into Mālwa at the beginning of the 18th century and a large part of what is now Madhya Pradesh had come under Marāthā rule by 1760. With the defeat of Peshwas (hereditary Marāthā prime ministers who centralized Marāthā rule) in 1761, the Sindhia (Marāthā) dynasty was established at Gwalior in the north and the Holkar dynasty (also Marāthā) at Indore in the southwest.

In 1817-18 the "Saugor-Nerbudda territories," as they were known, were ceded to the British; 43 years later this area and certain other districts were grouped into the Central Provinces, Berār being added in 1903. On the north and west, the Central India Agency was formed in 1854, with Mālwa, Bundelkhand, and Baghelkhand as the main units. Subsequent territorial changes were as described earlier in this article.

**The landscape.** *Relief.* Forested hills with steep slopes, extensive plateaus, and river valleys characterize the physiography of Madhya Pradesh. The state forms part of the Deccan Plateau and includes the Vindhya and Kaimur ranges in the west and north, which in places are 1,500 feet above sea level; the Sātpura-Mahādeo-Maikala ranges in the south have elevations of over 3,000 feet.

Northwest of the Vindhya Range is the Mālwa Plateau (1,500 to 2,000 feet). Other features are the Bundelkhand Plateau (north of the Vindhya), the Madhya Bhārat Plateau in the extreme northwest, the Baghelkhand Plateau in the northeast, the Chhattisgarh Basin in the east, and the Bastar Hills in the extreme southeast.

Madhya Pradesh is the source region of some of the most important peninsular rivers: the Narmada, the Tāpti, the Mahānadi, and the Wainganga (a tributary of the Godāvāri). Other rivers include the Chambal and other tributaries of the Yamuna and the Son (a tributary of the Ganges).

**Soils.** Fertile black soils are found in the Mālwa Plateau, in the Narmada Valley, and in parts of the Sātpuras. Eastern Madhya Pradesh has mainly red and yellow soils, which are sandy and less fertile than the black.

**Climate.** The climate is monsoonal (characterized by rain-bearing winds), with much of the rain falling from June to October. The season preceding the rains (March to May) is hot and dry, with temperatures everywhere higher than 85° F (29° C). The temperature falls during the rainy season. Winters are usually pleasant and largely dry. Generally speaking, rainfall decreases westward and northward, being 60 inches and above in the east and southeast, but less than 40 inches in the extreme west and less than 30 inches in the Chambal Valley.

**Forests and wildlife.** Some 33 percent of the state is under forest; about another 7 percent consists of permanent pasture or other grazing land. The main forested areas include the Vindhya-Kaimur ranges, the Sātpura-Maikala ranges, the Baghelkhand Plateau, and Bastar. Economically, the most important trees are teak, sal, bamboo, and salai (which yields a resin used for incense and as a medicine).

The period of sultanate rule

The rivers

Boundary changes in 1947

The forests abound in wild animals such as tigers, panthers, bison, chital (spotted deer), bears, wild buffalo, sambar (deer), and black bucks. Birds of many species are found. There are national parks at Kanha Kisli (famous for its swamp deer) and at Shivpuri; another park has been established at Bandhogarh (Rewa) and is known for its white tigers.

**Population.** A variety of tribes lives in Madhya Pradesh, including Bhil, Baiga, Gond, Korku, Kol, Kamar, and Maria. At the 1961 census, 6,700,000—about 20 percent of the total population—were classified as members of scheduled tribes. In at least 12 districts, more than 25 percent of the total population was tribal. In Jhābua in the extreme west, the percentage was about 85. The average density of population in 1971 was 243 per square mile. The distribution of the rural population is very uneven, high densities being found in the Mahānadi Valley, the Upper Wainganga Valley, the Lower Chambal Valley, and in the Tikamgarh, Rewa, Satna, and Jabalpur districts, as well as districts in scattered patches in western Madhya Pradesh. The provisional census figure for April 1, 1971, was almost 41,651,000, the growth rate being 2.5 percent per annum.

Hindi is the language most widely spoken. The state had in all 25,000,000 Hindi-speakers at the time of the 1961 census. Eastern Hindi, represented by the Awadhi, Bagheli, and Chhattisgarhi dialects, is spoken in Baghelkhand, Surguja, and Chhattisgarh, and also in the Jabalpur and Mandla districts. Bundeli, a Western Hindi dialect, is spoken in the central districts of Madhya Pradesh and in Bundelkhand; Malvi, recognized by some as a Western Hindi dialect, is the speech of western Madhya Pradesh. The Bhils speak Bhili, and Gondi is spoken by nearly 1,000,000 people.

The second most important language is Marathi (1,260,000 speakers). Urdu, Oriya, Gujarati, and Punjabi are each spoken by over 100,000 persons. Also spoken are Telugu, Bengali, Tamil, and Malayalam.

Hindus in the state numbered 30,000,000 at the time of the 1961 census, representing 94 percent of the total population. There are, however, sizable minorities of Muslims, Jains, Christians, and Buddhists. There is also a small Sikh population.

At the time of the 1961 census, there were more than 70,000 inhabited villages in Madhya Pradesh. In the greater part of the state, the number of settlements within 100 square miles of rural area was 45 or less.

In 1971 there were 11 urban agglomerations, each with a population exceeding 100,000—Indore (572,600), Jabalpur (533,750), Gwalior (406,760), Bhopāl (392,100), Ujjain (209,100), Raipur (205,900), Durg-Bhilai (245,300), Sāgar (154,800), Bilāspur (130,800), Ratlām (118,600), and Burhānpur (105,350). These 11 cities, with a total population of more than 3,075,000, together had only 613,700 inhabitants at the beginning of the 20th century. Besides these cities, there were about 230 towns with populations of less than 100,000.

**Administration.** Executive power in the state is vested in the governor, and there is a council of ministers to aid and advise him in the exercise of his functions. The legislative assembly has 297 members.

The state has been divided into seven divisions and 43 districts. The divisions are Raipur (which in 1971 had a population of about 6,587,000); Bilāspur (about 5,041,000); Jabalpur (about 7,357,000); Rewa (about 5,405,000); Gwalior (about 4,350,000); Indore (about 7,752,000); and Bhopāl (about 5,159,000).

Since the State Panchayat (village council) Act of 1962, local administration has been entrusted to about 12,800 village *pañcāyats*. In 1968 to 1969, there were more than 180 urban local authorities, including six municipal corporations.

**Social conditions.** **Health.** Malaria, which was formerly endemic throughout the state, has been largely eradicated. Diseases common in Madhya Pradesh are filariasis (a parasitic disease of the blood), tuberculosis, venereal diseases, leprosy, and dysentery. There were about 1,400 dispensaries and hospitals in the state in the early 1970s. There were also several eye hospitals, mental hospitals,

tuberculosis hospitals, and sanatoriums as well as a number of clinics for the treatment of tuberculosis. There were antirabies inoculation centres in every district, and several venereal-disease clinics.

**Education.** About 22 percent of the state population was literate in 1971; but only about 5 percent had had any schooling in 1961. In 1967 to 1968 there were more than 44,000 schools, in which more than 4,000,000 students were receiving primary, middle, or high school education. There were universities at Sāgar, Jabalpur, Raipur, Ujjain, Gwalior, Indore, Rewa, Bhopāl, and Khairāgarh (music); these, together with some 400 colleges in the state, had nearly 136,000 students enrolled. Jabalpur also has an agricultural university.

**Welfare.** The government has undertaken several social-welfare schemes, including adult literacy classes, *yuvak* ("youth") and *mahila mandals* ("women's clubs"), and youth competitions. Grants-in-aid are given to social welfare and physical welfare institutions, while the Directorate of Panchayats and Social Welfare also runs rescue homes, beggars' homes, and leprosy clinics. Scholarships are granted to crippled children, and there is a scheme to give aid to old people needing care. The government also runs schools for the deaf and dumb. Welfare schemes for tribal groups include scholarships, free books, and hostel facilities.

**Economy.** **Agriculture.** Agriculture is the basis of Madhya Pradesh's economy, and 88 percent of the rural workers in the state were cultivators or agricultural labourers in 1971. At this time only 41 percent of the total area of the state was under cultivation, though the cultivated acreage had been increased during the 1950s and 1960s. The distribution of the sown area is very uneven, being governed by variations in topography, rainfall, and soils. The chief cultivated areas are found in the Chambal Valley, the Mālwa Plateau, the Rewa Plateau, and the Chhattisgarh Plain. The Narmada Valley is another fertile area. Agriculture in Madhya Pradesh in the early 1970s was characterized by low productivity and the use of traditional methods of cultivation. Only about 7 percent of the sown area was irrigated. Irrigation was carried out chiefly by means of canals, tanks (village lakes or ponds), and wells; the main development in this respect had been through medium-sized or small projects executed during the various Indian five-year plans.

The most important crops are rice, wheat, *jowār* (sorghum), pulses (leguminous plants, such as peas, beans, or lentils), and peanuts (groundnuts). Rice is grown principally in the east, where rainfall is more than 50 inches; in western Madhya Pradesh wheat and *jowār* are more important. Other crops include linseed, sesame, and inferior millets which are grown in hilly areas.

**Minerals and mining.** Madhya Pradesh is rich in minerals, though these resources had not yet been fully exploited in the early 1970s. There are large reserves of coal and important deposits of iron ore, manganese ore, bauxite, limestone, dolomite, fireclay, and china clay. Diamond reserves at Panna were of particular interest.

**Power resources.** The state is well endowed with hydroelectric-power potentials. A pioneer hydroelectric scheme is the Chambal Valley project, which has been jointly developed with Rājasthān. There are also plans to harness the Narmada to produce hydroelectric power.

**Industry.** Before planned development took place, western Madhya Pradesh was the main industrial area—primarily producing consumer goods. The aim of the first three Indian five-year plans was to ensure balanced industrial development.

In the early 1970s there were more than 100 large- and medium-scale industries, important centres being Indore, Gwalior, Bhopāl, Ujjain, and Jabalpur. The only heavy industries were the iron and steel plant at Bhilai and the heavy electrical factory at Bhopāl, both government undertakings. Other government-owned factories include the newsprint factory at Nepa Nagar, the plant for the production of equipment for the Post and Telegraph Department at Jabalpur, and the ordnance factories at Katni and Jabalpur. As part of the planned development, industrial estates were established at Indore, Gwalior, Bhopāl,

The  
tribal  
groups

Languages

Divisions  
and  
districts

The  
universities

Industrial  
centres

Raipur, Bhilai, and Jabalpur. In the private sector, there were cement works, paper mills, sugar mills, and textile mills (cotton, woollen, silk, and jute), besides flour, oil, and saw mills. There were also some general engineering industries.

There are more than 2,000 registered small-scale industrial units in the state. The handloom industry is flourishing, and various traditional crafts are practiced.

**Transport and communications.** In comparison with other Indian states, Madhya Pradesh is rather poorly served with transport and communications facilities. The main railroads that pass through the state were originally laid down to connect the ports of Madras, Bombay, and Calcutta with their hinterlands. Inadequate transport facilities have hindered the development of the state's rich resources.

There are both broad-gauge and narrow-gauge rail lines. The five main broad-gauge lines are Bombay-Delhi via Bhopāl, Bombay-Howrah (Calcutta) via Jabalpur, Bombay-Howrah (Calcutta) via Raipur, Madras-Delhi, and Bombay-Delhi via Ratlām.

The state is connected with Delhi and Bombay by air via Bhopāl and Indore.

In the early 1970s there were more than 23,000 miles of roads in the state, including about 1,600 miles of national highways. The latter connected Āgra with Bombay, Allāhābād with Nāgpur, Jhānsi with Lakhnādon, and Raipur with Vishākhapatnam. Many districts had fewer than ten miles of roads for every 100 square miles of territory. In the absence of a dense rail network, roads played an important part in the developing economy. The construction of bridges across the Narmada and other rivers has greatly helped the development of all-weather traffic routes.

**Cultural life.** There are a number of temples, fortresses, and cave works in Madhya Pradesh that have left fascinating evidence for historical studies, both on the early story of mankind in general and on local dynasties and kingdoms. One of the earliest monuments was the *stūpa* (Buddhist mound forming a memorial shrine) at Bhārhut (c. 175 BC), near Satna, the remains of which are now in the Indian Museum at Calcutta. Another such monument is the *stūpa* at Sānchi (six miles south of Vidisha), originally constructed by Aśoka, emperor of India from about 265 to 238 BC; additions to the *stūpa* were made by the Śuṅga kings. The Bāgh caves near Mhow, with their wonderful paintings on Buddhist topics, merit a special mention; the Udayagiri caves (Brahmanical and Jain monasteries) near Vidisha exhibit art and architecture in the rock-cut tradition. Among the temples known the world over for their erotic art are those at Khajurāho in the Chhatarpur district in the north of the state; dating from AD 1000, they were built by the Candella kings. The temples at Gwalior and in its vicinity should also be mentioned. The palaces at Mandu (near Dhār) and the Gwalior Fort, perhaps the most impressive of the residences of the former princes of Madhya Pradesh, represent other notable architectural achievements.

Many of the tribal traditions in Madhya Pradesh are still vital and strong, though they have been exposed in varying degrees to outside cultural influences. A great deal of tribal mythology and folklore is also preserved. The *pardhān* (bards of the Gond) still sing of the legendary deeds of Lingo-pen, the mythical originator of the Gond tribe. The *Pandwāni* is the Gond equivalent of the *Mahābhārata* (one of the two great epics of India), while the *Lachmanjati* legend is the Gond equivalent of the *Rāmāyaṇa*, the other great epic. Other epics are also popular. All tribes have myths and legends regarding their origin. There are songs for the ceremonies of birth and marriage, while various dance styles have songs to accompany them. Folktales, riddles, and proverbs are another feature of the cultural heritage.

**BIBLIOGRAPHY.** The *Census of India, 1961*, vol. 8, *Madhya Pradesh*, pt. 2 (1963), is a collection of general population tables; while the *Statistical Abstract of Madhya Pradesh* (annual) is a compendium of Madhya Pradesh statistics. See also the *Economic and Statistical Atlas of*

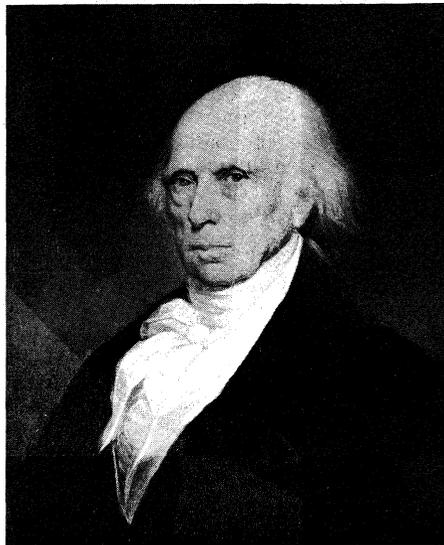

*Madhya Pradesh* (1958). An account of the state's economy is found in the NATIONAL COUNCIL OF APPLIED ECONOMIC RESEARCH, *Techno-Economic Survey of Madhya Pradesh* (1960). O.H.K. SPATE and A.T.A. LEARMONTH, *India and Pakistan*, 3rd ed. rev. (1967), is a general economic and regional geography. D.R. PATIL, *The Cultural Heritage of Madhya Bharat* (1953), deals with the pre-1956 state of Madhya Bharat in its geographical and cultural setting.

(N.P.A.)

## Madison, James

James Madison, fourth president of the United States, was one of the founding fathers of his country. He became known as the "father" of the Constitution because of his influence in planning and gaining ratification of the U.S. Constitution. He was secretary of state under Pres. Thomas Jefferson when Louisiana was purchased from France. The War of 1812 was fought during his presidency.

By courtesy of The New-York Historical Society

Madison, oil painting by A.B. Durand, 1833.

Madison was born March 16 (March 5, old style), 1751, at the home of his maternal grandmother, in what is now Port Conway, Virginia. The son and namesake of a leading Orange County landowner and squire, he lived for 85 years at Montpelier, in the shadow of the Blue Ridge Mountains. In 1769 he rode horseback to the College of New Jersey (Princeton University), selected for its hostility to episcopacy. He completed the four-year course in two years, finding time also to demonstrate against England and to lampoon members of a rival literary society in ribald verse. Overwork produced several years of epileptoid hysteria and premonitions of early death, which thwarted military training but did not prevent home study of public law, mixed with early advocacy of independence (1774) and furious denunciation of the imprisonment of nearby dissenters from the established Anglican Church. Madison never became a church member, but in maturity he expressed a preference for Unitarianism.

His health improved, and he was elected to Virginia's 1776 Revolutionary convention, where he drafted the state's guarantee of religious freedom. In the convention-turned-legislature he helped Thomas Jefferson disestablish the church but lost re-election by refusing to furnish the electors with free whisky. After two years on the governor's council, he was sent to the Continental Congress in March 1780. Five feet six inches tall, small boned, boyish in appearance, and weak of voice, he waited six months before taking the floor; but strong actions belied his mild manners. He rose quickly to leadership against the devotees of state sovereignty and enemies of Franco-U.S. collaboration in peace negotiations, contending also for the Mississippi as a western territorial boundary and the right to navigate that river through its Spanish-held delta. Defending Virginia's charter title to

Early life and political activities

The roads

Tribal mythology and folklore

the vast Northwest against states that had no claim to western territories and whose major motive was to validate barrel-of-rum purchases from Indian tribes, Madison defeated the land speculators by persuading Virginia to cede the western lands to Congress as a national heritage.

Following the ratification of the Articles of Confederation in 1781, Madison undertook to strengthen the Union by asserting implied power in Congress to enforce financial requisitions upon the states by military coercion. This move failing, he worked unceasingly for an amendment conferring power to raise revenue and wrote an eloquent address adjuring the states to avert national disintegration by ratifying the submitted article. The chevalier de la Luzerne, French minister to the United States, wrote that Madison was "regarded as the man of the soundest judgment in Congress."

Re-entering the Virginia legislature in 1784, he defeated Patrick Henry's bill to give financial support to "teachers of the Christian religion." To avoid the political effect of his extreme nationalism, he persuaded the states-rights advocate John Tyler to sponsor the calling of the Annapolis Convention of 1786, which, aided by Madison's influence, produced the Constitutional Convention of 1787.

There his Virginia Plan, put forward through Gov. Edmund Randolph, furnished the basic framework and guiding principles of the Constitution. Delegate William Pierce, of Georgia, wrote that in the management of every great question, Madison "always comes forward the best informed Man of any point in debate." Pierce called him "a Gentleman of great modesty—with a remarkable sweet temper. He is easy and unreserved among his acquaintances, and has a most agreeable style of conversation." Besides earning the title of father of the Constitution, Madison took day-by-day notes of debates, which furnish the only comprehensive history of the convention proceedings. To promote ratification he collaborated with Alexander Hamilton and John Jay in newspaper publication of *The Federalist Papers* (Madison wrote 29 out of 85), which became the standard commentary on the Constitution. His influence produced ratification by Virginia and led John Marshall to say that, if eloquence included "persuasion by convincing, Mr. Madison was the most eloquent man I ever heard."

Elected to the new House of Representatives, Madison sponsored the first ten amendments to the Constitution, placing emphasis, in debate, on freedom of religion, speech, and press. His leadership in the House, which caused Massachusetts congressman Fisher Ames to call him "our first man," came to an end when he split with Treasury Secretary Hamilton over methods of funding the war debts. Hamilton's aim was to strengthen the national government by cementing men of wealth to it; Madison sought to protect the interests of Revolutionary veterans. Hamilton's victory turned Madison into a strict constructionist of the congressional power to appropriate for the general welfare. He denied the existence of implied power to establish a national bank to aid the Treasury. Later, as president, he asked for and obtained a bank as "almost [a] necessity" for that purpose, but he contended that it was constitutional only because Hamilton's bank had gone without constitutional challenge. Unwillingness to admit error was a lifelong characteristic. The break over funding turned Congress into Madisonian and Hamiltonian factions, with Fisher Ames now calling Madison a "desperate party leader" who enforced a discipline "as severe as the Prussian" (Madisonians turned into Jeffersonians after Jefferson, having returned from France, became secretary of state).

In 1794 Madison married Dolley Payne Todd, a handsome, buxom, vivacious Quaker 16 years his junior, who rejected church discipline and loved social activities.

Madison left Congress in 1797, disgusted by John Jay's treaty with England, which frustrated his program of commercial retaliation against wartime oppression of U.S. maritime commerce. The Alien and Sedition Acts of 1798 inspired him to draft the Virginia Resolutions of that year, denouncing those statutes as violations of the First Amendment of the Constitution and affirming

the right and duty of the states "to interpose for arresting the progress of the evil." Carefully worded to mean less legally than they seemed to threaten, they forced him to spend his octogenarian years combatting South Carolina's interpretation of them as a sanction of state power to nullify federal law.

During eight years as Jefferson's secretary of state (1801-09), Madison used the words "The President has decided" so regularly that his own role can be discovered only in foreign archives. British diplomats dealing with Madison encountered "asperity of temper and fluency of expression." Senators John Adair and Nicholas Gilman agreed in 1806 that he "governed the President," an opinion held also by French minister Louis-Marie Turreau.

Although he was accused of weakness in dealing with France and England, Madison won the presidency in 1808 by publishing his vigorous diplomatic dispatches. Faced with a senatorial cabal on taking office, he made a senator's lacklustre brother secretary of state, Robert Smith, and wrote all important diplomatic letters for two years before removing him. Although he had fully supported Jefferson's wartime shipping embargo, Madison reversed his predecessor's policy two weeks after assuming the presidency by secretly notifying both Great Britain and France, then at war, that, in his opinion, if the country addressed should stop molesting U.S. commerce and the other belligerent continued to do so, "Congress will, at the next ensuing session, authorize acts of hostility . . . against the other." An agreement with England providing for repeal of its Orders in Council, which limited trade by neutral nations with France, collapsed because the British minister violated his instructions; he concealed the requirements that the United States continue its trade embargo against France, renounce wartime trade with Britain's enemies, and authorize England to capture any American vessel attempting to trade with France. Madison expelled the minister's successor for charging, falsely, that the President had been aware of the violation. Believing that England was bent on permanent suppression of American commerce, Madison proclaimed nonintercourse with England on November 2, 1810, and notified France on the same day that this would "necessarily lead to war" unless England stopped its molestations. One week earlier, unknown to Congress (in recess) or the public, he had taken armed possession of the Spanish province of West Florida, claimed as part of the Louisiana Purchase. He was re-elected in 1812, despite strong opposition.

With his actions buried in secrecy, Federalists and politicians pictured Madison as a timorous pacifist dragged into the War of 1812 (1812-15) by congressional war hawks. In fact, he sought peace but accepted war. As wartime commander in chief he was hampered by the refusal of Congress to heed pleas for naval and military development and made the initial error of entrusting army command to aging veterans of the Revolution. The small U.S. Navy sparkled, but on land defeat followed defeat. By 1814, however, Madison had lowered the average age of generals from 60 to 36 years; victories resulted, reversing British Cabinet policy and ending a war the principal cause of which had been removed by revocation of the Orders in Council the day before the conflict began. Contemporary public opinion in the United States, Canada, England, and continental Europe proclaimed the result a U.S. triumph. The Federalist Party was killed by its sedition in opposing the war, and the President was lifted to a pinnacle of popularity. Madison's greatest fault was delay in discharging incompetent subordinates, including Secretary of War John Armstrong, who had scoffed at the President's repeated warnings of a coming British attack on Washington and ignored presidential orders for its defense.

On leaving the presidency, Madison was eulogized at a Washington mass meeting for having won national power and glory "without infringing a political, civil, or religious right." Even in the face of sabotage of war operations by New England Federalists, he had lived up to the maxim he laid down in 1793 when he had said:

Madison's  
presidency

The  
father  
of the  
Constitu-  
tion

"If we advert to the nature of republican government we shall find that the censorial power is in the people over the government, and not in the government over the people."

Later life

Never leaving Virginia, for 19 years Madison managed his 5,000-acre (2,000-hectare) farm, cultivating it by methods regarded today as modern innovations; and, as president of the Albemarle Agricultural Society, he warned that human life might be wiped out by upsetting the balance of nature, including invisible organisms. He hated slavery, which held him in its economic chains, and worked to abolish it through government purchase of slaves and their resettlement in Liberia, financed by sale of public lands. When his personal valet ran away in 1792 and was recaptured—a situation that usually meant sale into the yellow-fever-infested West Indies—Madison set him free and hired him. Another slave managed one-third of the Montpelier farmlands during Madison's years in federal office. Madison participated in Jefferson's creation of the University of Virginia (1819) and later served as its rector. Excessive hospitality, chronic agricultural depression, the care of superannuated slaves, and the squandering of \$40,000 by and on a wayward stepson made him land-poor in old age. His last years were spent in bed, barely able to bend his rheumatic fingers, which nevertheless turned out an endless succession of letters and articles combatting nullification and secession—the theme of his final "Advice to My Country." Henry Clay called him, after Washington, "our greatest statesman." Madison died at Montpelier, on June 28, 1836.

**BIBLIOGRAPHY.** Madison's life is most competently and exhaustively treated in IRVING BRANT, *James Madison*, 6 vol. (1941–61), which sets out to counter the hitherto prevailing misrepresentation of the Madison and Jefferson administrations and particularly the derogation of Madison relative to Jefferson; *The Fourth President* (1970) is a selective condensation of the former into a single volume, which, ignoring nothing of importance, aims at bringing Madison's life and career into sharper focus; in the first part of *James Madison and American Nationalism* (1968), Brant provides an account of Madison's role in the formation and development of U.S. institutions against the background of the popular attitude, and in the second provides corroboratory documentary readings. A good one-volume biography is RALPH KETCHAM, *James Madison* (1971). *The Papers of James Madison*, ed. by W.T. HUTCHISON and W.M.E. RACHAL (1962– ), is the most extensive collection of Madison's writings, annotated and with background notes, the last volume so far in the series appearing in 1973. S.G. BROWN, *The First Republicans* (1954), is concerned with Madison, Monroe, and Jefferson, its main theme being the development in the 30 years after 1795 of the essential partisan ideas that bound together the republican faction. GALLARD HUNT (ed.), *The Writings of James Madison*, 9 vol. (1900–10), comprises Madison's public papers and private correspondence; he also edited *The Journal of the Debates in the Convention Which Framed the Constitution of the United States, May–September 1787, As Recorded by James Madison*, 2 vol. (1908), which is the only continuous and almost exhaustive record of that constitution. N.E. CUNNINGHAM, *The Jeffersonian Republicans* (1957), covering the period 1789–1801, traces the formation and operation of the party organization behind Jefferson's rise to the presidency, with ample treatment of Madison's role. C.E. HILL, *James Madison*, vol. 3 in S.F. BEMIS (ed.), *American Secretaries of State and Their Diplomacy* (1927–29), provides a survey of the chief political problems facing Madison as secretary of state from 1801. E. MCNALL BURNS, *James Madison, Philosopher of the Constitution* (1938), is concerned with the analysis of Madison's political philosophy and discusses its influence and significance. ADRIENNE KOCH, *Jefferson and Madison: The Great Collaboration* (1950), is a systematic study of the friendship of Jefferson and Madison in working out a comprehensive ideology of democracy and attempts to show how much Jeffersonian political philosophy owes to Madison; the same author's *Madison's "Advice to My Country"* (1966) consists of these essays on Madison's philosophy of moral and political discourse, arranged under the topics liberty, justice, and union. The first section of J.Q. ADAMS, *The Lives of James Madison and James Monroe, Fourth and Fifth Presidents of the United States* (1850), is devoted to an account and evaluation of Madison's political career and administrations; S.H. GAY, *James Madison* (1884), covers the period up to 1797; and W.C. RIVES, *History of the Life and Times of James Madison*, 3 vol. (1859–68), concentrates on the period from the American Revolution until 1797. S.K. PADOVER, *The Com-*

*plete Madison* (1953), organizes Madison's speeches and writings under apposite titles, including constitutional problems, political principles, and foreign affairs.

(I.Bt.)

## Madras

The fourth largest city in India, Madras is the capital of Tamil Nadu. Located on India's eastern coast, it covers an area of about 50 square miles (130 square kilometres). Though it does not have the commercial and industrial opulence of Calcutta or the planned beauty of New Delhi, the city presents a characteristic blend of the traditional and the modern. With a population of 2,470,000, most of Madras is less congested than other Indian cities; hence, the tenor of life is more peaceful.

Madras is the shortened name of the fishing village Madraspatnam, where the British East India Company built a factory in the 17th century. The Tamil-speaking Indians refer to the city as Chennai, an abbreviation of the name Chennapatnam, which was applied to the Indian section of the original British town.

### HISTORY

**Indian origins.** In their contemporary records the moneylenders of Madras referred to the pre-British villages as towns. Several of them, such as Mylapore, Tiruvottiyūr, and Triplicane, were small temple towns, the legends and history of which dated back to the 3rd or 4th century AD. The home-based industries and farming of the pre-British villagers were sufficiently productive to support several large temples, with their elaborate paraphernalia. In fact, it was local skill and industry that provided the basis for the development of British commerce at Madras.

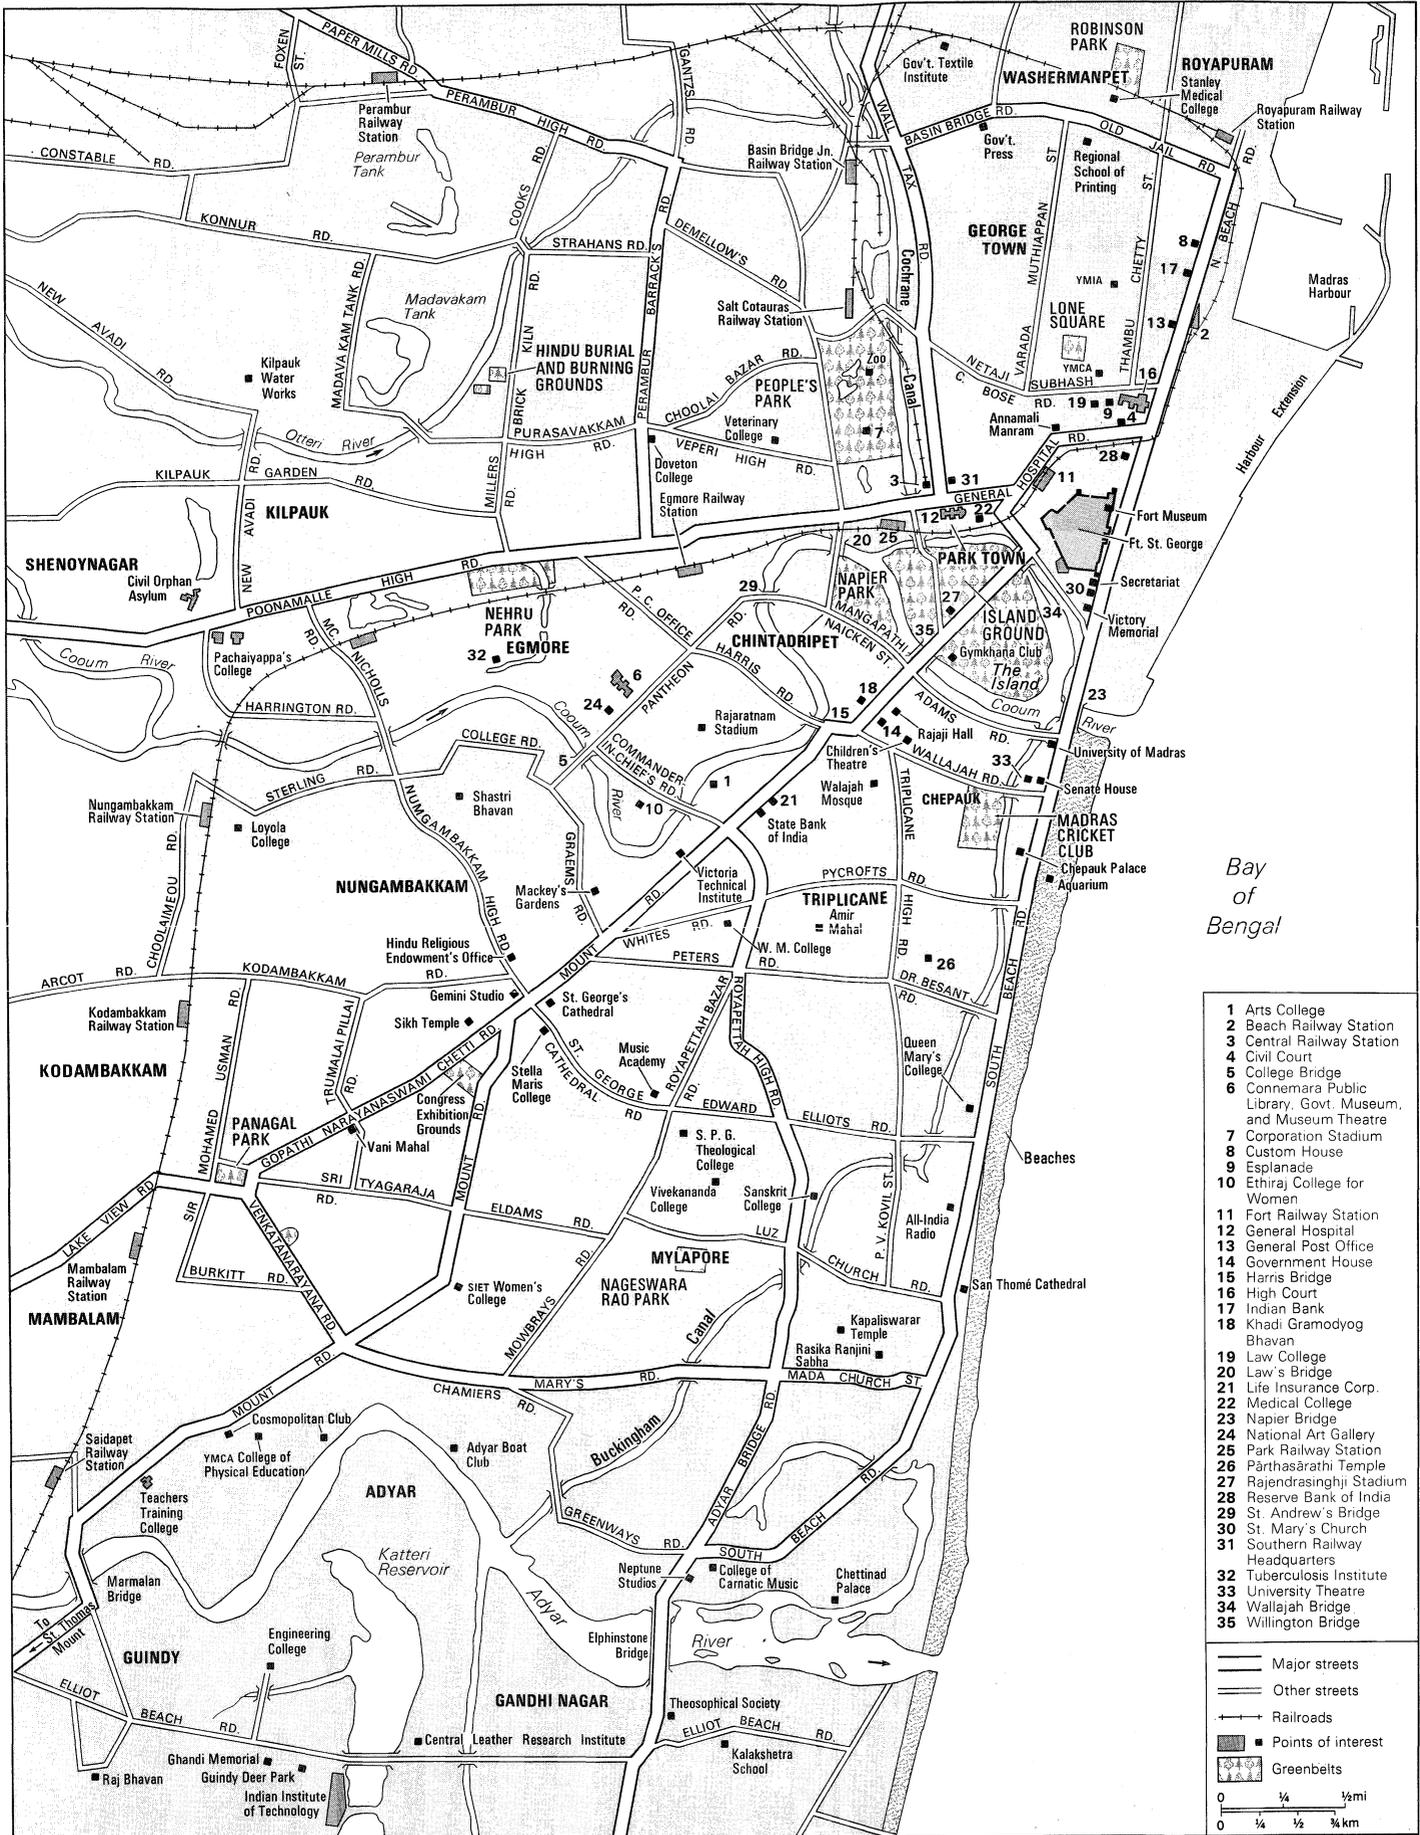

**The British town.** In 1639, Francis Day, an English agent of the East India Company, obtained permission to erect a fort and trading post at Madraspatnam. The site granted to the company was a stretch of sandy waste north of the Cooum River, which was occupied by a fishing settlement. Beyond the coastal ridge of sand were other small villages surrounded by rice fields. The weaving of cotton fabrics was a local cottage industry in the region, and the English merchants invited the weavers and native merchants to settle down in the neighbourhood of the proposed fort. By 1652 the new factory of Ft. St. George was recognized as a presidency (an administrative unit governed by a president). Between 1668 and 1749 the company acquired administrative control within a radius of five miles of Ft. St. George. At about 1801, by which time the last of the local rulers had been shorn of his powers, the English had become masters of southern India, and Madras had become their administrative and commercial capital.

During the earlier phases of the history of Madras, the English merchants lived in the fort—known as White Town. As their numbers increased and trade grew in volume, the merchants spread out into garden houses in Nungambakkam, Adyār, and Kilpauk. The Indian part of Madras—Black Town (now George Town)—also enlarged rapidly, as did the surrounding villages. In the course of three centuries, the rice fields, orchards, and swamps between the villages vanished and became residential areas.

### THE CONTEMPORARY CITY

**The city site.** Madras is situated on a low-lying, level strip of land on the Coromandel Coast of the Bay of Bengal. Its north-south length along the coast is about 11 miles, and its east-west width is about six miles. The highest part of the city is only 23 feet above sea level. For purposes of general administration, the city is one of the 14 districts of Tamil Nadu. Until 1946 the city's area was only 27 square miles; in order to alleviate congestion, however, urbanized villages to the south and west were incorporated in that year. Tiruvottiyūr and Ennore on the north, Avadi and Ambattur on the northwest, Kodambakkam on the west, and Nandanbakkam and Guindy on the southwest are fast-developing industrial suburbs. Ribbon development was in progress in the early 1970s, particularly along the Southern Railway line and

Madras.

trunk roads. Previously isolated residential and industrial areas were becoming interconnected.

**The environment.** *Climate.* The climate has been uncharitably described as "three months hot and nine months hotter." In fact, it does not have the extremely hot and humid summer of Calcutta, and sea breezes moderate the summer heat. May is the hottest month, with a mean temperature of 91° F (33° C); January is the coolest month, with a mean temperature of 75° F (24° C). Madras receives about 50 inches of rainfall a year, two-thirds of it between October and January and the rest between June and September. Several low-lying areas are subject to floods during the rainy season. It is a dusty city, but air pollution is not severe.

*Vegetation and animal life.* Trees in the area include coconut and palmyra palms, margosa, coral tree, pongam tree, pubescent baubinia, and tamarind, as well as white mangrove, Indian fir, portia tree, and rain tree. The spreading banyan tree at Adyār is famous for its size.

Among the common snakes are the rat snake and the green snake. Birds include the magpie, robin, woodpecker, and kingfisher. The garden lizard, the toddy cat (palm civet), and the hedgehog are also common.

**The city plan.** Madras developed without a plan from its 17th-century core, formed by the fort and Black Town. The business areas of the city are the North Beach Road, facing the harbour; the Esplanade in George Town; and Mount Road. To the north and northwest are the industrial areas; the main residential areas are to the west and south, and the old villages are in the centre.

The main streets in George Town generally run from north to south. The new residential extensions—including Mambalam, Shenoy Nagar, and Gandhi Nagar—are well planned and have better roads and amenities. Of the total land area 68 percent is occupied by residences and streets; the remainder is used for commerce, the harbour and railways, administration, parks and playgrounds, and for other purposes.

**Traditional neighbourhoods.** In the past, castes and religious communities were concentrated in different districts. Mylapore and Triplicane were mainly Brahmin neighbourhoods, Chepauk was Muslim, Royapuram was Christian, and Chintadripet and Washermanpet were inhabited by weavers. This pattern was changing in the early 1970s; the new suburbs, inhabited by more affluent citizens, are cosmopolitan in character.

**Transportation.** The city has more than 440 miles of paved roads, and more than 14 miles of metre-gauged and 9 miles of broad-gauged railway. Its bus service is nationalized, and there is an air terminal at Meenambakkam. Vehicles include autos, horse-drawn, two-wheeled jutkas (passenger vehicles drawn by a single horse), bullock carts, and handcarts. With poor sidewalks and unplanned roads, traffic problems are acute in congested areas, particularly in George Town.

**The population.** The population was about 2,470,000 in 1971, representing an increase of more than 43 percent at the 1961 census. A little over 37 percent of the people had immigrated into the city since 1941. Population density was almost 50,000 per square mile.

Of the total population at the 1961 census, some 72 percent spoke Tamil, 14 percent spoke Telugu, and 3 percent Malayalam. Urdu is spoken by nearly 5 percent of the population, and English is used as a subsidiary language by 17 percent of the Tamil-speakers. Almost the entire population is Hindu, but there are communities of Muslims and Christians.

**Housing and architecture.** Housing is generally unsatisfactory for more than half of the citizens, who live either in one-room huts or in one- or two-room "portions" of crowded houses. In the early 1970s the Tamil Nadu Housing Board, the City Improvement Trust, several cooperative house-construction societies, and the Slum Clearance Board were building better houses for the middle- and low-income groups. As old slums are cleared, however, new ones spring up.

Domestic architecture has been extensively modernized because of changes in building materials, though older houses with tiled roofs can still be seen. The most distinc-

tive buildings are the seven large city temples in the Dravidian style, situated in George Town, Mylapore, and Triplicane. Of the buildings of the British period, the Chepauk Palace and the University Senate House (both in the Deccan Muslim style) and the Victoria Technical Institute and the High Court buildings (both in the Indo-Saracenic style) are generally considered to be the most attractive. Modern skyscrapers, such as the Life Insurance Corporation building, had begun to appear in the early 1970s.

**The economy.** *Industry.* Industrial development in the Madras metropolitan area was rapid between about 1956 and the early 1970s. Industrial concerns include vehicle factories, an electrical engineering firm, rubber and fertilizer factories, and a refinery. There are two industrial estates, one for small-scale industries at Guindy and another at Ambattur for medium-scale industries. In 1961 there were about 870 factories, some 60 of which were owned by the government and about 800 of which were private concerns.

*Trade.* The principal commodities exported from Madras are leather, iron ore, mill-made and handloom cotton textiles, cotton yarn, peanuts (groundnuts), mica, onions, chillies, coffee, human hair, palm fibre for brushes, and sandalwood oil. The chief imports, which have three times the value of the exports, include wheat, machinery, iron and steel, ammonium sulfate, raw cotton, newsprint, urea (a nitrogenous compound used in fertilizers and in making plastics), soybean oil, drugs, petroleum products, and rock phosphate.

*Commerce.* Madras-based banks, such as the Indo-Commercial Bank and the Indian Bank, are now among India's large nationalized banks. The Tamil Nadu Industrial Investment Corporation and three other corporations and cooperative banking institutions aid large and small businessmen. The Madras Chamber of Commerce and Industry, the Andhra Chamber of Commerce, and the South India Film Chamber of Commerce play useful roles in the coordination of the city's business efforts. Import, export, and wholesale trade, as well as banking and industry, which were formerly in the hands of the British and later of north Indian Marwaris and Gujaratis, have come to be increasingly shared by Madras businessmen. A favourable investment climate has been created by the Tamil Nadu government, and the city has been able to attract capital from within the state and from abroad.

**Administration and social conditions.** *Political and governmental institutions.* The political parties are the Dravida Munnetra Kazhagam (DMK), the Indian National Congress, the Communist Party, the Swatantra Party, and the Muslim League. In the early 1970s the DMK, together with the Congress, commanded the most votes. The Communist movement was weak.

The state legislature, secretariat, and administrative departments are all located in the city. The state governor has his official residence in nearby Guindy, while government offices are scattered throughout the area. The several central government offices located in Madras include the Southern Railway headquarters in Park Town; the offices of the accountant general and of the postmaster general on Mount Road; the income-tax, passport, and other offices in Nungambakkam; and the headquarters of the southern command of the Indian Army at St. Thomas Mount.

Under the control of the state government, exercised through the Local Administration Department, the municipal administration is vested in the Corporation of Madras, established in 1687. It is composed of a mayor and 120 councillors who are elected by adult franchise.

*Public utilities.* The water supply, which is filtered, is obtained from Red Hills Lake, eight miles northwest of Madras, which is fed by channels from the Poondi and Tamarapakkam reservoirs on the Korttalaiyār River. When the monsoon rains fail—which happens frequently—Madras experiences acute water shortages. The Veeranam Project, expected to be completed by 1974, will bring water from the Cauvery River.

Because of the city's low altitude and high water table,

The Hindu  
Tamil-  
speaking  
population

The  
five  
political  
parties

drainage and sewage disposal problems are encountered. Sewage is pumped to the surface at several points and, finally, dumped into the sea. Storm water is drained into the stagnant Cooum River and into Buckingham and Cochrane canals. Market and street sanitation is poor, and mosquito control and garbage disposal are inadequate.

Electricity is supplied to the city from the Basin Bridge and Ennore thermal stations.

**Social conditions.** Madras has a number of state and municipal hospitals; the largest and oldest hospital is the state-run Madras General Hospital. Health centres include 14 large medical establishments and about 200 child-welfare centres and dispensaries. The city health department runs an infectious disease hospital, ensures that food is not adulterated, and enforces sanitation in public places, such as hotels and restaurants.

The city fire and police services are departments of the state government. There are 12 fire stations; 60 police stations are responsible for law and order and for controlling traffic.

Municipal and state governments and Christian missions are the most important educational agencies. The city runs more than 340 primary and middle schools and almost 30 high schools. These are of poor standard compared to the schools managed by Christian agencies and by the Ramakrishna Mission. Higher education in the arts and sciences is provided by a dozen colleges, three of which are state owned and the remainder, privately run. Professional education can be obtained in three state medical colleges, four colleges of engineering and technology, the College of Carnatic Music, the Kalakshetra (school of dance), the College of Arts and Crafts, and four teacher-training colleges.

The University of Madras has advanced centres of research in plant pathology, mathematical physics, biophysics, and Indian philosophy. The Indian Institute of Technology, the Central Leather Research Institute, and the Regional Laboratories of the Council of Scientific and Industrial Research are other noteworthy scientific institutions.

Harrison Forman

University of Madras.

**Cultural life.** **Cultural institutions.** The Madras Music Academy is an influential establishment devoted to the encouragement of Carnatic music (the music of the historic region between the southern Coromandel Coast of the Bay of Bengal and the Deccan Plateau). The Kalakshetra is a centre of dance and music, with an international reputation, and the Rasika Ranjini Sabha, in Mylapore, encourages the theatrical arts. The suburban town of Kodambakkam, with its numerous film stu-

dios, is described as the Hollywood of southern India. Three theatres—the Children's Theatre, the Annamali Manram, and the Museum Theatre—are popular. The Madras Government Museum has well-displayed collections illustrating the archaeology, history, vegetation, animal life, geology, and ethnology of Tamil Nadu. There is a small collection of East India Company antiquities in the Fort Museum and a collection of paintings in the National Art Gallery. The chief libraries are the Madras University Library and the Connemara Public Library.

**The media.** The press is influential and publishes in English, Tamil, and Telugu. Apart from the national daily, *The Hindu*, there are two other English dailies—*The Mail* and the *Indian Express*. Important Tamil dailies are the *Swadesamitran*, *Dinathanthi*, and *Dinamani*; the most popular Tamil weeklies are *Ananda Vikatan*, *Kalki*, and *Kumudam*.

The All-India Radio station at Madras broadcasts programs in Tamil, Telugu, Malayalam, and English.

**Recreation.** Madras is justly proud of its two-mile-long sandy beach and its promenade, the Marina, which on warm evenings is crowded by thousands of people. The city has a number of parks, the largest of which are the People's Park, Napier Park, Robinson Park, and the Island Ground. There is a zoo in the People's Park, a small aquarium on the Marina beach, and a deer park in Guindy, near the Gandhi Memorial.

Cricket is popular and most colleges have cricket teams. Matches of importance are played at the Madras Cricket Club grounds in Chepauk. Next in popularity comes lawn tennis, followed by football (soccer), basketball, and hockey. Sports facilities are provided by the Cosmopolitan, Gymkhana and Presidency clubs, the YMCA, the YWCA, the YMCA College of Physical Education, the Adyār Boat Club, the Madras Flying Club, and the numerous clubs and associations of the various caste and linguistic groups. Apart from the playing fields attached to educational institutions, Madras has two stadia—the Corporation Stadium and the Police Stadium, in Egmore.

**BIBLIOGRAPHY.** P.K. NAMBIAR, *Census of India 1961*, vol. 9, *Madras*, parts 1-9 (1965-67), contains a good account of the city. See also R. BALAKRISHNA, *Report on the Economic Survey of Madras* (1961), a basic reference work; and the CORPORATION OF MADRAS, *Administration Report for 1968-69* (1969). RAMA REDDY VENKATA, *City of Madras: Official Handbook* (1950), although out of date, presents a sound view of the city.

(A.Ai.)

## Madrid

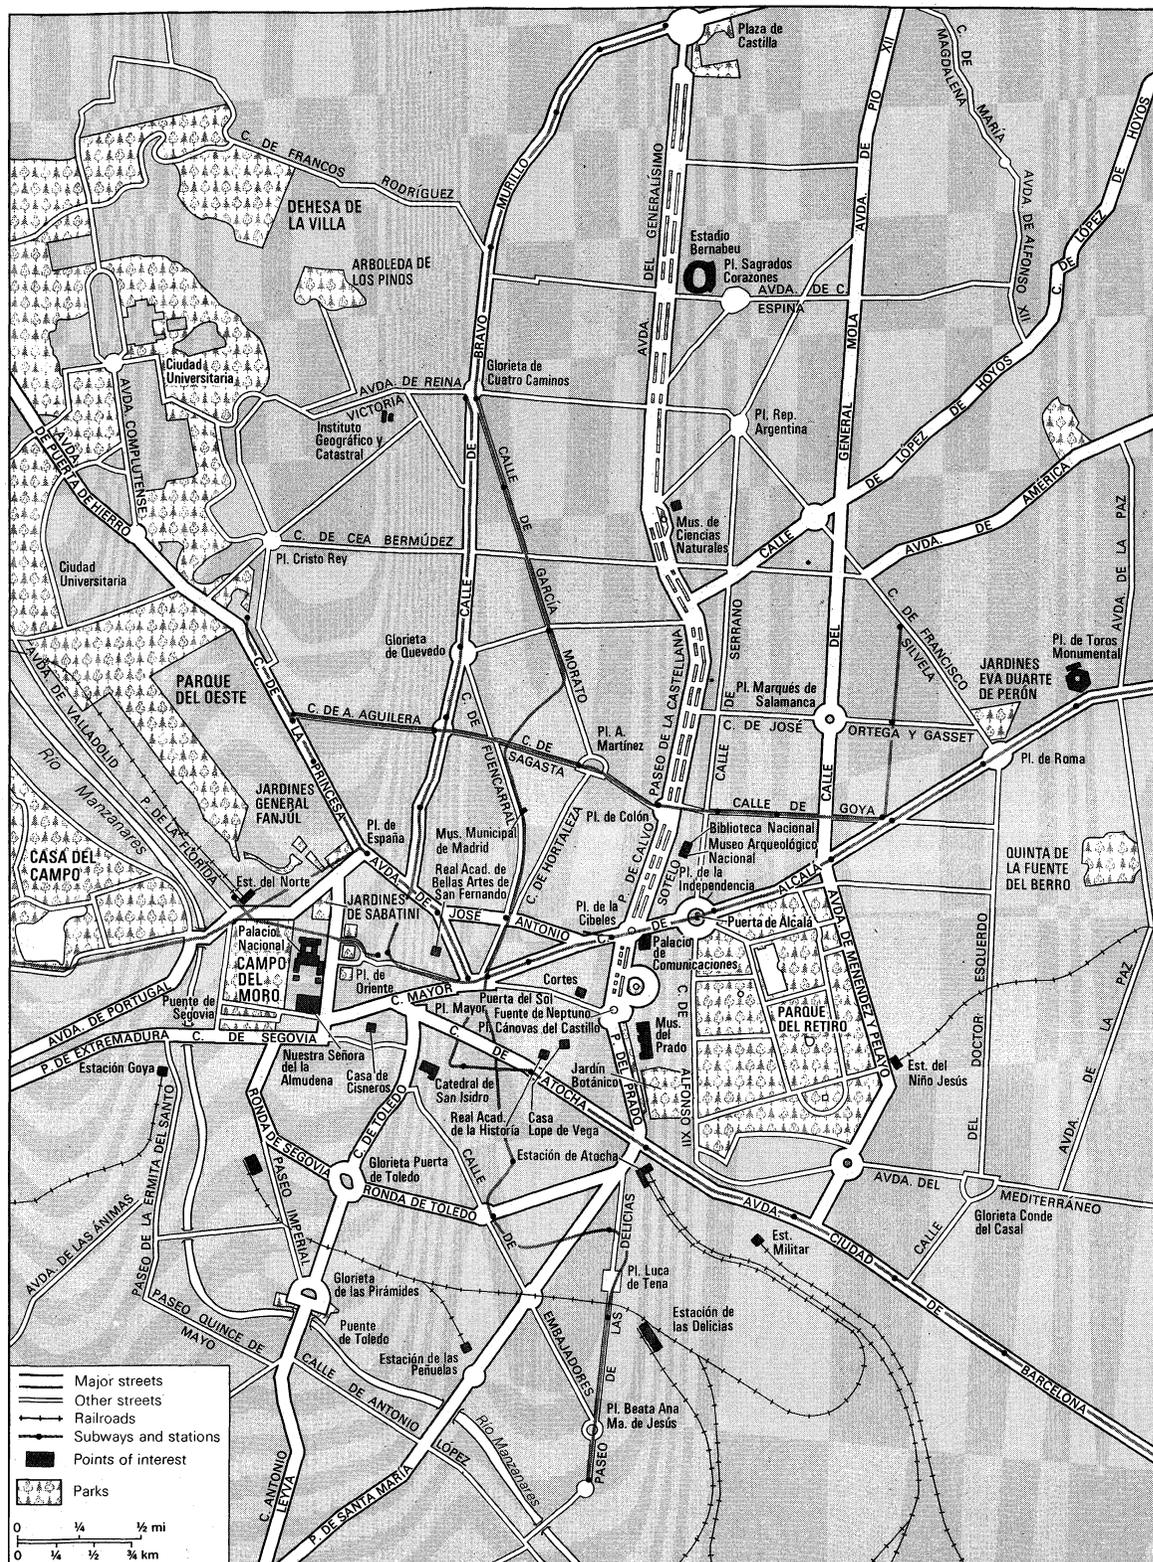

Almost exactly in the centre of the Iberian Peninsula, on the sun-beaten central highland of New Castile, the city of Madrid, capital of Spain and of Madrid Province and a sprawling modern metropolis, entered the 1970s with a population slightly in excess of 3,000,000. At an altitude of 2,100 ft (635 metres) above sea level, on an undulating plateau of sand and clay known as the meseta (from the Spanish *mesa*, "table"), it is the highest capital city in Europe.

There is no compelling geographical, economic, or military reason for Madrid to be where it is. Not on a major river (it is watered by the subdued Manzanares), not on a major trade route (the important highways came to Madrid in the wake of the kings), not the site of a religious shrine, nor a key military position, it was, during the Middle Ages, merely the location of a small Moorish fort named Majrit on a bluff over the river, a part of the outlying defenses of Toledo, 40 miles to the southwest. Political sagacity indicated that a new 16th-century capital should be founded in the centre of the country, but there were other towns in the region that were prettier, better sheltered from the harsh seasons, and more easily defensible against attack. Madrid's great advantage as the capital for a then recently united Spain was its obscurity, which guaranteed its political innocence and its independence of all established power save that of the king of Spain. Taken from the Muslim occupiers in 1083 by Alfonso VI of León and Castile, it had long been the resi-

Central Madrid.

dence of kings, and parliament (the Cortes) was first summoned there in 1329.

In 1561 Philip II established his court at Madrid, on what was to prove to be a permanent basis. It remained for his successor, Philip III, to make the city the nation's official capital, in 1607. The city that subsequently developed was broadly Spanish, rather than narrowly Castilian, in character, and it is now one of the most ebullient capitals of the Continent. It lies on tableland, open to the trumpet blasts of crystalline light and mountain wind. It is, as observers have remarked, a city in which light is more important than colour, grace more than beauty.

**CHARACTER AND SETTING**

In the Madrid of the 1970s a few 30-story buildings, locally esteemed as skyscrapers, contend with older spires, and there is a moderate amount of office building in the contemporary idiom. The city's outskirts are sown with new housing—luxury or low-cost, depending on the neighbourhood—but central Madrid gives an impression of continuity and stability, a rich blend of royal antiquity and steam-age solidity. The north-south axis, which changes its name four times in the four miles between the Prado Museum and the Bernabeu football stadium, is a broad boulevard with trees fronting the buildings on

National Palace and Gardens, Madrid.

either side and two tree-planted strips up the middle. The westernmost of these strips has mosaic pavements and fountains and kilometres of awning-sheltered outdoor cafes under the trees, lending an air of luxury and ease.

The increasing prosperity of Madrid has led to a vertiginous multiplication of the numbers of automobiles, and during the brassily hot summer months when the wind is stilled and there is no rain, the traffic fumes can curtain the streets and make it hard to see across the celebrated plazas. Nonetheless, Madrileños persist in their traditional promenades afoot, especially after sundown. One of the things they are said to find wonderful about their town is the *animación*, which they themselves supply.

The natives call themselves *gatos* (cats), originally a medieval compliment to the wall-scaling ability of Madrid soldiery, but today more of a reference to their sprightliness and to the tradition of nocturnal ambulation. When the weather is clement, then from eight in the evening until after midnight the *gatos* may be observed enjoying the sight of one another enjoying their city. The traditional dinner hour is 10 PM, the evening performance at theatres and cinemas begins at 11 PM, and Madrileños appear to get along on less sleep than other city dwellers. Though each year increasing numbers claim to have abandoned the recuperative siesta, office hours are still shaped to accommodate a tropical midday nap. The model siesta taker, at least according to John Milton Hay, who became the United States secretary of legation to Spain after having been Abraham Lincoln's secretary, was Isidro (Isidore), the patron saint of the city:

He was a true Madrilenian in tastes and spent his time lying in the summer shade . . . while angels came down from heaven and did his farm duties for him. . . . Every true child of Madrid reveres the example and envies the success of the San Isidro method of doing business.

The pace of life in Madrid is accelerating with increasing commercial activity and modernization. The population is swelling (1,000,000 inhabitants added in the decade 1960–70), and road traffic becomes daily more dense. These growing 20th-century pressures have not yet diminished the grave good manners of the *gato*, nor his readiness to laugh. Native wit, once as noted as the pure air and the delicious drinking water, has, however, appreciably dimmed. In 1911, when the central post office was completed, grandiose and pinnacled, a veritable cathedral among post offices, Madrid dubbed it Nuestra Señora de las Comunicaciones. Then, 25 years later, during the

Spanish Civil War (1936–39), the building, centre of the republic's communications, sustained 155 direct hits. Like a good many Madrid landmarks it was later restored so that it looked as if nothing had ever happened. While the fighting lasted, the light-hearted and courtly citizens—on both sides—became killers and wreckers of exceptional ferocity and joke making was for some time unseemly and the habit of gaiety broken.

The cultural life of Madrid has subsided since the early days of the 20th century. The overwhelming heritage of the novelist Cervantes, author of *Don Quixote*, the poet and dramatist Lope de Vega, and the monumental paintings of Goya and Velázquez seems too heavy for modern Madrileños: Madrid, the repository of past glories, is no longer the capital of living Spanish culture. Even the famed *tertulia* is almost extinct. This is a sort of informal seminar, a nonorganized club, foregathering at certain cafes, providing companionship and exchange of ideas, but above all exalted conversation. These have all but disappeared along with the plush and marble cafes that sheltered them.

Change as it may, change as it must, Madrid retains a passionate hold on the hearts of its inhabitants. Spaniards are noted for their fierce local allegiances, and the Madrileño has long been notable among the devoted. In the 17th century Madame d'Aulnoy, a French observer, wrote, "They believe Madrid to be the very centre of all glory and happiness. . . . They had rather choose to lead a mean, poor life without any train, grandeur or distinction, provided it be but at Madrid." Since that era, the local ideal of existence, before and after death, is summed up in the adage, "From Madrid to Heaven, and in Heaven a little window from which to look at Madrid."

#### GROWTH AND TOPOGRAPHY

When resident in Madrid the Spanish monarchs lodged in the captured Moorish Alcazar. The castle was little changed through the centuries until an earthquake tumbled portions of it in 1466. Henry IV of Castile (1454–74) built a medieval palace on the site and died there. Charles I enlarged it and Philip II continued the embellishment, including the addition of a theatre to the 500 rooms. Philip III, who made Madrid the capital *de jure* as well as *de facto*, was born there.

Destruction of the palace by fire in 1734 gave Philip V the chance to create a personal monument to supplement those national monuments, the Real Academia Española,

Palace

the Biblioteca Nacional, and the Real Academia de la Historia. He died 20 years before a Turinese architect, Giovan Sacchetti, had finished the work, which was much smaller and less ornate than the palace of 1,700-foot-long facades and 23 inner courts that the king had envisaged. What did emerge was nevertheless vast and weighty, a great marble and limestone quadrangle in Neoclassical style with elaborately decorated salons, including a ceiling painted by Tiepolo for the throne room. The armoury contains one of the world's great collections of body armour, as well as the swords of the conquistadores Cortés and Pizarro, and a magnificent campaign tent of Francis I, taken when the French king was captured at the Battle of Pavia (1525). It was from this armoury that the citizens snatched swords and pikes in a vain and bloody one-night uprising against Napoleon's occupying forces, on May 2, 1808.

Napoleon's brother Joseph occupied the throne from 1808 until 1813. One of his nicknames among his subjects was "el Rey Plazuelas," because of his passion for making clearings in the urban thickets of old Madrid. He created at least a dozen plazas, mostly by levelling convents constructed by previous occupants of the palace. The Plaza de Oriente, facing the palace, was cleared of 56 houses, a library, a church, and several convents. The last king of Spain to inhabit the palace was Alfonso XIII, whose apartments are preserved just as he left them when he abandoned throne and country in 1931.

Adjoining the palace on the south is Madrid's first cathedral, Nuestra Señora de la Almudena, for which construction began in 1895 and is still under way. The temporary status of cathedral was conferred upon the 17th-century church of San Isidro el Real.

For centuries the town huddled close to the castle and then began a slow expansion eastward. Eventually, it opened out in all directions but did not manage to cross westward to the far bank of the Manzanares River until 1948. Madrid's growth was achieved, as the novelist Benito Pérez Galdós noted, in *brusquedades* ("stages of abrupt growth"). Starting in the early part of the 17th century, these outward thrusts have occurred about every hundred years. The 20th-century push has been the greatest of all: between 1948–51, for example, the city swallowed its suburbs and enlarged itself tenfold, to cover an area of 205 square miles (531 square kilometres).

For much of its history, the city was referred to as *los Madriles* ("the Madrids"), because each quarter had its own distinct character. Later there grew up the custom of considering the city as composed of three *barrios* (districts): upper (*altos*), middle (*centrales*), and lower (*bajos*), the extremes indicating an economic as well as a geodetic level. The *barrios bajos*, spilling downhill from the Plaza Mayor along the Calle de Toledo toward the river, are still the poor and picturesque parts of Madrid, but many of their former inhabitants have moved even further downhill onto reclaimed marshland on both sides of the river where stand the large low-rent housing developments. Just over the brow of the hill is the Rastro, for generations a flea market with as many rare bargains as fleas. Today there are no fleas and the accent is on market.

In medieval times the town inched eastward up both sides of the Calle Mayor and the Calle Segovia, centring on the Straw Market (now the Plaza del Marques de Comillas) with the Moors jammed into the southwest corner, still called the Moreria. The whole of the medieval core of Madrid was no more than 500 yards long and 900 yards wide. Some of the street pattern of Madrid before the 16th century remains, but few buildings. Among the rare medieval structures is the much-restored Casa de los Lujanez, in the tower of which Francis I of France is said to have been imprisoned. In the same small square, the Plaza de la Villa, is the astonishingly small Madrid Town Hall, designed in the early 17th century by Juan Gómez de Mora adapting and mellowing the style favoured by the late King Philip II (1556–98). The *estilo desornamento*, as it was known, best typified by Philip's fortress-palace-abbey at the Escorial, produced sturdy red blocks out of which pushed stubby towers topped by gay, slender

slate steeples with flared skirts. The frivolity of the steeples relieved the austerity of the plain facades.

It was under the Habsburgs, starting with Philip II, that Madrid made its first brusque expansion. The Foreign Ministry (1634), originally the Court Prison, the Church of San Isidro, the Casa de Cisneros, and the Segovia Bridge over the Manzanares date from this time. The gem of "Austrian" Madrid, and perhaps the finest architectural creation of all Madrid, is the Plaza Mayor, one of Europe's most graceful and beguiling city squares. Built between 1617–19, it is an oblong 120 metres long and 100 metres wide surrounded by 68 balconied houses five stories high, struck with steeples in the royally approved style. Nine archways penetrate at oblique angles from surrounding streets, and today shops and restaurants occupy the street level beneath the continuous arcade. The plaza was dedicated with an eight-day fiesta celebrating the beatification of Isidro. In 1622 there were fireworks, bullfights (at that period still fought by noblemen on horseback), and a new Lope de Vega play to mark the canonization of Isidro and four other saints—Teresa of Avila, Ignatius of Loyola, Francis Xavier, and Philip Neri. Heretics condemned by the Inquisition went through their auto-da-fé (the execution of the judicial sentence) in the square but were led away for their immolation. Until 1765 common criminals were garroted publicly in the square. The Plaza Mayor's last bullfight was in celebration of Isabella II's royal wedding in 1846.

During the War of the Spanish Succession (1701–14) Madrid espoused the Bourbon cause against the Habsburgs, whose foreign troops succeeded in occupying the capital briefly. After the Bourbons were installed, there was a small flurry of building in the San Bernardo quarter, north of the Calle Mayor, employing a Baroque architecture, exemplified in the richly sculptured Toledo Bridge (1735). The Museo Municipal de Madrid in the Calle de Fuencarral has an ornate portal of this period.

The 16th-century university, after its removal from the town of Alcalá de Henares, was implanted in the San Bernardo neighbourhood in 1836 and removed again 90 years later to Ciudad Universitaria on the northwestern outskirts. In the front lines during the Civil War, Ciudad Universitaria was destroyed and has since been rebuilt and expanded. San Bernardo was bisected in 1910 by a broad new street driven through the tangled old neighbourhood from the Calle de Alcalá downhill to the Plaza de España, where the city's first tall 20th-century commercial buildings were erected. As its name—the Gran Vía—indicated, it was designed as the main street of the city, since crammed with cinemas, coffeehouses, shops and banks, and by the 14-story Telefónica, telephone exchange. Following the Civil War it was named Avenida José Antonio, after the martyr of the winning side, but Madrileños persist in calling it the Gran Vía.

The second Bourbon king, Charles III (1759–88), was called the mayor of Madrid, because of his devotion to the improvement and beautification of the town. In his ambition to make Madrid a noble, modern capital, he was aided by a trio of distinguished Neoclassical architects, Francisco Sabatini, Ventura Rodríguez, and Juan de Villanueva. He pushed the city still further eastward to the present Plaza de la Independencia, where stands the Alcalá city gate, a triumphal arch designed for the king in 1778. One of the many new buildings erected under Charles's reign was the central post office, in the wall of which is set Spain's zero-kilometre stone. In the Puerta del Sol, the structure was eventually occupied by the Ministry of Interior (Gobernación, which it is still popularly called), and since the Civil War by the headquarters of the national police. For local inhabitants this building's clock is one of the principal landmarks of the city. Those who crowd the Puerta del Sol to welcome the New Year carry little bags holding a dozen grapes, one to be swallowed at each stroke of midnight.

The name Puerta del Sol (Sun Gate) is thought to have originated because a sun was carved on the city gate, which stood there until 1510. For centuries the square was the physical and emotional centre of Madrid. Not only did the mail and passenger coaches from the rest of

Bourbon  
influenceCity  
regionsThe  
Puerta  
del Sol

Spain converge here (the subway, built in 1919, still does) but this was the first spot to be blessed with the innovations of 19th-century technology, from the first gas lamps in 1830 through the first mule trams and first public urinal to the first electric street lights and electric streetcars. When reconstruction of the plaza was decreed in 1856, protesters rioted and the government fell. Eventually the Puerta del Sol was given its new shape, but there were other reasons for continuing social disorder, which accelerated in tempo and seriousness through the 19th century and into the 20th until the monarchy was deposed in 1931. Crises continued and five years later the city was convulsed by civil war. After two years of siege, which saw the sacking of church properties, artillery and aerial bombardment, and house-to-house combat, the Nationalist insurrectionists took the Republican capital. The victorious general, with a fine flourish of historical irony, entered the city with a guard of Moors.

From the Puerta del Sol, the new Madrid of Charles III marched down the Calle de Alcalá, still one of the principal arteries of the city, fraught with ministries and ponderously ornate banking establishments, down to the Puerta de Alcalá. Just to the west of the city gate was the Buen Retiro Palace of Philip III, destroyed in the Peninsular War, and of which a remnant serves as a war museum. In the gardens Charles set up a porcelain factory, hoping to rival the work of the French royal pottery at Sèvres. He set aside another portion of the parkland for a botanical garden (1774), part of which was a physic garden from which he ordered medicinal herbs to be given free every morning to anyone who asked, an order still in force. He commanded the building of a museum of natural history and sciences, adjacent to the botanical garden, but died before it was completed. It was only after Ferdinand VII returned to ascend the throne after Napoleon's defeat that the construction was completed, and into it in 1819 the new king moved 311 pictures from the royal collections. This was the start of one of the world's major picture galleries, the Prado. Devoted to works primarily from the 15th to the early 19th century, it has more than 3,000 paintings, half of them on exhibition, with pride of place given to the Spaniards, especially Goya and Velázquez, whose effigies, in bronze, stand before the entrances. Other fine paintings, including some superb Goyas, hang in the Real Academia de Bellas Artes de San Fernando, another Charles III structure in the Alcalá. A Goya masterwork is a fresco done in 1798 for the court chapel of Charles IV, the Ermita de San Antonio de la Florida. After Goya died in France in 1828, he was taken back to Madrid and buried in the little white church. The dome, on which he painted the people of Madrid crowded around a balustrade listening to St. Anthony of Padua preach, provides a fitting memorial. A twin church was built alongside in 1928, and the original became a Goya monument.

At the time the fresco was painted, the street fronting the church, the Paseo de la Florida, was the promenade of fashionable Madrid, but in the early 19th century favour switched to the street that Charles III had laid out and landscaped in front of his museum and botanical garden quite on the opposite side of town. This was the Paseo del Prado, popularly known as the Salón del Prado. When the era of the palatial city hotel arrived, it was there, on opposite sides of the plaza bearing the Neptune fountain, that the Ritz and the Palace were established.

Off this huge plaza (Canovas del Castillo) is a far smaller one, where the Spanish parliament, the Cortes, is located. Built in the 19th century with a Neoclassic columned and porticoed entrance, it is one of the smallest parliament buildings in Europe. Further north, where the Prado crosses the Alcalá, there is another vast oval plaza, named Cibeles, for the central figure of its fountain. This grand crossroads also embraces an Apollo fountain and an obelisk commemorating the uprising of 1808. In 1830, the Paseo del Prado was continued northward by a new boulevard named the Paseo de los Recoletos (since renamed Calvo Sotelo, after another Nationalist martyr), which after a half mile or so becomes the Paseo de la Castellana, and much further on, the

Avenida del Generalissimo. The original road building was achieved by Joaquín Vizcaíno, mayor of Madrid (the mayor is traditionally a nobleman appointed by the national government), who also instituted street numbers for buildings (one to a plot rather than one to each building), street lighting, and municipal refuse collection.

Now the Paseo is the site of the newest tall office buildings, luxury hotels, apartment houses as well as embassies, the 2,200,000-volume Biblioteca Nacional, the Museo Arqueológico Nacional, and the Museo Español de Arte Contemporáneo, but for years it remained almost rural, bordered by imposing town houses set in great gardens. One of these mansions, now appropriately converted into a bank, belonged to the marqués de Salamanca, author of the true expansion of Madrid toward the north. On a plot parallel to the Paseo the banker-marquis in 1872 built 28 streets on a grid plan starting north from the Alcalá. This immediately became, and to a large extent remains, the chic quarter of Madrid. The main street of the Salamanca district is the Calle de Serrano, where small, exclusive, expensive shops serve a similarly qualified neighbourhood clientele. Salamanca razed the historic bullring on the Alcalá and replaced it with one built further east on the same road; this in turn was replaced in 1934 by another further east, though still on the Alcalá. Called El Monumental, it seats 23,000 spectators, is the largest bullring in Spain, and the only Moorish-styled edifice in town. Attached to it is a museum of bullfighting. To become a full-fledged matador, the Spanish *novillero* must take, or confirm his official test of mastery, the *alternativa*, in this ring. The season lasts from March through October.

The high point of the season is the festival of San Isidro, in mid-May, when there are 10 or 11 days of bullfighting. This is also the time of the soccer classic, Madrid versus Barcelona, and a plenitude of other sporting events, folk dancing displays, art shows, concerts, and plays. At this time of year begins the production of *zarzuelas*, open-air comic operettas, usually dating from the 19th century, singing the privilege and joy of living in Madrid.

Following the feast of the city's patron saint, each district in turn stages its own fiesta (*verbena*) for a week or two. As they succeed one another, sometimes overlapping, the summer is sung and danced away. Two of the *verbenas* spread into the large city parks at each end of the east-west axis, the Retiro behind the Prado and the Casa de Campo on the far side of the Manzanares. The garden of the long-vanished Buen Retiro Palace, opened to the public in 1869, has a rowing pond, a small zoo, a 1794 observatory, some rustic cafes, a few night club-restaurants, and trees with a special gift for giving a dense, grateful shade. The Casa de Campo was bought by Philip II in 1559 as a royal hunting preserve and still retains a good deal of its woodland. To its amenities, such as a boating lake and municipal swimming pool, a "park of attractions," with amusement park, theatre, night clubs, open-air dancing, and restaurants, was added in 1969, connected to central Madrid by aerial cable car.

Madrid has several other extensive parks, and many tree-shaded squares, some the location of the city's 30 museums. Among the varied collections are a railway museum, a reconstruction of Lope de Vega's house (in a street now named for Cervantes), and the still-functioning 16th-century convent of Las Descalzas Reales, an Order of Franciscan Poor Clares with a rich store of sculpture, painting, and tapestry. The city has more than 100 libraries, four of them noted for their source manuscripts and rare books: the Biblioteca Nacional, that of the Palacio Nacional, of the municipality, and that of the culturally once-powerful Ateneo (Atheneum).

For long, modern Madrid made its living from government, banking, insurance, and tourism and derived income as the transportation hub of the nation, with six principal stations serving Spain's converging rail lines. After World War II, however, Madrid became an important manufacturing city producing automobile and truck engines, electric and electronic equipment, plastics, rubber, aircraft, and optical goods.

Urban planning, under the jurisdiction of the Comisión

## Maecenas, Gaius

Rich and possessing an ancestry stretching back to Etruscan royalty, Maecenas was an outstanding diplomat and counsellor to the Roman emperor Augustus and the greatest patron of letters in all antiquity. His personal interest quite as much as his wealth made him the dedicatee of Virgil's *Georgics* and Horace's first three books of *Odes*. The same capacity for loyal friendship made Maecenas the most intimate associate of Augustus and permitted his important shaping of history. He was better as a lover of literature than as its practitioner. The tastelessly affected fragments of his extant work, parodied by Augustus and criticized by Seneca, reconcile one to the loss of the remainder. More important were his personal qualities: candour, simplicity, and warmth of affection. These won him the abiding friendship first of Virgil, then, through his mediation, of Horace (in 38 bc). Maecenas set out to interest Virgil, Horace, and Propertius in themes of public importance, hoping their genius would glorify Rome and the new regime. But he was no minister of propaganda, exploiting and misdirecting their talents. Virgil found the way to his own poetic fulfillment in the wider, noble themes of the *Aeneid*, while Horace and Propertius likewise went their own ways. Maecenas respected the poets' independence and artistic integrity.

Friendships with famous poets

Gaius Maecenas, marble bust. In the Palazzo dei Conservatori, Rome.

His place and date of birth are unrecorded (he was born in about 70 bc), but his mother's family, the Cilnii, had lorded it centuries earlier in Arretium (modern Arezzo, about 90 miles north of Rome), and this was apparently also the hometown of his father's family. Tacitus once calls him Cilnius Maecenas (Etruscans used the mother's family name), but officially he was Gaius Maecenas. His great wealth may have been partly inherited, but he owed his position and influence to Octavian, later the emperor Augustus. Maecenas felt that, though a knight (slightly humbler than a senator but basically a nonpolitical member of the privileged class), his lineage and power overtopped any senator's, and he refused a career as one.

He was perhaps present at Philippi (the battle, in 42 bc, in which Antony, at first an ally of Octavian, defeated Caesar's assassins Cassius and Brutus), though if he were there it was hardly as a combatant. As a counsellor he negotiated two years later the short-lived marriage of Octavian and Scribonia, designed to conciliate her kinsman the formidable Sextus Pompeius, last of the great republican generals. Before the year's end he had secured greater advantages for his leader: a treaty had ended the dangerous armed confrontation with Antony at Brundisium (modern Brindisi, on the eastern side of Italy's heel), and Antony had married Octavia, Octavian's sister. In 38–37 he persuaded Antony to come to Tarentum (Taranto, on the northernmost part of Italy's in-step) and lend the warships that Octavian needed to win complete control of the West. Maecenas administered Rome and Italy, while Octavian fought Pompeius, in 36, and Antony, in 31. Although holding no office or military command, he swiftly and secretly scotched a plot to kill Octavian on his return from the East. If not on this occasion, at least in general, Maecenas kept his hands unstained by bloodshed and, in an age of ruthless violence, won praise for his mildness and humanity.

During Octavian's continued absence from Rome, Maecenas shared with Agrippa (Octavian's executive lieutenant) the position of informal vicegerent. He could use Octavian's seal and even alter his dispatches at will and continued to be deeply involved with foreign and domestic affairs after Octavian, now Augustus, had established his principate (27). He was the most trusted of advisers, holding his own in competition with the Agrippa faction.

Maecenas shared Augustus' dynastic hopes and worked for the eventual succession of Marcellus, the Emperor's nephew. Meanwhile, Maecenas had recently married the beautiful, petulant Terentia. Her brother by adoption, Varro Murena, quarrelled with Augustus, was disgraced, and plotted his assassination. The conspiracy was detected and Murena executed, though Maecenas had earlier revealed the plot's discovery to Terentia, thus giving his kinsman a chance to escape. Augustus had to forgive the indiscretion, but from that point on Maecenas' influence waned. Agrippa had emerged from the crises of 23 as coregent, son-in-law, and Augustus' prospective successor. Maecenas had become a sick man, aging rapidly, though in 17 he was still sufficiently buoyant to mock Agrippa, the man without a pedigree, while Augustus pretended not to notice.

The domestic life of Maecenas was unhappy. Terentia tired of him and is said to have become Augustus' mistress. Maecenas, though hardly a model husband, was uxorious; his "daily divorce" of the morose Terentia provoked amused comment. He died childless in 8 bc and left all his wealth, including his palace and gardens on the Esquiline Hill (the eastern plateau of Rome), to Augustus, with whom he had never ceased to be on friendly terms.

Ancient writers dwelt on the contrast between the energy and abilities of Maecenas, the statesman, and the luxurious habits flaunted by Maecenas, the courtier. He was ever the Etruscan aristocrat, displaying hypercivilized, fastidious love of the good things of life, basically un-Roman but less reprehensible than moralizing satirists would have one believe. His severest critic, Seneca, disillusioned by his own failure to become Maecenas of a new Golden Age, denounced his undisciplined style of

Role as Octavian's vicegerent

Criticism by Seneca

writing as the reflection of a character undermined by good and bad fortune alike. He was "lolling Maecenas," with his tunic let down like a petticoat, hobnobbing with eunuchs or the notorious pantomimist Bathyllus. Maecenas certainly loved gracious living, jewelry, dainty food, wine, and women. He gave the Romans a taste for pantomime, heated swimming pools, and other harmless amenities. With his vast wealth he could be the most munificent of patrons, and every parasite in Rome knew it. It was in his circle of intimate friends that he revealed his discrimination and unerring judgment of men's character and quality.

**BIBLIOGRAPHY.** No trace of any formal biography of Maecenas survives from antiquity. His literary fragments are collected in R. AVALLONE (ed.), *Mecenate: I Frammenti* (1945). A recent biography is J.M. ANDRE, *Mécène, essai de biographie spirituelle* (1967). Two older works are R. SCHOMBERG, *The Life of Maecenas: With Critical, Historical and Geographical Notes*, 2nd ed. (1766), a brief life with very useful notes; and H. RICHER, *Vie de Mécènes, avec des notes historiques et critiques* (1746), also brief, with copious reference to contemporary sources.

(E.W.G.)

## Magellan, Ferdinand

Often referred to as the first circumnavigator of the earth, Ferdinand Magellan, since he died before the completion of the first voyage round the world, is more correctly described as initiator and leader of the Magellan-Elcano expedition. The voyage was successfully terminated by the Basque navigator Juan Sebastián de Elcano (del Cano). Fernão de Magalhães, the son of Rui de Magalhães and Alda de Mesquita, belonged to the Portuguese nobility; his birthplace was most probably Porto, which he left to serve as a page to Queen Leonor in Lisbon.

Magellan, painting by an unknown artist. In the Uffizi Gallery, Florence, Italy.

**Portuguese service.** In early 1505 he enlisted in the fleet of Francisco de Almeida, first Portuguese viceroy in the East, whose expedition, sent by King Manuel to check Muslim sea power in Africa and India, left Lisbon on March 25; at a naval engagement at Cannanore on the Malabar Coast of India, Magellan is said by the chronicler Gaspar Correia to have been wounded. Though Correia states that during this early period of his Indian service he acquired considerable knowledge of navigation, little is known of Magellan's first years in the East until he appears among those sailing in November 1506 with Nuno Vaz Pereira to Sofala on the Mozambique coast, where the Portuguese established a fort. In 1508 he was back in India, taking part, on February 2–3, 1509, in the great Battle of Diu, which gave the Portuguese supremacy over most of the Indian Ocean. Reaching Cochin in the fleet of Diogo Lopes de Sequeira, he left as one of the men-at-arms for Malacca. Magellan is mentioned as being sent to warn the commander of impending attack by Malays, and during the subsequent fighting courageously

saved the life of a Portuguese explorer, Francisco Serrão, who later from the Moluccas (Maluku) sent him helpful information about those islands. At a council held at Cochin on October 10, to decide on plans for recapturing Goa, he advised against taking large ships at that season, but the new viceroy, Afonso de Albuquerque, did so, the city falling on November 24; Magellan's name does not appear among those who fought. There is no conclusive evidence for the theory that during his Indian service he attained the rank of captain.

The Portuguese victories off the eastern coast of Africa and the western coast of India had broken Muslim power in the Indian Ocean, and the purpose of Almeida's expedition—to wrest from the Arabs the key points of sea trade—was almost accomplished; but without control of Malacca their achievement was incomplete. At the end of June 1511, therefore, a fleet under Albuquerque left for Malacca, which fell after six weeks. This event, in which Magellan took part, was the crowning Portuguese victory in the Orient. Through Malacca passed the wealth of the East to the harbours of the West, and in the command of the Malacca Strait the Portuguese held the key to the seas and ports of Malaysia. It remained to explore the wealth-giving Moluccas, the islands of spice. Accordingly, early in December 1511 they sailed on a voyage of reconnaissance and after reaching Banda returned with spice in 1512. The claim made by some that Magellan went on this voyage rests on unproved statements by Giovanni Battista Ramusio and Leonardo de Argenzola, and the want of evidence argues against its acceptance. Even if he did, in truth, reach the Moluccas, a further voyage—which he later commanded from Spain to the Philippines—was required to complete the circle of navigation.

In 1512 Magellan was back in Lisbon; the following year he joined the forces sent against the Moroccan stronghold of Azamor, and in a skirmish after its fall sustained a wound that caused him to limp for the rest of his life. Returning to Lisbon in November 1514 he asked King Manuel for a token increase in his pension, signifying a rise in rank. But unfounded reports of irregular conduct on his part after the siege of Azamor had reached the King, who, refusing his request, ordered him back to Morocco. Early in 1516 Magellan renewed his petition; the King, refusing once more, told him he might offer his services elsewhere.

**Allegiance to Spain.** Magellan therefore went to Spain, reaching Seville on Oct. 20, 1517. He was joined by the Portuguese cosmographer Rui Faleiro, and together they journeyed to the court at Valladolid. There, having renounced their nationality, the two men offered their services to King Charles I (later, Emperor Charles V). Magalhães henceforward became known by the Spanish version of his name—Fernando de Magallanes.

By decree of a papal bull, 1493, all new territories discovered or that should be discovered east of a line of demarcation (redrawn 1494) were assigned to Portugal, all that lay west to Spain. Magellan and Faleiro now proposed by sailing west to give practical proof of their claim that the wealth-giving Spice Islands lay west of the line of demarcation—that is, within the Spanish, not the Portuguese, hemisphere. On March 22, 1518, their proposal received royal assent; they were appointed joint captains general of an expedition directed to seek an all-Spanish route to the Moluccas. The government of any lands discovered was to be vested in them and their heirs, and they were to receive a one-twentieth share of the net profits from the venture; both were invested with the Order of Santiago. Magellan was convinced that he would lead his ships from the Atlantic to the "Sea of the South" by discovering a strait through Tierra Firme. This idea did not originate with him; others had sought a passage by which vessels sailing continuously westward would reach the East and thus avoid the route around the Cape of Good Hope, which was controlled by the Portuguese; in the royal agreement Magellan and Faleiro were directed to find "the" strait. The officials entrusted with East Indian affairs were instructed to furnish five ships for the expedition, prepared in Seville, where an unsuccessful attempt to wreck the project was made by Portuguese

Indian expedition

Expedition of the Moluccas

agents. Magellan's flagship, "Trinidad," had as consorts "San Antonio," "Concepción," "Victoria," "Santiago." An attack of insanity prevented Faleiro from sailing.

Magellan, who in 1517 married Beatriz Barbosa, daughter of an important official in Seville, said farewell to his wife and infant son Rodrigo before his ship left Sanlúcar de Barrameda on Sept. 20, 1519, carrying about 270 men, among whom nine countries were represented. The fleet reached Tenerife on September 26, sailing on October 3 for Brazil; becalmed off the Guinea coast, it met storms before reaching the line; on November 29 it was 27 leagues southwest of Cape St. Augustine. Rounding Cabo Frio, Magellan entered the Bay of Rio de Janeiro on December 13, then sailing south to the Río de la Plata vainly probed the estuary, seeking the strait. On March 31 he reached Port St. Julian in latitude 49°20' S, where on Easter day at midnight Spanish captains led a serious mutiny against the Portuguese commander. Magellan with resolution, ruthlessness, and daring resourcefulness quelled it, executing one of the captains and leaving another to his fate ashore when, on Aug. 24, 1520, the fleet left St. Julian.

After reaching the mouth of the Santa Cruz, near which "Santiago," reconnoitring, had been wrecked earlier, Magellan started south again, on October 21 rounding the Cape of the Virgins (Cabo Virgenes), and at approximately 52°50' S entered the passage that proved to be the strait of his seeking, later to bear his name. "San Antonio" having deserted, only three of his ships reached the western end of the passage; at the news that the ocean had been sighted the iron-willed admiral broke down and cried with joy.

On November 28 "Trinidad," "Concepción," and "Victoria" entered the "Sea of the South," from their calm crossing later called the Pacific Ocean. Tortured by thirst, stricken by scurvy, feeding on rat-fouled biscuits, finally reduced to eating the leather off the yardarms, the crews, driven first by the Peru Current and throughout the voyage by the relentless determination of Magellan, made the great crossing of the Pacific. Till December 18 they had sailed near the Chilean coast; then Magellan took a course northwestward; not till Jan. 24, 1521, was land sighted, probably Pukapuka in the Tuamotu Archipelago. Crossing the equinoctial line at approximately 158° W on February 13, the voyagers on March 6 made first landfall at Guam in the Marianas, where they obtained fresh food for the first time in 99 days. A *Memorial*, sent by Magellan to King Charles before leaving Spain, suggests that he knew (probably partly from Serrão's letters) the approximate position of the Moluccas; in sailing now from the Marianas to the Philippines instead of direct to the Spice Islands, he was doubtless dominated by the idea of early revictualing and the advantage of securing a base before visiting the Moluccas.

Leaving on March 9, Magellan's course west-southwestward next brought him to islands later called the Philippines, where at Massava he secured the first alliance in the Pacific for Spain, at Cebú the conversion to Christianity of the ruler and his chief men; but on Mactan Island, April 27, 1521, Magellan was killed in a fight with natives.

After his death only two of the ships, "Trinidad" and "Victoria," reached the Moluccas; only one, "Victoria" (85 tons), returned to Spain, under command of Elcano, originally master on "Concepción," and participator in the mutiny at Port St. Julian. For bringing home, on Sept. 8, 1522, the leaking but spice-laden ship, with only 17 other European survivors and 4 Indians, "weaker than men have ever been before," Elcano received from the emperor an augmentation to his coat of arms, a globe with the inscription "Primus circumdedisti me" ("You were the first to encircle me"). It had been left for Elcano, returning by the Cape route, to give practical proof that the earth was round.

**Achievement.** The supreme distinction of Magellan lies not in any feat of circumnavigation but in his bold conception and masterly direction of the enterprise that achieved that feat. The first navigator to cross the Pacific from East to West, he disproved the prevailing idea that a mere few days westward sailing from the New World

would bring ships to the East Indies. Instead, after a crossing lasting more than three months, he brought a fleet within easy distance of them. Magellan, with a character so complex and of such extreme contradictions, will remain an enigma; psychologically he cannot have been at peace with himself. For his transference of allegiance many writers have denounced him, bearing in mind that in his time the loyalty of a Portuguese to his sovereign was second only to his loyalty to his God; others have pointed out that in offering his services to another ruler Magellan did what Columbus, Cabot, and Vespucci had done, and that limitations imposed by nationality are irreconcilable with the advancement of knowledge. But on one thing all Portuguese are agreed: "he is ours."

The fullest account of the voyage is that of Antonio Pigafetta, Knight of Rhodes, native of Vicenza, who sailed with Magellan and returned with Elcano. The true text of the Italian version, translated, edited, and annotated by J.A. Robertson, is in *Magellan's Voyage Around the World by Antonio Pigafetta*, 2 vol. (1906). *The First Voyage Round the World by Magellan*, Hakluyt Society, vol. lii (1874), includes, as well as Pigafetta's account, the following by other members of the expedition: "The Genoese Pilot's Account of Magellan's Voyage" (believed to be Leon Pancaldo of Savona); the "Narrative of a Portuguese Companion of Odoardo Barbosa" (probably Vasco Gomes Galego, of Bayona, Galicia); the "Log-Book of Francisco Alvo or Alvaro," commencing Nov. 29, 1519, and recording on the return voyage the discovery in Cape Verde Islands that by sailing continuously westward a day had been "lost." This volume also contains the account of a contemporary writer, the "Discourse of M. Giovanni Battista Ramusio," and Gaspar Correia's account of the voyage (taken from *Lendas da India*, vol. ii, ch. xiv).

**BIBLIOGRAPHY.** Important introductory works to the life of Magellan include F.H.H. GUILLEMARD, *The Life of Ferdinand Magellan and the First Circumnavigation of the Globe, 1480-1521* (1890, reprinted 1971); E.F. BENSON, *Ferdinand Magellan* (1929); and VISCONT DE LAGOA, *Fernão de Magalhães: A sua Vida e a sua Viagem*, 2 vol. (1938). For chronicles of the voyage, see FRANCISCO LOPEZ DE GOMARA, *La Historia general de las Indias* (1554); and PIETRO MARTIRE D'ANGHERA, *The Decades of the Newe Worlde* (1555). For a historic interpretation of the voyage, see OSCAR KOELLIKER, *Die Erste Umseglung der Erde durch Fernando de Magellanes und Juan Sebastian del Cano, 1519-1522* (1908). The life and achievements of Elcano are discussed in MAIRIN MITCHELL, *Elcano: The First Circumnavigator* (1958).

(M.Mi.)

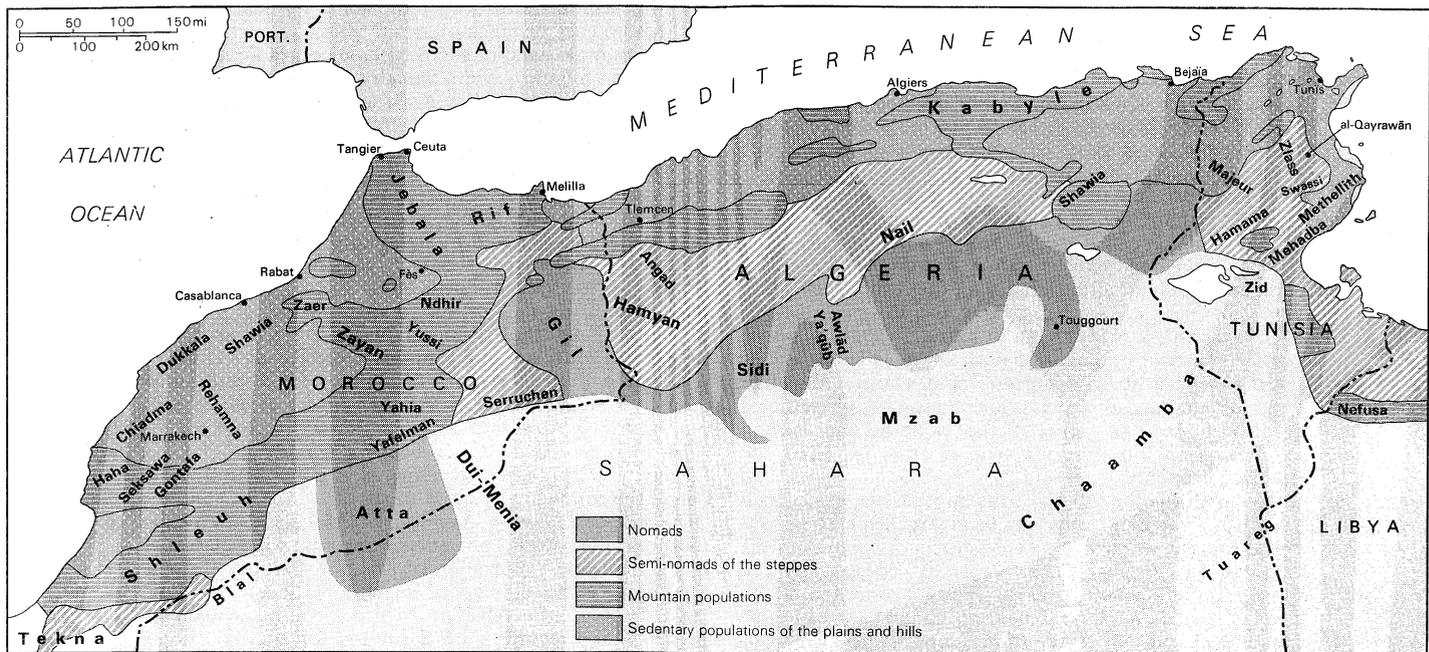

## Maghrib, Cultures of the

Arab writers gave the name Maghrib (Setting Sun, or the West) to the regions of North Africa conquered by the Muslims between the years 670 and 700. The word Maghrib denotes the whole of Morocco, Algeria, and Tunisia and the western part of Libya known as Tripolitania. It is bounded on the south by the Sahara.

The country of the Atlas, as the Greeks named it, is distinguished from the rest of the Islāmic world by its population and history. The native peoples have been able to resist successive invaders from the vastness of their mountain ranges. Yet Punic, Roman, and Christian influences left their successive marks. In the 7th and 8th centuries, the victorious Arabs, by imposing Islām and the language of the Qur'ān, absorbed the Maghrib into the Muslim civilization once and for all. Nevertheless, the North African societies have preserved their cultural identity throughout the centuries.

The people of the Maghrib are ethnically Berbers and Arabs. The Berbers have lived in the Maghrib since ancient times, probably originating in a mingling of races in the Paleolithic and Neolithic periods. The Berber stock displays a wide variety of physical characteristics; their social and cultural characteristics are also quite diverse. Underlying all these differences, however, is a common ethnic substratum. A long succession of invasions, ranging from the Phoenicians to the Arabs and finally to the French, did not lead to much interbreeding. Some foreign minorities settled in the towns, but the rural Maghrib

received little new blood. The second wave of Arab invasions in the 11th and 12th centuries consisted of Bedouins, a few tens of thousands of nomads from the Middle East.

The mixture of languages and ways of life makes a simple classification of the peoples of the Maghrib impossible. There are Arabized Berbers, where tribes of the latter have come under Arab cultural influence. It must also be remembered that nomadic tribes lived in the Maghrib long before the Muslim conquest. Although the area has been largely taken over by the Islāmic language and civilization, there still exist populations in the mountainous regions and in certain oases who have retained predominantly Berber idioms and traditions.

Between one-fifth and one-quarter of the population (about 6,000,000) still speak Berber. The proportion rises as one moves westward, reaching two-thirds in Morocco. Berber is a purely oral language, composed of hundreds of different dialects that can be classified in three groups: (1) Mašmūdāh (or Tachelhit), spoken by the Shleuhs of the Anti-Atlas and Haut Atlas mountain regions of Morocco, a people who are sedentary arboriculturists; (2) Šanhājah, the dialects of the sedentary Kabyle mountain people, the semi-nomadic sheep grazers of the Moyen Atlas, and the Tuareg pastoralists of the Sahara; (3) Zanātah, dialects originating in the eastern Maghrib (Tripolitania, Tunisia, and Constantine). The Shawia (Chaouia) people of the Aurès area represent the most important Berber group in this region. But some Zanātah-speaking tribes moved westward, and their dialects are also found in the oases of Touggourt and Mzab and in Morocco.

By far the majority of the population of the Maghrib speak some form of Arabic. This is quite different from classical Arabic, known only by educated people. In the towns, in the Petite Kabylie regions and in the western Rif Mountains, pre-Hilālien dialects are spoken; elsewhere, the Bedouin forms of Arabic are heard.

#### TRADITIONAL PATTERNS OF CULTURE

All Maghrib societies were organized around two central institutions, Islām and the clan. Islām transcended the family, ordering all life, spiritual and secular, by a body of unbreakable rules. The social structures, from political organizations to the home, are built around the word of God as laid down in the Qur'an and in Muslim tradition. Although many differences exist between urban society,

where Muslim orthodoxy prevails, and the rural societies, where Berber beliefs and customs still exist, all the people of the Maghrib belong to the community of believers. Islām has sanctified the ancient values of the Maghrib's patriarchal societies. To seek the will of Allāh means above all that the believer must submit to the will of his parents. The pre-Islāmic cults are thus sublimated by the precepts of the Qur'an; popular traditions are incorporated into religious ritual. As a religion of everyday life, Islām has a code of practical conduct governing the whole range of private and public behaviour, combining complex ritual with spiritual exercise, indissolubly linking the religious and the secular.

The politeness that dominates all social intercourse is not merely the refined courtesy of the bourgeois or the nomads' traditional hospitality; it is above all an expression of the state of being of the believer, in possession of his tradition and proclaiming his convictions. In the roughest country community, good manners are the rule: the *hashūmah*, a term that combines modesty, shame, and reserve, weaves a subtle etiquette of courtesy among men and women, old and young, members of the group and strangers. Whether at home or in the mosque, at the public baths or the market, with father or brother, wife or son, every inhabitant of the Maghrib knows what is proper to say or to do according to his age, sex, and status. This code of behaviour guarantees social cohesion and the priority of the group over the individual; it favours the survival of communities in regions that are inhospitable and insecure. In the same way, Berber groups, converted to Islām, found in the universal vocation of their religion the strength necessary to challenge the political supremacy of the Arabs.

#### Social organization. Local and territorial organization.

For many sedentary groups as well as for nomads, the fundamental sociopolitical group has been the tribe. The founders of dynasties depended upon their tribe when creating their kingdoms or empires, which were often short-lived. Subject to historical vicissitudes and the hazards of the climate, the tribe could group together several hundred or several thousand households. A powerful tribe could organize other tribes into a strong confederacy, while a weak tribe would be absorbed by an allied or conquering tribe.

The members of a tribe call themselves *banī 'amm*, or cousins (literally, "paternal uncle's sons"). They claim descent from a common ancestor, the founder and name-

Importance of religion and the family

sake of the tribe; e.g., the Awlād Ya'qūb tribesmen are the children of Ya'qūb. In reality, these ancestors are rather legendary characters (relatives of the Prophet, holy men, famous warriors), worshipped as heroes and whose tombs are pilgrimage centres. This fictitious consanguinity is a system of allegiance to the protector of the group, who serves as its guide, its invisible defender, and its permanent mediator with the supernatural powers.

With the exception of some Berber districts in which the same population has lived since time immemorial, the tribe does not identify itself with an ancestral ground. Over the centuries, a tribe may move its location by 100 miles or more. These movements can be explained partly by pastoral necessity, partly by the fact that group solidarity prevails over individual attachment to inherited land. This solidarity reveals itself above all in such matters as war, the drawing of lots for plots of agricultural land, and the protection of common pastures. The tribe is composed of a number of rural communities and is governed by a *jamā'ah*, or assembly, composed of representatives of the important families. Normally, the Berber *jamā'ah* elects its chief, whereas the Arab tribes frequently have a hereditary system of chieftainship.

The tribe is composed of three to six segments (*firqahs*), which are patrilineal clans based on certain patterns—fictitious pedigrees, an ancestral name, or political or economic practices—that have been transposed into a tribal organization. Membership in a clan is not necessarily linked to vicinity; for example, in Kabylie, each village constitutes an autonomous *firqah*, whereas in the Aurès area a village can contain several different *firqahs*.

*Family and kinship patterns.* The biological kinship of a family differs from the mythical kinship of the clan or tribe. All descendants of the male offspring of a common ancestor belong to the same family. The consanguinity must be actual in order to be legitimate in the eyes of Muslim orthodoxy. Berber customs, on the other hand, allow legitimation or adoption. All the family members have certain rights concerning the family heritage and certain obligations, according to their level of kinship; they also share responsibility for every member's acts (e.g., collective responsibility in the case of murder). In the Berber villages, the houses of a large family are often grouped together in the same district. Elsewhere, the "great family" disperses in many domestic units, living in autonomous farmsteads or in isolated camps. Kinship forms the basis of all social organization; the domestic unit, the extended family, the clan, and the tribe are concentric circles of kinship, each denoting a certain range of obligations. As an Arab proverb has it: "Myself against my brothers; my brothers and myself against my cousins; and my cousins, my brothers, and myself against the world." The nucleus of the domestic group consists of close relatives living under the firm authority of the head of the family—a grandfather, father, or elder brother. A married son continues to live with his father; a girl, if she does not marry a cousin on her father's side (preferential marriage), goes to live with her husband's family; if widowed, repudiated, or divorced, a woman returns to live with her parents. Sometimes three or four generations live together in a household comprising as many as 50 people.

To belong to a respected family, to be the bearer of an honourable name, is of great importance, since social status depends on that of one's family. The family imposes upon its members a discipline that dictates the position and tasks of each person. Fear of banishment (the supreme sanction) guarantees the submission of the individual to the interests of the collectivity. The fundamental unity, however, arises from mutual confidence and is not subjection to a tyrannical sovereign. The family head controls and administers everything, but he can do nothing without the implicit consent of the others. The balance of opposing forces amounts to a kind of authoritarian democracy.

*Stratification.* The dualities of town and country, sedentary and nomadic, were fundamental in the traditional Maghrib societies. In the cities, life was dominated by an

ancient bourgeoisie often of Spanish or Turkish descent. There were separate Jewish and European quarters. The area near the town walls was inhabited by the humbler classes, newcomers, and seasonal workers. The black slaves were dispersed around their masters' homes. Closed in on itself, the town drew its prestige from its religious functions. In the absence of the clergy, the *qādi*, or judge, was the leading personality of the town, sharing his eminence with the *'ulamā'*, or doctors of the law.

In the rural communities, the social group known as Sharifs is highest in the class hierarchy. They are reputed to be descendants of the Prophet and to possess supernatural powers. The Sharifs are venerated in the same way as the heads of religious brotherhoods and the saintly men known as *marabouts*. The next highest social position in these self-sufficient communities is accorded to families known more for the bravery and wisdom of their members than for the size of their herds or plantations.

The nomads constituted a permanent threat to the village societies. The nomads were herdsman, while the villagers were tillers of the soil. In addition, the villagers were Berbers, while the nomads represented the Bedouin conquerors. Nevertheless, a modus vivendi was generally established. In exchange for their livestock and goods, the nomads were allowed to graze their flocks on the land of the sedentary communities, which, in turn, sold them their cereal products. In the oases, the inhabitants cultivated palm trees belonging to the nomads, who, in return, protected them against the raids of hostile tribes.

*Socialization and education.* The boy is removed from his mother's influence at an early age; after circumcision at six or seven, his education is taken over by male kinsmen. He learns to distrust the opinion of women; as a Maghrib proverb runs, "Angels and men work for unity; Satan and women work for division." Obedience and respect are taught at an early age. The spontaneous brotherly relationship is replaced at ten or 12 years of age by a more formalized, distant relationship: boys learn to address their older brothers with deference and avoid them in public places. To their parents, children owe total submission at the risk of being cursed if they disobey. At the same time, male and female cousins learn equalitarian relationships, which are as important in social life as the hierarchical ones. The family, as the guardian of tradition, hands on the many customs of daily life.

In the town but rarely in the country, the boys often attended the Qur'anic school, where they learned the basics of reading and writing and got the Qur'an by heart. In the mosques they received a complementary education in grammar and Muslim law. Only two towns in the Maghrib possessed Muslim universities: Tunis (az-Zaytūnah Mosque) and Fès (the Qarawīyīn Mosque). Here students received an education in law and religion, along with fundamentals of grammar, astronomy, and geography.

*Economic systems. Settlement patterns and housing.* The variety of dwellings reflects the different ways of life and the cultural diversity of the Maghrib. Broadly speaking, there are three types of shelter: the house, the hovel (*gourbi*), and the tent. The well-to-do family's house, constructed in the shade of the mosque, is a mixture of Spanish and Moorish architecture. The rooms open onto a central patio. There are no exterior windows, although roof terraces allow conversation among women of the neighbourhood. In the outlying parts of the town, sumptuous palaces surrounded by gardens and outbuildings stand next to apartment houses and poor tenements.

In the mountains the Berber villages perch cautiously on the slopes, like refuges. Their defensive aspect is often strengthened by fortified collective barns known as *agadir*, *guelâa*, or *gasr*. On certain Mediterranean mountainsides one sees houses with double-thatched roofs. Elsewhere, the houses are built with terraces and walls of stone, mud, or sun-dried brick. The Saharan Berbers have created a spectacular form of architecture using mud, examples of which are the *tighremt*, a rectangular fortress with a tower at each corner, and the *ksar*, a fortified

The  
Sharifs

The  
agnatic  
family

Berber  
villages

village surrounded by towers and bastions; this form of building is also seen in Morocco.

In the plains, the sedentary groups generally live in hamlets of hovels (*gourbi*) and tents. These are people engaged in cereal farming and herding but always at the mercy of nomads or mountain tribes on the lookout for workable land. The *gourbi* is a hut made of branches or earth, covered with thatch, that can easily be erected wherever the group moves. An enclosure of thorny plants or prickly pears surrounds the cabin and serves as an animal fold during the night.

In the steppes live the true nomads. Their tents, similar to those of the Bedouins, are made of long strips (*flij*) woven by the womenfolk from wool, camel's hair, or goat hair and sewn together. The four side walls are made of the same fabric. The dwelling is supported by wooden posts and held in place by ropes of wool or hair. Matting or carpets cover the ground inside. At night the tents are grouped in a circle, forming an enclosure for the herd.

**Production and technology.** The economy of the desert is predominantly pastoral, as is also that of the steppes and of certain coastal plains where the natural vegetation is conducive to the raising of sheep, goats, and dromedaries. The nomads follow their herds in the search for pasture, camping in the south in the winter and passing the summer in the Atlas Mountains of the north or in the maritime hills.

Agricultural practices

The cultivation of corn and barley is done with rudimentary techniques. The ground is left fallow every other year but not fertilized. Plowing begins after the autumn rains, with a wooden plow drawn by two animals. Harvesting is done by sickle and threshing by letting the livestock trample the sheaves. Every family head who owns a plow and a team has the right to work the common land. In regions where there is privately owned land, there are small farmers (*fellahs*) and also men (*khammāsīn*) employed by others in return for one-fifth of the harvest. But the irregular rainfall, the political instability, the property laws, and above all the priority accorded to grazing do not encourage farmers to improve their soil.

In the oases and certain mountains, however, peasants have inherited proven agricultural techniques. Despite the poor quality of the land, an intensive mixed farming—cereals, vegetables, olives, dates, fruit orchards—supports a dense population.

There is little manufacturing. Except for milling, work in the villages is done by hand in small family workshops using archaic tools. The activities consist mainly of making clothes and tools and of building. Most of the clothes are coarse woollens, although sometimes a weaver may produce more delicate work for a wealthy customer. Tanneries exist everywhere to process the hides of cattle, sheep, and goats, which are dyed with such local pigments as saffron and cochineal. The leather industry employs many specialized craftsmen, such as shoemakers, saddlers, and morocco leather tanners. The urban construction industry employs artists, such as mosaicists, potters, and sculptors in plaster and in wood; they have helped to make Maghribian architecture famous.

**Property and exchange.** Houses, gardens, plantations, and livestock are private property and can be inherited. In principle, the family unit is predominant but each relative can demand that he be given his share of the property. In order to avoid breaking up the family heritage or to modify the order of succession, charitable foundations (*ḥabūs*) are often created. These are untransferable, but the donee can assign the life interest to the beneficiary of his choice.

As a rule, however, all land belongs to the Muslim community, including conquered territory whose tenants pay an annual rent or lands conceded to loyal tribes by the sultans and *bey*s. Tribes and clans that own their land distribute plots to each family, divide up the water supplies, and administer the pastureland.

Outside each town a weekly livestock market is held. Other weekly markets (*sūqs*) take place in country areas. Peddlers sell articles made in Europe or by town craftsmen. Trade between different regions is limited, and

goods are carried by camels and mules. The Maghrib as a whole exports agricultural products, such as cereals, wool, leather, and livestock, and imports cloth, sugar, coffee, and tea.

**Belief and aesthetic systems.** Religious beliefs in the Maghrib combine Islām with local traditions. Muslim theologians have denounced many a heresy, an ancient task in this land where St. Augustine used to flay the Donatists. While the main ritual obligations are observed by the whole population, only a minority of educated citizens conform to the orthodoxy of the Qur'ān. Even this orthodoxy admits the existence of "spirits," against which people must protect themselves. In the activities of daily life it is as important to protect oneself against hostile powers as it is to seek divine favour, and this is done through a variety of practices. A pregnant woman wears amulets and sometimes a talisman of black pearls in the form of a hand (the hand of Muḥammad's daughter Fāṭimah). Into the ear of the newborn child the father murmurs the Muslim profession of faith. On the seventh day after birth, the child is named, and a sheep is sacrificed.

Religious syncretism

Animal sacrifices are typical features of Muslim feasts. The sacrifice of a sheep on the day of 'Īd al-Aḏḥā ('Īd al-Kabīr), the grandest festival of Islām, commemorates the offering of Abraham. A sacrifice, followed by a communal meal, also accompanies the pilgrimage to the saints' tombs, precedes the annual plowing, and is used in efforts to cure sickness or to overcome a woman's sterility. Sacrifice renews the pact of alliance between the living and the dead; the spilling of blood continues the contract with the ancestors, who protect the family and the clan in a world dominated by invisible forces. The cult of the dead conditions the agrarian rituals of the Berbers, since fecundity, namely life, depends on the goodwill of the spirits of the Earth. The symbolic representations of the crop-growing cycle are identical with those marking the stages of man's life. The rituals of possessing the ground and fertilizing it guarantee permanence of life. These moments of plowing and sowing are a period of rejoicing and marriage. Inversely, funeral rites accompany the harvest. The last sheaf of corn ends the cycle, and the dead return beneath the ground.

The agrarian rites that punctuate the solar year are accompanied by Muslim festivals that follow the lunar calendar. The religious year opens with the 'Āshūrā, the festival of children and also of ancestors, whose tombs are visited. The Mūlūd, commemorating the birth of the Prophet, is a joyous ceremony; several religious brotherhoods choose this day to organize their great annual festival. The 'Īd al-Fiṭr ('Īd as-Ṣaḡhīr) and the 'Īd al-Aḏḥā are canonical celebrations held throughout the Muslim world. The first, known as the "little festival," marks the end of the Ramaḏān fast. There is much gaiety, and gifts are made to the poor. The second is the "great festival," marking the last rite of the pilgrimage to Mecca. These religious ceremonies are also family ceremonies, accompanied by feasting and visiting.

Islām provides the chief aesthetic inspiration for the craftsmen of the towns. Urban architecture and furniture show the influence of the Middle East and of Muslim Spain. Córdoba, Seville, and Granada were particular sources of inspiration for the Maghrib, and Andalusian exiles spread their refined techniques from Fès to Tunis. This Hispano-Moorish art had its strongest impact in Morocco. Tunisia was also strongly influenced by the artistic trends of Fāṭimid Egypt in the 10th and 11th centuries and later, like Algeria, by those of the Ottoman Empire.

Arts and crafts

Religious architecture expresses the deep unity of Muslim art, showing in its forms the originality of the Maghrib. For example, the prayer room of the Great Mosque of Tlemcen is composed of 13 long naves, with wooden beams and covered in tiles. The middle nave has two domes. The minaret is a quadrangular tower, topped by a square edifice at the base of which is the platform from which the muezzin calls the believers to prayer. The decoration of Maghrib mosques consists of multiple variations of the lobed arch and the cornice, with linear ele-

ments on the walls, such as epigraphy, geometric designs, and flora, either sculpted or designed in mosaic.

Berber art objects have a rectilinear decoration, the richest motifs deriving from the chevron or lozenge and varying from one tribal group to another. The overall composition is simple, with alternating decorated and coloured strips, as in the woollen carpets of the Moyen Atlas region. Pottery is handmade, without a wheel, and glazed in an oven; it is very similar to Neolithic potteries, although the richest wares recall certain ancient Aegean ceramics.

#### RECENT TENDENCIES

The 19th century saw the beginning of a period of far-reaching political and economic change. The French conquest of North Africa, followed by the massive immigration of Europeans, introduced the French language and European culture. The political power of the tribes was destroyed. A strong centralized power dominated the whole country. This, in turn, was ultimately destroyed by nationalism and the desire for emancipation.

Social  
changes  
since  
independ-  
ence

By July 1962 the entire Maghrib was independent. The new political regimes in Algeria, Morocco, and Tunisia have tried to rediscover their cultural identity and to develop their economies. There has been a rapid evolution of institutions, social structures, and collective values. New elites have emerged; the present-day civil servants and technicians form a middle class very different from the traditional petty bourgeoisie from which many of them come. Industrialization has created a class of factory workers. At the same time there has been a mass exodus of uprooted peasants to the cities, where they form a sub-proletariat living in shantytowns. Modern hygiene has lowered the death rate so that the natural population increase has become among the highest in the world; this has caused considerable migration into the prosperous agricultural regions and to the large coastal towns, as well as an outflow of workers to France. These movements have in turn contributed extensively to the breakdown of family groups and traditional communities. They have allowed an intensive mixing of the population, established new kinds of social relationships, and led to profound changes in attitudes and conduct.

Although there is a striking difference between town and country and between developed and undeveloped areas, the rural areas should not be regarded as lost in the past. Since the 1930s many of the rural societies of the Maghrib have begun to modernize. To plains that were previously underexploited, advanced agricultural techniques have brought vineyards, olive groves, and the intensive production of citrus fruits and vegetables. Road and railway networks carry foreign ideas and products to regions that were formerly isolated, while "villages of colonization" and rural towns have introduced urban ideas and products into the countryside. The colonial regime limited and distorted cultural contacts between Europeans and the people of the Maghrib, but it was also the vehicle of technical progress and a symbol of modernity. If foreign domination exploited the national resources, it also introduced a monetary economy and new ways of behaviour. The priority given by the post-colonial governments to economic development has intensified the process of change.

Like all societies in transition, the Maghrib displays a number of cultural contradictions. Along with an emphasis on Arab-Islamic origins, there has been an increase of contacts with the industrialized countries. The Arabization of education has been accompanied by the teaching of French in the rapidly expanding school system. While Islām has assumed its former place in public life, political and administrative activity is determinedly secular.

Effects of  
moderniza-  
tion

Despite the growth of the towns, the majority of the population in the Maghrib remain rural. The old family values continue to have a strong influence on social life. While the extended family group is becoming rare, solidarity among male relatives is still an imperative. One is obligated to give help to distant cousins and to former allies of one's village or *douar* (district). Social relationships, even in the most modern enterprises, remain deeply

personalized. Even in the civil service, the formal, hierarchical relationships are often paralleled by informal ones that provide the real chain of command.

Except for a small Europeanized minority, most of the population favour large families. Even though many people think that the very high birth rate of the old days is no longer desirable, families with three or four children are very common. Celibacy is frowned upon; children, particularly girls, are married as soon as possible. While the emancipation of young people, especially in the towns, has tended to reduce paternal influence, marriages are still commonly arranged by the family, preference being given to a paternal cousin, some other relative, or at least a member of one's *douar*.

The position of women has improved since independence. The development of education for young girls and the increase of female employees in business have tended to break down the strict separation of men and women in public life. More and more women are seen without veils, at least in the big towns, although few women appear in public places.

The evolution of customs and ideas has not spared religious life. Strict conformity is disappearing; there is more tolerance for those who do not strictly observe the fast of Ramaḍān or who drink alcoholic beverages. But the general fervour of religious observances shows the common fidelity of everyone to Islām.

There have been profound changes in the hierarchy of status and prestige. For everyone, the civil servant is the symbol of social success. Among country people, to become a salaried worker is an enviable promotion. Class consciousness has spread throughout society, although tensions between civil servants, workers, small-town clerks, and peasants are tempered by the traditional system of relationships. At the same time, the desire for material improvement, coupled with the impatience of the masses and their increasing interest in politics, tends to widen social antagonisms. The future of the Maghrib will depend largely on the choices of the younger generation, which, for the first time in the Maghrib's history, will be predominantly an educated one.

**BIBLIOGRAPHY.** An excellent handbook is NEVILL BARBOUR, *A Survey of North West Africa*, 2nd ed. (1962). A good geographical reference book is JEAN DESPOIS, *L'Afrique du Nord* (1964). There are many works devoted to Muslim civilization, including H.A.R. GIBB, *Mohammedanism: An Historical Survey* (1949); S.D. GOITEIN, *Studies in Islamic History and Institutions* (1966); D.T. RICE, *Islamic Art* (1965); and JOSEPH SCHACHT, *An Introduction to Islamic Law* (1964). The best history of the trans-Saharan trade is E.W. BOVILL, *The Golden Trade of the Moors* (1958). Works on the religious beliefs of the Maghrib include ERNEST GELLNER, *Saints of the Atlas* (1969); G.E. VON GRUNEBaum, *Muhammadian Festivals* (1958); JEAN SERVIER, *Les Portes de l'année: rites et symboles: l'Algérie dans la tradition méditerranéenne* (1962); and EDWARD A. WESTERMARCK, *Ritual and Belief in Morocco* (1926). Among the most interesting anthropological studies are: JACQUES BERQUE, *Les Structures sociales du Haut-Atlas* (1955); LLOYD CABOT BRIGGS, *The Living Races of the Sahara Desert* (1955) and *Tribes of the Sahara* (1960); CARLETON S. COON, *Tribes of the Rif* (1931); JULIEN COULEAU, *La Paysannerie marocaine* (1968); ROBERT DESCLOITRES and LAID DEBZI, *Systèmes de parenté et structures familiales en Algérie* (1963); JEAN DUVIGNAUD, *Chebika, Mutations dans un village du Maghreb* (1968); and ROGER LE TOURNEAU, *Les Villes musulmanes de l'Afrique du Nord* (1957) and *Fez in the Age of the Marinides* (1961). Contemporary changes are discussed in ANDRE ADAM, *Casablanca: essai sur la transformation de la société marocaine au contact de l'Occident* (1968); JACQUES BERQUE, *Le Maghreb entre deux guerres* (1962); ROBERT and CLAUDINE DESCLOITRES and JEAN-CLAUDE REVERDY, *L'Algérie des bidonvilles: le Tiers-Monde dans la cité* (1961); and HORACE MINER and GEORGE DE VOS, *Oasis and Casbah: Algerian Culture and Personality in Change* (1960). For the politics of the new countries, see DOUGLAS E. ASHFORD, *National Development and Local Reform: Political Participation in Morocco, Tunisia and Pakistan* (1967); CHARLES F. GALLAGHER, *The United States and North Africa: Morocco, Algeria and Tunisia* (1963); CLEMENT HENRY MOORE, *Tunisia Since Independence* (1965); and IRA WILLIAM ZARTMANN, *Destiny of a Dynasty: The Search for Institutions in Morocco's Developing Society* (1964).

## Magic

Magic is a term used for a wide range of phenomena, from the elaborate ritual beliefs and practices that are at the core of many religious systems, to acts of conjuring and sleight of hand for entertainment. Used in the former sense magic is a social and cultural phenomenon found in all places and at all periods, with varying degrees of importance.

### NATURE AND SIGNIFICANCE

Magic essentially refers to a ritual performance or activity that is thought to lead to the influencing of human or natural events by an external and impersonal mystical force beyond the ordinary human sphere. The performance involves the use of objects or the recitation of spells or both by the magician. The nature of magic is frequently misunderstood because of uncertainty as to its definition, its relationship to other religious behaviour and institutions, and its social and psychological functions. This uncertainty is largely a consequence of 19th-century views on cultural and historical evolution that set magic apart from other religious phenomena as being especially prevalent in archaic and primitive societies and as merely a form of superstition without cultural or theological significance. This view has led to magic being considered as different and distinct from other religious rites and beliefs and the overlooking of its essential similarity and connection with them, since both magical and non-magical rites and beliefs are concerned with the effects on human existence of outside mystical forces. The frequently held view that magical acts lack the intrinsically spiritual nature of religious acts, comprising external manipulation rather than supplication or inner grace, and that they are therefore of a simpler and lower kind in theological terms, has compounded the misunderstanding. The definition given above recognizes a main point of distinction between magic and other religious phenomena, in that the latter are concerned with a direct relationship between men and spiritual forces, whereas magic is regarded as rather an impersonal or technical act in which the personal link is not so important or is absent, even though the ultimate force behind both religious and magical acts is believed to be the same. The distinction made by Émile Durkheim (1858–1917), a seminal French sociologist of religion (see below), that a religious practitioner has a congregation whereas a magician has a clientele, is also a meaningful one. The difficulty of definition of magic and its differentiation from religion is due largely to Western ethnocentric views. In Judeo-Christian belief it has been distinguished from other religious acts, but this distinction is not always found in other religious systems and in fact would appear to be unusual. Many writers have referred to "magico-religious" phenomena, a convenient blanket term.

Magic is often confused with witchcraft, especially in the history of European religions. Modern anthropologists, however, make the useful distinction between magic as the manipulation of an external power by mechanical or behavioral means to affect others, and witchcraft as an inherent personal quality to the same ends. In this classification, the word sorcery is used for magic that aims to harm other people; that is, sorcery is "black" magic, whereas magic used for beneficent ends is "white" magic. This distinction does not always hold for specific societies but is a useful one in analysis. Divination, the skill of understanding mystical agents that affect people and events, should be distinguished from magic in that its purpose is not to influence events but rather to understand them. The ultimate mystical power of diviners, however, may be thought to be the same as that behind the forces of magic. In some societies, magicians act as diviners, but the two skills should be distinguished. Magicians are often confused with priests, shamans, and prophets, mainly because many activities of the other personages include acts that are traditionally defined as "magical"; *i.e.*, while essentially they are regarded as intermediaries between men and gods or spirits, in the sense of acting in

a direct personal relationship, some of their acts are also impersonal or "magical." It is often, perhaps usually, impossible clearly to distinguish between priests and magicians; as stated above, the distinction is largely a Western ethnocentric one and lies in the kind of actions they perform in particular situations rather than in any true distinction between the kinds of practitioners themselves.

### HISTORY AND DISTRIBUTION

Magic in one form or other appears to be a part of all known religious systems, at all levels of historical development, although the degree of importance given to it varies considerably. The term has been used loosely by many writers, especially when discussing European magic. Also the ethnographic accounts of small-scale preliterate societies vary in the degree to which they contain detailed descriptions even when magic is important in a particular culture. Thus the analyses of magic in its total cultural setting are remarkably few.

Knowledge of magic in prehistory is limited by lack of reliable data. Many cave paintings and engravings, from all parts of the world, have been claimed to represent figures practicing hunting magic and sorcery, but this can at present be no more than conjecture or interpretive reconstruction (see PREHISTORIC RELIGION). More certain information about magical phenomena is available for the ancient Near Eastern and Greco-Roman cultures, Christian Europe, and contemporary preliterate societies.

**Magic in the ancient world.** There are many recorded texts of what appear to be magic spells and formulae from ancient Mesopotamia and Egypt. Most accounts of these cultures class almost all records of ritual as forms of magic and as examples of magical or mythopoeic ways of thought. This is usually because the writers themselves assumed that these cultures were examples of "prelogical" modes of thought (as compared with the thought of civilized man), and so took any religious record as evidence of this. The pharaohs of Egypt, for example, were what are usually called "divine kings," and as such had powers believed to control nature and fertility. Many writers refer to their powers as magical, but the evidence is rather that they were representations of royal omnipotence, expressing the power and the permanence of the kingship, their believed magical powers being contingent on their divine status. Examples of true magical spells and formulae are recorded from both Mesopotamia and Egypt; *e.g.*, spells to ward off witches and sorcerers. Spells addressed to gods, to fire, to salt, and to grain are recorded from Mesopotamia and Egypt, as are spells said by sorcerers and including necromancy or invocation of the spirits of the dead, who were referred to as a last resort against evil magic. Excellent examples of spells are recorded from the earliest times, and especially in Greco-Egyptian papyri of the 1st to the 4th centuries AD. They include both magical recipes involving animals and animal substances, and also instructions for the ritual preparations and purification necessary to ensure the efficacy of the spells.

In ancient Roman culture much importance was given to sorcery and counter-sorcery, both forms of magic. These seem to have been associated with the development of new urban classes whose members had to rely on their own efforts both in material and magical terms to defeat their rivals and to rise in the new regimes, where individual merits and talents were rewarded. Spells are recorded to ensure victory in love as well as in business, games, and academic pursuits such as oratory. With these are counter-spells to defeat rival sorcerers.

**Magic in Christian Europe.** For the European Middle Ages and later periods there is a vast corpus of written records. As is known from recent anthropological and historical work on witchcraft, magic, and religious syncretism, magic is specially prevalent during periods of rapid social change and mobility, when new personal relations and conflicts assume greater importance than the more traditional kin and family relations more typical of times of social stability. This appears to have been true in Europe also, and particularly at the times when

Magic and religion

Magic in Egypt and Mesopotamia

accusations of magic against its rivals were part of the struggle of the church to assert its spiritual and temporal hegemony. There are three main aspects to the history of European magic, much of which is ill-described and almost always without adequate accounts of the full cultural setting. One is that of magic and sorcery in petty everyday relationships at the village and community level from the end of the Classical world until recent years when beliefs in magic have in general become weakened. In most cases these beliefs were part of the culture of lowly rural people and records are scant. An exception was sorcery used by wealthier and urban people, especially in Italy and Spain from the 14th century onward, a concomitant of increased social mobility and growth of class hierarchies. A second aspect is the better known but frequently misunderstood belief in magic defined by the church as the heretical practice of making pacts with the devil and evil spirits. Saint Augustine and other early Christian writers had considered magic to be a relic of paganism and removable by conversion and education. After a papal bull in 1320, magic came to be defined as heresy, and the Inquisition's records begin to mention the Witches' Sabbath (midnight assembly in fealty to the devil) and the Black Mass (a travesty of the Christian mass) as forms of magic and witchcraft, the two being regarded as synonymous. They were defined as magic because of the supposed use of material objects, philtres, spells, and poisons. The spells included the perverted use of prayers and the use of sacred writings and objects for diabolical ends. This aspect of European magic has persisted into recent times in the activities of self-styled satanists.

Whereas these forms of magic were regarded as evil and symptomatic of heresy, the third aspect has usually been considered as good, or "white," in intent. This is the use of magic as part of the alchemical tradition. It is true that many reputed alchemists were considered as evil magicians, acquiring their knowledge by a pact with the devil (as in the Faust legends), probably because much of their knowledge came from Kabbalistic sources (esoteric Jewish mysticism). But most of them were considered to be essentially in the main and culturally acceptable Judaic and Christian traditions, their antisocial pretensions and activities not being central to the alchemical studies and being as much simple trickery as anything else (as in the activities of the 18th-century charlatan Alessandro Cagliostro and others).

**Magic in preliterate societies.** Most knowledge of magic in its social setting is derived from anthropological accounts of people of the non-Western world who today believe in magic. The importance of first-hand anthropological accounts, even though many anthropologists tend to make use of the ethnocentric distinction between religion and magic, is that they show how the people themselves actually regard magic and what they actually do with it and against it, rather than relying on the records of inquisitors and missionaries whose duty it was to stamp out magic. Detailed descriptions of magic come mostly from accounts of societies in Oceania and Africa; information from other parts of the world is less adequate although it is clear that magic is equally widespread elsewhere. It is reported particularly from many Muslim societies where pre-Islamic beliefs still exist, as in Malaya and Indonesia. A difficulty in this respect is that accounts only rarely distinguish magic from witchcraft and divination, both of which are found in virtually every known Oriental society.

#### STRUCTURE AND FUNCTIONS

**Structure.** A general point to be made is that the frequent tales of peoples living in fear of evil magicians and black magic are merely fanciful travellers' stories. Magic is normally regarded as an everyday aspect of religion used to explain certain kinds of events and to help bring about desired eventualities. Like most religious phenomena, magic may be regarded with some sense of awe and mystery, but this is more often a sign of the importance given to it than of fear or terror. Typically people perform magical acts themselves or they go to a magi-

cian, a person unusually knowledgeable in the art, who knows how to observe the necessary ritual precautions and taboos, and who may be a professional consulted for a fee. Depending upon the beliefs of the particular culture, the skill may be transmitted by inheritance or bought from other magicians, or may be invented by the magician for himself. Magicians may be consulted for nefarious purposes, to protect a client from the evil magic of others, or for purely benevolent reasons. It seems universal that magic is morally neutral, although the emphasis in any particular society may be on either good or evil magic.

In some religions, especially those of small-scale preliterate societies, magic may be considered as important and even central to religious belief; whereas in others, especially in the main world religions, it may be unimportant, and often regarded as a mere superstition that is not acceptable to official dogma. It has often been maintained that magic is important in societies that possess a particular world view or cosmology, in which a scientifically or empirically correct cause-effect relationship between human and natural phenomena is seen as a symbolic one. This view, which is associated particularly with the British anthropologist Sir James Frazer (1854-1941), is based on a misunderstanding of patterns of thought in pre-scientific cultures. It is true that they may lack the scientifically accurate knowledge of Western industrial societies, but the importance of this may be exaggerated. To some extent it is true: members of pre-industrial societies may use magical techniques (for example, rain-making) whereas in an industrial society it is known that such techniques are instrumentally ineffective. But magic is also performed for expressive purposes, *i.e.*, stating and maintaining the formal culture and organization of the society, so that rainmaking magic has also the function of stressing the importance of rain and the farming activities associated with it.

It has been stated that magic includes the use of material objects, or the recitation of spells; *i.e.*, the use of words that are attributed an innate essence or power of their own. There are usually considered to be three main elements in magic: the spell, the rite itself, and the ritual condition of the performer. This was first stated by the anthropologist Bronisław Malinowski (1884-1942) in his study of the Trobriand Islanders of Melanesia. With the spell may be included the material objects or "medicines" used in many other societies.

**The spell.** The importance of the spell or incantation has been somewhat exaggerated by the influence of Malinowski's work. Among the Trobriand Islanders this aspect is extremely important: the immaculateness of the words is regarded as essential to the efficacy of the rite. Among the Maori of New Zealand this element is thought so important that a mistake in the recitation of a spell would lead to the magician's own death. Frequently spells have an archaic or esoteric vocabulary that adds to the respect in which the rite is held. But in many societies the spell is of minimal importance, the magician using his own words and regarding the content as being more significant.

**Material objects or "medicines."** Equally widespread—perhaps more so than the use of spells—is the use of material objects, often known in the literature as "medicines" (hence the popular use of the term medicine man for magician). The nature of the medicines varies greatly. Among many peoples the medicines are in fact poisons that may actually cause the desired effect (as among some African peoples who place magical poisons in rivers to stun and catch fish, but regard them as they do any other "medicines"—that are not in fact efficacious). More usually they do not empirically bring about the effect but in some way present it; for example, it is common practice for a magician to try to harm another person by destroying something from his body (*e.g.*, hair or nail-parings), or something that has been in contact with him (*e.g.*, a piece of clothing or other personal possession). From the beneficial aspect, this is similar to the old European belief that to touch the king's garment would cure scrofula (swelling or tuberculosis of the lymphatic

The  
magical  
view

glands). Another kind of symbolism is exemplified by the Trobriand use of light vegetable leaves in rites to ensure a canoe's speed, symbolizing the ease by which it will glide over the water; the Azande of the Sudan place a stone in a tree fork to postpone the setting of the sun; many Balkan peoples used to swallow gold to cure jaundice.

*The rite.* The significance of the magical rite itself is often overlooked by those who hold the view that magic is something apart from religion. But it seems universal that magic is practiced only in formal and carefully defined ritual situations. The rite itself may be symbolic, as with the sprinkling of water on the ground to make rain or the destruction of a waxen image to harm a victim.

*Condition of the performer.* The ritual nature of magical performances may also be seen in a third element, that of the condition of the performer. Even though regarded as an everyday and "natural" phenomenon, magic is none the less considered as potentially dangerous and polluting, as is any sacred or religious object or activity. Both the magician and the rite itself are typically surrounded by the observance of taboos, by the purification of the participants, and so on. The magician may observe restrictions on certain foods or on sexual activity, and he may be regarded as polluting to other people at these times. There are two obvious reasons: failure to observe such precautions nullify the magic, and they indicate to the participants and others the importance of the rite itself and the ends desired. They mark off the rite from ordinary and profane situations and invest it with sanctity and more than usual importance.

*Functions.* The functions of magic are several, but there are two main aspects, the instrumental and the expressive. A basic feature of magical rites and beliefs is that the practitioners believe that these are instrumental; *i.e.*, they are designed to achieve certain ends in nature or in the behaviour of other people. This is the aspect that is usually the most important for the people concerned and regarded as most important by past writers on the subject. The symbolic or expressive aspect is always present, however; it is precisely because of its symbolic content that magic may best be understood as a part of any system of religion.

*Instrumental functions.* Malinowski and his followers have distinguished three main instrumental functions: the productive, the protective, and the destructive. Productive magic is concerned to bring about a good harvest, to increase the food supply, to ensure a successful outcome to some creative or productive activity both in terms of human labour and of natural bounty. Malinowski showed clearly how it may foster confidence in situations in which technology is weak or uncertain; his famed example of the Trobriand Islanders making magic when fishing in the open sea but not doing so when fishing in the calm and protected lagoon makes the point clearly. In addition, productive magic may also assist the efficient organization of labour and give greater incentive to those who feel confident of success. Protective magic aims to prevent or remove danger, to cure sickness, and to protect an individual or community from the vagaries of nature and the evil acts of others. Again, it may give confidence for people to continue their normal ways of life and activities. Destructive magic is sorcery, directed specifically against other people to harm them or their activities. It has been pointed out that the fear of this form of magic may reduce individual initiative since a successful or wealthy person in an egalitarian society may fear the sorcery of those jealous of him. On the other hand, the use of counter-magic against it rids a community of its internal fears and tensions.

*Expressive functions.* The expressive functions of magic are symbolic, and usually latent in the sense that the performers may not themselves be immediately aware of them. They have largely to do with the effects of individual acts upon society at large. It is in regard to this point that the part played by magic in a total system of religion may be seen (see below *Magic, religion, and science*).

#### MAGIC, RELIGION, AND SCIENCE

**Magic and religion.** The relationship of magic to other religious phenomena depends on three main considerations. The first is the nature of the power toward which the rites are directed. The eminent British anthropologist Edward B. Tylor (1832–1917) and his successors distinguished a personal, conscious, and omnipotent spiritual being as the object of religious ritual; magical performances have no power in themselves but are usually thought by the people to be an expression of an external, impersonal force in nature, for which the Melanesian term *mana* has typically been used. A second consideration is that of the personnel involved: the magician and those who go to him. As noted above, Durkheim pointed out that a priest has a church or congregation whereas the magician has a clientele. A religious ritual has as its principal function (in sociological terms) the maintenance of a sense of cohesion among the members of the church, whereas the magical rite lacks this function, and is, indeed, often anti-religious in quality. This view has been influential in the past and has by now become part of general anthropological thinking, although some of its details have been ignored by recent researchers, as it is based mainly on Australian aboriginal data that are today more accurately known and are not directly relevant elsewhere.

The third consideration is that of the function of magic and of other religious phenomena. The magician may see the overt function of his action as instrumental, as geared to a specific end; the external observer may accept this but also see a latent function. Malinowski, for example, maintained that much of Trobriand magic was performed as an extension of human ability, as a power beyond the normal or understood. It had as its most important function the instillation of confidence in situations where human knowledge and competence cease. In addition, the rite helps to throw the importance of the activity and the cooperation needed for it into relief and thus to help maintain the high social value of cooperation in a small community beset by disruptive jealousies and competition over scarce and difficult resources. A.R. Radcliffe-Brown (1881–1955) pointed out in his work on the Andaman Islanders that their magical rites and precautions at childbirth and death may comfort those concerned, although they are also irksome, but that their main function is to highlight the social importance of birth and death and to bring to public notice the changes in patterns of local and kinship organization that follow them. Some of the hypotheses of Malinowski and Radcliffe-Brown are today regarded as questionable and are difficult of definitive proof, but they have been influential in later studies in that they were concerned not only with the individual's belief in magic but also with its function in the total social system.

In brief, it may be said that religious rites are ways of acting out beliefs about the relationships of man to God, man to man, and man to nature. Magic is rather a way of achieving certain ends beyond the knowledge and competence of everyday people, especially in technologically limited societies, and of expressing these desires in symbolic terms. There are certain functions that are common to both: the provision of explanation for the otherwise inexplicable; a means of coping with the unusual and mysterious; and the enhancing of the social values of certain activities and situations and of coordinating socially valuable activities.

**Magic, technology, and science.** The problem of the relationship of magic to technical and scientific knowledge has concerned most writers on the subject. Magical rites contain at least superficial similarities to nonmagical technical activities. In each the actor performs an action that he expects will have a certain consequence. The distinction between the two processes made by Tylor and Frazer (see below) was that the magician assumes a direct cause-effect relationship between the action and the later event, whereas in empirical fact the relationship is one of the association of ideas only. Many writers have pointed out that magic is used when technical knowledge is missing or uncertain. This view does not really state that

Taboos,  
purifica-  
tions, and  
precautions

Distinctive  
functions  
of magic  
and  
religion

magic is a substitute for technical knowledge but that its performance gives confidence to people aware of their technical limitations (as in the example of Trobriand fishing magic mentioned above). The magician does not regard his magic as being the same kind of activity as weeding a field or sharpening a knife; the magical rite is of a different order, dealing with external and mystical forces.

A problem that is relevant here is that of the scientific proof of the efficacy of magic. Why do people continue to believe in magic when it is clear (at least to outside observers) that there is empirically no cause-effect relationship between a magical rite and the desired and supposed consequence? The main purpose of magic is not so much to achieve a certain technical end as to perform an act that has symbolic or psychological value. It is thus pointless to test it, in the sense that a Christian does not test the efficacy of prayer as he might that of an internal combustion engine. The problem was discussed by Tylor (see below), who produced reasons why failure of magic was not easily apparent. The idiom of magic pervades all in contact with it and cannot be tested scientifically in its own terms, so that tests as to the magic's efficacy are not in fact tests at all but rational statements about common-sense experience.

#### THE MAIN THEORIES OF MAGIC

There is a voluminous literature on magic. The earliest studies were those of Judaic and Christian scholars concerned with the relationship of magic to their faiths, both as relics of paganism and as heresy. During the latter part of the 19th century, anthropologists entered the field, with the aim of analyzing magic by looking at cases as reported from peoples throughout the world and to see the place of magic in the evolution of all religions of mankind from prehistory to the contemporary world.

**Anthropological.** The first important figure was E.B. Tylor, who, in his *Primitive Culture* (1871), regarded magic as a "pseudo-science" in which the "savage" postulated a direct cause-effect relationship between the magical act and the desired event, whereas in reality the link is one of the association of ideas only. Although Tylor regarded magic as "one of the most pernicious delusions that ever vexed mankind," he studied it not as a superstition or heresy but as a phenomenon based on the "symbolic principle of magic," a logical scheme of thought founded on a quite rational process of analogy. He also faced the question of why the believer in magic did not realize its inefficacy. His reasons included the frequent association of magic with empirical behaviour, nature often performing what the magician tries to do; the attribution of failure to the breaking of taboos or to hostile magic forces; the plasticity of the notions of success and failure; and the weight of cultural belief and authority behind the magician. He also realized that magic and religion are parts of a total system of thought; they are not alternatives but complementary, and thus not stages in the evolutionary development of mankind—although he considered that magic and animistic beliefs decreased in the later stages of history.

Frazer's theory

In *The Golden Bough* (1890 and later editions) James G. Frazer refined Tylor's views on magical thought, discussed the relationship of magic to religion and science, and placed them all in a grandiose evolutionary scheme. He analyzed the principles of thought that lay behind the false cause-effect relationship between magical and natural events. They were that "like produces like, or that an effect resembles its cause" (the Law of Similarity) and that things once in physical contact with each other later continue to act on each other at a distance (the Law of Contact or Contagion). Magic based on the former he called homeopathic magic, that based on the latter he called contagious magic. He added the notion of taboo as negative magic, acting on the same principles of association. He accepted Tylor's linking of magical and scientific thought as both being based on the belief that a particular act necessarily or invariably results in a particular effect, magic thus being a "spurious system of natural law."

Frazer also developed an evolutionary scheme for mag-

ic and religion. He saw magic and religion as belonging to different stages in the development of human thought. Magic was prior because it seemed to him to be logically more simple, because he assumed (erroneously, as was shown later) that the Australian aborigines, examples of an archaic people, believed in magic but not in religion, and because magic forms a substratum of superstition even in advanced societies. Individuals in the earliest cultures must have come to realize the inefficacy of magic and the powerlessness of men to control nature; from this they postulated the existence of omnipotent spiritual beings who required supplication to direct nature as men wanted. Thus there came into existence religion. The final stage in this schema is when men begin to recognize the existence of empirical natural laws, aided by the discoveries of alchemy and then of science proper. With this final development religion joins magic as superstition.

These writers, and their followers such as Robert Ranulph Marett (1866–1943), regarded magic as essentially an individual and intellectual matter, one of the ways in which individuals think about the world. Another line of writers has widened the discussion by regarding the problem as essentially one of the social function of magic. The first such writers of note were the French sociologists Marcel Mauss (1872–1950) and Emile Durkheim. Durkheim, in *The Elementary Forms of the Religious Life* (Eng. trans., 1915), considered that magical rites comprised the manipulation of sacred objects by the magician on behalf of individual clients; the socially cohesive significance of religious rites proper, by the priests, was therefore largely lacking. His views were followed by A.R. Radcliffe-Brown (*The Andaman Islanders*, 1922) and to a lesser extent by Bronislaw Malinowski (*Argonauts of the Western Pacific*, 1922, and various papers brought together as *Magic, Science and Religion*, 1925), the latter influenced more by Frazer and the early psychoanalysts. Radcliffe-Brown's main hypothesis has been mentioned above: the social function of magic was to express the social importance of the desired or protected event. Malinowski, on the other hand, regarded magic as being opposed to religion, and as directly and essentially concerned with the psychological needs of the individual. It acted to extend his normal knowledge and competence; to provide confidence in situations of technical uncertainty by "ritualizing optimism"; to express desires that are otherwise unrealizable in a small and technically limited community; and, as counter-magic, to explain failure. Malinowski's influence has been marked, due largely to the fact that his was the first detailed and first-hand account of the actual working of an ongoing system of magic. Other writers, notably R.R. Marret in England and Robert Lowie and Alexander Goldenweiser in the United States, differed from Tylor and Frazer in pointing out that the distinction between magic and religion is largely untenable, reflecting an ethnocentric distinction between the "natural" and the "supernatural" that is not made by most other religions.

In recent years there have been many reports of the working of systems of magic, especially from Africa and Oceania. On the whole they have followed Malinowski and Radcliffe-Brown and have been based on the single most important work on the topic that has appeared since them, E.E. Evans-Pritchard's (1902– ) *Witchcraft, Oracles and Magic Among the Azande* (1937). He shows concisely how magic is an integral part of religion and culture, being used to explain events the normal understanding and control of which are beyond the technical competence of this southern Sudan people. The Azande accept magic as a normal part of nature and society, together with witchcraft and oracles. These various phenomena form a closed logical system, each part of which buttresses the other and provides a rational system of causation of both natural order and the social order as well as disorder or coincidence.

**Psychological.** These various anthropological approaches to magic have had the advantage of regarding it as a social phenomenon rather than one of individual psychology. The views of Tylor and Frazer, however,

Theories of Malinowski, Radcliffe-Brown, and E.E. Evans-Pritchard

are eventually psychological in nature, since they are based on their notions of individual ways of thought. Their work was considerably based on that of Herbert Spencer and Wilhelm Wundt, thinkers of pronounced psychological interest, and was followed by anthropologists with psychological views on origins of magic and religion, such as Lowie, Paul Radin, and Goldenweiser, all of whom were concerned with the problem of the individual psychological status of believers. Much of Malinowski's work depends on providing psychological reasons for belief in magic. Sigmund Freud (*Totem and Taboo*, 1918) had at one time considerable influence in his view that magic, the earliest phase in the development of religious thought (following Frazer), was similar in its essential processes to the thought of children and neurotics. This view was based on his theory of the "Omnipotence of Thought," by which savages, children, and neurotics all assumed that wish or intention led automatically to the fulfillment of the desired end. This view has long been abandoned as a tenable hypothesis, due not so much to its inherent misunderstanding of the expressive nature of magical ritual as to the general recognition that the assumption of the similarity between primitive, infantile, and neurotic modes of thought is false; it arose largely from the ignorance of the nature of primitive culture before the development of modern anthropological field researches.

**Conclusion.** The study of magic as a distinct cultural phenomenon has a long history in anthropological and historical studies. Although the distinction between it and other religious phenomena may often heuristically be useful, it cannot be studied in isolation as was once the fashion. It is essentially an aspect or reflection of the worldview held by a particular people at a particular stage of development in scientific and technical knowledge. It is thus a part, although to the people concerned often a very important part, of their total system of religion and cosmology.

**BIBLIOGRAPHY.** The more important earlier anthropological writings on magic include: SIR EDWARD BURNETT TYLOR, *Primitive Culture: Researches into the Development of Mythology, Philosophy, Religion, Art, and Custom*, 2 vol. (1871, reprinted 1958); SIR JAMES GEORGE FRAZER, *The Golden Bough*, 3rd ed., 12 vol. (1911-15); HENRI HUBERT and MARCEL MAUSS, *Esquisse d'une théorie générale de la magie* (1904); EMILE DURKHEIM, *Les formes élémentaires de la vie religieuse* (1912; Eng. trans., *The Elementary Forms of the Religious Life*, 1915); and SIGMUND FREUD, *Totem und Tabu* (1913; Eng. trans., *Totem and Taboo*, 1918). The more important reports of magic in particular societies include: BRONISLAW MALINOWSKI, *Argonauts of the Western Pacific: An Account of Native Enterprise and Adventure in the Archipelagoes of Melanesian New Guinea* (1922, reprinted 1960); and "Magic, Science and Religion," in N.J.T. NEEDHAM (ed.), *Science, Religion and Reality* (1925, reprinted 1948); A.R. RADCLIFFE-BROWN, *The Andaman Islanders* (1922, reprinted 1964); and E.E. EVANS-PRITCHARD, *Witchcraft, Oracles and Magic among the Azande* (1937). More recent general and comparative studies are: HUTTON WEBSTER, *Magic: A Sociological Study* (1948); R.H. LOWIE, *Primitive Religion* (1948); W.J. GOODE, *Religion among the Primitives* (1951); FRANZ STEINER, *Taboo* (1956, reprinted 1967) M. DOUGLAS (ed.), *Witchcraft Confessions and Accusations* (1970); and M. and R. WAX, "The Notion of Magic," *Curr. Anthropol.*, 4: 495-518 (1963). There are also useful articles in the collections of essays, W.A. LESSA and E.Z. VOGT (eds.), *Reader in Comparative Religion: An Anthropological Approach*, 2nd ed. (1965); and JOHN MIDDLETON (ed.), *Magic, Witchcraft, and Curing* (1967). For European magic the most reliable works are E.M. BUTLER, *Ritual Magic* (1949); ELIPHAS LEVI, *Histoire de la Magie* (1860; Eng. trans., *The History of Magic*, 4th ed., 1948, reprinted 1963); H.C. LEA (comp.), *Materials toward a History of Witchcraft*, 3 vol. (1939); and K. THOMAS, *Religion and the Decline of Magic: Studies in Popular Beliefs in 16th and 17th Century England* (1971).

## Magnesium Products and Production

Magnesium is a silvery-white metallic element similar in appearance to aluminum but weighing approximately one-third less. It has a density of 0.0628 pound per cubic inch (1.738 grams per cubic centimetre). Like many other metals, magnesium in its pure form has few appli-

cations, but magnesium alloys are widely used, particularly where light weight and high strength are important, as in aerospace and automotive applications. The chemical compounds of magnesium have wide application in industry, medicine, and agriculture.

**History.** The English chemist Sir Humphry Davy is said to have produced an amalgam of magnesium (an alloy with mercury) in 1808 by reduction of the oxide, using a mercury cathode. But the first free metallic magnesium was produced in 1828 by the French scientist A.-A.-B. Bussy. His work involved the reduction of fused magnesium chloride by metallic potassium.

In 1833 the English scientist Michael Faraday was the first to produce magnesium by the electrolytic reduction (breaking down by an electric current) of magnesium chloride. Magnesium remained a laboratory curiosity until 1886, when I.G. Farbenindustrie of Germany undertook the manufacture of metallic magnesium on a production basis, using Faraday's electrolytic process.

Until 1915 Germany was the sole producer of magnesium, but during World War I this source was shut off from most of the world. Operations to produce magnesium were initiated in the United States by several organizations, most successfully by the Dow Chemical Company of Midland, Michigan. The Dow process, involving the electrolytic reduction of magnesium chloride, originally utilized deep brine wells at Midland as the raw material source, but these have been superseded by the use of seawater.

**Raw material sources of magnesium.** A number of extractive methods are used in the recovery of metallic magnesium from its raw sources. These methods vary considerably depending upon the type of primary raw mineral, which may be found either in mineral deposits or in aqueous solutions.

Among the raw ore deposits, the most common minerals are the carbonates dolomite (a compound of magnesium and calcium carbonates,  $MgCO_3 \cdot CaCO_3$ ) and magnesite, or magnesium carbonate ( $MgCO_3$ ). The oxide mineral brucite, magnesium oxide associated with water ( $MgO \cdot H_2O$ ), is less common, while the chloride mineral carnallite, a compound of magnesium and potassium chlorides and water ( $MgCl_2 \cdot KCl \cdot 6H_2O$ ), is rarer still.

Magnesium is recoverable from aqueous solutions of brine wells, but by far the largest source of magnesium is the oceans of the world, where it appears in its chloride form. While seawater is only approximately 0.13 percent magnesium, this proportion remains quite constant and represents an almost inexhaustible source of supply—approximately 12,000,000,000 pounds (5,500,000,000 kilograms) of magnesium per cubic mile of seawater.

The uniformity of magnesium content in seawater facilitates standardization in process recovery and offers certain economic advantages, which can vary with geographic location of the producer.

**Refining and recovery.** Magnesium is produced by two distinctly different methods. One is the direct reduction of the magnesium ores by strong reducing agents such as carbon, silicon, etc. The other is by electrolytic reduction of magnesium chloride. In the past, magnesium produced by direct reduction was of higher purity than that derived by electrolytic reduction, but because of process refinements, this is no longer the case. Where power costs are low, electrolytic reduction is the cheaper method; and, indeed, it accounts for much the greater part of world production.

**Electrolytic reduction processes.** Both the early German process and the Dow process use magnesium chloride as the basic source, differing primarily in the characteristics of the electrolytic cell employed.

The flow chart of the Dow process is shown in Figure 1 and represents the method used by the Dow plant near Freeport, Texas, where abundant natural gas is available for cheap power; nearby Galveston Bay provides an inexhaustible supply of lime in the form of oyster shells. In this process, seawater is mixed with calcium hydroxide in a processing unit called a flocculator. The calcium hydroxide is obtained by processing oyster shells. In the flocculator the calcium from the calcium hydroxide is

exchanged with the magnesium from the magnesium chloride in the seawater, forming the insoluble precipitate magnesium hydroxide. The seawater containing the magnesium hydroxide precipitate flows from the flocculator to large settling tanks. After the magnesium hydroxide has settled on the bottom, it is pumped out as a slurry, filtered, and converted to magnesium chloride by reaction with hydrochloric acid. After drying, the magnesium chloride is fed to electrolytic cells where it is broken down into magnesium metal and chlorine gas.

**Direct reduction processes.** Among the several direct reduction processes for the production of magnesium, by far the most important is the ferrosilicon process (sometimes referred to as the Pidgeon process for its originator, L.M. Pidgeon of Canada).

In the ferrosilicon process, dolomite is calcined (converted to lime by heating) and mixed with finely pulverized ferrosilicon Si-Fe. This mixture is briquetted and then placed in retorts at approximately 1,200° C (2,192° F). The direct reduction takes place within these retorts under very carefully controlled process conditions, the pressure and temperature being especially critical. A flow chart for the ferrosilicon direct-reduction process is shown in Figure 2.

The reaction taking place in the retorts is as follows:

The dolomite combines with the ferrosilicon to yield metallic magnesium and a combination of calcium and silicon oxides and iron.

Several hours are required for the reduction cycle. The magnesium yield may run from 30 to 500 pounds, depending upon retort size. For the process to compete economically with electrolytic reduction methods, plants must be located near sources of raw materials and power.

**The metal and its alloys.** Primary commercial magnesium metal is approximately 99.8 percent pure when produced by either of the methods. It is cast into small ingots or pigs, usually weighing from 20 to 50 pounds (9 to 23 kilograms). Higher purity can be attained by further processing in which the metal is remelted in a vacuum.

Many nonstructural uses of magnesium utilize the unalloyed metal, while specific alloy compositions are required for structural uses.

**Nonstructural applications.** The use of magnesium as an alloying element in aluminum-base alloys constitutes its greatest metallurgical application. In these aluminum alloys, magnesium is present in amounts ranging from less than 1 percent to approximately 10 percent. The use of the magnesium enhances the mechanical properties, as well as the corrosion resistance of such alloys. Similarly, pure aluminum is used as an alloying element in many magnesium-base alloys and has a similar beneficial effect upon structural properties.

Magnesium is frequently used to protect steel against corrosion by a method known as cathodic protection. When magnesium comes into electrical contact with steel in the presence of water, the magnesium corrodes sacrificially, leaving the steel intact. Ship hulls, water heaters, storage tanks, bridge structures, pipelines, and a variety of other steel products are protected in this manner.

Magnesium has been used in military pyrotechnics for many years and has found numerous uses in incendiary devices, flares, etc. Magnesium, in the form of finely divided particles, has been used as a fuel component, particularly in solid rocket propellants.

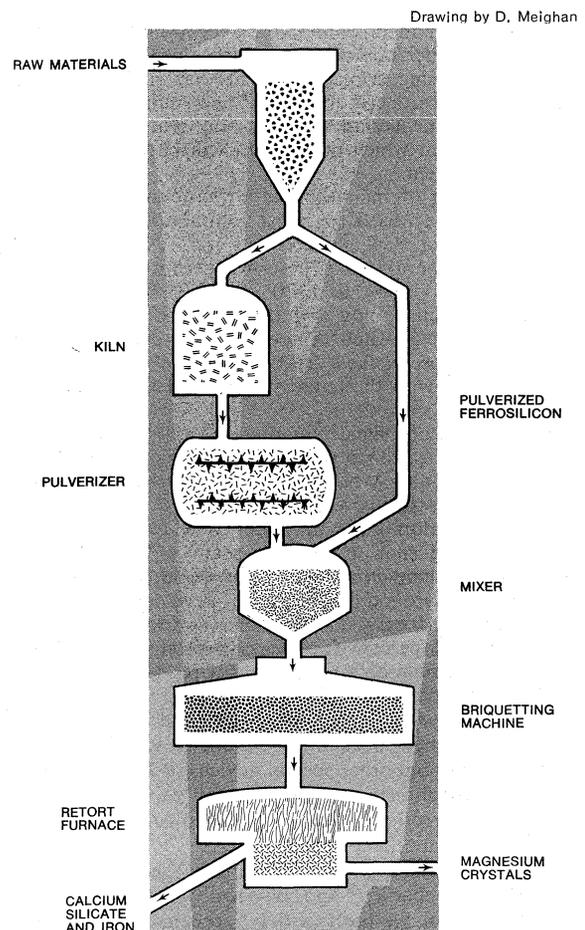

Figure 2: Stages in the ferrosilicon magnesium process.

Magnesium metal is used as an alloying element in zinc die castings to promote dimensional stability and to improve mechanical properties. It is also used as an oxygen scavenger and desulfurizing agent in the manufacture of copper and nickel alloys and as a reducing agent in the manufacture of titanium and zirconium.

The use of magnesium in making nodular cast iron is well established and is based upon the nodular form imparted to the graphite present. This, in turn, gives cast iron vastly improved mechanical properties.

The magnesium dry cell

The magnesium dry cell has achieved some degree of prominence, particularly for specialized applications in which long storage life and light weight are desirable. Such dry cells usually consist of magnesium plus either silver chloride or cuprous chloride. When activated with water, these dry cells rapidly build up voltages of 1.3 to 1.8 volts per cell. Silver chloride-magnesium cells operate with constant potential in the range of  $+94^{\circ}$  to  $-54^{\circ}$  C ( $200^{\circ}$  to  $-65^{\circ}$  F). Cuprous chloride-magnesium cells exhibit similar output characteristics but with somewhat lower power output per unit of weight. Both cells use synthetic porous fibers for separation of the electrodes. The shelf life of both is almost indefinite, and the primary usage is in military applications.

The use of magnesium in photoengraving plates, a relatively new use of the metal, is based primarily upon its ease of etching by certain reagents.

**Structural applications.** Magnesium is useful as a structural metal when it is alloyed with small amounts of other metals. These alloying metals are aluminum, zinc, manganese, silver, zirconium, lithium, thorium, and the rare-earth metals. In most cases, the alloying elements form intermetallic compounds that permit heat treatment for enhanced mechanical properties as well as other benefits, such as corrosion resistance, size stabilization, and improved fabricability.

Structural forms of magnesium include sand, permanent mold, and die castings as well as extrusions, forgings, and rolled sheet and plate.

Magnesium alloys are fabricated by most of the methods used for other metals and show exceptionally good machining characteristics. While magnesium alloys do require careful processing in machining, fire hazard is minimal if the metal is properly handled. Accumulation of large quantities of magnesium chips or fines is usually the only circumstance in which magnesium will burn in an industrial environment.

Forming at elevated temperatures

The forming of magnesium into structural shapes follows the pattern used for most common metals, such as aluminum and steel, except that it is usually done at elevated temperatures. These temperatures may vary from  $160^{\circ}$  to  $400^{\circ}$  C ( $320^{\circ}$  to  $750^{\circ}$  F), depending upon the specific alloy and the degree of deformation. The need for elevated temperatures is ascribed to the hexagonal close-packed crystal structure of magnesium as compared with the cubic structure of the other common metals.

The welding of magnesium alloys is accomplished readily by either resistance welding or inert-gas-shielded arc welding (see also WELDING, BRAZING, AND SOLDERING). Normally the type of equipment used for the resistance welding of aluminum may be used for magnesium, whether it be spot welding or seam welding. For arc welding of magnesium, an inert gas shield (helium, argon, or a mixture) around the weld area prevents oxidation and contamination from the surrounding atmosphere. Depending upon the type of weld, the arc is produced by either a tungsten electrode or a magnesium wire. The latter serves as both electrode and filler rod.

Magnesium structures also are formed by the use of rivets and other mechanical fasteners, such as screws, bolts, inserts, and other special devices. When using these types of attachments, the danger of galvanic (electrochemical) corrosion is very real, particularly since the fasteners are not made of magnesium.

Because of the ease of fabrication, together with the attractive mechanical and physical properties, magnesium alloys have been widely accepted in structures where light weight and high strength are needed. The

aerospace industry consumes large amounts of magnesium alloys in aircraft, rockets, and missiles. These applications include all types of castings, extrusions, rolled products, and forgings. Magnesium castings have found especially wide acceptance since high-integrity castings with excellent mechanical properties have been developed through improved foundry techniques. Gearbox housings, aerodynamic surfaces, and hardware chassis are typical applications. The environment of space makes possible the use of magnesium alloys that would not be suitable for similar applications in an earth environment. This is because the low-pressure, dry atmosphere does not sustain galvanic corrosion. Orbiting space satellites probably contain more magnesium than any other metal.

Magnesium alloys in outer space

In the late 1950s special compositions of magnesium alloys were developed for use in high temperature applications. These alloys contain thorium, silver, rare earth metals, or zirconium or combinations of all these in various amounts, enabling magnesium to be used at temperatures up to approximately  $320^{\circ}$  C ( $610^{\circ}$  F), as compared with  $150^{\circ}$  C ( $300^{\circ}$  F) for conventional alloys.

One of the newer magnesium alloys, containing 14 percent lithium and 1 percent aluminum, has excellent damping (vibration-suppression) characteristics. It has found numerous uses in structures where resonant vibration problems existed.

The varied commercial uses of magnesium structural alloys include luggage frames, hand trucks, ladders, business machines, camera bodies, power tools, tooling fixtures, and race-car wheels. Magnesium has found substantial use in tools used by masons and plasterers because of its light weight and resistance to alkalis. Magnesium die castings are extensively used, notably in automobiles.

**Magnesium compound products.** The compounds of magnesium form an important group of chemicals that are widely used in industry, medicine, and agriculture. Some of these chemicals are formed as by-products of primary magnesium metal production while others are synthesized by specific chemical processes.

The best known medical compounds are milk of magnesia,  $Mg(OH)_2$ , and the hydrous magnesium sulfate popularly known as Epsom salts,  $MgSO_4 \cdot 7H_2O$ .

Epsom salts

Magnesium has had a traditional place in the field of organic chemistry since the discovery of Grignard reagents in 1900. This group of reagents is represented by  $RMgX$ , in which R is an organic radical and X is one of the halides: chlorine, bromine, or iodine. Organomagnesium compounds are important in many organic chemical syntheses such as conversion of aldehydes and ketones to alcohols.

Magnesium carbonate,  $MgCO_3$ , is one of the most widely used magnesium compounds in industry. It is used in large quantities for refractory (high-temperature) bricks and linings of open-hearth furnaces used in steel manufacture. In this application, magnesite and dolomite ores are the principal sources of supply.

While basic magnesium carbonate serves primarily as a component of insulating compounds, the technical (high-purity) grade is widely used for fireproofing and as a filler for paper, plastics, paints, and varnishes. The principal pharmaceutical uses are as a bulking compound in powder formulations and as an antacid.

The most important use of magnesium chloride is in the recovery of magnesium metal, but it is also used in wall-plaster compositions and as a fireproofing agent for wood.

In addition to its medical applications, magnesium sulfate is used as a tanning agent, a conditioning agent for cotton, a mordant for dyeing wool, and as a component of fertilizers.

**Economic importance.** Although the greatest production of magnesium metal occurred during the war years of 1943 and 1944, expanded uses have required steadily increasing tonnages since that time. The U.S. Bureau of Mines estimated in 1970 that the total world production of primary magnesium was 243,250 short tons (220,673 metric tons). Three nations accounted for nearly 85 percent of this production: the U.S. (112,007 short tons), the U.S.S.R. (55,000 short tons), and Norway (39,000 short tons).

**BIBLIOGRAPHY.** *Encyclopedia of Chemical Technology*, 2nd ed., vol. 12 (1963), a comprehensive text detailing the production methods of primary magnesium metal; C.S. ROBERTS, *Magnesium and Its Alloys* (1960), a thorough review of the history of magnesium, production methods, alloys, and uses; W.H. GROSS, *The Story of Magnesium* (1949), historical data on magnesium presented in an interesting manner; AMERICAN SOCIETY FOR METALS, *Magnesium* (1946), semi-technical data on the progress of magnesium production and its uses at that time period, *Metals Handbook*, 8th ed., vol. 1 (1961), excellent illustrations on magnesium applications and property data on the material; M. CAMPBELL and H. HATTON, *Herbert H. Dow: Pioneer in Creative Chemistry* (1951), a classic story of the man who pioneered magnesium in the U.S.; J.H. RIZLEY, *Magnesium: A Material of the Space Age* (1960), a paper on the use of magnesium in space presented at the Magnesium International Conference of May 1960.

(J.H.R.)

## Magnetic Resonance

Magnetic resonance is said to occur when atoms or atomic nuclei respond to the application of certain magnetic fields by absorbing or emitting electromagnetic radiation. The principles of magnetic resonance are applied in the laboratory to analyze the atomic and nuclear properties of matter.

In order to understand magnetic resonance, which may be either electron-spin resonance or nuclear magnetic resonance, it is necessary to understand magnetic moments and the effect of magnetic fields on them.

### GENERAL CONSIDERATIONS AND HISTORY OF RESONANCE INVESTIGATIONS

**First principles.** The classical model of the atom posits negatively charged electrons in orbit about a positively charged nucleus of protons and neutrons. An electron speeding in an orbit is like any other mass, such as a stone on the end of a string, moving in a circle: its speed can be characterized by a mechanical angular momentum, which also depends on its mass and orbital radius, and is represented by a vector that points at right angles to the plane of rotation. A moving electric charge produces a magnetic field; thus, the motion of an electron in its orbit gives rise to a magnetic field that is not unlike that of a tiny bar magnet in that it is a dipole, having a north and south pole. Specifically, it is said to have a magnetic dipole moment, or a magnetic moment, a term that expresses the amount of torque or turning force a dipole such as an orbiting electron or bar magnet will experience when it is placed in the given magnetic field. The magnetic moment, too, is represented by a vector pointing in a direction at right angles to the plane of rotation. Although the angular-momentum vector and magnetic-moment vector coincide, they may point in opposite directions, depending on the sign of the rotating charge and the direction of rotation.

Thus, because a moving charge produces a magnetic field, a subatomic particle having angular momentum and charge has a magnetic moment associated with it. Not only does an electron rotate about the nucleus in an orbit, but it spins on its own axis; hence, in addition to having an orbital angular momentum and orbital magnetic moment, it has a spin angular momentum and a consequent spin magnetic moment. Inside the atom, the nucleus also possesses an angular momentum due to the rotation of itself or its parts, and so it, too, has a magnetic moment, called its nuclear magnetic moment, or magnetic moment due to nuclear spin.

Orbital and spin electronic moments are expressed in Bohr magnetons; *i.e.*, a fundamental atomic unit equal to the product of the electron charge and Planck's universal constant (that associates a quantum of energy with frequency of vibration) divided by the product of four pi ( $\pi$ ) times the electron mass and the velocity of light, or  $\beta = eh/4\pi mc$ , in which  $\beta$  represents a Bohr magneton,  $e$  is electronic charge,  $h$  is Planck's constant,  $m$  is the electron mass, and  $c$  is the velocity of light. There is also a nuclear magneton equal to the product of the electron charge and Planck's constant divided by the product of four pi ( $\pi$ ) times the proton mass and the velocity of light, or  $\beta_n = eh/4\pi Mc$ , but it is 1,836 times smaller because

this number is the ratio of the mass  $M$  of the proton to the mass  $m$  of the electron.

When a bar magnet is placed in a steady magnetic field, it experiences a torque because its north pole seeks the south pole of the field, and vice versa. When the magnet comes to rest, it is said to be in the parallel position; work would be required to change its orientation to a position other than parallel. This means that the system can store potential energy. The energy associated with the magnet depends, therefore, on its magnetic moment, the strength of the pervading magnetic field, and the angle of direction that the bar magnet makes with respect to the magnetic field.

Atoms and nuclei, because of their magnetic dipole moments, are also endowed with potential energy when subjected to a strong, external magnetic field. The magnetic energy (energy state) of the atomic or nuclear dipole is restricted because the angular momentum with which it is associated must conform to a quantum mechanics rule which states that angular momentum of the atom or nucleus must be a whole multiple (such as one, two, or three times) of a fundamental unit of angular momentum; thus the magnetic energy of the atom or nucleus is said to be quantized. A large number of atoms will have many energy states, each characterized by a different quantum of energy.

Such energy states can be shown schematically by a series of horizontal parallel lines, called an energy level diagram, in which each energy state is represented by a single line, or energy level. When a dipole is parallel to a magnetic field it has the least amount of potential energy and is in the ground state or lowest energy level; when antiparallel, it is in the highest energy level.

In magnetic-resonance experiments, when atoms are placed in a strong magnetic field, the electrons and nuclei of the atoms will seek various energy levels. If, in addition, an alternating magnetic field, relatively weak and oscillating at the proper synchronous or resonant frequency, called the resonant magnetic field, is applied in a plane at right angles to the strong magnetic field, many of the atoms and nuclei can, as will be explained later, be induced to shift to higher energy levels; *i.e.*, their moments will be flipped over—that is to say, from parallel to antiparallel. The consequence of the transition between two levels is that energy will be extracted from the resonant magnetic field and can be displayed on a magnetic-resonance spectrometer as part of a magnetic-resonance spectrum (Figure 1). The frequency of the resonance

Quantized energies

Magnetic moment

Bohr magnetons

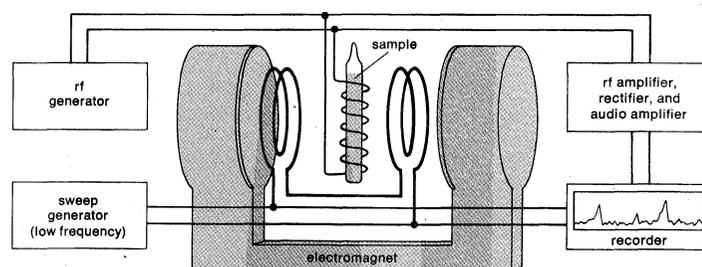

Figure 1: *Magnetic resonance device.* Sample to be measured is placed between poles of a direct current (dc) electromagnet. A radio frequency (rf) magnetic field is generated by the coil surrounding the sample. The sweep generator coils augment the dc electromagnet so that its static field can be changed slightly until resonance occurs. At the moment of resonance, the magnetic moments of the sample absorb energy from the rf field, which is displayed as a peak in the recorder. By synchronizing the sweep generator and the recorder, many resonances can be scanned to give a spectrum.

magnetic field applied to the sample determines the transitions that take place, depending on which of the magnetic moments are to be affected: those arising from electrons, nuclei, or both. The resulting spectrum can, of course, be analyzed so that the scientist will know what energies and energy perturbations are involved. Resonance frequencies in the microwave region (in the neighbourhood of a centimetre in wavelength) are used for electron-spin resonance (ESR) and at radio frequency

(high frequency—very high frequency [HF—VHF] band, 10–100 megacycles) for nuclear magnetic-resonance (NMR) studies. Both ESR and NMR are major, powerful investigative tools employed in most branches of science—in physics, in chemistry, in biology, and even in geology, and archaeology.

**Early studies.** The first observation of resonance due to electron spin, or electron-spin resonance (ESR), was made in 1944 by a Soviet physicist Y.K. Zavoysky using several concentrated salts of the iron group. Later, an increase in sensitivity made it possible to observe the resonance in dilute samples in which only a fraction of the atoms carry electron magnetic moments. The better resolution of resonance lines in dilute samples led to the important discovery that they were split into finer lines, called the electron-spin-resonance hyperfine structure. The ever-increasing sensitivity of electron-spin-resonance detecting equipment has permitted study of such phenomena as structural defects in crystals that give them their colour, free radicals (a type of molecular fragment, with unpaired electron spins) in liquid and solid samples, free or conduction electrons in metals, and metastable states (those energy states that are relatively long lived because transfer from them by radiation is prohibited) in molecular crystals.

The first observations of nuclear magnetic resonance (NMR) were made in the U.S. in 1946 by Felix Bloch, William W. Hansen, and Martin E. Packard with the protons of water and independently by Edward M. Purcell, Robert V. Pound, and Henry C. Torrey with the protons of paraffin. The number of nuclear species in which scientists observed NMR increased rapidly until it included practically all the stable nuclei with nuclear moments greater than zero, about one hundred nuclear species. New discoveries with NMR include electric quadrupole effects (an electric quadrupole consists of a charge distribution equivalent to a special arrangement of two electric dipoles), the observation of an important shift of NMR lines in metals, multiplet line splitting in liquids due to chemical structure and to the influence of one nuclear

spin on another and the presence of NMR in superconductors (conductors having negligible electrical resistance).

Besides pure ESR and NMR, double-resonance methods have been employed with both simultaneously, such as electron-nuclear-double resonance and dynamic nuclear polarization. It is difficult to discuss the complete theory of magnetic resonance without resorting to vector and tensor analysis. The theory underlying electron-spin resonance and nuclear magnetic resonance is common to both kinds of resonances and an elementary presentation is given below.

#### MAGNETIC RESONANCE IN BULK MATTER

**General theory.** Every magnetic dipole (spin system) can be represented by a vector  $\mu$  that is determined by the magnitude and direction of its magnetic moment. In Figure 2, this vector is depicted as lying along the axis about which an atomic nucleus (as an example) is spinning. Any particle, such as an electron, proton, neutron, and many species of atoms and nuclei, that has both a magnetic moment and a mechanical angular momentum and that is surrounded by a magnetic field (symbolized by the vector  $H$  characterizing the strength and direction of the magnetic field) will experience a force such that the spin axis (and magnetic-moment vector) will precess around the magnetic field direction, describing a cone about it. The behaviour of the spinning nucleus will be analogous to the precession of a spinning top about a line in the direction of the Earth's gravitational pull. According to classical electrodynamics, the frequency ( $\omega_L$ ) of the Larmor precession (number of rotations per second of the magnetic-moment vector about the magnetic-field vector) should be independent of the orientation angle ( $\theta$ ), that is, the amount that the spin axis is tilted away from the field direction. But according to quantum mechanics, the orientation angle of a single nucleus can assume only certain limited values because the angular momenta of the nucleus are quantized, corresponding to an equal number of magnetic energy states. (In practice, the resultant magnetization of a large number of nuclei is observed, and so it can make any angle with the applied field.)

In magnetic-resonance devices, a small oscillating field ( $H'$ ) is superimposed on a large constant field ( $H$ ), as shown in Figure 2, and has an angular velocity ( $\omega$ ) in a plane perpendicular to the magnetic-field direction. For simplicity, one can imagine that a small precessing bar magnet is substituted for the nucleus and that the superimposed magnetic field (vector  $H'$ ) represents another bar magnet rotating about the large constant field ( $H$ ) direction as an axis. When the rate of rotation ( $\omega$ ) of the superimposed field magnet is different from the Larmor frequency  $\omega_L$  of the nuclear magnet, the two magnets will be out of phase, or not synchronized; the nuclear magnet will successively be attracted and repulsed (tilted) by the superimposed rotating magnet during complete revolutions, with the nuclear magnet wobbling only slightly. When they are synchronized, however, there will be a steady force acting on the nuclear magnet. Thus, in magnetic resonance, when the frequency of the superimposed magnetic field is equal to the Larmor frequency, the orientation angle will change suddenly and the nucleus will be raised or lowered to another energy state. This synchronism is the condition of resonance. When a spin system is raised to a higher state, energy is extracted from the superimposed field, and vice versa. The use of an oscillating field to produce resonance is sometimes referred to as "driving a resonance."

**Analysis.** Every experiment in magnetic resonance involves detecting the resonance; *i.e.*, ascertaining that the transition has actually taken place. Magnetic resonance (MR) makes use of electromagnetic detection, in which the energy liberated or absorbed in a transition is precisely that which is measured. The interpretation of MR in bulk matter is considerably complicated by the relationship of the spins with each other and with the other degrees of freedom of the sample. This complication, however, turns out to be an asset rather than a drawback for magnetic resonance, because it is the very existence of

First observations

Larmor precession

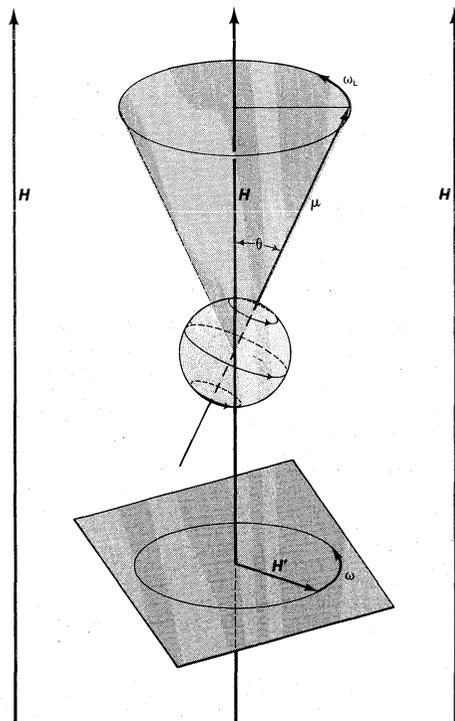

Figure 2: Precession of a magnetic dipole moment  $\mu$  in the presence of a constant field  $H$  and a rotating field  $H'$ .

The dipole precesses due to the Larmor effect with angular velocity  $\omega_L$  about the field direction  $H$ , whereas the superimposed field  $H'$  rotates about the field direction with angular velocity  $\omega$ . At resonance, the frequency of the superimposed field rotation and the Larmor precession are equal.

these interactions that makes MR such a remarkable tool for the study of bulk matter.

In many kinds of atoms all of the electrons are paired; that is, the spins are oppositely directed and therefore neutralized, and there is no net spin angular momentum or magnetic moment. In other species of atoms there are one or more electrons that give rise to a cooperative effect between their spins, or between their spins and orbital motions. It is therefore possible for any of these atoms to acquire or lose various quantum multiples of energy, and in a large assembly of identical spin systems, the energy states of the systems will be characterized by many different energy levels. What has been said of electron-spin systems may also be said of many species of nuclei, in that there can be a coupling effect between the spin of a nucleus and an external magnetic field, so that nuclei can lie in different energy states. Indeed, one odd-numbered nucleon can give rise to two different energy states because its spin is either  $-\frac{1}{2}$  or  $+\frac{1}{2}$  nuclear magnetons.

The structure of a crystal system is in the form of a lattice; it is composed of atoms arranged in layers in an orderly manner. Atoms are not fixed in position at the lattice sites but vibrate about the sites as centres. Each vibration implies a mechanical energy; because of the restrictions of quantum mechanics theory, these energies are quantized into what is known as phonons, having energies equal to Planck's constant times frequency. Phonons make up the thermal energy of a crystal. When the lattice sites are occupied by spin systems, electronic or nuclear, it is possible for the phonons and spin systems to interact; that is, to exchange energy in quantum multiples. Spin systems gaining phonon energy give rise to higher energy levels, and vice versa. If the exchange is such that there is thermal equilibrium—a constant energy exchange keeps the thermal energy in balance—the phenomenon is known as spin-lattice relaxation. Other types of motion of the atoms, such as free or restricted rotation of groups of atoms, random motion due to diffusion, etc., can also give rise to thermal spin-lattice relaxation.

During spin-lattice relaxation, successively higher energy levels will be occupied by fewer spin systems because the population of a given energy level is regulated according to the absolute temperature of the material. Should the material be placed in a radio-frequency field generator, as in magnetic resonance, and should the radio-frequency field be sufficiently strong, spin systems will be raised from one energy level to a higher one until all of the levels are populated equally, a situation known as saturation. Thus, the saturating effect of magnetic resonance is opposed by spin-lattice relaxation. The amount of electromagnetic energy absorbed gives a measure of the energy levels.

For magnetic fields of the order of a few kilogauss (gauss is a unit of magnetic intensity; the horizontal intensity of the Earth's magnetic field is roughly 0.2 gauss) currently used in laboratories, nuclear magnetic-resonance (NMR) frequencies fall into the radio-frequency or broadcasting range, whereas electron-spin-resonance (ESR) frequencies occur in the microwave or radar range. For instance, the proton NMR frequency in a field of 10 kilogauss is 42,577 megahertz (million cycles per second), and in the same field the ESR frequency of a free spin is 28,000 megahertz. With regard to sensitivity, the number of spins detectable by magnetic resonance varies widely with the applied field, the temperature, the nature of the sample, and for NMR the nuclear species; under the best conditions, it can be as low as  $10^{18}$  spins for NMR and  $10^{10}$  spins for ESR.

An important aspect of magnetic resonance in bulk matter is the finite width of resonance lines. Part of this width is caused by the spin-lattice relaxation that, by inducing relaxation transitions between spin levels, shortens the lifetimes of these levels and broadens them accordingly. This result follows from Heisenberg's uncertainty principle that the inaccuracy in measurement of energy, manifested as a widening of an energy level, increases as the lifetime of the state decreases.

Usually, a larger contribution to line width originates in

spin-spin interactions. These are the typical interactions between two dipole moments in which, for example, local fields act on a spin, the fields being produced by its neighbouring spins. There is a wide variation in direction and magnitude of local fields by the many spins of the sample, which results in a width that is far greater in solids than that due to spin-lattice relaxation. In NMR, local fields have strengths of only a few gauss; in ESR it can be a few thousand gauss for similar concentrations of spins. These enormous contributions by local field interaction explain why samples must be dilute in order to give reduced line widths.

The values quoted above are those actually observed in solids; the lines observed in liquid samples are one hundred to one million times narrower, due to a phenomenon known as motion narrowing. Because the local field fluctuates in a random fashion and at a fast rate, each spin is acted on by only the average value of the local field taken over many fluctuations. Whereas in liquids the instantaneous value of the local field is of the same order of magnitude as in solids, the effective line width is reduced by as much as one-millionth in NMR and one-hundredth in ESR.

Another type of narrowing, specific to ESR in concentrated samples, is the so-called exchange narrowing. The exchange interaction that exists between two neighbouring electronic spins can be interpreted qualitatively as an interchange of their orientation within a finite time. By a mechanism similar to that of motion narrowing, this interaction results in a narrowing of ESR lines by a factor of one hundred or so. Exchange narrowing does not operate in dilute samples because of the short range over which exchange interactions take place.

#### NUCLEAR MAGNETIC RESONANCE

**Nuclear magnetic resonance in solids.** Most observations of nuclear magnetic resonance (NMR) in solids are made in diamagnetic substances (substances in which the electron spins are paired off in opposite directions to neutralize one another so that there is no residual magnetic field from electrons), and thus the shape of the NMR line is determined by the positions of the nuclear spins alone. In the absence of atomic motion in rigid lattices (crystals), it is possible to determine molecular structures not observable by other means.

In many solids, even at low temperatures, there exist internal movements of relatively large amplitude caused by atomic diffusion and free or restricted rotation of groups of atoms. These movements modulate the local field and have a drastic effect on the shape of the NMR line. A study of these effects as a function of temperature can supplement the other physical measurements.

In metals, the nuclei are influenced by an electronic field produced by the alignment of the spins of the conduction electrons (electrons not bound to atoms that move freely through the metal) by the applied field. This condition results in a relative shift of the resonant frequency that is characteristic of the metal for NMR, which has a different value for an insulator.

Metallic shifts, varying in size from a small fraction of a percent (0.025 percent for lithium) to a few percent (2.5 percent for mercury), provide important information on the magnetic susceptibility, the wave functions of quantum mechanics that describe energy states, and the density of states of conduction electrons in the metal. In superconductors, the shape of the NMR line provides detailed information on the penetration and distribution of the magnetic field inside the superconductor. In ferromagnets or antiferromagnets (crystals in which not all electrons are paired), the NMR is shifted by the internal magnetic fields produced by the array of ordered electronic spins. In ferromagnets the shift is a measure of the lattice magnetization; in an antiferromagnet there are at least two shifts that give the magnetization of each antiferromagnetic sublattice separately, a result unattainable by conventional magnetic measurements.

For nuclei with quantum spins greater than one-half, the NMR spectrum is modified by the existence of nuclear electric quadrupole moments (an electric quadrupole

Spin-lattice relaxation

Importance of line width

Motion narrowing

Magnetic resonance in metals

consists of a charge distribution equivalent to a special arrangement of two electric dipoles), which interact with the electric fields that exist at the nuclear sites. As the fields are electric rather than magnetic, these interactions remain unchanged when the direction of the nuclear spin is reversed. In their presence, the various transitions correspond to different frequencies and the NMR is split into several lines. The positions and the widths of these lines and their dependence on the orientation of the magnetic field with respect to the crystal axes provide information on the microscopic distribution of electric charge around the nucleus.

**Nuclear magnetic resonance in liquids.** The most important consequence of the extraordinary sharpness of nuclear magnetic resonance (NMR) lines in liquids, caused by motion narrowing, is the possibility of measuring the chemical shifts; that is, the separations between NMR lines from nuclear spins of the same species but in different molecular environments. The physical origin of chemical shifts is the following: an external magnetic field applied to a diamagnetic substance polarizes the closed electron shells of the atoms and produces a small magnetic field, proportional to the external field, which shifts the NMR line with respect to its position for the bare nucleus; *e.g.*, one which is devoid of electrons. The bare nucleus itself is never observed, but the atomic diamagnetic shifts that correspond to atoms located in different molecular sites are slightly different, and it is their differences that produce the chemical shifts. As an example, the proton NMR spectrum of a molecule of ethyl alcohol, with the formula  $\text{CH}_3\text{-CH}_2\text{-OH}$ , exhibits three peaks with relative weights or intensities of 3:2:1. In more complicated molecules such spectra contain much chemical information and can help in the determination of unknown molecular structures.

The multiplicity of lines is further increased by the interaction between nuclear spins. As already mentioned in connection with motion narrowing in liquids, the usual magnetic dipolar interactions are averaged out by molecular motion and do not split the NMR spectra. There exists, however, an indirect interaction between nuclear spins, caused by the electrons, that splits the resonance line of a specific nuclear spin into many components.

High-resolution nuclear magnetic resonance has become one of the most prized tools in the fields of organic chemistry and biochemistry. On the experimental side, the requirements to be met by the equipment are severe. In order to match natural line widths of a fraction of a cycle, the applied magnetic fields must have a relative stability and homogeneity throughout the sample better than one part in  $10^6$ . Special magnets that give uniform fields and are stabilized, devices that twirl samples in order to smooth out the magnetic inhomogeneity, and sophisticated radio-frequency detection equipment are commercially available. The trend toward higher fields (over 100 kilogauss), resulting from superconducting solenoids, improves the resolution by increasing the chemical shift splittings and the signal-to-noise ratio.

**Magnetic mapping.** The measurement of the precession frequency of proton spins in a magnetic field can give the value of the field with high accuracy and is widely used for that purpose. In low fields, such as the Earth's magnetic field, the NMR signal is expected to be weak because the nuclear magnetization is small, but special devices can enhance the signal a hundred or thousand times. Incorporated in existing portable magnetometers, these devices make them capable of measuring fields to an absolute accuracy of about one part in one million and detecting field variations of about  $10^{-8}$  gauss. Apart from the direct measurement of the magnetic field on Earth or in space, these magnetometers prove to be useful whenever a phenomenon is linked with variations of magnetic field in space or in time, such as anomalies arising from submarines, skiers buried under snow, archaeological remains, and mineral deposits.

#### ELECTRON-SPIN RESONANCE

**Theory.** In contrast to nuclear magnetic resonance, electron-spin resonance (ESR) is observed only in a re-

stricted class of substances. These substances include transition elements—that is, elements with unfilled inner electronic shells—free radicals (molecular fragments), metals, and various paramagnetic defects and impurity centres. Another difference from NMR is a far greater sensitivity to environment; whereas the resonance frequencies in NMR in general are shifted from those of bare nuclei by very small amounts because of the influence of conduction electrons, chemical shifts, spin-spin couplings, and so on, the ESR frequencies in bulk matter may differ from those of free spins or free atoms by appreciable factors. This difference is due to the orbital magnetism originating in the orbital electronic currents circulating in unfilled subshells of the atom. The distortion of these shells by the interactions existing in bulk matter modifies considerably the orbital magnetic contribution to the observed ESR frequency.

A model that has been highly successful for the description of magnetism in bulk matter is based on ligand field theory concerned with the effect of the crystal lattice on the magnetic centre under study. As an explanation of the large amount of detailed and accurate experimental evidence accumulated in ESR work, the ligand field model, depending heavily on the mathematical apparatus of group theory, has risen to a high level of sophistication. Basically, the effect of the crystal field is to reduce (quench) the magnetism caused by orbital motion, the more so the lower the symmetry of the field. In quantum mechanics, the existence of orbital momentum is closely related to the rotational symmetry of the free atom. To some extent the orbital magnetism is preserved against ligand fields of low symmetry by the spin-orbit coupling of the electrons. Its effect is to associate closely the spin and orbital momentum of an atom to form a resultant angular momentum. The ligand field, being electric rather than magnetic, is powerless against spin moment, however, and if the orbital momentum is closely coupled to the spin, the orbital momentum partakes of a certain immunity from the reduction caused by the crystal field.

The total energy of the magnetic centre consists of two parts: (1) the energy of coupling between magnetic moments due to the electrons and the external magnetic field, and (2) the electrostatic energy between the electronic shells and the ligand field, which is independent of the applied magnetic field. The energy levels, found by standard quantum mechanical methods, give rise to a spectrum with many different resonance frequencies, the fine structure.

Another important feature of electron-spin resonance is the hyperfine structure—that is, the interaction of the electronic magnetization with the nuclear moment—which is quantized by the nuclear spin. The magnetic electron dipoles produce a magnetic field at the nucleus, and its interaction with the nuclear moment is an energy that can be added to the total energy of the interaction in the ligand field together with an energy for the nuclear interaction with the applied field. Each component of the fine-structure resonance spectrum thus is split further into many so-called hyperfine components.

If the electronic magnetization is spread over more than one atom it can interact with more than one nucleus; and in the expression for hyperfine levels, the hyperfine coupling of the electrons with a single nucleus must be replaced by the sum of the coupling with all the nuclei. When the magnetic electrons are strongly localized on a single atom, the main hyperfine coupling relative to its nucleus is much larger than the couplings with the neighbouring nuclei. Each main hyperfine line is then split further by the smaller couplings into what is known as superhyperfine structure.

The key problem in electron-spin resonance is, on one hand, to calculate from first principles the parameters (variables) of the total energy of the interaction in the ligand field plus the applied magnetic field and, on the other hand, to extract these same parameters from an analysis of the observed spectra. The confrontation of the two sets of parametric values permits a detailed quantitative test of the microscopic description of the structure of matter in the compounds studied by ESR.

Chemical shifts

High-resolution spectroscopy

Super-hyperfine structure

**Electron-spin resonance in transition elements.** The transition elements include the following groups of atoms: the iron group, the lanthanide or rare-earth group, the palladium group, the platinum group, and the actinide group; the lanthanide and iron groups are, by far, the most extensively studied. The resonance behaviour of the compounds containing these elements is conditioned by the relative strength of the ligand field and the spin-orbit coupling. In the lanthanides, for instance, the ligand field is weak and unable to uncouple the spin and orbital momentum, leaving the latter largely unreduced. On the other hand, in the iron group, the components of the ligand field are, as a rule, stronger than the spin-orbit coupling, and the orbital momentum is strongly reduced.

Although the transition-element compounds have been studied by such means as static magnetic measurements and specific-heat measurements, the advent of ESR has marked a new understanding of these substances. Thus, until the advent of ESR it was generally admitted that the structure of the paramagnetic centres in the iron group and the lanthanide group were purely ionic (ions of the crystal bound together solely by their electrostatic attraction), the magnetic electrons being completely localized on the transition ion. The discovery of superhyperfine structure, with the neighbouring nuclei, demonstrated conclusively that some covalent bonding to neighbouring ions exists.

**Defects, impurity centres, and free radicals.** With few exceptions, the magnetic moments of the numerous defects (imperfections such as vacancies at lattice sites) and impurity centres in crystals that give rise to an observable ESR have the characteristics of a free electronic spin. In the study of these centres, the role of hyperfine and superhyperfine structure is paramount: it provides a mapping of the electronic magnetization and establishes the correctness of the model chosen to describe the defect. As an example, one of the best known of crystal defects, the *F*-centre, a term for an electron captured in the vacancy of a negative ion in alkali halides, has an ESR line with no central hyperfine structure, but the electronic magnetization spills over the neighbouring ions and gives rise to an extensive superhyperfine structure.

As an example of ESR in impurity atoms, the most widely studied by resonance are the atoms of such elements as phosphorus, arsenic, and antimony, substituted in such semiconductors as silicon and germanium. Again, extensive theoretical and experimental studies of hyperfine and superhyperfine structure give detailed information on the theory of these impurities.

Free radicals, having unpaired electronic spins, are ideally suited for study by electron-spin resonance. They can be studied in a concentrated form in which the lines are considerably narrowed and the hyperfine structures washed out by exchange, or to the contrary, caused by the sensitivity of ESR, in very dilute solutions. This sensitivity is particularly important for the study of very short-lived species that have to be created inside the detecting cavity. The ESR of free radicals in solutions gives an extreme wealth of hyperfine lines because the magnetic electron is not localized on one nucleus but interacts with several nuclei of the radical (mainly protons, but also nitrogen-14 and phosphorus-31). A high-resolution ESR of free radicals, in many respects analogous to high-resolution NMR, has been developed.

An important development in the study of free radicals is the electron-spin resonance of excited triplet energy levels or states of organic molecules, such as naphthalene, in which two electronic spins, paired off to a total spin of zero in the ground or lowest state, combine to form a spin value of one in a higher, excited state. The excited state, which has a sufficient lifetime—a few seconds—to be observed by ESR, may be raised by ultraviolet excitation to an even higher state, with subsequent de-excitation.

#### COMBINED ELECTRON-SPIN AND NUCLEAR MAGNETIC RESONANCES

When a spin system offers more than one resonance, it may be advantageous to study two or more of them simultaneously. In general, this study involves driving

one resonance while detecting the other. Thus, an apparatus with two oscillating magnetic fields is employed, one for the driver and the other for the detector. Driving an NMR and detecting its effect on an ESR is known as ENDOR (electron-nuclear double resonance), whereas driving an ESR to increase a nuclear magnetization, observed by NMR, is DNP (dynamic nuclear polarization).

The main purpose of electron-nuclear double resonance is to measure accurately hyperfine and superhyperfine splittings. In the ENDOR method, driving an NMR resonance changes the populations of at least one of the energy levels between which occurs an observed ESR transition, and thus the strong ESR signal is measurably modified. ENDOR thus combines the sensitivity of ESR with the resolution of NMR and is widely used for detailed mapping of electron-spin densities by resolving superhyperfine structures. In the dynamic nuclear polarization (DNP) method known as solid effect, a strong microwave field of a frequency that is the sum or difference of electronic and nuclear Larmor frequencies, can transfer to the nuclei of a diamagnetic sample a polarization equal or opposite to that of fixed paramagnetic impurities embedded in the sample, an enhancement of a hundred to a thousand. The solid effect is widely used for making polarized proton targets for nuclear and high energy physics.

**BIBLIOGRAPHY.** An introductory work on the subject nuclear magnetic resonance (NMR) is E.R. ANDREW, *Nuclear Magnetic Resonance* (1956); on electron-spin resonance (ESR), G.E. PAKE, *Paramagnetic Resonance* (1962). An intermediate work covering both NMR and ESR is C.P. SLICHTER, *Principles of Magnetic Resonance* (1963). More advanced and comprehensive works include: (on NMR), A. ABRAGAM, *The Principles of Nuclear Magnetism* (1961); and (on ESR), A. ABRAGAM and B. BLEANEY, *Electron Paramagnetic Resonance of Transition Ions* (1970).

## Magnetism

The phenomenon known as magnetism is most familiar through the compass, indicating the direction of the Earth's magnetic poles, and through small permanent magnets used in household fixtures and as children's toys. Permanent magnets are pieces of iron or certain metal alloys with strong attraction or repulsion for one another. Most of the important properties of magnetism, however, are connected with the relations between magnetism and current electricity, which may be summarized as follows:

1. An electric current flowing along a wire generates a magnetic field in the space around the wire. The strength of this field is proportional to the size of the current and diminishes as the distance from the wire increases. The field can be made strongest by winding the wire into a coil of many turns and can be concentrated in space by filling the volume inside the coil with iron, thus creating a device known as an electromagnet, in which the magnetic field can be controlled by adjusting the size of the current flowing in the coil.

2. When placed in a magnetic field, a wire carrying an electric current experiences a mechanical force. The magnetic field may be generated by a permanent magnet or, more commonly, by a second coil also carrying an electric current. Magnetic forces provide the fundamental motive power in electromagnetic machinery; powerful forces can be generated by comparatively small machines and be conveniently controlled by adjustment of the size of the currents.

3. When a coil of wire is situated in a magnetic field that is increasing or decreasing, an electrical voltage proportional to the rate of change of the field is created in the coil. This is the phenomenon of electromagnetic induction that forms the basis of the dynamo. A coil rotated in a magnetic field generates an alternating voltage, and an alternating current (ac) flows if the coil is connected to a continuous electrical circuit. By a special arrangement of connections to the rotating coil, it is possible to draw direct current (dc) instead of alternating current from the coil.

These three principles constitute the scientific basis of

ENDOR and  
DNP

Free  
radicals

Electro-  
magnetic  
induction

the electrical power industry. Electrical power is generated by the dynamo, itself driven by a source of mechanical energy dependent on coal, oil, waterpower, or nuclear energy. The magnitude of alternating voltages and currents can be changed by a transformer, consisting of primary (input) and secondary (output) coils, the voltage being increased and the current diminished by the same factor in the secondary coil in proportion to the ratio of the number of turns on the secondary coil to the number on the primary. Such transformers operate with efficiencies of over 99 percent. Electric power is used in industry and in the home for heating and lighting and to drive electromagnetic machines of all sizes. It is used for heavy-duty traction on electrified railways and for light-duty traction in small, mobile delivery vans.

An electric current consists of moving electrical charges (usually electrons, the most elementary form of charge), and in a magnetic field the force on a conductor carrying an electric current arises from the forces exerted on the moving charges by the magnetic field. Such forces have many technical applications, such as the rapidly changing deflection of an electron beam in a television display tube, moving back and forth and up and down across the screen to form a picture. Specially designed configurations of magnetic fields are used to focus the electron beam in a cathode ray tube and in electron microscopes and to control the motion of charged particles in accelerators and other instruments used in atomic and nuclear physics.

### MAGNETISM: NATURAL AND APPLIED

**Magnetism in nature.** Magnetism plays an important role in various ways in the investigation of atomic and nuclear structures. The motion of an electron in an orbit around the nucleus of an atom is equivalent to a minute loop of electric current (Amperian current loop), which behaves as an atomic magnet, called a magnetic dipole moment. Each electron also possesses a rotation about its own axis, known as electron spin; this is again equivalent to a circulating electric current with its own magnetic dipole moment. For an atom with many electrons, the dipole moment resulting from the various orbital and spin dipole moments depends on the arrangement of the electrons within the atom, and measurement of this magnetic dipole moment gives an important clue to atomic structure. Similar but smaller dipole moments occur in nuclei and in subnuclear particles called mesons. These moments are usually measured by means of the Zeeman effect. In the Zeeman effect, an atom or nucleus subjected to a magnetic field has an additional potential (stored) energy associated with the orientation of its magnetic dipole moment in the field, and this changes the size of any quantum of energy which may be emitted as electromagnetic radiation. The frequency of the radiation is correspondingly affected, as well as its state of polarization—that is, the plane of vibration in which it occurs.

A body moving in a straight line has a momentum equal to the product of its velocity and mass; moving in a curved path, the angular momentum is the product of its angular velocity and moment of inertia. According to a simplified quantum theory of the atom, an electron in orbit can have an angular momentum equal only to whole multiples of the unit Planck's constant divided by two times pi ( $h/2\pi$ ). Also, according to quantum theory, only certain orientations of the dipole are possible, the number of them being dependent on the angular momentum of the atom or nucleus. In the Zeeman effect, a line in the optical spectrum of an atom is split into a number of components. The atomic angular momentum can be deduced from the number of components, and the size of the magnetic dipole moment from the separations between the components in a known magnetic field. In terms of frequency such separations lie in the range  $10^6$  to  $10^{11}$  hertz (one hertz is one cycle per second) and are most accurately measured by spectroscopic methods. Such methods are also of especial value in investigating the motion of conduction electrons (electrons free to move through a solid and thus become moving charges forming an electric current) in metals and semiconductors and the interactions of atomic magnetic moments with their surroundings in solids. A process that has become a major tool in the investigation of chemical structure and in chemical analysis, particularly in liquids in which exceptionally high accuracy and sensitivity can be attained, is called nuclear magnetic resonance; it is a technique whereby the small local change in an external magnetic field caused by the motion of the adjacent atomic electrons is detected when a nuclear dipole moment is introduced.

When atoms are chemically combined in molecules or are assembled in regular structures such as solids, they normally become ions (charged atoms or molecules) that have no resultant electronic magnetic dipole moment. Certain so-called transition groups of the periodic table, including the iron group and the rare-earth group, are major exceptions to this rule. Elements and compounds containing ions of these groups are of great technical and scientific importance, particularly because of ferromagnetism, a phenomenon that occurs when the ionic dipole moments are subject to mutual interactions that cause them to be oriented parallel to each other. This spontaneous magnetization is of macroscopic size and enormously greater than can be obtained by the orientation of atomic dipoles by an external magnetic field at ordinary temperatures. Ferromagnetism is used in making permanent magnets, in electromagnetic machinery and the electric power industry, and (to a lesser extent) in the electronics industry.

The Earth possesses a magnetic moment, ascribed to the existence of electric currents set up in its core by the revolution of the planet about its own axis. The magnetic field of the Earth affects the motions of electrons in the electrified region of the atmosphere known as the ionosphere and of charged particles approaching from outside. Magnetic rocks and particular rock formations cause local disturbances of the Earth's field, an effect exploited in geophysical exploration. The residual magnetization acquired by rocks on cooling in the Earth's magnetic field provides a record of this field in past geological time, which indicates that it has reversed its direction several times in the last few million years. On a smaller scale the clay walls of brick and pottery kilns similarly record the Earth's field at the time of the last firing, providing a method of magnetic dating based on known changes in the Earth's field in recent millennia. Around such sites, now buried, local variations in the Earth's magnetic field can be detected and form the basis of an important method of archaeological prospecting.

Many stars possess magnetic fields that affect the frequency and polarization of the light and radio waves emitted by them. In the case of the Sun such effects are used to map local changes in the region of sunspots and other disturbances.

**Magnetism in technology.** In technology, magnetism is employed on a wide-ranging scale, from enormous electromagnets used to lift massive loads to small electro-

magnets

magnets used for the recording of sound and television pictures on magnetic tape. The use of applied magnetic fields for the rapid reversal of the direction of magnetization of magnetic oxides or thin metallic films of iron alloys is being exploited in computer memories. The use of high magnetic fields with specially shaped configurations has been explored as a method of containing the plasma of charged ions at the temperatures of about  $100,000,000^{\circ}\text{C}$  required to produce nuclear power from controlled fusion reactions. For many such applications superconducting magnets may be used. In recent years new materials have provided superconducting compounds able to withstand high current densities without losing their superconducting property. Once established, a current continues to flow through them indefinitely without loss of energy, and a coil carrying such a current acts like a permanent magnet. The cost of refrigerating the material to a temperature well below its superconducting transition temperature (about  $15^{\circ}\text{K}$  or  $-258^{\circ}\text{C}$ ) is less than that of the power dissipated in the finite resistance of the electrical circuit of a conventional electromagnet. The distribution of electrical power over long distances without loss, using underground superconducting cables continuously refrigerated, has been proposed, but there are serious technical problems in avoiding temporary interruptions of the supply through breakdown in the refrigeration and other associated equipment.

#### HISTORY

**First observations and uses.** The mineral magnetite, a magnetic oxide of iron, appears in Greek writings from as early as 800 BC. The mineral, which even in the natural state has a strong attraction for iron, was mined in the Greek province of Magnesia, in Thessaly. According to Lucretius, the Roman author of the long philosophical poem *De rerum natura* in the first century AD, the name magnet derives from the province and its inhabitants. Pliny the Elder, however, ascribes the name to its discoverer, the shepherd Magnes, "the nails of whose shoes and the tip of whose staff stuck fast in a magnetick field while he pastured his flocks."

The first  
magnetic  
compass

The name lodestone, by which the mineral was generally known in English, signifies leading stone and refers to the first application of magnetism, the compass. Some writers believe that the compass was in use in China as early as the 26th century BC; others, that it was introduced to China only in the 13th century AD, its invention being of Italian or Arab origin. The earliest extant European reference is by the Englishman Alexander Neckam (died 1217).

The first known experimental investigation of the lodestone is described in a Latin treatise, dated 1269, by Petrus Peregrinus de Maricourt. By mapping the direction assumed by a small rectangular piece of iron on the surface of a spherical lodestone, he obtained lines that circled the lodestone and intersected at two points in the same way as lines of longitude on the Earth intersect at the poles. By analogy, he called these two points the poles of the magnet.

In England William Gilbert repeated and extended such experiments, assembling all the available knowledge of magnetism in a treatise, *De Magnete*, published in 1600. From its similarity in magnetic behaviour to the spherical lodestone, he recognized that the Earth itself is a magnet. He also discovered that when heated to a bright red heat, lodestone loses its magnetic properties but then regains them on cooling.

**Studies based on classical physics.** In 1785 the French physicist Charles Coulomb, using a torsion balance, established the inverse square law of force (Coulomb's law) between both electric charges and magnetic poles. In each case, like poles repel one another, whereas unlike poles attract one another. From these results, the theory of magnetostatics, the study of steady-state magnetic fields, was developed, using the concept of a magnetic potential analogous to the electric potential. (Magnetic poles were postulated with properties analogous to electric charges.)

The origin of magnetic properties remained a mystery,

but a major step forward occurred in 1820, when a Danish physicist, Hans Christian Ørsted, observed that an electric current flowing in a wire affected a nearby magnet. (The same discovery had been made and reported by Gian Domenico Romagnosi, an Italian jurist, in *Gazetta di Trentino*, August 3, 1802, but was ignored.) Ørsted's discovery started work in many countries. In France, a physicist, François Arago, showed that a current acts like an ordinary magnet, in its ability both to attract iron filings and to induce permanent magnetism in iron needles. André-Marie Ampère, a French physicist, experimentally established quantitative laws of magnetic force between electric currents. He suggested that internal electric currents are responsible for ferromagnetism, and, with Arago, he demonstrated that steel needles become more strongly magnetic inside a coil carrying an electric current. Ampère's suggestion that there are internal circulating currents of molecular size in a metal was developed by Wilhelm Eduard Weber, a German physicist, to explain how a substance may be unmagnetized when the molecular magnets point in random directions. Under the action of an external force they turn to point in the direction of the force; when all point in this direction, the maximum possible degree of magnetization is reached, a phenomenon known as magnetic saturation.

In England, Faraday discovered that under the action of an external magnetic force all substances become magnetic to a greater or smaller degree. He named this force the magnetic field in 1845. He also found that the plane of vibration of polarized light is rotated when the light passes through a medium in a direction parallel to a magnetic field (the Faraday effect). His most celebrated discovery (made in 1831) was electromagnetic induction, in which an electrical voltage is induced in a circuit subjected to a changing magnetic field. Electromagnetic induction was also discovered independently in the United States by Joseph Henry, but it was the publication of the treatise *Experimental Researches in Electricity* by Faraday in 1839–55 that led to his ideas being cast into a mathematical form by the British scientist James Clerk Maxwell (*Treatise on Electricity and Magnetism*, 1873). This great unification of the theory of the two subjects culminated in Maxwell's discovery that his equations predicted electromagnetic phenomena with a wavelike nature; these electromagnetic waves were calculated to travel with a velocity close to (indeed, identical with) that of light. In Germany the experiments of physicist Heinrich Hertz in 1886 verified the existence of electromagnetic waves; the waves that Hertz discovered are now known as radio waves.

Maxwell's theory is the pinnacle of achievement in treating electric and magnetic fields on the macroscopic scale. At the microscopic or molecular level, progress in theory followed the discovery of the electron and the development of the electron theory of matter by a Dutch physicist, Hendrick Antoon Lorentz. A further landmark was the discovery (1896) by his pupil Pieter Zeeman of the splitting of the spectroscopic lines emitted by an atom in an intense magnetic field. Lorentz showed how such a splitting could be attributed to the change in motion of atomic electrons under the action of the magnetic field.

In the same era, the detailed and accurate researches of Pierre Curie showed how induced magnetism in paramagnetic substances (*i.e.*, with dipoles aligned in the direction of a magnetic field) varies with temperature, and that a ferromagnetic substance behaves like a paramagnetic substance above a certain characteristic temperature now known as the Curie temperature. In 1905 the temperature variation of the paramagnetism was explained by French physicist Paul Langevin on the basis of statistical theory, each molecule being assumed to possess a permanent magnetic dipole moment. Two years later another French physicist, Pierre-Ernest Weiss, extended the theory by postulating the existence in ferromagnetics of an internal field due to mutual interactions between the atomic magnets; this causes the magnets spontaneously to assume parallel orientations, giving a macroscopic magnetic moment even in the absence of an external field.

The work  
of Michael  
Faraday

**Studies based on quantum physics.** Classical physics offered no explanation of the origin or size of this internal field, enormously greater than could arise from purely magnetic forces. Even more fundamental, it offered no explanation of the existence of permanent atomic magnetic moments, a problem the solution of which depended on the discovery of a satisfactory model for the structure of the atom. The major advance came with the introduction in 1913 by Niels Bohr, the Danish physicist, of quantization (a restriction to unit quantities) of the angular momentum of electrons moving round the nucleus in the nuclear atom proposed by the physicist Ernest Rutherford in England. This orbital motion of an electron is essentially an Amperian current loop, and quantization of the angular momentum results in quantization of the magnetic moment. In 1921 Wolfgang Pauli of Austria suggested the name Bohr magneton for the fundamental unit of atomic moment, and in 1922 two physicists, Otto Stern and Walther Gerlach, in Germany, demonstrated experimentally the existence of such atomic moments and their spatial quantization, by the deflection of a beam of atoms moving through an inhomogeneous (of nonuniform intensity) magnetic field. A further advance was the suggestion (1921) of United States physicist Arthur Compton that the electron also possesses a spin about its own axis, with a corresponding magnetic moment.

Bohr  
magneton

The remaining discrepancies between theory and experiment disappeared in the mid-1920s after the development of wave mechanics and the new quantum mechanics. The relativistically correct quantum theory of an English physicist, Paul A.M. Dirac (1928), gave a satisfactory explanation of the intrinsic spin and magnetic moment of the electron. He and Werner Heisenberg, a German physicist, showed the existence of the previously unknown exchange forces, electrostatic in origin, that play an important role in determining the structure of atoms with more than one electron and also account for the nature and size of the internal field postulated by Weiss to explain ferromagnetism. The theory of complex atoms and of magnetic effects in solids was rapidly developed thereafter. In 1936 Louis Néel, in France, put forward the idea of antiferromagnetism, and in 1948 the idea of ferrimagnetism, in which neighbouring atomic magnets are aligned in antiparallel directions, the opposing moments being equal in the former case and unequal in the latter. Since 1945 major advances have followed from the experimental study of magnetic solids by means of magnetic resonance and neutron diffraction (rays of neutrons, the fundamental uncharged particles of atomic nuclei, may be diverted from their paths according to the magnetic properties of crystals with which they interact), with corresponding improvements in the detailed theoretical understanding of the properties of such assemblies of atomic magnets.

#### GENERAL PHENOMENA OF SIMPLE MAGNETIC SYSTEMS

Lodestone was the only naturally occurring magnetic material known to the ancients, but a bar of iron could be magnetized by stroking it a number of times in the same direction with a permanent magnet or even by gentle tapping with the bar oriented in a north-south direction. Such magnetization is easily diminished by rough mechanical usage; it can be reduced to zero, or even reversed, in the presence of a stronger magnet. For this reason iron is called a soft magnetic material. Iron alloys such as steel are more difficult to magnetize, but, once produced, the magnetization is also more difficult to remove and will withstand rougher handling. Such materials are known as hard magnetic materials.

With progress in chemical technology it was found that the elements cobalt and nickel and many alloys and compounds are magnetic. Lodestone, the mineral magnetite (formula  $[\text{Fe}_3\text{O}_4]$ ), is one of a number of magnetic oxides. There are many elements and compounds that become strongly magnetic only at low temperatures, but for most technological applications the need is for room-temperature materials. Present-day permanent magnets are made from special alloys or oxides, and the best results are obtained through complex metallurgical and

Perma-  
nent  
magnets  
today

thermal processes that increase their magnetic hardness. There are also in use a number of specially treated alloys that are magnetically much softer than iron.

**Magnetic attraction and repulsion.** Some important properties of a permanent magnet can readily be demonstrated. If such a magnet is suspended or pivoted so that it can rotate about a vertical axis, it is found that one end invariably seeks the magnetic north (the direction of which, except in high latitudes, is near the geographical north) and the other the magnetic south. This well-known property of the magnetic compass is the basis of its use as an aid in navigation.

If iron filings are sprinkled over a magnet, they cling to it in a definite pattern. Each filing becomes a tiny magnet under the influence of the permanent magnet, and the attractive forces involved are those between two magnets. The filings cling most densely near the ends of the magnet, where the magnetic poles are located. Poles always occur in pairs of opposite kind, north and south, and it is not possible to have one without the other. If a magnet is broken, new poles appear near the break in such a way that each piece has two opposite poles.

If two bar magnets are placed close together, they are found either to attract one another or to repel one another. The force of attraction or repulsion is small when the magnets are far apart, and it increases rapidly as the magnets approach one another. Attractive forces appear when poles of opposite sign are close together; repulsive forces are found when poles of the same sign are close together. Briefly, like poles repel and opposite poles attract.

This result gives rise to some semantic confusion in the nomenclature for magnetic poles. The north pole of a compass needle is the pole that points toward (that is, is attracted by) the north magnetic pole of the Earth. It is more accurately known as a north-seeking pole. By analogy with electrical charges, the terms positive and negative magnetic poles may be used rather than north and south poles. These may sometimes be designated by the symbols  $+q_m$  and  $-q_m$ , respectively, in which the subscript  $m$  denotes magnetic. Thus, poles of the same sign repel one another, and poles of the opposite sign attract one another.

The fact that forces act between magnets not in contact poses a philosophical difficulty, that of action at a distance. This difficulty is overcome by the postulates that every magnet is surrounded by a magnetic field and that a magnet placed in a magnetic field is subject to a magnetic force produced by that field. The concept of such a field of force is lent the appearance of reality by scattering iron filings over a smooth surface lying on top of a magnet. Each filing behaves as a minute compass needle, indicating the direction of the field at the point where it lies. The filings are also attracted into positions where the field is strongest, so that regions in which the density of filings is greatest are those of largest field strength—e.g., close to the poles of the magnet.

If a tiny compass needle is suspended near a magnet, the direction it assumes can be marked on a piece of paper. If the needle is moved a little in the direction in which it points, it takes up a slightly different orientation. If this process is repeated continuously, the lines that are traced out begin at one pole of the magnet and terminate at the other pole. Such lines are known as lines of magnetic force and indicate the orientation of the magnetic field in the vicinity of the magnet (Figure 1A). These lines are identical with those indicated by the use of iron filings but may be mapped more precisely with a compass. The magnetic force is greatest where the lines of force crowd most closely together.

The effects of magnetic attraction and repulsion may be ascribed to the properties of the lines of force. A tension is assumed to act along the lines of force (Figure 1B), so as to produce a pull on the poles where the lines of force terminate and a mutual repulsion between adjacent lines where they run parallel to one another, as shown in Figure 1C.

**Magnetic moment.** Bar magnets may be circular, square, or rectangular in cross section without materially altering their properties. If a bar magnet is cut crosswise

of the  
magnetic  
field

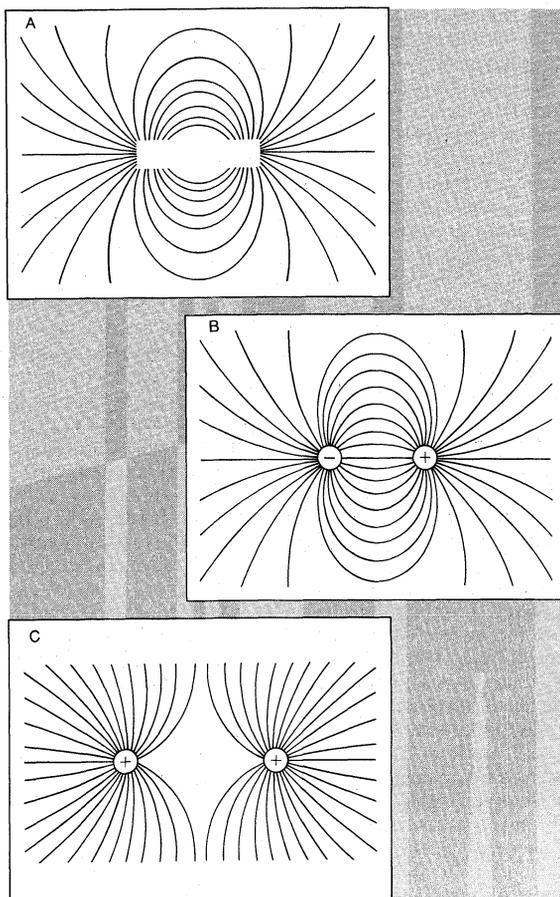

Figure 1: *Magnetic lines of force.* (A) Lines of force of a bar magnet. (B) The attraction between two unlike magnetic charges can be attributed to tension along the lines of force. (C) The repulsion between like charges is attributed to repulsion between adjacent lines of force.

Intensity  
of  
magneti-  
zation

into two parts, the magnetic force exerted at large distances is proportional to the length of each portion; and if the magnet is divided longitudinally, the force exerted by each portion is proportional to the cross section of each portion. This suggests that the material possesses a fundamental property per unit volume, known as the intensity of magnetization or, more briefly, as the magnetization, denoted by the symbol  $M$ , a vector. (Vectors symbolically represent the direction and size of quantities and are often represented in drawings by arrows. Vector quantities are printed in boldface in this article.) The whole magnet has a magnetic moment  $m$  equal to the intensity of magnetization times the volume of the magnet ( $M \times V$ ). The pole strength (the size of the magnetic charge,  $q_m$ ) is equal to the magnetic moment ( $m$ ) divided by the length ( $l$ ), and the intensity of magnetization ( $M$ ) is equal to the pole strength divided by the area ( $A$ ) of the cross section. These relations are expressed in the equation

$$m = M \times (l \times A) = M \times V = q_m \times l.$$

On the right-hand side of the equation, the length is represented as a vector  $l$  to show that the magnetic moment acts along that direction; the pole strength  $q_m$  is not a directed quantity.

**The inverse-square law.** *Force between two magnetic poles.* The force acting between two magnetic poles separated from each other is proportional to the magnitude of each of the two poles, divided by the square of the distance between them. The force is directed along the line joining the poles; it is a force of repulsion if the poles are of the same sign (*i.e.*, both north-seeking poles or both south-seeking) and a force of attraction if they are of opposite sign (one north-seeking, the other south-seeking). In SI (International System of Units, see below) units, the force ( $F$ ) is measured in newtons (a

force of one newton accelerates a mass of one kilogram one metre per second per second), the distance of separation ( $r$ ) in metres, and each magnetic pole ( $q_m$  and  $q'_m$ ) in ampere-metres. Expressed as an equation, the law of force becomes

$$F = \frac{\mu_0 q_m q'_m}{4\pi r^2},$$

in which  $\mu_0/4\pi$  is a constant with the magnitude  $10^{-7}$  newton—(ampere)<sup>-2</sup>.

Because the force on a pole  $q'_m$  is proportional to its magnitude  $q'_m$ , it is convenient to define a magnetic quantity  $B$  by the relation

$$F = q'_m B.$$

Here  $B$  is the force on unit magnetic pole; it is a vector the direction of which is that of the force  $F$  and its properties are like those of any mechanical force vector.

From the equation for the law of force (above) between two poles, it follows that at a distance  $r$  from a magnetic pole  $q_m$  the magnitude ( $B$ ) of the magnetic quantity  $B$  is equal to the constant of proportionality mentioned above times the magnetic charge ( $q_m$ ) divided by the distance squared, or

$$B = \frac{\mu_0 q_m}{4\pi r^2}.$$

**Gauss's theorem.** The magnetic quantity  $B$  is a vector that points away from the pole if pole  $q_m$  is positive and toward it if it is negative. The lines of force, or lines of the magnetic quantity  $B$ , from a single pole  $q_m$  spread out radially. If a sphere of radius  $r$  is drawn with its centre at the pole, the number of lines of force crossing the sphere is independent of its radius. This number is known as the magnetic flux and is denoted by the symbol  $N$ , which is simply proportional to the size of the pole  $q_m$ —*i.e.*,  $N = \mu_0 q_m$ . The lines of force terminate only on a magnetic pole, and the inverse-square law of force is represented geometrically by the fact that the number of lines crossing unit area of the sphere diminishes with the square of its radius. The unit of magnetic flux is known as the weber, and the value of the magnetic quantity  $B$  is given by the flux per unit area or the flux density. Its unit is the weber per square metre, or tesla.

More precisely,  $B$ , the force on unit magnetic pole, is defined as the flux per unit area normal (perpendicular) to the direction of  $B$ . Any small area  $dS$  making an angle  $\theta$  with the direction of  $B$ , by the laws of trigonometry, will have an area normal to  $B$  when multiplied by the cosine of  $\theta$ —*i.e.*,  $dS \cos \theta$ . An infinitesimal amount of flux, designated as  $dN$ , through the area will therefore be the product of  $B$  and the elemental normal area, or  $dN = (B \cos \theta) dS$ . With this definition of  $dN$ , the total flux ( $N$ ) through any closed surface is defined by integrating  $dN$ , *i.e.*,  $N = \int dN$ ; that is to say,  $N = \int (B \cos \theta) dS$ , and the relation stated above,  $N = \mu_0 q_m$ , holds for any closed surface surrounding the pole  $q_m$ . If more than one pole is enclosed,  $N = \mu_0 \Sigma q_m$ , in which  $\Sigma q_m$  symbolizes the net total pole strength enclosed, allowing for the signs of the various poles. This relation is due to a theorem of the 18th-century German mathematician Carl Friedrich Gauss: for a magnet with poles  $+q_m$  and  $-q_m$ , the total flux through a surface enclosing the magnet is zero. This does not imply that the value of  $B$  is everywhere zero; it implies only that in some places it acts outward through the surface and in others inward, in such a way that the total flux through the surface is zero.

**Magnetic potential.** In mechanics it is often more convenient to work in terms of energy (a scalar quantity having magnitude but no direction, like magnetic charge) than in terms of force (a vector quantity); and the same is true in magnetism. When a magnetic pole is moved, work must be done against any force acting on it if it is moved in the direction opposite to the force, and, conversely, work will be done (or can be extracted) by the magnetic pole when it moves in the force direction.

Thus, no work is done in moving a magnetic pole around a closed path in a magnetic field. It follows that

Magnetic  
flux

Work  
required  
to move  
a magnetic  
pole

the work done in moving a pole  $q'_m$  from a point  $A$  to a point  $B$  is independent of the route followed. Otherwise  $q'_m$  could be returned to  $A$  by another route on which more work is extracted than was expended in the initial movement to  $A$ . The net effect would be that work could be extracted by movement around the complete path without any other change in the system, giving the possibility of a perpetual motion machine that is contrary to the laws of mechanics.

This result makes it possible to define a useful quantity, the magnetic potential. If unit pole is brought from an infinite distance to a distance  $r$  from a pole  $q_m$ , the work done is equal to a constant times the pole strength divided by the distance, or  $(\mu_0/4\pi)(q_m/r)$ , and is independent of the route taken. The magnetic potential ( $\phi$ ) is defined as the quotient, pole strength divided by distance,  $\phi = q_m/r$ ; and the product of a constant times the magnetic potential,  $(\mu_0/4\pi)\phi$ , is the quantity of work that could be extracted by letting unit pole move from the point at  $r$  to infinity.

**Magnets and magnetic forces.** If a magnet consisting of two separated magnetic poles,  $+q_m$  and  $-q_m$ , is placed in a uniform flux density  $B$ , equal and opposite forces  $+q_mB$  and  $-q_mB$  act on the two poles, parallel and antiparallel to  $B$ . No net translation force is exerted on the magnet as a whole, but there is a torque or couple tending to turn the magnet about its centre point. The equilibrium position of the magnet is parallel to the flux density  $B$ , and the mechanical couple is maximum when it is at right angles to the flux density.

If the magnet is pivoted and free to turn about its centre, like a compass needle, it will oscillate about the direction of  $B$ . Measurement of the period for a complete oscillation of a small magnet is used to compare the magnitudes of different flux densities  $B$ . The device is known as an oscillation magnetometer.

Transla-  
tional force

If the magnet is in a nonuniform flux density, the forces acting on the two poles are not equal and opposite, and there will be a net translational force on the magnet. The attraction of a permanent magnet for iron filings arises from this translational force. Each filing acquires an induced magnetic moment parallel to  $B$  and is therefore attracted toward the regions where  $B$  is largest, nearest the poles of the magnet. The magnitude of  $B$ , due to the magnet, may be calculated in a number of ways; *e.g.*, by making use of the potential  $\phi$  at an arbitrary point. It may conveniently be divided into two components at right angles to each other, called the angular component ( $B_\theta$ ) and the radial component ( $B_r$ ).

**The magnetic field of the Earth.** As was first explicitly realized in the year 1600 by William Gilbert, the magnetic flux density at the surface of the Earth (and also outside the Earth) is very nearly that which would be created by a large magnet at the centre of the Earth, directed along a diameter joining the north and south magnetic poles. The magnetic equator is a great circle round the Earth equidistant from the two magnetic poles, and the magnetic latitude ( $\lambda$ ) is measured from the magnetic equator in the same way as the geographical latitude is measured from the geographical equator.

The direction of the component of the magnet flux density  $B_\theta$  is along the great circle from the south to the north magnetic pole passing through the point in question, so that a small magnet pivoted so as to turn in a horizontal plane will point toward magnetic north. This is the principle of the magnetic compass, the most important technological application of magnetism over many centuries.

The vertical component  $B_r$  of the Earth's field is zero at the magnetic equator ( $\lambda = 0^\circ$ ) and a maximum at the magnetic poles ( $\lambda = 90^\circ$ ). If a small magnet is pivoted about a horizontal axis so that it is free to rotate in a vertical plane containing the magnetic poles (*i.e.*, parallel to a line of magnetic longitude), it will set at an angle to the horizontal known as the angle of dip or the magnetic inclination. This direction is that of the resultant magnetic field of the Earth at the point on its surface. The value of  $B$  is just twice as great at the poles as at the equator. At the equator the angle of dip is zero, and  $B$  is entirely horizontal, whereas at the poles the field is entirely verti-

cal. The angle of dip is then  $90^\circ$ , and the needle of a dip circle points directly up and down, a result used to locate the exact positions of the magnetic poles.

Short-term variations in the Earth's magnetic field are mostly ascribed to electrical currents in the ionosphere, but there are also long-term variations, in both the size of the field and its direction and in the location of the magnetic poles. In recent decades the north magnetic pole has been located in the Arctic islands north of Canada, and the south pole in Adélie Coast, Antarctica. The angle at which a magnetic compass sets away from geographical north is known as the magnetic variation or declination; the declination is small near the equator but can be extremely large in high latitudes. In Europe the declination has been west of north for about 300 years; in London it reached a maximum of  $24^\circ$  west in about 1800, but in the 16th century it was east of north. Because of the variation in the declination over the surface of the Earth, the magnetic compass is being superseded for navigation by the gyroscopic compass, which indicates the true geographical north (see EARTH, MAGNETIC FIELD OF).

Magnetic  
declination

**Magnetic units.** The strength of two magnets may be compared by measuring the forces they exert on a third magnet, but this does not give a unit in terms of which a quantity such as magnetic pole strength ( $q_m$ ) can be expressed. Years ago this difficulty was circumvented by using the inverse-square law of force, stated above, setting the quantity  $(\mu_0/4\pi)$  at unity, and defining the unit of  $q_m$  as that magnetic pole which, placed at unit distance from an identical pole, repels it with unit force. In the centimetre-gram-second (or cgs) system, the unit of distance is the centimetre and that of unit force the dyne, so that two unit magnetic poles one centimetre apart repel each other with a force of one dyne. A system of magnetic units was then constructed for quantities such as flux, flux density, magnetic moment, etc., by combining the definition of unit magnetic pole with the mechanical units of the cgs system, using the relations between the various quantities as expressed in the laws of magnetism. This system is known as the centimetre-gram-second electromagnetic system of units.

A parallel system of electrical units, also using cgs units, grew up from the inverse-square law for electrical charges, defining unit electrical charge as that charge which repels an identical charge at a distance of one centimetre with a force of one dyne. The system, known as the cgs electrostatic system of units, is not independent of the cgs system of magnetic units since it may be related to the electromagnetic system through the relations (see below) that determine the magnetic forces generated by electric currents. In the electrostatic system, unit electric current arises from a flow of one unit of electric charge per second. The magnetic effect of this current can be related to the force it exerts on unit magnetic pole, and, by this means, an electromagnetic unit of electric current can be defined. Following the work of Maxwell, which showed that light waves are a form of electromagnetic radiation, it became clear that the ratios of any unit expressed in the two systems is equal to a constant  $c$ , or to  $c^2$ , in which the constant  $c$ , equal to  $2.998 \times 10^{10}$  centimetres, is the velocity of electromagnetic waves in vacuum. For example, the electromagnetic unit of current is greater than the electrostatic unit by a factor  $c$ . Since this factor  $c$  has the dimensions of velocity (all physical quantities can be expressed in various combinations of length, mass, and time, called dimensions), electric and magnetic units in the two systems do not have the same dimensions except for purely mechanical quantities, such as length, time, force, energy, etc.

In 1960 it was agreed internationally that a single system of units, the International System of Units (SI), should be adopted. The basic mechanical units are the metre for length, the second for time, and the kilogram for mass, all usually referred to as mks units. Other mechanical units are built up by the standard relations. For example, one unit of force (the newton =  $10^5$  dynes) will accelerate a mass of one kilogram at the rate of one metre per second per second. The unit of energy (the joule =  $10^7$  ergs) is the work done in moving a distance of one

Measurement in mksa units

metre against a force of one newton; the unit of power (one joule per second) is the same as the watt, the practical unit of electrical power. By the addition of one electrical unit, chosen to be the unit of electric current (the ampere), a complete single set of electric and magnetic units based on the mks units has been developed: the metre-kilogram-second-ampere system (mksa).

The relations between electric current and magnetic force (see below) give the ampere-metre as the unit of magnetic pole strength ( $q_m$ ). Because the unit of force is the newton, it follows from the inverse-square law that the quantity  $(\mu_0/4\pi)$  cited above is fixed and is a dimensional quantity, equal to  $10^{-7}$  newton—(ampere)<sup>-2</sup>. Unit magnetic flux density  $B$  exerts a force of one newton on a magnetic pole of one ampere-metre. This gives a unit for the flux density of one newton—(ampere-metre)<sup>-1</sup>; but an equivalent unit generally employed is related to the unit (the weber, after Wilhelm Eduard Weber, a German physicist) of magnetic flux  $N$ . This unit for the magnetic flux density  $B$  is equal to a flux of one weber per square metre and is called the tesla (named in honour of the United States inventor, Nikola Tesla). A set of mksa units for magnetic quantities is given in Table 1. Two

Table 1: Some Electric and Magnetic Quantities

quantity	symbol	dimensions	mksa unit
Electric current	$I$	current	ampere
Electric charge	$Q$	current $\times$ time	coulomb
Electric voltage	$V$	power $\div$ current	volt
Electric resistance	$R$	voltage $\div$ current	ohm
Magnetic pole strength	$q_m$	current $\times$ length	ampere-metre

useful relations between the metre-kilogram-second-ampere and centimetre-gram-second electromagnetic systems are that the ampere is exactly one-tenth of the cgs electromagnetic unit of current, and for magnetic flux density the tesla is exactly  $10^4$  gauss, in which the gauss is the cgs electromagnetic unit.

## II. Magnetic effects of steady electrical currents

Following the discovery in 1820 by Ørsted of the effect of an electric current on a nearby compass needle, the experiments of Ampère and others elucidated the nature of the forces between circuits carrying electric currents. They found that two long parallel wires carrying currents in the same direction attract one another, but if one current is reversed in direction the wires repel one another. Experiments on small coils showed that at large distances, not only were the forces between two such coils similar to those between two small bar magnets but also one coil could be replaced by a bar magnet of suitable size without changing the forces. The magnetic moment of this equivalent magnet was determined by the dimensions of the coil, its number of turns, and the current flowing round it.

The law governing the forces between such circuits is more complicated in its mathematical formulation than the inverse-square law between two point magnetic charges. It is simpler and more useful to approach the subject in two steps, giving, first, the formula for the magnetic flux density associated with an element of a circuit carrying a current and, second, the force exerted on such an element by a magnetic flux density due to another source.

### MAGNETIC FIELDS

**Magnetic flux density.** The magnetic flux density at a point a distance  $r$  from an element of wire carrying a

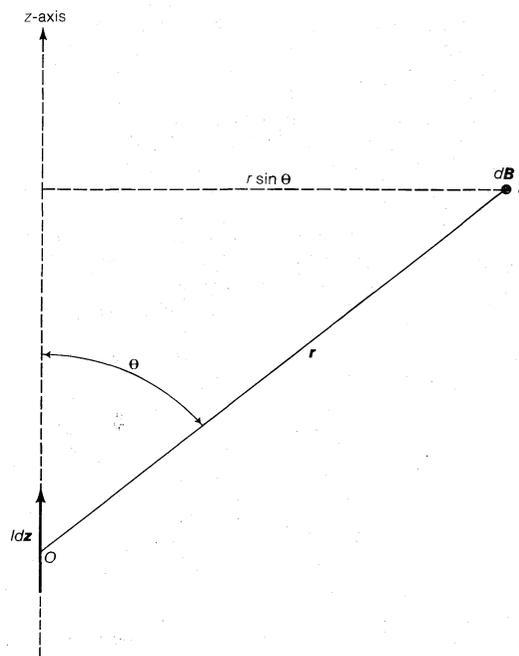

Figure 2: The law of Biot and Savart. Flux density  $dB$  is directed into page (see text).

current  $I$  is given by the law of Biot and Savart (after two French physicists, Jean-Baptiste Biot and Félix Savart). Figure 2 shows an element of wire  $dz$ , parallel to the  $z$ -axis, situated at the point  $O$ . At the point  $P$ , the element of flux density (designated as  $dB$ ) is perpendicular to both the element  $dz$  and the vector  $r$  (called radius vector) joining  $O$  to  $P$ ; it is directed (Figure 2) downward into the plane of the page. In magnitude  $dB$  is proportional to the current  $I$  and to the length  $dz$ , and it varies as the sine of the angle ( $\theta$ ) between the element of wire  $dz$  and radius vector  $r$ ; it is inversely proportional to the square of the distance  $r$ . Mathematically this is expressed:

$$dB = \frac{\mu_0 I \sin \theta}{4\pi r^2} dz.$$

For the more general case of an element of wire not necessarily parallel to the  $z$ -axis, but represented by the vector  $ds$  at the origin  $O$  with components  $(dx, dy, dz)$ , the flux density at a point  $P$  can be expressed in the vector product form of the Biot and Savart law as proportional to the current divided by the distance cubed, times the vector product of the element  $ds$  and the radius vector.

$$dB = \frac{\mu_0 I}{4\pi r^3} [ds \times r].$$

The vector product of two vectors is a vector mutually perpendicular to each; in this example, if  $ds$  is along the  $z$ -axis, and  $r$  is along the  $z$ -axis, then  $dH$  will be along the  $y$ -axis. In practice a current  $I$  cannot flow in an isolated element of wire, but the formula of Biot and Savart can be integrated along the wire to find the flux density of a complete circuit. For an infinitely long straight wire parallel to the  $z$ -axis, the integrated flux density is proportional to the current  $I$  and inversely proportional to the distance  $a$  from the wire—i.e.,  $B = \mu_0 I / 2\pi a$ . At any point  $P$  it is perpendicular both to the wire and to the line joining  $P$  to the nearest point on the wire; that is, the lines of constant flux density  $B$  are closed circles centred on the wire.

**Magnetic force on a current.** In the presence of a flux density  $B_y$  directed along the  $y$ -axis, a current  $I$  flowing in an element of wire  $dx$  parallel to the  $x$ -axis experiences a force  $dF_x$  parallel to the  $z$ -axis given by the product of the current, the element length  $dx$ , and the  $y$  component of the flux density, or  $dF_x = IdxB_y$ . The direction of the force is given by the so-called right-hand rule: if a right-handed screw is turned from the  $x$ -axis (the direction of the current element) toward the  $y$ -axis (the direction of  $B_y$ ), the force is in the direction in which the screw advances (the  $z$ -axis). More generally, if the current  $I$

Law of Biot and Savart

flows in an element of wire  $ds$  (not necessarily lying parallel to the  $z$ -axis) with components  $(dx, dy, dz)$  and the flux density  $\mathbf{B}$  has components  $(B_x, B_y, B_z)$ , the force ( $dF$ ) on the element may be expressed as the current times the vector product of the element  $ds$  and flux density, or  $dF = I(ds \times \mathbf{B})$ . The direction of the force is again that in which a right-handed screw advances when turned from a direction parallel to the element  $ds$  of wire to the direction of  $\mathbf{B}$ .

Forces acting between two current circuits

This expression for the force may be combined with the law of Biot and Savart to find the forces acting between two current circuits. A simple illustration is given by the example of two infinitely long wires parallel to each other and to the  $z$ -axis, separated by a distance  $a$ , carrying currents  $I_1$  and  $I_2$ , with the shortest line joining the two wires lying along the  $x$ -axis, and with the first wire carrying current  $I_1$ , and the second wire current  $I_2$ . At any position on the wire carrying the current  $I_2$  the magnetic flux density due to the first wire has the sole component ( $B_y$ ). It is equal to a constant times the current in the first wire divided by the distance of separation and is directed into the surface of the page—i.e.,  $B_y = \mu_0 I_1 / 2\pi a$ . This produces a force ( $dF_x$ ) on an element of length  $dz_2$  of the second wire equal to minus the current in the second wire times the element length of the second wire times the magnetic flux due to the first wire, or  $dF_x = -I_2 dz_2 B_y$ . Substituting the value of the magnetic flux  $B_y$  from above, the force on the element  $dz_2$  is equal to minus a constant times twice the product of the two currents divided by the separation times the element length; i.e.,  $dF_x = -(\mu_0/4\pi)(2I_1 I_2/a) dz_2$ . This equation shows that there is a force per unit length on the right-hand wire equal to minus  $(\mu_0/4\pi)(2I_1 I_2/a)$ , the negative sign meaning that the force acts towards the first wire provided that the two currents  $I_1$  and  $I_2$  have the same sign; that is, that they flow in the same direction along the two wires. A similar calculation shows that the first wire  $I_1$  experiences an identical force per unit length, attracting it towards the second wire. If the two currents flow in opposite directions, the forces on the wires are forces of repulsion. Thus the forces between parallel currents differ from those between magnetic poles: like currents attract one another, but like poles repel one another.

The force between two such currents provides a method of defining the unit of current by reference to the mechanical unit of force. In SI units (mksa) the constant  $(\mu_0/4\pi)$  is equal to  $10^{-7}$  henry per metre, and two parallel wires each carrying one ampere of current at a distance one metre apart attract one another with a force of  $2 \times 10^{-7}$  newton per metre length of wire. The constant  $(\mu_0/4\pi)$  is in fact chosen to make the unit of current identical with the absolute ampere, once defined as precisely one-tenth of the cgs electromagnetic unit of current.

**Effect of a magnetic medium.** The results given above apply when the current-carrying wires are in vacuum, and a modification is needed when a magnetizable medium is present. The force on a current element  $I ds$  in a field  $\mathbf{B}$  is still given by the equation  $dF = I [ds \times \mathbf{B}]$ , but the flux density produced by a current is changed by the presence of a magnetic medium. There are now two contributions: (1) a direct contribution from the current, as given above by the law of Biot and Savart; (2) a contribution from the magnetization of the medium that equals the product of a constant ( $\mu_0$ ) and the density of magnetization ( $\mathbf{M}$ ) or magnetic moment per unit volume of the medium; i.e.,  $\mu_0 \mathbf{M}$ .

The total flux density  $\mathbf{B}$  is the sum of these two contributions. It follows that from the current alone the contribution is  $\mathbf{B} = \mu_0 \mathbf{M}$ , a quantity denoted by the new symbol  $\mu_0 \mathbf{H}$ , in which the vector  $\mathbf{H}$  is known as the magnetic field; that is,  $\mu_0 \mathbf{H} = \mathbf{B} - \mu_0 \mathbf{M}$ . On this basis the law of Biot and Savart is rewritten as  $d\mathbf{H} = (I/4\pi r^3) [ds \times \mathbf{r}]$ , in which, as before,  $r$  is the radius vector drawn from the current element  $I ds$  to the point at which magnetic field infinitesimal  $d\mathbf{H}$  is measured. This equation is correct in the presence of a magnetizable medium; the previous one is correct only in the absence of such a medium.

In many magnetic media the magnetization  $\mathbf{M}$  is parallel to and proportional to the product of the field  $\mathbf{H}$  and a

quantity,  $\chi$ , that is known as the magnetic susceptibility:  $\mathbf{M} = \chi \mathbf{H}$ . This equation may now be substituted into the one for the total flux density cited above; i.e.,

$$\mathbf{B} = \mu_0(\mathbf{H} + \mathbf{M}) = \mu_0(\mathbf{H} + \chi \mathbf{H}) = \mu_0 \mathbf{H}(1 + \chi).$$

Thus, calling the terms  $(1 + \chi)$  by the symbol  $\mu$ , known as the magnetic permeability, the total flux density is equal to the product of the two constants and the magnetic field; i.e.,  $\mathbf{B} = \mu \mu_0 \mathbf{H}$ . In the absence of magnetic media, the magnetic susceptibility is zero and the magnetic permeability is one, and hence the total flux density can be simply written as  $\mathbf{B} = \mu_0 \mathbf{H}$ ; the quantity  $\mu_0$  is sometimes called the permeability of free space, and  $\mu$  is then known as the relative permeability. The quantities  $\chi$  and  $\mu$  are both pure numbers, but  $\mu_0$  is a dimensional quantity, as discussed previously.

In the presence of a magnetic medium, the value of  $d\mathbf{B}$  corresponding to the law of Biot and Savart is greater by a factor  $\mu$  than it would be in vacuum, and the flux density  $\mathbf{B}$  of any circuit is increased by the same factor. Because the force on a second circuit carrying a current is determined by  $\mathbf{B}$ , it follows that the forces between two such circuits are increased by a factor  $\mu$  through the presence of the magnetizable medium. For air,  $\mu$  differs from unity by about one part in 1,000,000; so that a correction is needed only for the most accurate experiments. On the other hand, in materials such as soft iron,  $\mu$  can be large (as much as 10,000): this is extremely important in the phenomenon of electromagnetic induction (see below), in which the magnetic flux through a circuit is involved.

**Magnetomotive force.** The modified law of Biot and Savart given above may be used to calculate the magnetic field  $\mathbf{H}$  around an infinite straight wire carrying a current  $I$ , in the same way as above. At a distance  $a$  from the wire, the magnitude of the field  $H$  is  $(I/2\pi a)$  and, again, the lines of constant field are circles around the wire as centre (more accurately stated, the surfaces of constant  $H$  are circular cylinders having a common axis, the wire). The integral of  $H$  around such a circle has the value  $(2\pi a)H = I$ , a result that is independent of the radius of the circle. More generally, this result can be expressed as: the integral of the scalar product of magnetic field and element of path  $ds$  is equal to the current enclosed by the path; i.e.,  $\oint \mathbf{H} \cdot d\mathbf{s} = I$ , whatever closed path of integration is taken, a result known as Ampère's law

Magnetic susceptibility

Ampère's law

The integral  $\oint \mathbf{H} \cdot d\mathbf{s}$  around a closed path is known as the magnetomotive force. It differs from the magnetic potential  $\phi$  (see above) in that it is not a single-valued function of position, but increases by an amount  $I$  each time a complete path is made around the wire carrying the current  $I$ . If the path does not link (enclose) the current, then the integral  $\oint \mathbf{H} \cdot d\mathbf{s}$  equals zero.

In general, this result can be written as: the integral, taken over a closed path, of the scalar product of magnetic field and path element is equal to the sum of all currents threading (enclosed by) the path round which the integral is taken, currents flowing in the reverse sense being counted as negative. In equation form  $\oint \mathbf{H} \cdot d\mathbf{s} = \sum n I_n$ . The importance of this result is that it is independent of the presence of a magnetizable medium.

#### MAGNETIC MOMENT OF A CURRENT LOOP

**Equivalent magnet.** The size and direction of the magnetic field  $\mathbf{H}$  set up by a system of wires or of coils carrying electric currents may be calculated from the law of Biot and Savart.

It may be shown as a general rule that a small plane coil of  $n$  turns and of area  $A$ , carrying a current  $I$ , produces the same magnetic field at distances large compared with the dimensions of the coil as a magnet of moment  $(nIA)$ . The equivalent magnet is directed normal to the plane of the coil, its positive pole being on that side of the coil to which a right-handed screw would advance if rotated in the same sense as that of the current flow.

The equivalence may be completed by considering the forces on a loop or flat coil of wire carrying a current  $I$  in the presence of a magnetic flux density  $\mathbf{B}$ . It is found that the forces acting on the coil are equal and opposite and

there is no net translational force on the coil, but they do form a couple or torque, and this torque is such that the plane of the coil tends to assume a position at right angles to the direction of magnetic flux. The torque is identical to that on a magnet directed perpendicular to the plane of the coil, of moment  $IA$  (or  $nIA$  for a coil of  $n$  turns),  $A$  being the area of the coil.

Although the similarity between the inverse-square law of force for magnetic poles and the corresponding law for electrical charges might seem to suggest that there are two kinds of magnetic poles, there is a fundamental difference. Electrical charges, plus and minus, can be separated from one another, and exist independently. On the other hand a magnet broken in two will become two magnets (called magnetic dipoles), each with its own positive and negative poles, and the two magnetic poles are equal and inseparable. This result, together with the fact that a current loop behaves as a magnet, leads to the conclusion that there are no real magnetic poles, and no such pole has ever been isolated. Instead, only magnetic dipoles exist, and magnets consist of assemblies of such dipoles. Such dipoles are of atomic size, and arise from loops of current set up by the circulation of electronic charges within the atom. Thus the source of all magnetism lies in electric currents, macroscopic or microscopic.

Electric current as the source of all magnetism

An immediate consequence of this conclusion is that the lines of magnetic flux density  $B$  are everywhere continuous, since they terminate only on nonexistent true magnetic poles. From Gauss's theorem (see above) it follows also that the net flux of  $B$  through any closed surface is zero. In a vacuum, in which the magnetic field  $H = B/\mu_0$ , the same is true of the lines of  $H$  (provided no electric currents flow), but their behaviour is different at the surface of a magnetic medium. Here the lines of  $B$  are continuous, but the lines of  $H$  terminate on the apparent magnetic charges at the surface. At such a surface the components of  $B$  normal to the surface are the same inside and outside the medium, but the normal components of  $H$  are  $(B/\mu_0)$  just outside and  $(B/\mu_0) - M$  just inside. The change in the normal component of  $H$  is just equal to the apparent pole strength per unit area of the surface, which is equal to  $M$ , the density of magnetization of the magnetic medium. The components of  $H$  tangential to the surface are the same inside and outside.

**Magnetic vector potential.** The concept of magnetic vector potential is frequently used in mathematical derivations of magnetic fields caused by steady and time-varying electric currents. The mathematical form of the vector potential is more simple than the flux density  $B$  expressed in the Biot-Savart law. Although the vector potential will not be discussed further, it should be stated here that the magnetic vector potential and the magnetic flux density are related, but not in a simple way.

#### THE SOLENOID AND ITS FIELD

Although permanent magnets are convenient for many applications, they suffer from two serious disadvantages; the flux density  $B$  cannot easily be adjusted in size (or switched off), and its maximum value is limited to that of the material of the magnet. In contrast, the flux density produced by an electric current is readily adjusted by controlling the current, and much larger values can be attained if sufficient electrical power is available (see also MAGNETS and ELECTROMAGNETS).

A fairly uniform flux density of moderate size is readily produced by a solenoid, a coil of wire uniformly wound round a circular cylinder. For a solenoid of infinite length, the magnetic field is uniform inside the solenoid and is directed along the axis, being equal to the total number of turns ( $n$ ) and the current ( $I$ ) per unit length of the cylinder. For a solenoid of finite length, the magnetic field is not quite uniform, but the uniformity near the centre can be improved by adding extra turns at each end. In modern designs, specially shaped conductors are used instead of wires; at high current densities, flux density values over ten tesla (100,000 gauss) can be obtained, but the power consumption exceeds one megawatt ( $10^6$  watts) if high homogeneity, or uniformity, over a large volume such as 500 cubic centimetres is required. The

Flux densities of modern magnets

development of special alloys that retain their superconducting property even in high fields has greatly reduced the operating costs of such solenoids, a factor which generally outweighs the disadvantage of continuous refrigeration to liquid helium temperatures.

### III. The motion of charged particles in magnetic and electric fields

The motion of electrical charges under the action of electric and magnetic forces is a subject of wide-ranging importance. It forms the basis of many devices developed to measure the charge, mass, and velocity of atomic particles, or to accelerate them to high energies for use as atomic projectiles. Details of atomic and nuclear structure and the magnetic fields of stars are revealed by study of their spectroscopic lines in emission or absorption. Charged particles from the Sun or from space are deflected as they enter the magnetic field of the Earth. The motion of electrons in the ionosphere (region of the upper atmosphere) profoundly influences the transmission of radio waves. Electronic devices depend on control of the movements of electrons in a vacuum tube or in a semiconducting solid.

The primary atomic particles are the electron, with a negative electric charge of  $-1.602 \times 10^{-19}$  coulomb, and a mass (at rest) of  $9.109 \times 10^{-31}$  kilogram; the proton, with a positive electric charge numerically equal to that of the electron, but a mass 1,836 times greater; and the neutron, with no electric charge and a mass almost equal to that of the proton. The nucleus of an atom of atomic number  $Z$  contains  $Z$  protons and  $(A - Z)$  neutrons, its mass ( $A$ ) being close to  $A$  times that of the proton. The proton and neutron (and also the electron) have radii of about  $10^{-15}$  metre, and the size of the nucleus is only a few times larger. A neutral atom contains  $Z$  electrons, at varying distances from the nucleus up to about  $10^{-10}$  metre, which is the typical size of an atom. Ions are negatively or positively charged particles formed by the addition or removal of some of these electrons, and their charge is equal to, or is a simple multiple of, that of the electron. Electrons and nuclei may be considered as point electric charges in their interaction with external fields; for many purposes this is true also of atomic ions. The electron, proton, and neutron each possess a magnetic dipole moment; so also do many nuclei, atoms, and ions.

#### THE FORCE ON A MOVING CHARGE

A flow of electric current arises from the movement of electrical charge. The current  $I$  is measured by the amount of charge passing any given point in unit time; if an element of charge ( $dq$ ) passes in a time  $dt$ , the instantaneous value of the current is a differential expression:  $I = dq/dt$ . If the charge  $dq$  has velocity  $v$ , it moves a distance  $ds$  in time  $dt$ , that is,  $v = ds/dt$ . Multiplying both sides of the former equation by  $ds$ , the current may thus be written in the form  $I ds = v dq$ , in which  $ds$  and  $v$  are vectors. This relation makes it possible to translate equations applicable to current elements into corresponding equation for moving charges. The force  $dF$  on a current element  $I ds$  in a flux density  $B$  was given in the section above on the magnetic force on a current as the vector product  $dF = I [ds \times B]$ , and hence substituting for  $I ds$  its equivalent, the force on the charge  $dq$  is  $dF = dq [v \times B]$ . For a charge  $q$  having dimensions so small that  $B$  is uniform over the volume occupied by the charge, this equation becomes: force equals charge times vector product of velocity and flux density; i.e.,  $F = q [v \times B]$ .

The law of Biot and Savart for the magnetic field, namely,  $dH = (I/4\pi r^3) [ds \times r]$  due to a current element  $I ds$ , may be similarly transformed to find the field of a moving charge, giving the equation that the magnetic field is equal to an elemental charge times the vector product of velocity and radius vector divided by the distance cubed; i.e.,  $dH = (dq/4\pi r^3) [v \times r]$ . For an elemental charge  $dq$  moving in the plane of the page (Figure 3), the field  $dH$  at any point in the page is normal to the vector representing the velocity and to the radius vector drawn from the charge to the point. In Figure 3, the field  $dH$  is normal both to  $v$  and to  $r$ , and is directed downwards into the

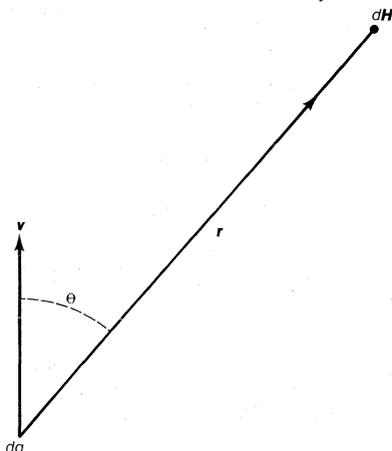

Figure 3: Magnetic field associated with a moving charge. Charge  $dq$  is moving with velocity  $v$  in the plane of the page, and the magnetic field  $dH$  at any arbitrary distance  $r$  is directed into the page.

page; its size is directly proportional to the charge, the velocity, and the sine of the angle ( $\theta$ ) between the two vectors, and inversely proportional to the square of the distance between the point and the charge; i.e.,  $dH = dq v \sin \theta / (4\pi r^2)$ .

Two electric charges moving parallel to one another experience a magnetic force of attraction, like two parallel currents, but the magnetic force is usually small compared with the electrostatic force of repulsion between them. For two separated electric charges moving with velocity  $v$ , the ratio of the magnetic to the electric force is equal to the ratio of the square of the charge velocity to the square of the velocity of light, or  $v^2/c^2$ . Thus the magnetic forces are relatively unimportant until the velocities approach that of light. For currents flowing in wires the situation is quite different because the currents may be large (one ampere is equivalent to  $6 \times 10^{18}$  electrons passing per second), whereas the electrostatic forces are absent since there is no net electric charge on the wire. Thus in electric machinery large forces are generated by the use of the magnetic forces between currents, not by electrostatic forces between charges.

#### MOTION OF CHARGES IN A UNIFORM FLUX DENSITY

**Dynamics.** As stated earlier, the force ( $F$ ) acting on a moving electric charge by a magnetic field is equal to the charge ( $q$ ) times the vector product of velocity ( $v$ ) and flux density ( $B$ )—i.e.,  $F = q [v \times B]$ —and its direction is normal to both the velocity and flux vectors. Under the action of such a force the particle moves in a circle of radius  $r$ . The force necessary to hold the particle in its orbit (centripetal force) is equal to the mass ( $M$ ) of the particle times its velocity squared, divided by the radius, or  $M(v^2/r)$ . The centripetal and magnetic forces are necessarily equal, and thus equating the two equations yields another equation of motion—i.e., mass times the quotient of velocity and radius is equal to charge times flux density, or  $M(v/r) = qB$ —and because the quantity ( $v/r$ ) is just the angular velocity ( $\omega_e$ ), then angular velocity is equal to the factor, charge over mass, times the flux density, or  $\omega_e = (q/M)B$ . The angular velocity thus depends only on the ratio ( $q/M$ ) which is a characteristic of the particle, and the flux density  $B$ . The time ( $\tau$ ) taken to complete a circle is the angle  $2\pi$  divided by the angular velocity, which becomes  $\tau = 2\pi M/qB$ . The importance of this result is that the angular velocity and period are independent of the velocity of the particle. The circle in which it moves is in the plane normal to  $B$ , and its radius, from the equation of motion, is proportional to the linear momentum  $Mv$  of the particle, and inversely proportional to its charge  $q$  and the value of  $B$ , or  $r = Mv/qB$ . These two results form the basis of a number of methods of determining experimentally the ratio ( $q/M$ ) from the angular velocity (or from the period) in a given

flux density, and also the velocity  $v$  of the particle if the ratio ( $q/M$ ) is known.

In a flux density of one tesla, an electron completes one circle in a time of  $3.57 \times 10^{-11}$  second, corresponding to some 28,000,000,000 revolutions per second. If it has previously been accelerated through a potential drop of five kilovolts, its speed is  $4.2 \times 10^7$  metres per second, and the radius of the circle is  $2.4 \times 10^{-4}$  metre, or about one quarter of a millimetre. Under the same conditions a proton, having the same (positive) charge as an electron, and a mass 1,836 times greater) completes a circle in  $6.6 \times 10^{-8}$  second (some 15,000,000 revolutions per second); its velocity is  $10^6$  metres per second, and the radius of the circle is about 0.01 metre (a centimetre).

At velocities approaching that of light, account must be taken of the relativistic effect which causes an increase of mass measured by an observer relative to whom the particle is moving. Already at an energy corresponding to a potential difference of 18 kilovolts, an electron reaches a velocity one quarter that of light, and the relativistic correction reduces its velocity by about 3 percent. For protons a correction of this size is reached only when the accelerating potential is greater by the ratio of the masses, a factor of 1,836.

Such corrections have important consequences in the design of accelerators and other devices for particles moving with velocities approaching that of light. The angular frequency does not remain independent of the energy of the particle, though the radius of the circle in which it travels is proportional to the linear momentum  $Mv$ , in which  $M$  is the actual mass as increased by the relativistic effect.

**Applications.** The circular motion of a charge in the plane normal to the flux density can be used to produce magnetic focussing, a concept that may be explained by the example of a source of charged particles, such as the electron gun of a cathode ray tube, that produces electrons moving almost parallel to the flux density vector  $B$ . A particle emerging at a small angle from this direction has a velocity component parallel to  $B$  and a transverse component perpendicular to  $B$ . This transverse component causes the particle to move in a helix, its path as viewed looking along  $B$  being a circle in the plane normal to  $B$ . After a time specified by the equation for time to complete a circle, given above—i.e.,  $\tau = 2\pi M/qB$ —it will have completed one circle, and to the observer appears to have returned to its original point. This is true for all particles with the same value of the ratio ( $q/M$ ), such as electrons, whatever the direction and magnitude of the initial transverse component. If the forward velocity is the same for all particles, in time  $\tau$  they move forward a distance equal to this time times the forward velocity component, and all come together to a point at this distance from the source. In effect, they have been focussed to form an image of the original point; if they come from a number of sources, the image will be a reproduction of the object formed by the sources.

The motion of an electron in a tight helix round a high flux density can be used to keep electrons in a vacuum tube moving in a narrow beam over long distances. Even if the electrons initially travel in parallel directions, the forces caused by their mutual electrostatic repulsion tend to spread them out as the beam moves on. The magnetic force can be utilized to counteract the electrostatic forces and focus the beam at the desired position.

The deflection of a beam of charged particles through some desired angle may also be achieved by magnetic forces. When particles of mass  $M$  and charge  $q$ , travelling with velocity  $v$ , enter a region with a flux density  $B$ , normal to its path, the particles will continue in the same plane and move in an arc of a circle of radius  $r = Mv/qB$ . On emerging into another field-free region, the beam will continue in a straight line, thus having been deflected from its original direction. For an electron accelerated through a potential drop of five kilovolts to a velocity of  $4.2 \times 10^7$  metres per second, the value of the flux density needed to produce a deflection through 45 degrees in a path length of five centimetres is about  $5 \times 10^{-3}$  tesla (50 gauss). Forces between two moving charges

Deflection of particle beam

typical figures, the flux density is produced by two pairs of coils on either side of the neck of the tube, one pair controlling the horizontal deflection and the other the vertical deflection. The regular cycle of changes in the currents through the two pairs of coils, triggered by the incoming signal from the aerial, generates the scanning of the electron beam across the fluorescent screen at the front of the display tube.

Similar methods are used to deflect beams of protons and other charged ions in devices used in nuclear physics. If the ions are heavy the flux density must be correspondingly larger and is usually provided by the narrow gap of an iron-cored magnet with pole faces shaped to the path of the beam. The dimensions of the gap are determined by the size of the beam and of the vacuum envelope in which it moves.

#### MOTION OF CHARGES IN COMBINED ELECTRIC AND MAGNETIC FIELDS

**Dynamics.** A particle with electric charge  $q$  in an electric field  $E$  experiences a force  $F = qE$ , which is in the same direction as the electric field if the charge is positive and in the reverse direction if the charge is negative. A uniform electric field is conveniently produced by a pair of plane parallel metal plates between which a voltage  $V$  is maintained. If the separation between the plates is  $d$ , the field is equal to the voltage divided by the distance, or  $E = V/d$ , normal to the plates; it is measured in volts per metre, unit field being produced by one volt across two plates one metre apart. In such a field the force on a charge of one coulomb is one newton.

If a magnetic flux density  $B$  is also present, the total force is given by the vector equation  $F = qE + q[v \times B]$ . A significant difference between the electric and magnetic forces is that the latter depend on the velocity of the particle, whereas the former do not.

**Applications.** This difference in forces is utilized in many devices, a simple example being a velocity filter, which selects particles of a given velocity. An electric field is produced between a pair of parallel plates, with a

Velocity filter for particles

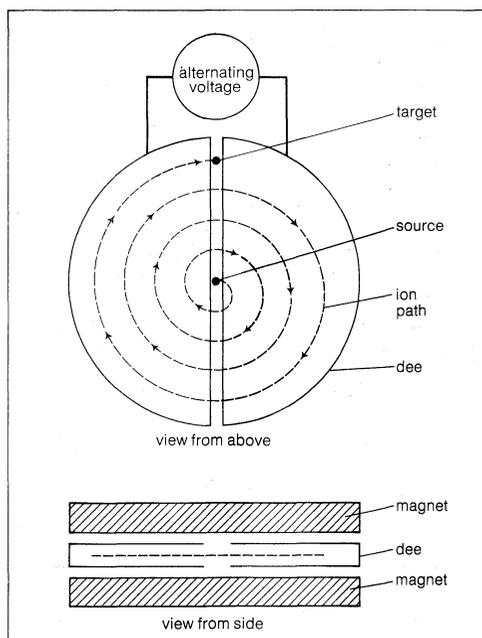

Figure 4: Acceleration of ions in cyclotron.

flux density  $B$  parallel to the plates. Particles of charge  $q$  enter in a beam parallel to the plates, but perpendicular to  $B$ . Only particles having velocities close to the ratio of magnitude of the electric field to the magnetic flux density ( $E/B$ ) emerge from the plates, the range of these selected velocities being smaller the longer the plates and the narrower the gap between them.

The cyclotron, proposed in 1930 to accelerate charged particles (usually protons), also relies on the constant

time taken by an ion to complete a circle in a uniform flux density so long as the relativistic increase in mass is unimportant. Between the poles of a massive electromagnet weighing many tons, an evacuated space contains two pairs of flat semicircular plates, known from their shape as dees (Figure 4). Within either pair of plates there is no electric field, and charged particles from a source near the centre move in a semicircle because of the force exerted by the magnetic flux density, the time taken to complete a semicircle being proportional to the particle mass and inversely proportional to the charge on each particle and the flux density (but independent of the orbit radius). If a voltage  $V$  exists between the two dees, ions (charged particles) crossing from one dee to the other gain an amount  $qV$  in energy if the voltage is in the direction required to accelerate them. Because of their increase in energy and momentum, the ions move in a larger semicircle inside the other dee, but still take the same time round. Provided the voltage is reversed by the time they cross back to the first dee, they are again accelerated and gain another increment of energy  $qV$ . This behaviour of charged particles to keep step with the oscillating voltage is called cyclotron resonance. The particles complete many revolutions, until the radius of the semicircle has increased to a point at which the ions strike a target at the outside edge of the dee. Energies corresponding to falling through a potential of many million volts can be attained, though the voltage across the dees is only 50,000 to 100,000 volts. A sinusoidal oscillating voltage is maintained between the dees by power from an electronic oscillator, the frequency of which must equal (or be a multiple of) the cyclotron frequency. If the oscillator frequency is not quite equal to the cyclotron frequency, the ions may be initially accelerated but the voltage across the dees gradually changes phase relative to the time of arrival of the ions; they cease to be accelerated and are retarded at each transit when the phase error approaches  $180^\circ$ .

Such an effect occurs through the progressive change in the cyclotron frequency of an ion because of the relativistic increase in mass as its kinetic energy approaches the rest energy  $M_0c^2$ . For electrons the rest energy is equivalent to a potential drop of about 500,000 volts, or 0.5 MeV (million electron volts), but for protons it is about 1,000 MeV and they can be accelerated to some hundreds of million electron volts. The radius of the semicircle traversed by an ion is proportional to its linear momentum ( $Mv$ ), and the size of a cyclotron must increase correspondingly; for high energies the magnet cost is large because of the great area over which a uniformly high value of flux density (one to two tesla) is required.

In modern high energy machines such as the synchrotron the diameter of the orbit is several hundred metres and is kept constant so that a high flux is required only at a given radius ( $r$ ). When the particle velocity  $v$  is close to the velocity of light  $c$ , it remains substantially constant, and the alternating frequency ( $\nu_0$ ) of the accelerator voltage must satisfy the relation that the velocity of light divided by the frequency is equal to  $2\pi$  times this given radius; i.e.,  $2\pi r = c/\nu_0$ . Electrons can be injected at velocities approaching that of light when the flux density  $B$  is small, and  $B$  is then increased in time in such a way as to keep the angular velocity, which is equal to  $\omega_c = qB/M$ , equal to  $2\pi\nu_0$  as the mass  $M$  increases. Heavy particles such as protons can be injected only with velocities considerably less than the velocity of light, and both  $\nu_0$  and  $B$  must be varied with time in a way to keep the radius of the orbit constant. Particle energies of 30,000 MeV have been achieved in proton synchrotrons; machines for energies 10 times greater are being built.

At low energies, where relativistic effects are negligible, cyclotron resonance has been used to determine the charge to mass ratio ( $q/M = \omega_c/B$ ) of the electron and proton and as a mass spectrometer for heavy ions.

#### MAGNETIC DIPOLE MOMENTS

**Atomic moments.** A current  $I$  moving in a circular wire of radius  $r$  has an equivalent magnetic moment equal to the product of the current and enclosed area; that is,  $m = I(\pi r^2)$ . The current, however, arises from the

Electro-magnets in cyclotrons

motion of electric charges, and a charge moving in such a circle with velocity  $v$  also has an equivalent magnetic moment. If the charge is  $q$ , the current  $I$  is equal to the charge passing any point on the circle per unit time,  $qv/2\pi r$ , since the quantity  $2\pi r/v$  is the time required by the charge to make one revolution. Thus the equivalent moment is the product of current and area ( $\pi r^2$ ), or  $m = qvr/2$ . This expression can be related to the mechanical angular momentum, equal to the product of mass, velocity, and radius, or  $G = Mvr$ , in which  $M$  is the mass of the particles; thus  $m = (q/2M)G$ , in which both vectors  $m$  and  $G$  are normal to the plane of the coil. This relation also holds for a charge  $q$  of mass  $M$  moving in an orbit under a central force directed towards a fixed point.

The natural unit of magnetic moment in an atomic system

In an atom, an electron of charge  $e$  and mass  $M_e$  moves in an orbit around the heavy nucleus with constant angular momentum  $G$ , but on quantum theory  $G$  is restrained to be an integral multiple of  $(h/2\pi)$ ,  $h$  being Planck's constant. This gives a natural unit of magnetic moment for an atomic system, equal to  $(e/2M_e)(h/2\pi)$  or  $(eh/4\pi M_e)$ , also equal to  $(e\hbar/2M_e)$  if the symbol  $\hbar$  is used for  $(h/2\pi)$ . This unit is known as the Bohr magneton, and its value is  $9.273 \times 10^{-24}$  ampere-(metre)<sup>2</sup>. Because of the negative charge of the electron, its magnetic moment  $m$  is a vector parallel to but in the opposite direction to the mechanical angular momentum  $G$ , both vectors being perpendicular to the plane of the orbit.

Each electron possesses also a spin about an internal axis. The spin angular momentum for each electron is given by the equation  $\frac{1}{2}(h/2\pi) = \hbar/2$ , but the spin magnetic moment is given by the equation  $m_s = -g_s(e/2M_e)(\hbar/2)$ , in which the constant  $g_s$  is 2.0023, so that the spin moment is close to one Bohr magneton in spite of the half integral value for the angular momentum.

For an atom as a whole the resultant angular momentum ( $J\hbar$ ) is also quantized in integral or half integral multiples of  $\hbar$ , but the relation between its magnetic moment and the angular momentum ( $J\hbar$ ) is complicated by the presence of contributions from both spin and orbit of each electron. Nevertheless, the atomic magnetic moment can be written as equal to  $-g(e/2M_e)$  times the atomic angular momentum ( $J\hbar$ ), in which  $g$  is a pure number that can be calculated if details of the atomic structure are known. The term  $g(e/2M_e)$  is called the magnetogyric ratio and is symbolized by the Greek letter gamma ( $\gamma$ ).

**Nuclear moments.** This intimate connection between angular momentum and magnetic moment also applies to nuclei, many of which have a net angular momentum ( $I\hbar$ ) equal to an integral or half integral multiple of  $\hbar$ . The nuclear magnetic moment may be written as  $m_n = g_n(e/2M_p)$  times the nuclear angular momentum ( $I\hbar$ ), in which  $e$  is now the charge on the proton and  $M_p$  its mass. The latter is 1,836 times that of the electron, and nuclear magnetic moments are smaller than those of atoms by a factor of this order. The quantity  $(e\hbar/2M_p)$  equals  $5.051 \times 10^{-27}$  ampere-(metre)<sup>2</sup> is used as the unit of nuclear magnetic moment, or nuclear magneton. As the nucleus is positively charged, most (but not all) nuclear moments are positive in sign; that is, the moment vector points in the same direction as the angular momentum vector. The value of the factor  $g_n$  varies widely, depending on the structure of the nucleus. Even for the elementary nuclear particles it has no simple value, being +5.58 for the proton and -3.83 for the neutron. These both have angular momentum  $\hbar/2$ , but the values of the factor  $g_n$  and the fact that the neutron has a magnetic moment but no electrical charge, indicate that they are fundamentally different from the electron.

These results illustrate the fact that, for both an atom and a nucleus, the magnetic moment  $m$  is parallel and proportional to the net angular momentum  $G$ . This is expressed in the equation  $m = \gamma G$ , in which the magnetogyric ratio has the dimensions of charge divided by mass. This ratio is of order  $-(e/2M_e) = 8.8 \times 10^{10}$  coulombs per kilogram for an atom, and of order  $(e/2M_p) = 4.8 \times 10^7$  coulombs per kilogram for a nucleus. Similar results hold for short-lived subnuclear particles, such as mesons, if the appropriate value of the mass of the particle is used in the value of the magnetogyric ratio.

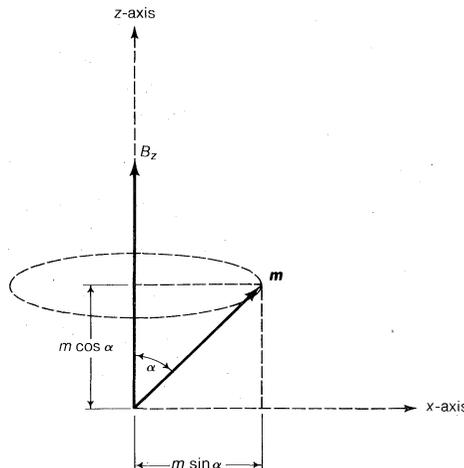

Figure 5: Precession of magnetic dipole moment  $m$  about  $B_z$  (see text).

**Magnetic resonance.** When a particle with a magnetic moment  $m$  is placed in a magnetic flux density  $B$  it experiences a couple (equal and opposite forces on a body form a couple)  $[m \times B]$ , and its angular momentum changes at the rate  $dG/dt = [m \times B]$ . From the relation above  $m = \gamma G$ , and thus  $dm/dt = \gamma[m \times B]$ , a vector equation that can be solved using Cartesian coordinates ( $x$ ,  $y$ , and  $z$  coordinates, mutually perpendicular). If the flux density has the single component  $B_z$  along the  $z$ -axis (Figure 5), the time rate of change of the magnetic moment's  $x$ -component ( $m_x$ ) is equal to the magnetogyric ratio times the  $y$ -component of the magnetic moment times the flux density—i.e.,  $dm_x/dt = \gamma m_y B_z$ ; likewise,  $dm_y/dt = -\gamma m_x B_z$ ;  $dm_z/dt = 0$ . The last equation shows that the component  $m_z$  is constant; if  $m$  is at an angle  $\alpha$  to  $B$ ,  $m_z = m \cos \alpha$ . The other two equations have solutions corresponding to a circular motion of the component  $m \sin \alpha$  about the direction  $B_z$ , with angular velocity  $-\gamma B_z$ . The whole motion consists of a precession of  $m$  about the direction  $B_z$  at a constant angle  $\alpha$ , with this angular velocity. The negative sign indicates that the direction of precession is that of a left-handed screw advancing along  $B_z$  if  $\gamma$  is positive, or a right-handed screw if  $\gamma$  is negative.

This precessional motion is similar to that of a toy top or gyroscope, spinning about its own axis, thus having angular momentum; in the Earth's gravitational field it experiences a couple formed by its weight acting through the centre of gravity and the equal and opposite reaction at the point of support. The rate of precession about the vertical is independent of the angle of inclination of the top to the vertical.

In the magnetic case, when the magnetic component  $B_z$  equals one tesla, the frequency of precession ( $\gamma B_z/2\pi$ ) is close to  $3 \times 10^{10}$  hertz (revolutions per second) for an electron or atom with a  $g$  factor equal to two, and in the region of  $10^7$  hertz for a nucleus, depending on the value of  $g_n$ ; for the proton it is slightly more than  $4 \times 10^7$  hertz. The precessional motion may be detected by applying perpendicular to the component  $B_z$  an oscillatory magnetic field at the resonant frequency ( $\gamma B_z/2\pi$ ); this changes the angle  $\alpha$ , and thus alters the energy  $-mB_z \cos \alpha$  of the magnet in the flux density  $B_z$ . This phenomenon is known as magnetic resonance, and has many applications (see MAGNETIC RESONANCE). The magnetogyric ratio may be determined with great precision from the resonance frequency in a known flux density; then, conversely, an unknown flux density  $B_z$  can be measured accurately. The most important technical application is in analytical chemistry, in which nuclear magnetic resonance can detect the minute variations in flux density due to local movements of the electrons characteristic of each molecule.

#### IV. Magnetic effects of varying currents

The discovery that an electric current is surrounded by a magnetic field, as shown by the deflection of a compass

Precessional motion

needle, immediately raised the question of whether or not an electric current can be produced in a circuit in the neighbourhood of a magnet. A French physicist, Augustin-Jean Fresnel, argued that since a steel bar can be magnetized by passing a current through a metallic helix surrounding it, it was natural to try to see if the bar magnet would not in turn create an electric current in an enveloping helix. In the following decade many ingenious experiments were devised, but the expectation that a steady current would be induced in a coil near to a magnet had the result that any transient effect of bringing up the magnet was either accidentally missed, or its importance was not appreciated if observed.

The crucial experiment was carried out by Faraday in August 1831: two coils of wire were wound on a ring of soft iron (Figure 6). The second circuit was connected to

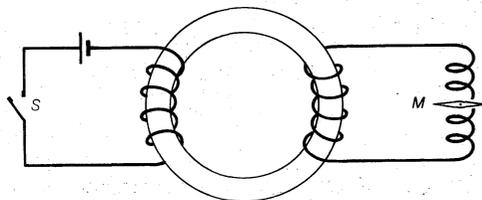

Figure 6: Faraday's magnetic induction experiment. When the switch *S* is closed in the primary circuit, a momentary current flows in the secondary circuit, giving a transient deflection of the compass needle *M*.

a copper wire extended over a compass needle so far away that it could not be affected directly by a current in the first circuit. When the first circuit was connected to a battery, Faraday observed a momentary deflection of the compass needle, followed by a damped oscillation and return to its original position. A similar deflection, but in the opposite direction, occurred when the primary current was switched off. Joseph Henry, a physicist working in Albany, New York, also recognized the momentary nature of the induced current, but his quite independent experiment was not published until after he had received the news of Faraday's work. In his paper (July 1832) Henry also reported and correctly interpreted an effect of "self-induction"—the production of sparks when a long helical conductor is disconnected from a battery.

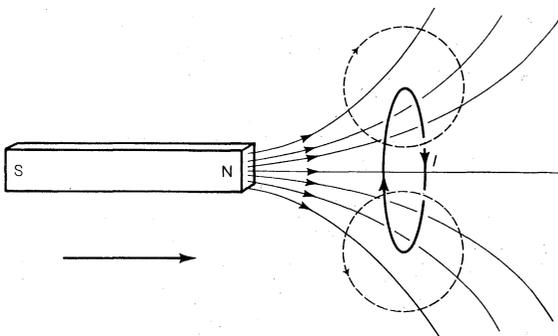

Figure 7: Principle of Lenz's law. When the magnet moves towards the coil, an induced current *I* flows in such a direction that its own magnetic flux (broken lines) opposes the increase of flux through the coil from the magnet.

#### THE LAWS OF ELECTROMAGNETIC INDUCTION

In the following years further experiments by Faraday resulted in his enunciation of the two laws of electromagnetic induction: (1) when the flux of magnetic induction through a circuit is changing, an electromotive force (emf) is induced in the circuit; (2) the magnitude of the emf is proportional to the rate of change of the flux.

Lenz's law

The sign of the emf is determined according to Lenz's law (after Friedrich Lenz, a German physicist), which states that it is such that any current flow is in the direction which would oppose the change of flux causing the emf. For example, in Figure 7, if the magnet is moved towards a closed loop of wire so that the magnetic flux

through the loop increases, the induced current flows in such a direction that its own flux circling the wire opposes the increased flux of the magnet through the loop.

These laws are expressed in an equation stating that the electromotive force (*V*) around the circuit is equal to minus the rate of change with time of the instantaneous value of the magnetic flux (*N*) through the circuit. It is expressed as  $V = -(dN/dt)$ . The electromotive force is the line integral of the electric field round the circuit—i.e.,  $V = \oint E \cdot ds$ —and the flux *N* is equal to the integral of the normal component of *B* taken over a surface bounded by the circuit.

The equation of electromagnetic induction contains no arbitrary constant: an electromotive force of one volt is generated in a circuit in which the magnetic flux is changing at the rate of one weber per second.

The discovery of electromagnetic induction laid the foundation for the electric power industry. If a coil of wire is rotated with angular velocity  $\omega$  in such a way that the magnetic flux (*N*) at any time *t* through the coil varies as the cosine of an angle  $\omega t$  so that  $N = N_0 \cos \omega t$ , in which  $N_0$  is *N* at its maximum, an alternating voltage  $V = -dN/dt = N_0\omega \sin \omega t$  is induced in the coil. The arrangement is an elementary form of dynamo; when current is drawn from it through an external circuit, electric power is produced, and mechanical power is consumed in driving the rotating coil.

#### INDUCTANCE AND MAGNETIC ENERGY

**Self-inductance and mutual inductance.** When a current *I* flows in a circuit, it sets up a magnetic field and there is a flux *N* of magnetic induction through the circuit arising from its own magnetic field. At every point the latter is proportional to the current *I*, and the flux *N* is therefore also proportional to *I*. This may be written  $N = LI$ , in which *L* is a constant that depends on the geometry of the circuit and the permeability of the medium in which it is immersed. The quantity *L* is called the self-inductance of the circuit and is equal to the total flux through the circuit when unit current (one ampere) is flowing. The self-inductance has unit value (one henry) if the flux is one weber when the current is one ampere.

Self-inductance of a circuit

If there is a second coil nearby, there will be a flux  $N_2$  through the second circuit when a current  $I_1$  flows in the first circuit. Again  $N_2$  is proportional to  $I_1$ , and, therefore,  $N_2 = M_{21}I_1$ , in which  $M_{21}$  is known as the mutual inductance between the two circuits, its unit being also the henry. Conversely, a current  $I_2$  in the second circuit creates a flux  $N_1$  in the first circuit, given by  $N_1 = M_{12}I_2$ . The potential energy of the system, from the formula  $U_p = -NI$ , may be written either as  $U_p = -N_2I_2 = -M_{21}I_1I_2$ , or as  $-N_1I_1 = -M_{12}I_2I_1$ , showing that the mutual inductances  $M_{12}$  and  $M_{21}$  are equal to each other.

As the force between the circuits can be found from the rate of change of potential energy  $U_p$  with the distance between them, an absolute measure of current is obtained from a calculation of the mutual inductance and the measurement of the force in an instrument known as an electro-dynamometer. In one design capable of a precision of one part in 50,000, two coils are attached to the beams of a balance, and these suspended coils are free to move inside two fixed coaxial coils. The same current flows through all four coils in series in such a way that the force on one coil is downward and that on the other is upward. The torque due to the current is balanced by a weight. Because the torque is proportional to the current squared, the direction of the current is unimportant, and any such electro-dynamometer can also be used to measure alternating current.

For circuits of simple geometry the inductance can be found from first principles by computing the field and hence the flux due to the current flow. For an infinitely long solenoid, wound with *m* turns per unit length and carrying a current *I*, the magnetic field inside is uniform and equal to  $H = mI$ . If the core of the solenoid has permeability  $\mu$ , the flux ( $N'$ ) through each turn is  $N' = \mu\mu_0 AmI$ , in which *A* is the cross-sectional area of the solenoid. The self-inductance per unit length, containing *m* turns, is therefore

$$L' = mN'/I = \mu\mu_0 m^2 A.$$

For a solenoid of length  $d$ , large compared with its diameter, this formula is still nearly correct, and the total self-inductance is

$$L = L'd = \mu\mu_0 m^2 Ad.$$

If a short coil of  $n$  turns, insulated from the first coil, is wound closely round the solenoid, the mutual inductance is

$$M = nN'/I = \mu\mu_0 mnA.$$

If two coils are closely wound together, so that all the flux generated by one coil passes through the other, and vice versa, the ratio of the fluxes  $N_1$  and  $N_2$  through the two coils will just be equal to the ratio of the number of turns  $n_1$  and  $n_2$  on the two coils. For a current  $I_1$  in the first coil  $N_1/N_2 = (L_1 I_1)/(M I_1) = L_1/M = n_1/n_2$ ; whereas for a current  $I_2$  in the second coil,  $N_2/N_1 = (L_2 I_2)/(M I_2) = L_2/M = n_2/n_1$ . Hence  $L_1/M = M/L_2 = n_1/n_2$ , and therefore the mutual inductance squared is equal to the product of the self inductances; i.e.,  $M^2 = L_1 L_2$ .

**Transformer and induction coils.** If the flux through the two coils is changing, the voltages induced in the two coils will be in the ratio of the two voltages ( $V_1$  and  $V_2$ ); that is,  $V_1/V_2 = (dN_1/dt)/(dN_2/dt) = n_1/n_2$ . Such a device is used as a transformer; if a changing voltage  $V_1$  is applied to the primary coil, a changing voltage  $V_2$  of a different magnitude is induced in the second coil. The voltage transformation ratio is  $n_2/n_1 = V_2/V_1$ , and the transformer may be used to "step up" or "step down" the voltage according to whether or not the number of turns  $n_2$  is greater than  $n_1$  or the reverse.

Historically, the first important application of electromagnetic induction was in the production of high voltages by the induction coil. Insulated coils of a few turns of heavy wire to carry the primary current, and many turns of fine wire for the secondary, were wound round a bundle of iron wires. A high voltage was produced in the secondary on interruption of the primary current, provided by a small battery. Early circuit breakers were cranked by hand, but an automatic circuit breaker was used in 1838. Notable improvements in construction were made so that by 1877 a spark in air 42 inches long could be produced. The induction coil was the standard method of producing high voltages in a number of fundamental experiments, including the discovery of the electron by a British physicist, J.J. Thomson (1897), and of X-rays by Wilhelm Röntgen (1895), a German physicist; the production of radio waves by Hertz (1886); and the wireless transmission of telegraphic signals by Marconi of Italy (1896). Millions of small coils have been used in automobiles to fire spark plugs, but for other purposes high voltages are now produced by electronic devices.

**Betatron.** The acceleration of charged particles is another application of electric field induction. In the phenomenon of electromagnetic induction a magnetic flux density that changes with time is surrounded by lines of electric field. Charged particles that move along such lines can be accelerated, and the magnetic flux density can simultaneously be used to hold them in an orbit of fixed radius. This is the principle of the betatron, first successfully used to accelerate electrons by a United States physicist, Donald William Kerst, in 1940.

For a typical betatron, in each revolution the electrons gain only about 100 electron volts in energy, and special care is needed in the design to focus them into a stable orbit in which they may travel for  $10^5$  to  $10^6$  revolutions, attaining a final energy in the range of ten to 100 million electron volts. The magnetic flux is varied sinusoidally at a low frequency of 100 to 200 hertz, acceleration taking place only during that quarter of the cycle in which the magnetic flux is increasing and in the right direction. At the end of the accelerating period extra coils are momentarily energized to expand the orbit so that the electrons strike a target, giving a copious supply of high energy X-rays.

**Magnetic energy and mechanical forces.** When a battery is connected to an inductive circuit, work is done by the battery in creating a flow of current against the re-

verse, or back, electromotive force generated by the rising current in the inductance. If there is no resistance or other source of loss in the circuit, the energy from the battery is not dissipated but is stored as magnetic energy in the inductance; this energy resembles the kinetic energy of a moving mass, which is the stored energy corresponding to the work done by a force in accelerating the mass from rest to its final velocity. When the battery is disconnected from the circuit, an induced electromotive force appears in the direction tending to maintain the current flow, and severe sparking at the switch may occur. The stored energy for a large electromagnet can be extremely high, and to avoid damage to the magnet and its associated circuits, precautions such as the provision of an electrical resistance in parallel with the switch are needed. Then, when the switch is opened, current flows instead through the resistance, decaying slowly so that the induced electromotive force, proportional to the rate of change of the current, is kept small. The magnetic energy is then dissipated in heating the protective resistance.

In a self-inductance  $L$ , the work done in creating a current  $I$  from zero is one-half times the self-inductance times the current squared ( $\frac{1}{2} LI^2$ ), and this is the magnetic energy stored in the self-inductance. In the same way, stored energy is associated with the mutual inductance of a pair of circuits.

The energy stored in an inductive circuit carrying a current is often regarded as associated with the magnetic field round such a circuit. For a length  $l$  of an infinite solenoid, the stored energy ( $U$ ) is  $U = \frac{1}{2} IN = \frac{1}{2} I \times (B \times ml \times \text{area of cross-section } A)$ , in which  $m$  is the number of turns per unit length. The magnetic field  $H$  in such a solenoid is equal to  $ml$ . Hence,  $U = \frac{1}{2} BH \times (\text{area} \times \text{length}) = \frac{1}{2} BH \times \text{volume}$ . This is an example of the finding that the stored energy per unit volume is  $\frac{1}{2} BH$ , or one-half the scalar product of the flux density ( $B$ ) and magnetic field ( $H$ ); i.e.,  $\frac{1}{2} (B \cdot H)$ , if the vectors  $B$  and  $H$  are not parallel to one another.

## V. General properties of magnetic materials

### THE CLASSIFICATION OF MAGNETIC SUBSTANCES

All substances are magnetic to some extent; either they possess a magnetic moment in the absence of an external magnetic field, as in the case of so-called permanent magnets, or they acquire a magnetic moment when placed in a magnetic field. For most substances of the latter type, at moderate field strengths, the magnetic moment per unit volume ( $M$ ) is linearly proportional to the strength of the applied field ( $H$ ), and the magnetic properties are specified by the magnetic susceptibility ( $\chi$ ), defined by the relation  $M = \chi H$ , in which  $M$  is the magnetic moment per unit volume of the substance.

Faraday's original classification of magnetic substances into diamagnetic and paramagnetic in 1845 was based on observation of the force exerted on the substance in an inhomogeneous magnetic field. In a magnetic flux density  $B$  increasing in the  $x$ -direction with a gradient (spatial rate of change)  $dB/dx$ , this force is equal to  $m$ , the magnetic moment acquired by the sample (equal to  $MV$ , in which  $M$  is the magnetization per unit volume and  $V$  is the actual volume of the sample) times the field gradient  $dB/dx$ ; i.e.,  $F = m(dB/dx) = (MV)(dB/dx)$ . But  $M = \chi H$  and  $B = \mu_0 H$ , and therefore the force from the equations above is:

$$F = V(\chi H) (dB/dx) = V(\chi\mu_0)H(dH/dx).$$

This equation shows that if the magnetic susceptibility  $\chi$  is positive, the force is in the direction of increasing field strength, whereas if  $\chi$  is negative, it is toward the direction of a smaller field strength. Measurement of the force  $F$  in a known field  $H$  and a known gradient ( $dH/dx$ ) is the basis of a number of accurate methods of determining the susceptibility.

Substances for which the magnetic susceptibility is negative are classified as diamagnetic. The susceptibility is small, of the order of  $-10^{-5}$  per unit volume (one cubic metre) of solids and liquids, and  $-10^{-8}$  for gases. A characteristic feature of diamagnetism is that the magnetic moment of unit mass in a given field is virtually

Energy stored as inductance

Faraday's classification of magnetic substances

constant for a given substance over a very wide range of temperature. It changes little between solid, liquid, and gas; the variation in the susceptibility (the magnetic moment per unit volume) between solid or liquid and the gas is almost entirely due to the change in the number of molecules per unit volume. This indicates that the magnetic moment induced in each molecule by a given field is primarily a property characteristic of the molecule.

Substances for which the magnetic susceptibility is positive are classed as paramagnetic. In a few cases (including most metals) the susceptibility is independent of temperature, but in most compounds it is strongly temperature dependent, increasing as the temperature is lowered. Measurements by Pierre Curie in 1895 showed that for many substances the susceptibility is inversely proportional to the absolute temperature  $T$ ; that is, it is equal to a constant divided by the absolute temperature,  $\chi = C/T$ . This result is known as Curie's law and the constant  $C$  as the Curie constant. The laws of thermodynamics are such that Curie's law cannot be valid down to absolute zero temperature, and even at room temperature a more accurate equation in many cases is obtained by modifying the above equation using a fixed temperature ( $\theta$ ):  $\chi = C/(T - \theta)$ , known as the Curie-Weiss law. From the form of this last equation it is clear that at the temperature  $\theta$  the value of the susceptibility should become infinite. This is interpreted as follows: because the susceptibility is the ratio of the magnetic moment to the applied field,  $\chi = M/H$ , an infinite value of the susceptibility means that a finite value of the magnetic moment per unit volume exists even when no external field is present ( $H = 0$ ); the material has a spontaneous magnetization, and at temperatures smaller than  $\theta$  it is a ferromagnet. Its magnetic properties are then very different from those in the paramagnetic or high temperature phase. In particular, although its magnetic moment can be changed by the application of a magnetic field, the value of the moment attained in a given field is not always the same and depends on the previous magnetic, thermal, and mechanical treatment of the sample.

Curie-  
Weiss law

#### INDUCED AND PERMANENT ATOMIC MAGNETIC DIPOLES

From the atomic viewpoint, the basic distinction is between (1) substances the constituent atoms or ions of which have no permanent magnetic dipole moments, and (2) substances in which some or all of the constituent atoms do possess such permanent moments. In the first class, application of a magnetic field produces a small change in the motion of the atomic electrons, which results in the appearance of a small induced magnetic moment in each atom, proportional in size to the magnitude of the applied field. The bulk magnetic moment of a sample, representing the sum of the individual atomic moments, is thus also proportional to the applied field, giving a susceptibility equal to the magnetic moment divided by the applied field, which is independent of the field strength  $H$  and is also substantially independent of temperature. In a diamagnetic substance the induced moment in each atom is in the direction opposite to that of the applied field, giving a negative susceptibility. In fact this effect is present in all substances, but in substances of the second class it is almost always outweighed by much larger paramagnetic effects, giving an overall positive susceptibility.

In substances of the second class, when no field is present, the permanent atomic dipole moments point at random, giving no resultant magnetization of the sample. When a field is applied, the dipoles are no longer completely randomly oriented, there being an excess in the number pointing with the field over the number pointing against the field. Thus a net bulk magnetic moment in the direction of the field corresponds to a positive susceptibility.

The forces opposing alignment of the dipoles with the field are thermal in origin, and weaker at low temperatures. The excess number of dipoles pointing with the field is determined by the product of the dipole moment of the atom or ion ( $m$ ) and the flux density ( $B$ ), divided by the product of Boltzmann's constant ( $k = 1.380 \times 10^{-23}$  joule per degree) and absolute temperature ( $T$ ); that is, ( $mB/kT$ ). For small values, the number is linearly pro-

portional to this quantity, giving a magnetization proportional to the flux density and inversely proportional to the absolute temperature, corresponding to Curie's law. At values of this quantity ( $mB/kT$ ) sufficient to align nearly all the dipoles with the field, the magnetization approaches a saturation value corresponding to the limit where all dipoles are completely aligned.

Conduction electrons in metals form an important exception to this rule. The effect of quantum statistics is to give a constant excess number aligned with the field (except at temperatures approaching  $10^4$ ° K). This results in a positive susceptibility independent of temperature, small in size, and comparable with the diamagnetic contribution, so that the overall susceptibility of a metal may be positive or negative (Figure 8).

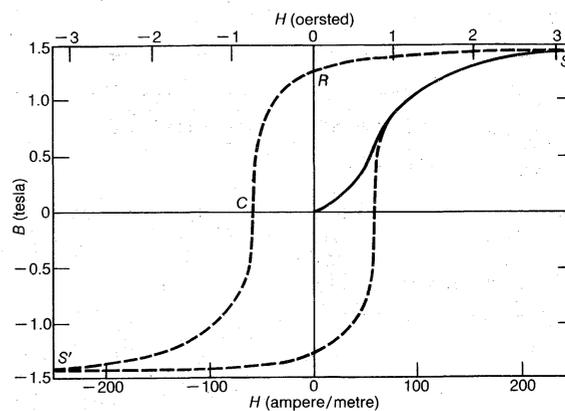

Figure 8: The susceptibility of a kilogram mole of the atomic elements. Broken lines connect the alkali metals (paramagnetic) and the rare gases of the atmosphere (diamagnetic).

In addition to the forces exerted on atomic magnets by an external magnetic field, there exist mutual forces between the atomic dipoles themselves. Such forces vary widely between different substances, but below a certain transition temperature (characteristic of each substance and primarily determined by the size of the mutual interactions) they produce an ordered arrangement of the orientations of the atomic dipoles even in the absence of an external field. The mutual forces tend to align neighbouring dipoles either parallel to one another, or antiparallel. In the former case, the spread of parallel alignment of the atomic dipoles throughout large volumes of the substance results in ferromagnetism, with a permanent magnetic moment on a macroscopic scale. On the other hand, if equal numbers of atomic dipoles are aligned in opposite directions, and the dipoles are of the same size, no macroscopic permanent moment is set up. This is known as anti-ferromagnetism. If the atomic dipoles are not of the same magnitude, and those pointing, say, to the right are all different in size from those pointing to the left, there will be a resultant permanent magnetic moment on a macroscopic scale, an effect known as ferrimagnetism. A simple schematic representation of these different possibilities is shown in Figure 9. In all cases, above the characteristic transition temperature, the material behaves as a paramagnet; it acquires a macroscopic magnetic moment only when an external field is applied, though the size of the moment is affected by the presence of the mutual forces between the dipoles.

dipole  
forces

#### MAGNETISM OF MATTER

**Diamagnetism.** When an electron moving in an atomic orbit experiences a magnetic flux density  $B$ , the force exerted on the moving electronic charge  $e$  produces a small change in the orbital motion, consisting of a precession of the orbit about the direction of  $B$  with an angular velocity. As a result, each electron acquires an additional angular momentum  $G$ , which, when summed over all electrons, gives a total magnetic moment ( $M$ ) equal to minus the number ( $N$ ) of atoms in the sample, times electronic charge ( $e$ ) squared divided by six times the mass ( $M_e$ ) of a single electron, times the flux density,

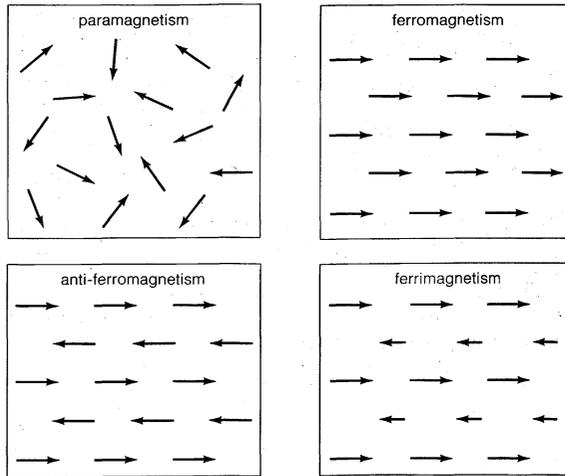

Figure 9: Arrangement of the atomic dipoles in different types of magnetic materials.

By courtesy of Electrical Engineering

times the sum of the mean square radii of all the electron orbits in each atom, symbolized by  $\Sigma \langle r^2 \rangle$ —i.e.,  $M = -N(e^2/6M_e)B \Sigma \langle r^2 \rangle$ —but  $B = \mu_0 H$ , and hence the susceptibility  $\chi$ , in equation form, is

$$\chi = M/H = \mu_0 M/B = -\mu_0 N(e^2/6M_e) \Sigma \langle r^2 \rangle.$$

The negative sign of this susceptibility is a direct consequence of Lenz's law. When  $B$  is switched on, the change in motion of each orbit is equivalent to an induced circulating electric current in such a direction that its own magnetic flux opposes the change in magnetic flux through the orbit; that is, the induced magnetic moment is directed oppositely to  $B$ .

Since the magnetic moment  $M$  is proportional to the number  $N$  of atoms (or ions), it is sometimes preferable to quote the ratio  $M/H$  for a sample not necessarily of unit volume. For unit mass, the mass susceptibility  $\chi_{mass} = \chi/\rho$ , in which  $\rho$  is the density (a unit mass of one kilogram occupies a volume of  $1/\rho$  cubic metres). For a kilogram mole (the molecular weight in kilograms), having a mass of  $X$  kilograms, in which  $X$  is the molecular weight containing  $6.023 \times 10^{26}$  molecules, the numerical value of the molar susceptibility (that is, the susceptibility per unit mole) is

$$\chi_{mole} = -3.55 \times 10^{12} \Sigma \langle r^2 \rangle.$$

For an atom the mean value of  $\langle r^2 \rangle$  is about  $10^{-21}$  (metre)<sup>2</sup>, and  $\chi_{mole}$  has values in the region of  $-(10^{-8}$  to  $10^{-9})Z$ ; the atomic number  $Z$  equals the number of electrons in each atom. The quantity  $\Sigma \langle r^2 \rangle$  for each atom is almost completely independent of temperature, and so is the diamagnetic susceptibility. It is also nearly independent of the surroundings of the atom, and most substances obey a simple additive rule known as Wiedemann's rule, which states that when a mass  $m_1$  of a salt of mass susceptibility  $\chi_1$  is dissolved in a mass  $m_2$  of solvent of mass susceptibility  $\chi_2$ , the mass susceptibility of the solution is given by  $(m_1\chi_1 + m_2\chi_2) = (m_1 + m_2)\chi$ , or  $\chi = (m_1\chi_1 + m_2\chi_2)/(m_1 + m_2)$ . This rule assumes that the susceptibilities of the isolated components are unaltered in solution, so that they can simply be added. Similar results hold approximately for ions in chemical compounds.

**Paramagnetism.** Paramagnetism occurs primarily in substances in which some or all of the individual atoms, ions, or molecules possess a permanent magnetic dipole moment. For a free ion this has the magnitude  $m = -gJ(h/2\pi)(e/2M_e) = -gJ(eh/4\pi M_e) = -gJ\beta$ , in which the quantity  $J(h/2\pi)$  is the resultant angular momentum of the ion, and  $(eh/4\pi M_e) = \beta = 9.273 \times 10^{-24}$  ampere-(metre)<sup>2</sup> is the Bohr magneton. By quantum theory,  $(2J + 1)$  values (e.g., 2, 3, 4, ...), of the orientations of the dipole are allowed, and in a magnetic flux density  $B$  each has a different potential energy equal to minus the scalar product of the magnetic dipole moment

and the flux density, or  $-m \cdot B = +(g\beta B)m_J$ , in which  $m_J$  has the values  $J, J - 1, J - 2, \dots, -(J - 1), -J$ . The fraction of dipoles with a given value of  $m_J$  (the component of  $J$  in the direction of  $B$ ) is proportional to the exponential  $(-g\beta B m_J/kT)$ , and the net magnetization ( $M$ ) may be written in terms of the saturation value ( $M_s$ ) for the magnetization as  $M/M_s = f(g\beta B/kT)$ . The function  $f$  is known as the Brillouin function. For values of magnetic flux equal to approximately one tesla and temperature to  $1^\circ$  K the function  $f$  approaches one; all dipoles are aligned parallel to  $B$  and the magnetization has the saturation value  $M_s = Ng\beta J$  (Figure 10). At lower

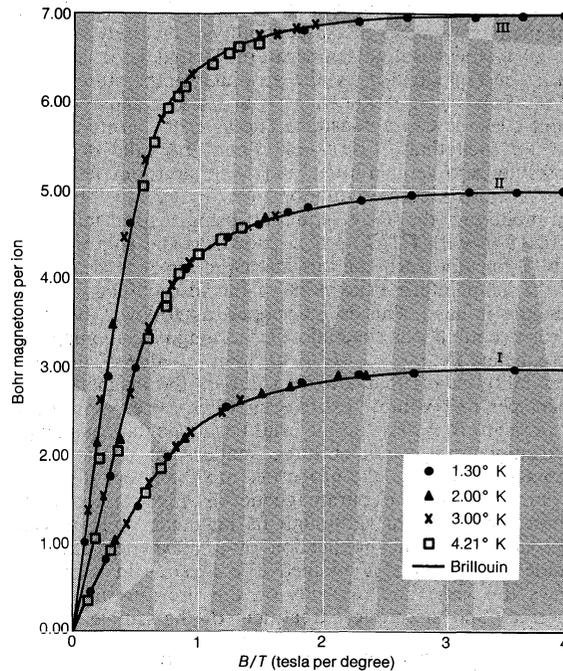

Figure 10: The approach to saturation in the magnetization of a paramagnetic substance following a Brillouin curve. The curves I, II, and III refer to ions for which  $g=2$  and  $J=3/2, 5/2,$  and  $7/2$ , respectively, the substances being chromium potassium alum, iron ammonium alum, and gadolinium sulfate octahydrate.

values of the ratio  $B/T$  the function depends slightly on the value of  $J$ ; when  $J$  equals  $1/2$ , it has the form

$$M/M_s = \frac{e^x - e^{-x}}{e^x + e^{-x}} = \tanh x,$$

in which  $x$  has the value  $1/2 g\beta B/kT$ .

When  $(g\beta B/kT)$  is very much less than the value one, the function is proportional to the ratio  $B/T$ , giving  $\chi = M/H = \mu_0 M/B = \mu_0 Ng^2 \beta^2 J(J + 1)/3kT$ . A plot of  $1/\chi$  against temperature gives a straight line through the origin, corresponding to Curie's law; for atomic paramagnets  $\chi$  is of order  $10^{-2}/T$  per kilogram mole, which is much larger than the diamagnetic susceptibility at ordinary temperatures.

In substances containing nuclear magnetic dipoles there is a further contribution to the susceptibility. The size of the nuclear dipole is only about one thousandth of that of an atom, and the nuclear susceptibility  $\chi_n$  can be written  $\chi_n = \mu_0 Ng_n^2 \beta_n^2 J_n(J_n + 1)/3kT$ , in which  $g_n \beta_n$  is the nuclear magnetic moment. Per kilogram mole,  $\chi_n$  is of order  $10^{-8}/T$ , and in solid hydrogen this just exceeds the electronic diamagnetism at  $1^\circ$  K.

From its derivation, Curie's law should hold when  $mB \ll kT$  (i.e., the first term is small compared to the second) provided that no other forces act on the atomic dipoles. In many solids the presence of internal forces causes the susceptibility to vary in a complicated way with temperature. In a few compounds in which there are no permanent atomic dipoles, the application of a magnetic field may induce dipoles the sizes of which are proportional to the field, as in diamagnetism; however, such induced dipoles point with the field, giving a small positive

Molar  
susceptibility

Nuclear  
susceptibility

susceptibility, constant over a wide range of temperature. The conduction electrons in metals have such a susceptibility, but for a different reason. Each carries a permanent dipole moment due to the electron spin, but the random thermal energy resisting alignment in an external field is the kinetic energy associated with the motion of the electrons within the conductor. The fractional excess of dipoles pointing with the field is a function of  $(mB/W)$ , in which  $W$  is the maximum kinetic energy of the conduction electrons. At ordinary temperatures  $W$ , and hence also the susceptibility, is independent of temperature.

**Ferromagnetism. Molecular fields.** A ferromagnetic substance contains permanent atomic magnetic dipoles, the difference from a paramagnetic substance being that the dipoles are spontaneously oriented parallel to one another even in the absence of an external field. This is due to mutual interactions between the dipoles, which, with very rare exceptions, arise from exchange forces. A simple empirical representation of the effect of such forces invokes the idea of an effective internal or molecular field  $H_{int}$ , which is proportional in size to the magnetization  $M$ ; that is,  $H_{int} = \lambda M$ , in which  $\lambda$  is an empirical parameter. If this internal field is included with an external field  $H$  in the theory of paramagnetism, a magnetization  $M$  results, given by  $M = \chi_p (H + \lambda M)$ , in which  $\chi_p$  is the susceptibility that the substance would have in the absence of the internal field  $\lambda M$ . Assuming that the susceptibility is equal to the ratio of the Curie constant to the absolute temperature ( $\chi_p = C/T$ ), corresponding to Curie's law, the equation  $M = C(H + \lambda M)/T$  has the solution

$$\chi = M/H = C/(T - C\lambda) = C/(T - T_c).$$

This result, the Curie-Weiss law, is valid at temperatures ( $T$ ) greater than the Curie temperature ( $T_c$ ). At such temperatures the substance is still paramagnetic, magnetization being zero when the field is zero, but the effect of the internal field is to make the susceptibility larger than that given by Curie's law. A plot of  $1/\chi$  against  $T$  still gives

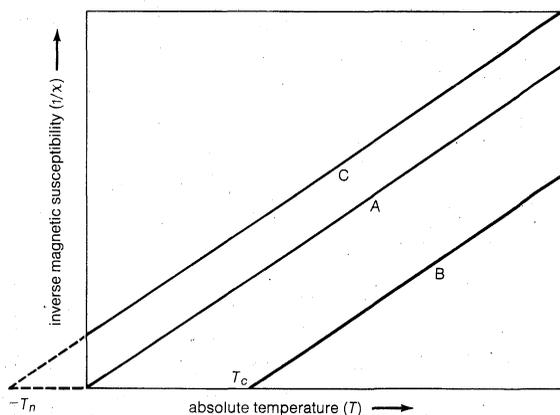

Figure 11: Plot of  $1/\chi$  (the reciprocal of the susceptibility) against  $T$  (the absolute temperature). (A) Curie's law, (B) Curie-Weiss law for a ferromagnet with Curie temperature  $T_c$ , (C) Curie-Weiss law for an antiferromagnetic substance.

a straight line (Figure 11), but  $1/\chi$  becomes zero when the temperature reaches the Curie temperature. Inasmuch as  $1/\chi = H/M$ , at this temperature  $M$  must be finite even when the magnetic field is zero. Thus, below the Curie temperature, the substance has a spontaneous magnetization  $M$  in the absence of an external field—the essential property of a ferromagnet. Table 2 gives Curie temperature values for some ferromagnetic substances.

In the ferromagnetic phase below the Curie temperature, the spontaneous alignment is still resisted by the random thermal energy, and the spontaneous magnetization  $M$  is a function of temperature. The magnitude of  $M$  can be found from the paramagnetic equation for the reduced magnetization ( $M/M_s$ ); i.e.,  $M/M_s = f(mB/kT)$  by replacing  $B$  by  $\mu(H + H_{int}) = \mu(H + \lambda M)$ , giving an equation that can be solved numerically if the function  $f$  is known. When  $H$  equals zero it can be written:

Table 2: Curie Temperatures for Some Ferromagnetic Substances

	Curie temperature °K
Iron	1,043
Cobalt	1,394
Nickel	631

MnBi	630
MnAs	318
Fe <sub>2</sub> O <sub>3</sub>	893

$$\frac{M}{M_s} = f \left\{ \frac{(M/M_s)}{(T/T_c)} \right\},$$

showing that the curve of  $(M/M_s)$  should be a unique function of the ratio  $(T/T_c)$  for all substances that have the same function  $f$ . Such a curve is shown in Figure 12,

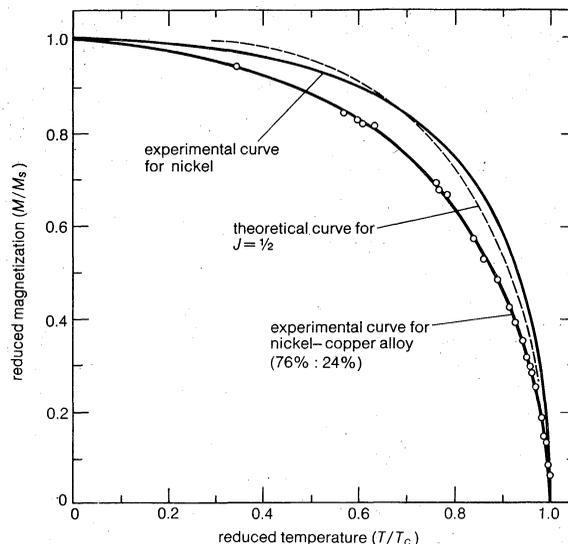

Figure 12: The reduced magnetization  $M/M_s$  as a function of reduced temperature  $T/T_c$  for a ferromagnet.

together with experimental results for nickel and a nickel-copper alloy.

The molecular field theory explains the existence of a ferromagnetic phase and the presence of spontaneous magnetization below the Curie temperature. The molecular field needed is, however, of enormous size, corresponding to a flux density of about 1,000 tesla in iron. This is far larger than can be produced by purely magnetic forces, and its origin remained a mystery until the quantum mechanical exchange forces were discovered by the physicists P.A.M. Dirac in England and W. Heisenberg in Germany. Its size also leads to the expectation that the magnetization should be little influenced by application of a comparatively small external field, but experimentally the situation is just the opposite. For iron the magnetization curve is shown in Figure 13 (solid curve) as a plot of flux density  $B$  against external field  $H$ . The variation is nonlinear, and  $B$  reaches its saturation value  $S$  in quite small fields. The relative permeability  $\mu = B/(\mu_0 H)$  attains values of  $10^3$  to  $10^4$ , in contrast to an ordinary paramagnet, for which  $\mu = 1 + \chi$  is about 1.001 at room temperatures.

On reducing the external field  $H$ , the flux density  $B$  does not return along the magnetization curve, and even at  $H = 0$  its value is not much below the saturation value (Figure 13, broken line). Its value at this point  $R$  is known as the residual flux density, and the retention of magnetization in zero field is called remanence. When the external field is reversed, the value of  $B$  falls and passes through zero (point  $C$ ) at a field strength known as the coercive force. Further increase in the reverse field  $H$  sets up a reverse flux density  $B$  that again quickly reaches a saturation value  $S'$ . Finally, as the reverse field is removed and a positive field applied, the flux density traces out the lower broken line back to a positive saturation value.

Curie temperature

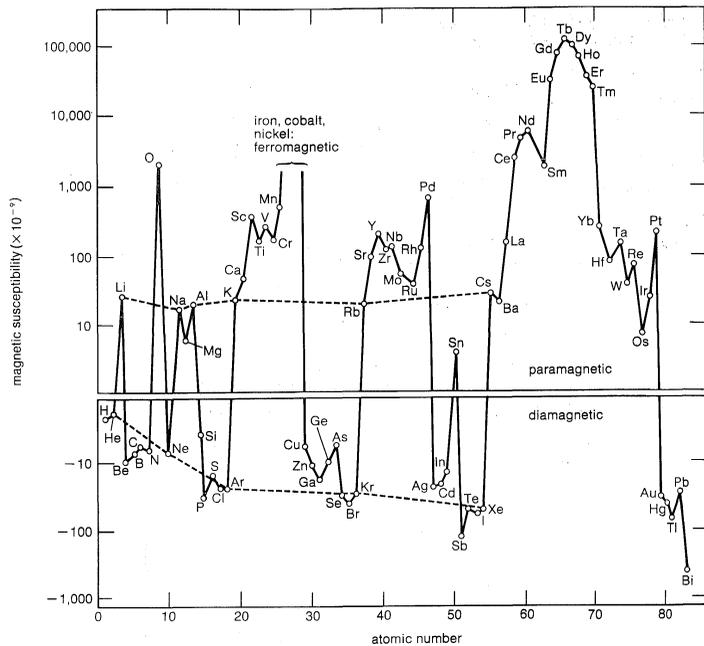

Figure 13: The magnetization curve (solid curve) and hysteresis loop (broken curve) for a ferromagnet.

Further cycles of  $H$  repeat the broken curve, known as the hysteresis curve, the change in  $B$  always lagging behind the change in  $H$ . The hysteresis curve is not unique unless saturation is attained in each direction; interruption and reversal of the cycle at an intermediate field strength results in a hysteresis curve of smaller size.

**Domains.** To explain these phenomena, Weiss suggested that a ferromagnetic substance contains many small regions (called domains) in each of which the substance is magnetized locally to saturation in some direction. In the unmagnetized state these directions are distributed at random or in such a way that the net magnetization of the whole sample is zero. Application of an external field produces changes in the direction of magnetization of part or all of the domains, setting up a net magnetization parallel to the field. In contrast with the microscopic scale of orientation of the atomic dipoles in a paramagnetic substance, the magnetization of a ferromagnetic substance involves re-orientation of the direction of magnetization of the domains on a macroscopic scale, giving large changes in the net magnetization when quite small fields are applied. Such macroscopic changes are not immediately reversed on reducing the size or changing the direction of the applied field, thus accounting for the presence of hysteresis and the possibility of a finite remanent magnetization even in the absence of an external magnetic field.

The technological applications of ferromagnetic substances are widespread, and the size and shape of the hysteresis curve are of overwhelming importance. A good permanent magnet must have a large spontaneous magnetization in zero field (*i.e.*, a high retentivity) and a high coercive force to prevent its being easily demagnetized by an external field. Both of these imply a "fat" hysteresis loop, typical of a hard magnetic material. On the other hand, ferromagnetic substances subjected to alternating fields, as in a transformer, must have a "thin" hysteresis loop, because of an energy loss per cycle that is determined by the area enclosed by the hysteresis loop. Such substances are easily magnetized and demagnetized and are known as soft magnetic materials.

**Anti-ferromagnetism.** In another class of substances, known as anti-ferromagnetics, the mutual forces between pairs of adjacent atomic dipoles are again due to exchange interactions but are of signs opposite to those in ferromagnets. As a result, adjacent dipoles tend to line up anti-parallel to each other instead of parallel. At high temperatures the material is paramagnetic, but below a certain characteristic temperature there exists an ordered anti-

parallel alignment of the dipoles. The transition temperature  $T_n$  is known as the Néel temperature, after the French physicist Louis-Eugène-Félix Néel, who proposed this explanation of the magnetic behaviour of such materials in 1936.

The ordered anti-ferromagnetic state is naturally more complicated than the ordered ferromagnetic state, since there must be at least two sets of dipoles pointing in opposite directions (Figure 14). With equal numbers of

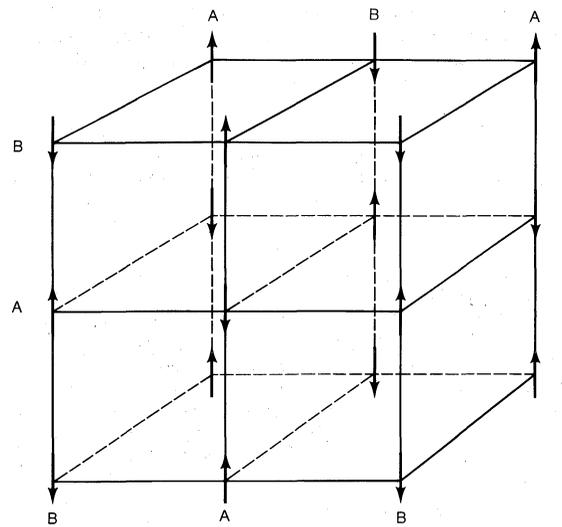

Figure 14: The antiparallel arrangement of neighbouring dipoles in an anti-ferromagnetic substance with two sublattices.

dipoles of the same size on each set, there is no net spontaneous magnetization on the macroscopic scale, and for this reason anti-ferromagnetic substances have few commercial applications. When an external field is applied, a small net magnetization is set up giving a positive susceptibility, but in the ordered state as the temperature is reduced the susceptibility falls (Figure 15).

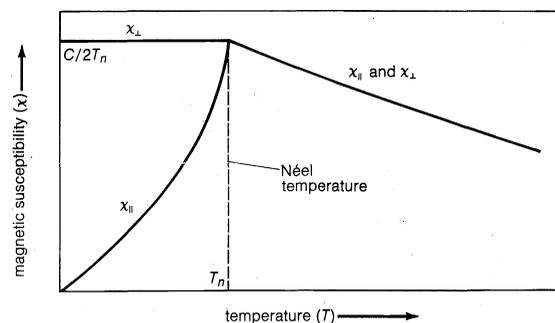

Figure 15: The susceptibility of an anti-ferromagnet. Below the Néel temperature ( $T_n$ ) the susceptibility,  $x_{\parallel}$ , measured when an external field is parallel to the spontaneous magnetization (fixed in the crystal), falls with decreasing temperature, and perpendicular to this direction  $x_{\perp}$  remains constant (see text).

For the purpose of analysis such an anti-ferromagnetic arrangement is regarded as consisting of two interlocking sublattices  $A$  and  $B$ , on one of which all the dipoles point, say, upward, and on the other all point in the reverse direction. Within each sublattice there thus exists a ferromagnetic alignment that may be ascribed to the action of a molecular field. The latter is due mainly to antiparallel interaction with dipoles on the other sublattice, though there may be some interaction with other dipoles on the same lattice. If the latter is neglected, the effective field  $H_A$  acting on a dipole of sublattice  $A$  is  $H - \lambda M_B$ , in which  $H$  is the external field and  $-\lambda M_B$  the molecular field, assumed proportional to the magnetization  $M_B$  of the other sublattice. Similarly for sublattice  $B$  the effective field  $H_B$  is  $H - \lambda M_A$ . In each case the negative sign is needed to represent the forces responsible for antiparallel alignment.

Above the transition temperature the magnetization of

Importance of hysteresis

Action of the molecular field in an anti-ferromagnetic arrangement

each sublattice is given by the equation  $M_A = \frac{1}{2}(C/T)H_A$ ,  $M_B = \frac{1}{2}(C/T)H_B$ , in which  $C$  is the Curie constant and the factor  $\frac{1}{2}$  appears because each sublattice contains only half of the dipoles. The total magnetization  $M$  is  $M = M_A + M_B = (C/T)(H - \frac{1}{2}\lambda M)$ . Hence the susceptibility becomes  $\chi = M/H = C/(T + \frac{1}{2}\lambda C) = C/(T + T_n)$ , a result similar to the Curie-Weiss law for ferromagnetism except for the positive sign in the denominator. A plot of  $1/\chi$  against temperature gives a straight line (Figure 11) but the intercept on the  $T$  axis is at  $-T_n$ .

Unlike the case of ferromagnetism, the ratio  $H/M$  does not become zero at any positive temperature, as the equation  $M = M_A + M_B = 0$  always holds if  $H = 0$ . The criterion for the appearance of spontaneous magnetization on the two sublattices is that  $M_A - M_B$  should be different from zero. From the equations above,

$$M_A - M_B = (C/2T)(H_A - H_B) = (C\lambda/2T)(M_A - M_B),$$

or

$$(M_A - M_B)(1 - C\lambda/2T) = 0.$$

This equation is satisfied either if  $M_A - M_B = 0$ , which holds in the paramagnetic region, or if  $(1 - C\lambda/2T) = 0$ , when  $M_A - M_B$  can be finite. This gives a transition temperature  $T = T_n = C\lambda/2$ , below which an ordered anti-ferromagnetic state exists because of the molecular fields (at  $H = 0$ ):

$$H_A = -\lambda M_B = -\lambda(-M_0) = +\lambda M_0;$$

$$H_B = -\lambda M_A = -\lambda(+M_0) = -\lambda M_0.$$

These fields maintain a positive magnetization  $+M_0$  on sublattice  $A$  and a negative magnetization  $-M_0$  on sublattice  $B$ .

The exchange forces between the magnetic ions are anti-ferromagnetic in nature in the majority of insulating chemical compounds. Values of the Néel temperature for a number of typical anti-ferromagnetic substances are given in Table 3.

Néel temperature °K	
Cr	311
MnF <sub>2</sub>	67
NiF <sub>2</sub>	73
MnO	116
FeO	198
CuCl <sub>2</sub> ·2H <sub>2</sub> O	4.3
NiCl <sub>2</sub> ·6H <sub>2</sub> O	5.3

**Ferrimagnetism.** Lodestone, or magnetite, has the chemical formula  $Fe_3O_4$ , and belongs to a class of substances known as ferrites. Ferrites, and some other classes of magnetic substances discovered more recently, possess many of the properties of ferromagnetic materials, including spontaneous magnetization and remanence. Unlike the ferromagnetic metals, they have a low electrical conductivity. In alternating magnetic fields this greatly reduces the energy loss due to eddy currents (see ELECTRICITY), and since these losses rise with the frequency of the alternating field, such substances have become of great technical importance in the electronics and radio industries.

A notable property of these materials is that the bulk spontaneous magnetization, even at complete magnetic saturation, does not correspond to the value expected if all the atomic dipoles are aligned parallel to each other. The explanation was put forward in 1948 by Néel, who suggested that the exchange forces responsible for the spontaneous magnetization were basically anti-ferromagnetic in nature, and that in the ordered state they contained two (or more) sublattices spontaneously magnetized in opposite directions. In contrast to the simple anti-ferromagnetic substances just considered, however, the sizes of the magnetization on the two sublattices are unequal, giving a resultant net magnetization parallel to that of the sublattice with the larger moment. For this phe-

nomenon Néel coined the name ferrimagnetism, and such substances are known as ferrimagnetic materials.

Inequality of the magnetization of the two sublattices can arise in a number of ways. A simple arrangement, in which all the atomic dipoles on one sublattice are different in magnitude from those on the other sublattice (Figure 9), seldom occurs in practice. The arrangement shown in Figure 16A, with two equal and opposite dipole

Inequality of magnetization in sublattices

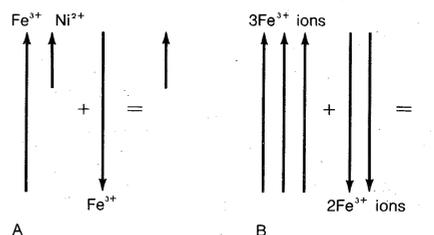

Figure 16: Division of the atomic dipoles between the two sublattices in the ordered state of (A) a ferrite such as  $NiFe_2O_4$ , and (B) yttrium iron garnet,  $Y_3Fe_5O_{12}$ . In A the net moment is that of the  $Ni^{2+}$  ion; in B it equals that of one  $Fe^{3+}$  ion.

moments but with an additional third moment on one sublattice, is typical of some ferrites, such as  $NiFe_2O_4$ . Here the equal and opposite moments are located on the  $Fe^{3+}$  ions, the third moment being on the  $Ni^{2+}$  ion. The net moment per formula unit  $NiFe_2O_4$  is then just equal to that of the  $Ni^{2+}$  ion alone. Similarly, the formula  $Fe_3O_4$  for magnetite should be written  $Fe^{2+}(Fe^{3+})_2O_4$ , the net magnetic dipole moment for this unit being just that of the  $Fe^{2+}$  ion. The values of the Néel temperature for such ferrites are well above room temperature, as shown by the examples in Table 4.

Table 4: Néel Temperatures of a Number of Ferrites of the Type  $MFe_2O_4$

Néel temperature (°C)	
Manganese, $Mn^{2+}$	573
Ferrous, $Fe^{2+}$	858
Cobalt, $Co^{2+}$	793
Nickel, $Ni^{2+}$	858
Copper, $Cu^{2+}$	728

In another typical ferrimagnetic arrangement, all the atomic dipoles are equal in size, but there are more dipoles on one sublattice than on the other, as illustrated in Figure 16B. The best known example of this type is yttrium iron garnet, chemical formula  $Y_3Fe_5O_{12}$ . Here both the yttrium and oxygen ions carry no atomic moment, all such moments being located on the five  $Fe^{3+}$  (ferric) ions. These are divided between the two sublattices in the ratio three to two, so that the net moment per formula unit is just equal to that of a single ferric ion. The Néel temperature is  $545^\circ K$ , or  $272^\circ C$ .

Above the Néel point the susceptibility of a ferrimagnetic substance varies with temperature in a complicated manner. A simple theory due to Néel gives the relation

$$\frac{1}{\bar{\chi}} = \frac{T}{C} + \frac{1}{\chi_0} - \frac{\sigma}{(T - \theta)},$$

in which  $C$ ,  $\chi_0$ ,  $\sigma$ , and  $\theta$  are constants. With suitable values for these constants, a reasonably good fit can be obtained to the variation of  $1/\bar{\chi}$  with temperature for yttrium iron garnet (Figure 17).

#### ATOMIC STRUCTURE AND MAGNETISM

The intimate connection between magnetic moment and angular momentum means that permanent dipole moments, of the order of the Bohr magneton in size, exist only in atoms or molecules that possess a net electronic angular momentum. Within an atom, each electron has (1) its own orbital magnetic moment associated with its orbital motion round the nucleus, and (2) its own spin magnetic moment associated with its spin about its internal axis. Each magnetic moment and each angular mo-

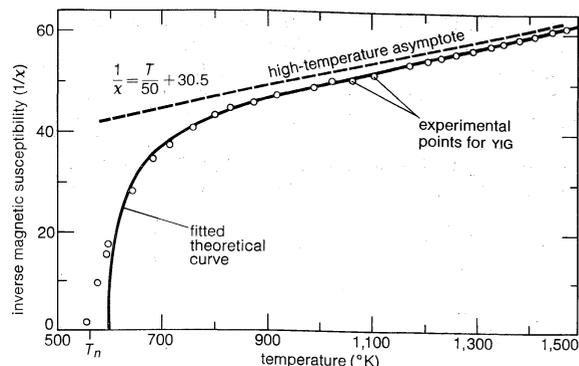

Figure 17: Inverse magnetic susceptibility ( $1/x$ ) of the ferromagnetic substance yttrium iron garnet (YIG).

mentum can be represented by a vector, and for the atom as a whole the net magnetic moment is related to the net angular momentum (orbit and spin) of all the electrons, which is a vector sum of the angular momenta of the individual electrons. This vector sum is formed in a way that depends on the forces within the atom that determine its electronic structure. Within an atom there are shells of electrons, such that each electron state within a shell has the same individual orbital and spin magnetic moment, the only difference being that the vectors representing these magnetic moments are differently oriented in space. When every such state within a shell is occupied by an electron, the net angular momentum of the filled shell is zero, and so is the net magnetic moment. This result greatly simplifies the position, making the net angular momentum and magnetic moment of the whole atom just equal to the vector sums of these quantities for the remaining electrons in the partly filled shells.

An atom or ion in which all the electron shells of lowest energy are filled with electrons and there are no electrons in partly filled shells is an especially stable structure. When atoms enter into chemical combination, they normally exchange or share electrons in such a way that all the electrons are accommodated in filled shells, giving no permanent atomic magnetic moment, but there are a number of exceptions to this rule. A molecule with an odd number of electrons, such as nitric oxide (NO) or nitrogen peroxide ( $\text{NO}_2$ ), must have a permanent magnetic moment; this occurs also in a few molecules with an even number of electrons, a well-known example being oxygen ( $\text{O}_2$ ). These three substances form the chief paramagnetic gases.

In the solid or liquid state, permanent atomic moments occur in ions belonging to the transition groups of the periodic table. The best known are the iron group, containing the elements titanium (atomic number or  $Z = 22$ ) to copper ( $Z = 29$ ), and the rare-earth group, cerium ( $Z = 58$ ) to ytterbium ( $Z = 70$ ); others are the palladium group, molybdenum ( $Z = 42$ ) to palladium ( $Z = 46$ ), the platinum group, rhenium ( $Z = 75$ ) to platinum ( $Z = 78$ ), and the actinide group starting with protoactinium ( $Z = 91$ ) and continuing through uranium ( $Z = 92$ ) to the heavier man-made transuranic elements. More precisely, the magnetic ions can be defined by the number of electrons in the partly filled shell. The iron group, with 18 electrons in closed shells, has between one and nine electrons in the  $3d$  shell; the rare-earth group, with 54 electrons in closed shells, has between one and 13 electrons in the  $4f$  shell. These figures refer to the ground state (the state of lowest energy) of the ion, which is the stable state at ordinary temperatures. Electrons can be excited into higher states, with a characteristic magnetic moment, but this is a transient phenomenon. Further, defects may exist in a crystal lattice or be induced by irradiation, with an abnormal electronic state carrying a magnetic moment. Such excited states or defects involve only a minute fraction of the ions in the crystal.

The paramagnetic susceptibility for a known number of ions can be found from measurements on solutions or on solid compounds (such as those in Figure 10) in which the magnetic ions are so far apart that the effect of any

mutual interactions between them is negligible. Corrections must be made for the diamagnetic susceptibility of all the ions present. For the rare-earth group, experimental values of the effective magnetic moment per ion are close to those calculated from the structure of the ions, both the orbital and the spin magnetic moments contributing in full. In the iron group the situation is more complicated, and the ionic moment is closer to that expected from the electron spin alone. The reason for this is that in a compound the magnetic electrons are subjected to electrical interactions with the neighbouring electrically charged ions. In the iron group these change the orbital motion of the magnetic electrons so drastically that their magnetic moments are practically eliminated, leaving only the spin magnetic moment. In the rare earths such effects are much smaller, though they can be seen in the behaviour of the susceptibility at low temperatures. Magnetic resonance has played a leading role in unravelling the details of these effects.

Such electrical interactions also play an important role in the ordered state of ferromagnetic, anti-ferromagnetic, and ferrimagnetic compounds. Exchange interaction between the ions determines the orientation of their dipoles relative to one another but not how they are oriented within a crystal lattice relative to the crystal axes. The latter is sometimes determined by magnetic interactions between the ions, but in many cases the electric interactions play a dominant role since their symmetry reflects the ordered array of electrically charged ions of which the crystal lattice is composed. Particularly in the rare-earth metals they give rise to a complicated three-dimensional arrangement of the atomic magnetic moments in the ordered state. Such arrangements have been determined experimentally from the scattering of beams of neutrons in these substances (neutron diffraction). The experiments are similar to the use of X-rays to reveal the detailed arrangement of ions in a crystal lattice, which acts like a three-dimensional diffraction grating. Because they possess an intrinsic spin and magnetic moment, neutrons (unlike X-rays) are sensitive to the direction of the ionic magnetic moment and are scattered in directions that are determined by the periodic nature in the ordered state of the three-dimensional array of magnetic moments.

## Magnetohydrodynamic Devices

Magnetohydrodynamics is the study of the behaviour of electrically conducting fluids (either liquids or gases) in the presence of electric and magnetic fields. Magnetohydrodynamics today is primarily concerned with gases. At ordinary temperatures and pressures, gases are composed of electrically neutral atoms or molecules, and do not conduct electricity. At temperatures of several thousand degrees centigrade or above, however, the motions of the gas particles are violent enough to dislodge some of the outer electrons from the atoms. The electrons thus freed and the resulting positive ions are easily made to move by an electric field; such ionized gases (plasmas) are usually good conductors of electricity. Magnetohydrodynamic (MHD) devices generate electric current by the interaction of an electrically conducting fluid, such as a plasma, and a magnetic field. Closely related are electrogasdynamic (EGD) devices, which generate electric current by the interaction of an electrically insulating, or nonconducting, fluid carrying charged particles or ions, and an electric field.

### GENERAL CONSIDERATIONS

**Principles of operation.** Direct energy conversion, as performed by MHD and EGD devices, involves the direct transformation of heat or radiation into electricity, rather than first to mechanical energy, and then to electricity. In a conventional power plant, the energy stored in a fossil or nuclear fuel generates heat to produce steam, which in turn drives a generator to produce electricity. By contrast, energy in MHD or EGD devices is transformed to electricity directly from the thermal and kinetic energy of the fluid. Only the fluid inside the MHD or EGD device is in motion; the device itself has no moving parts. Because of this, the device can operate at extremely high temperatures, which would destroy the metals and lubricants in a conventional steam turbine.

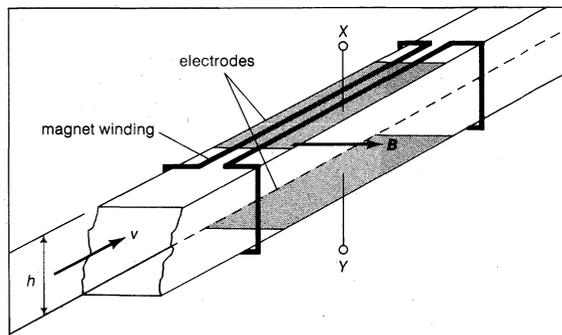

Figure 1: Operating principles of a magnetohydrodynamic electrical generator (see text).

**MHD generator operation.** Figure 1 illustrates the basic principles of a magnetohydrodynamic (MHD) electrical generator. The conducting fluid passes through a duct that has two opposite conducting walls (electrodes) and two opposite insulating walls. A strong magnetic field ( $B$ ) is established at right angles to the duct. As the conducting fluid flows through the duct and the magnetic field with a velocity  $v$ , it generates an electrical voltage across the electrodes  $xy$ . The actual voltage generated depends on the velocity of flow, the strength of the magnetic field, and the height  $h$  (or diameter) of the duct. This voltage could measure velocity of flow, and the device would become a flowmeter.

If an electrical load of some kind, such as a light bulb, is connected across the electrodes, current will flow through the load. Inside the duct, a direct current flows between the two electrodes. This current exerts a retarding force on the fluid, and work must be done by the fluid to overcome this force. The work thus extracted from the fluid is converted to electricity. The retarding force is called electromagnetic braking.

The reverse effect can also be made to take place. If an electric current is driven through the fluid by an external

battery or generator, a force is exerted on the fluid and the device becomes a pump. This technique may be applied effectively to pump liquid metals such as mercury and molten sodium.

**EGD generator operation.** An electrogasdynamic (EGD) device also extracts power directly from fluid flow, but the principles of operation are different (Figure 2).

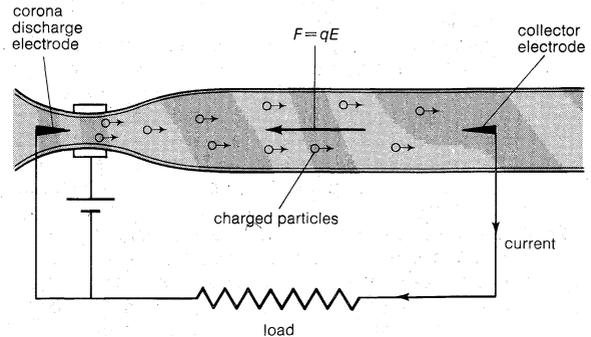

Figure 2: Operating principles of an electrogasdynamic converter (see text).

Basically, the fluid flow is used to force an electrical charge, in the form of ions or charged particles, from a region of low voltage to a region of high voltage, against an electric field  $E$ . If the ions are collected at the far end of the generator, a current,  $I$ , can flow through a load. The electrostatic retarding force,  $F$ , on the fluid is  $qE$  per unit volume, in which  $q$  is the charge density and  $E$  the collector electrode voltage divided by the distance between electrodes, and the flow does work against this force. If, instead, the electric field is reversed, the ions are forced ahead more rapidly and the device becomes a pump. The charged particles are formed by passing the fluid through an electrical discharge in which the voltage is high enough to produce ionization.

**Historical background and applications.** The basic principles of magnetohydrodynamics and electrogasdynamics have been known for over a century. The essential features of the interaction between an electrically conducting fluid and a magnetic field, and of electrostatics, were described by Michael Faraday in the 1830s. Practical MHD and EGD devices have had a much shorter history, however. The first large experimental MHD generator was constructed in the U.S. in 1938 by B. Karlovitz and D. Halász. These experiments were unsuccessful, however, because neither the properties of ionized gases nor the need for very high gas temperatures were sufficiently understood. By 1959, technology had progressed sufficiently so that 10 kilowatts of electric power were generated with an MHD device. Extensive research and development continues in France, Germany, Great Britain, Japan, Poland, the Soviet Union, and the U.S.

Early attempts to construct a practical high-voltage EGD generator were reported in the U.S. in 1932, and in France in 1935. Large scale work on EGD generation of electricity from fossil fuel dates from the late 1960s, with development work begun in the United States.

The magnetohydrodynamic interaction finds practical application today in flowmeters, accelerators, pumps, and generators. Electromagnetic flowmeters, in use for several decades, do not interfere with fluid flow and have no moving parts. They are used to measure liquid metal flow, flow of arterial blood, and ocean currents.

Electromagnetic or MHD pumps, easy to make corrosion-resistant, and with no moving parts, are often used in handling liquid metal. When used with gaseous working fluids, these devices are called MHD accelerators; space-flight propulsion systems based on the MHD interaction have been proposed.

### MAGNETOHYDRODYNAMIC POWER GENERATION

The most important application for magnetohydrodynamics is power generation. In large public-utility plants that burn fossil fuel, significantly more efficient conversion of fuel to electricity and consequent savings in fuel

and reduction of waste heat can be achieved with an open-cycle MHD generator topping (described later) a conventional steam power plant.

In open-cycle operations, the working fluid (gas) is eventually exhausted to the atmosphere; in closed-cycle systems, the fluid is reused. Topping means that the gases generated by burning the fuel (coal, oil, gas) are first passed through an MHD generator and then on to a conventional steam generator.

Closed-cycle nuclear-fuelled MHD systems are possible. A gas, heated to a very high temperature by the nuclear reactor, may be passed first through an MHD generator and then through the steam plant. After losing all of its (heat) energy, the gas may be returned to the nuclear reactor for reheating. In the early 1970s, MHD techniques appeared to have more promise than EGD for large-scale power generation.

**Power-generating systems.** In an open-cycle MHD power-generating system, the working fluid that is exhausted to the atmosphere must be cheap and nontoxic. The only practical fluid is the gaseous product of fossil-fuel combustion with air or oxygen. The simplest open cycle consists of a combustion chamber or furnace in which fuel burns with an oxidizer at high pressure to produce a high-temperature working fluid, a nozzle through which the combustion gases are accelerated to a high velocity of around 1,000 metres or 3,300 feet per second, and an MHD duct in which electrical power is extracted from the flow. A diffuser is used to retard the gases before they enter the atmosphere, and to raise the pressure to atmospheric.

The quantity of power that can be generated by a given amount of fluid depends in part upon its electrical conductivity. At the highest temperatures attainable with fossil fuels (about 3,000° C, 5,430° F), electrical conductivity of the combustion gases is too low to obtain adequate power yield. Consequently, the fluid is seeded with a material such as potassium, which ionizes easily and raises power yields to acceptable levels.

As the gas expands in the MHD duct and power is extracted, the gas cools and its electrical conductivity falls rapidly. At about 2,000° C (3,630° F), the MHD power-generation process ceases to be economically attractive, and the simple open-cycle system thus has a low efficiency. Since the exhausted gas is still hot in comparison with normal power-plant working fluids, the efficiency of the simple open-cycle system can be substantially increased by recovering the energy remaining in the gas stream with conventional methods.

**Open cycle with heat recovery.** Heat energy recovered from the MHD duct exhaust gas is used in two ways. First, it heats the high-pressure air fed to the combustion chamber. Second, the remaining heat is used to produce steam in a conventional boiler and power is generated in the conventional way.

The heat-recovery unit also recovers the seed; when the MHD exhaust gas cools, the seed material condenses on the boiler and heat-exchanger walls and is collected. Once heat recovery is complete, an electrostatic precipitator removes any remaining seed or other particulate matter and the gases are discharged through a smokestack. About 40 percent of the net thermal energy entering the heat-recovery unit can be converted into electrical power. The overall efficiency of a combined MHD-steam plant (45 to 55 percent) is thus substantially greater than that of the simple open-cycle MHD system (10 to 20 percent).

**Closed-cycle systems.** An alternative is the closed-cycle gas MHD system in which the working fluid, at high pressure, is heated in a nuclear reactor before it enters the MHD generator. Because the working fluid is recycled, its cost is no longer of primary concern, and the gas can be chosen for its heat-transfer and electrical properties. Helium is the most attractive gas, and cesium though expensive is the most easily ionized seed material. This system may be practical for bulk power generation because it offers a potential means of obtaining greater efficiencies from advanced-fission reactors. The top gas temperatures required are lower than peak open-cycle temperatures because certain processes can be used to increase electrical

conductivity. A heat-recovery plant is still employed, however, because the conductivity of the fluid is too low for the process to be attractive at temperatures that are high by conventional steam-plant standards.

Closed-cycle, liquid-metal systems are also being developed. These are a compromise between the higher thermal efficiency of gas-cycle MHD systems and the advantage of higher conductivity obtained by using liquid metal as the working fluid. Liquid metals have much higher electrical conductivity than seeded gases at all temperatures; power yields per given quantity of fluid can be about ten times higher than in MHD devices using ionized gases (plasma).

Many liquid-metal cycles have been proposed both for space power and central power-station applications. In these, the liquid metal is heated in a nuclear reactor; part of the flow is vapourized, and the vapour is accelerated to a high velocity in a nozzle; the vapour mixes with and accelerates the liquid flow; when the vapour and liquid are separated, the liquid enters the MHD generator where part of its kinetic energy is converted to electricity. Liquid-metal systems are less efficient than gas systems.

**MHD generator geometries.** For liquid-metal MHD systems, the linear duct with a single electrode on each side as shown in Figure 1 is adequate. In gaseous systems designed for bulk power generation, however, a more complicated electrode geometry is required because of the Hall effect (named after its discoverer, U.S. physicist E.H. Hall), in which the motion of the electrons that carry the current, transverse to the magnetic field, produces an additional electric field along the duct axis. This additional electric field, called a Hall field, causes axial currents that seriously decrease electrical efficiency of the generator. To prevent this, each electrode is divided into segments, each of which is connected to separate loads (Figure 3A). The result is a Faraday generator. (In Figures 3A through 3E, the load current is represented by  $I$  and the magnetic field by  $B$ .)

The Hall effect

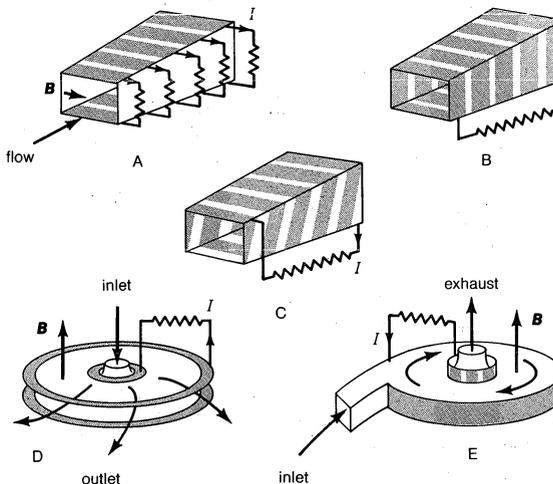

Figure 3: Magnetohydrodynamic generator geometries. (A) Faraday, (B) Hall, (C) diagonal, (D) disk, and (E) vortex. The shaded areas are electrodes; the load current is represented by  $I$  and the magnetic field by  $B$  (see text).

When the Hall effect is very pronounced, the transverse currents may be short circuited in the linear duct and the axial current used to generate power with a single load (Figure 3B); this is called a Hall generator. The advantage of the Hall generator with its single load, and the higher efficiency of the Faraday generator can be combined by diagonally cross-connecting electrodes (Figure 3C).

Other duct designs or geometries have been proposed to counteract the Hall effect. One is the disk generator (Figure 3D), in which the gas flows radially outward between two disks. The short-circuited transverse currents of the linear Hall generator now flow in closed circles around the centre of the disks, and no intermediate electrodes are required. Power is generated with the radial current and radial electric field.

Closed-cycle systems

Seeding fluid with potassium

A vortex geometry (Figure 3E) has been proposed to reduce the wall area of the generator when the Hall effect is small. Reducing wall area of the generator makes it more efficient, lowering costs. In this vortex generator the flow spirals inwards, the magnetic field is perpendicular to the walls, and the inner and outer cylinders are the electrodes.

**Performance and efficiency.** The processes occurring within the MHD generator that determine its performance are power extraction and electromagnetic braking throughout the duct volume, and heat transfer and friction at the duct walls. Power extraction and heat transfer decrease the thermal energy of the fluid; electromagnetic braking force and wall friction decrease its pressure and momentum.

Heat transfer to the duct walls and friction losses must be kept small. Heat transfer lowers the fluid temperature, which, in a gas cycle, reduces the electrical conductivity and therefore increases losses due to the increased electrical resistance of the fluid. Wall friction increases the pressure required at the duct inlet for a given power output. Because the electrical conductivity decreases as pressure increases, additional resistive losses result. Since both these processes are wall effects, whereas the desired interaction, power extraction, takes place throughout the duct volume, the larger the generator the more efficient its performance will be. For this reason only large MHD generators are practicable. Even for a 2,000 MW (megawatt) unit, heat losses to the generator walls are 10 to 20 percent of the MHD power output. The heat lost is recovered in the steam plant, but at a much lower efficiency.

Only part of the work done by the flow against the electromagnetic braking force is extracted as electrical energy. The remaining part is dissipated within the generator as a result of the electrical resistance of the fluid. Excessive dissipation is undesirable because it reduces generator efficiency. To prevent this, the external load is matched to the internal resistance of the generator, thus limiting dissipation to about one-quarter of the power generated.

Electrical losses also occur at duct inlet and exit and near the duct walls. At the entrance and exit to the magnetic-field region, closed current loops within the fluid cause additional dissipation. Since the electrode walls of the duct are cooler than the main flow, gas resistance and resulting electrical dissipation increase near the walls as well. In addition, each electrode segment short circuits the axial electric Hall field near the wall. As a result, currents flow axially in the gas and return along the electrode, again increasing resistive losses. Though each of these effects taken separately is small, together they can significantly degrade performance in a large MHD generator.

The overall cycle efficiency of a combined MHD-steam plant is equal to the net electrical power output divided by the thermal input. The net power output is the sum of the electrical output from the MHD generator and the electrical output from the steam plant, less the power required for the air compressor, the steam-plant auxiliaries, the MHD-plant auxiliaries, and the losses incurred in converting the MHD power from direct current to alternating current. For the open cycle, the thermal input is the rate at which fuel flows into the combustor multiplied by its heating value. For the closed cycle, the thermal input is the rate of heat transfer to the working fluid in the reactor.

For a large central-power generating station with a fossil-fuel thermal input of 2,000 megawatts, plant-performance design studies predict power outputs from the MHD duct varying from 600 to 800 megawatts depending on the assumptions made. With a steam-cycle efficiency of 42 percent, the efficiencies of the combined MHD-steam plant predicted for these designs lie between 45 and 55 percent.

**Practical design considerations.** *Production of the hot working fluid.* In gas MHD systems, an easily ionized seed material such as cesium or potassium is added to the gas stream in amounts up to 1 percent of the total gas flow. Though only about 1/1000 of the seed atoms have to be ionized to produce the required electrical conductivity within the MHD duct, gas temperatures above 2,700° C

must be attained in the open-cycle combustor. With fossil fuels such temperatures require combustion with either oxygen, air preheated to 1,200° to 1,600° C, or oxygen-enriched air at intermediate temperatures.

For central, station power generation, only preheated air is economical; a high-temperature air heater is essential. The demanding requirements of large air flow and high air-outlet temperature of at least 1,200° C, coupled with the corrosive nature of the seeded hot gas and the pressure difference between air and MHD exhaust gas, place this plant item at the limits of current technology.

In closed-cycle gas systems, acceptable electrical conductivities can be achieved at lower temperatures, but a number of significant problems are encountered in maintaining their conductivity, and extracting the MHD power. Various instabilities that occur dissipate a substantial part of the energy. Solutions to all of these problems were not yet in sight in the early 1970s.

*The MHD duct.* The MHD duct must operate for extended periods under extremely arduous conditions. For the linear duct one pair of walls must be electrical insulators, and the other, segmented electrode structures. All walls must be water cooled to withstand the high gas temperature, though the heat flux should be held to a minimum. In the open cycle the seed and slag-laden combustion gas is corrosive; special materials are required to withstand chemical and electrochemical erosion. The duct structure must also withstand the high electromagnetic forces on current-carrying elements.

Insulator wall designs consisting of a matrix of separately cooled metal pegs set in an insulating background have been found satisfactory. The electrodes present a more difficult materials problem. To provide efficient electron emission into the gas, the electrode surfaces must be hot, but the hotter the surface, the greater the damage from fluxing and erosion. High-temperature ceramic oxides, such as stabilized zirconia, which are conductors and electron emitters when hot, are the favoured materials. Water-cooled metal supports provide structural integrity and electrical contact to the ceramic blocks. The individual electrode segments are then separated by corrosion-resistant insulator strips and built up into a segmented electrode wall. Erosion and destruction of the ceramic are still a major problem. The only electrode structure that has operated successfully in a power-producing channel for hundreds of hours, required a replenishment system, in which zirconia added to the gas stream deposited on the electrode surface at a rate equal to the erosion.

*The magnet.* A magnetic field of 5 to 6 tesla (webers per square metre) is required for the MHD generator. (The weber unit of magnetic flux, in linking a circuit of one turn produces an electromotive force of one volt in it as it is reduced to zero at a uniform rate in one second.) Though higher fields would increase power density, the electric fields in the duct, the forces in the magnet windings, and the magnet costs become impractically high at fields above this value. For the linear duct, the magnet geometry is unusual; a double-saddle geometry as shown in Figure 1 is preferred since it provides an almost uniform field across the duct and allows the channel to pass straight through the magnet.

The conductor choice lies between copper at room temperature, cryogenically cooled aluminum and sodium, and superconductors such as niobium-titanium. For central-station generation, the higher initial cost of the superconducting (zero electrical resistance) winding is more than offset by the power consumption of resistive windings. Because the energy stored in the magnet is enormous, the magnet must be protected from damage during rapid shutdown. For peaking or emergency power the magnet requirements are different. Since a superconducting magnet requires continuous refrigeration, an iron-core copper magnet, self-excited by part of the generator output (and not requiring such refrigeration), may be preferred.

*Steam plant and seed recovery.* The heat-recovery unit contributes one-third to one-half of the combined plant output so that its capital cost and efficiency are important factors. In many respects, the steam plant topped by an

Reducing  
dissipation

Supercon-  
ducting  
magnets

MHD generator is similar to a conventional plant. The major differences are: radiant heat transfer in the boiler is reduced as the MHD exhaust contains no soot; the seed-laden gas is more corrosive; seed deposits on the boiler tubes reduce heat-transfer rates; the air heater must be incorporated into the heat-recovery unit; and most of the conventional regenerative-boiler-feed water heaters are eliminated because the feed water now cools the MHD duct and combustion chamber, reducing the steam-cycle efficiency.

The heat-recovery unit also recovers the seed. Since the cost of the injected potassium seed is several times the cost of the fuel, 99 percent seed recovery is required for an economic system. The cost of cesium seed would require 99.9 percent recovery, which is probably impractical. About 80 percent of the seed is deposited in the air heater and steam plant, the remaining 20 percent is removed in an electrostatic precipitator. The seed is then processed and recycled.

**Environmental factors.** One benefit of increased overall efficiency is reduced heat loss to the environment. The thermal pollution of lakes and rivers caused by the discharge of condenser-cooling water from conventional fossil-fuelled and nuclear plants is a significant and increasing problem.

Conventional fossil-fuelled plants are a major source of sulfur oxides, nitrogen oxides, and particulates. The higher combustion temperatures in the MHD system substantially increase the nitrogen oxides, though the sulfur oxides remain unchanged. The need to recover the seed requires a cleaning system that removes a high percentage of all particulates, though additional gas cleaning equipment is also required.

#### ELECTROGASDYNAMIC DEVICES

**Electrostatic-generator performance.** The EGD device illustrated in Figure 2 has several attractive features. Like MHD devices, it has no moving parts and high gas temperatures can be used. Since the gas must be an electrical insulator instead of a conductor, an EGD device can operate over the whole available gas temperature range. (Conductance of a gas changes with temperature.) Thus EGD is not restricted to "topping" applications, as is MHD. The electrical output is direct current, very high voltage, and is therefore suitable for long distance transmission without any need for dc/ac converters and transformers.

For a number of complex reasons, however, EGD generator performance is rather limited. For example, the electrical output of a single EGD channel (or generator) does not exceed about 50 watts. The size is limited by the electrical breakdown strength of the gas and the maximum useful voltage between electrodes. Considerable unavoidable energy loss is part of the EGD process. Thus, with today's technology, EGD generator performance still has serious drawbacks. In comparison with MHD devices, the large difference in size of the two devices is one drawback. The MHD generator size is not limited in any fundamental way; the EGD converter is limited by the very high electric fields required for high power densities.

**Electrostatic power generation.** When an EGD device is incorporated into a power-generating cycle, high-pressure, high-temperature gas expands through the EGD generator, and power is extracted from the flow. Because the power extracted in each single EGD converter is small, however, the pressure drop across each unit is small, and many units must be connected in series and in parallel to obtain acceptable cycle efficiency and power output for bulk power generation.

Fossil-fuel-fired open-cycle systems have been proposed. In these, air would be compressed and burned with fossil fuel at high pressure in a combustor; the hot gases carrying small particles (usually fly ash) would enter the EGD generator, where the particles would be charged at the entrance to each channel. At each channel exit, the current would be collected; at the next channel entrance the ash particles would be recharged. All of the corona and collector electrodes would be connected in parallel since the voltage across each stage is high (1,000,000 volts)

and any other connection would give a still higher voltage. Depending on the assumptions made, the efficiencies predicted for such cycles can be comparable with conventional power-generating systems, and it is expected that the capital cost of the EGD device could be much lower. The assumptions on which the design and performance calculations would have to be based had not yet been proven experimentally by the mid-1970s. A closed-cycle system with helium heated as it passes through a nuclear reactor before it enters the EGD generator has also been suggested.

#### PRESENT STATUS AND FUTURE PROSPECTS

Aside from MHD flowmeters and pumps for special applications, the greatest promise for MHD devices is in central-station power generation. The open-cycle system, with an MHD generator topping a conventional steam unit, has the potential for using our large fossil-fuel reserves more effectively through higher cycle efficiencies.

A number of technical problem areas remain, however, particularly in regard to the high-temperature air heater and long-life requirements for the MHD duct. It is not possible, therefore, to estimate precisely the capital costs of a central-station MHD-steam system, nor to be sure what increase in efficiency over a conventional fossil-fired plant can be attained. MHD systems must also compete with developments in the nuclear-power industry. In Great Britain and France, the economic advantages of MHD were not thought sufficient to make the substantial development costs worthwhile; their extensive MHD research programs had been discontinued by 1970. In the Soviet Union, however, which has the largest MHD effort in the world, work on a substantial scale continues with the construction of an MHD-steam pilot plant of 75-megawatt output in Moscow. In the U.S. it is expected that development of individual plant items will continue, but that construction of a complete pilot plant will await better solutions to the remaining technical problems. There are no prospects at present for developing closed-cycle MHD systems on a comparable scale. The prospects of EGD for bulk power generation are not promising. The large number of parallel and series units required for a generator of useful size makes the concept of marginal feasibility. The EGD converter may find use, however, as a small, high-voltage power supply.

## Magnets and Electromagnets

The use of the magnet and its electrical counterpart, the electromagnet, is the foundation of much of modern technology. The development of theories of magnetism was an important part of the work of the great 19th-century physicists, but a full understanding of the phenomenon had to await the development of the 20th-century ideas of quantum mechanics. Present understanding has led to the development of modern, powerful, permanent-magnet materials on the one hand and to the versatile ferrites—direct descendants of the lodestone—on the other.

This article describes electromagnets and permanent magnets and their applications in many devices, from motors and generators to computers. A more detailed description of the phenomenon of magnetism and its historical development appears in the article MAGNETISM.

## MAGNETIC PROPERTIES

By the end of the 19th century all the known elements and many compounds had been tested for magnetism, and all were found to have some magnetic property. The most common was the property of diamagnetism, the name given to materials exhibiting a weak repulsion by both poles of a magnet. Some materials, for example, chromium, showed paramagnetism, being capable of weak induced magnetization when brought near to a magnet. This magnetization disappears when the magnet is removed. Only three elements, iron, nickel, and cobalt, showed the property of ferromagnetism; that is, the capability of remaining permanently magnetized. Among the known compounds of these elements, only one of iron, in particular the iron oxide  $\text{Fe}_3\text{O}_4$ , showed ferromagnetic properties; this is, of course, the lodestone.

Alongside the considerable scientific work aimed at the understanding of magnetism, there was a steady technical development producing better permanent magnets. The discovery of electromagnetism provided the means of making stronger magnets. The bar of material, usually iron, was placed in a long coil through which a heavy current was passed. It was soon discovered that among magnets produced in this way some retained their magnetism indefinitely while others lost it over a relatively short period of time. It was also found that a ferromagnetic material would exhibit saturation; *i.e.*, there was a maximum strength attainable by the magnet that could not be exceeded, no matter how large a current was passed through the magnetizing coil.

**Magnetization process.** The quantities now used in characterizing magnetization were defined and named by William Thomson (Lord Kelvin) in 1850. The symbol  $B$  denotes the magnitude of magnetic flux density inside a magnetized body, and the symbol  $H$  denotes the magnitude of magnetizing force, or magnetic field, producing it. The two are represented by the equation  $B = \mu H$ , in which the Greek letter mu,  $\mu$ , symbolizes the permeability of the material and is a measure of the intensity of magnetization that can be produced in it by a given magnetic field. The modern units of the International Standard (SI) system for  $B$  are teslas (T) or webers per square metre ( $\text{Wb}/\text{m}^2$ ) and of  $H$  as amperes per metre (A/m). The units were formerly called, respectively, gauss and oersted. The units of  $\mu$  are henrys per metre. (All of these terms reflect the important work on magnetism and electricity of the 19th-century German physicist Wilhelm E. Weber, the French physicist André-Marie Ampère, the 18th- and 19th-century German mathematician Wilhelm Karl Friedrich Gauss, the 18th- and 19th-century Danish physicist Hans Christian Ørsted, and the 19th-century U.S. physicist Joseph Henry.)

**Hysteresis** All ferromagnetic materials exhibit the phenomenon of hysteresis, a lag in response to changing forces based on energy losses resulting from internal friction. If  $B$  is measured for various values of  $H$  and the results are plotted in graphical form, the result is a loop of the type shown in Figure 1, called a hysteresis loop. The name describes the situation in which the path followed by the values of  $B$

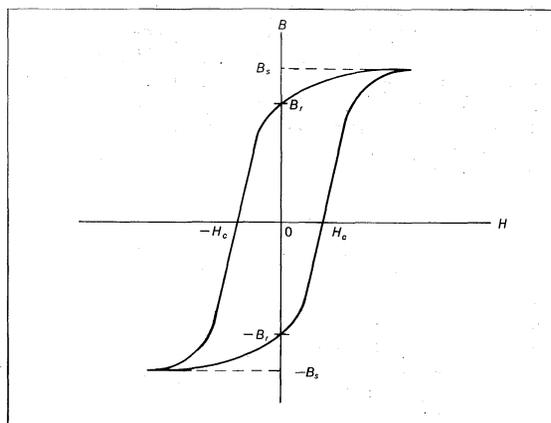

Figure 1: Typical hysteresis loop (see text).

while  $H$  is increasing differs from that followed as  $H$  is decreasing. With the aid of this diagram, the characteristics needed to describe the performance of a material to be used as a magnet can be defined.  $B_s$  is the saturation flux density and is a measure of how strongly the material can be magnetized.  $B_r$  is the remanent flux density and is the residual, permanent magnetization left after the magnetizing field is removed; this latter is obviously a measure of quality for a permanent magnet. It is usually measured in webers per square metre. In order to demagnetize the specimen from its remanent state, it is necessary to apply a reversed magnetizing field, opposing the magnetization in the specimen. The magnitude of field necessary to reduce the magnetization to zero is  $H_c$ , the coercive force, measured in amperes per metre. For a permanent magnet to retain its magnetization without loss over a long period of time,  $H_c$  should be as large as possible. The combination of large  $B_r$  and large  $H_c$  will generally be found in a material with a large saturation flux density that requires a large field to magnetize it. Thus, permanent-magnet materials are often characterized by quoting the maximum value of the product of  $B$  and  $H$ ,  $(BH)_{max}$ , which the material can achieve. This product  $(BH)_{max}$  is a measure of the minimum volume of permanent-magnet material required to produce a required flux density in a given gap and is sometimes referred to as the energy product.

At the end of the 19th century it was known that high-carbon steel made the most permanent magnets (high  $H_c$ ), and that the addition of a small amount of cobalt improved the value of  $(BH)_{max}$ . On the other hand, Swedish iron, a highly refined, well-annealed pure iron, made good electromagnets (high  $B_s$ , low  $H_c$ ) that lost their magnetization almost completely on the removal of the magnetizing field. Nickel was a relatively poor magnetic material in its pure state, but the addition of iron greatly increased its permeability so that low values of field  $H$  produced relatively high magnetic flux density  $B$ .  $H_c$ , however, was generally low.

The 20th century has seen an enormous development in magnetic alloys and compounds, particularly from the 1930s onward. Since that time  $(BH)_{max}$  has been increasing at an average rate of 3,500 to 4,000 joules per cubic metre ( $\text{J}/\text{m}^3$ ) per year.

It was suggested in 1907 that a ferromagnetic material is composed of a large number of small volumes called domains, each of which is magnetized to saturation. In 1931 the existence of such domains was first demonstrated by direct experiment. The ferromagnetic body as a whole appears unmagnetized when the directions of the individual domain magnetizations are distributed at random. Each domain is separated from its neighbours by a domain wall. In the wall region, the direction of magnetization turns from that of one domain to that of its neighbour. The process of magnetization, starting from a perfect unmagnetized state, comprises three stages: (1) *Low magnetizing field*. Reversible movements of the domain walls occur such that domains oriented in the general direction of the magnetizing field grow at the expense of those unfavourably oriented; the walls return to their original position on removal of the magnetizing field, and there is no remanent magnetization. (2) *Medium magnetizing field*. Larger movements of domain walls occur, many of which are irreversible, and the volume of favourably oriented domains is much increased. On removal of the field, all the walls do not return to their original positions, and there is a remanent magnetization. (3) *High magnetizing field*. Large movements of domain walls occur such that many are swept out of the specimen completely. The directions of magnetization in the remaining domains gradually rotate, as the field is increased, until the magnetization is everywhere parallel to the field and the material is magnetized to saturation. On removal of the field, domain walls reappear and the domain magnetizations may rotate away from the original field direction. The remanent magnetization has its maximum value.

The values of  $B_r$ ,  $H_c$ , and  $(BH)_{max}$  will depend on the ease with which domain walls can move through the

Ferromagnetism

Domain  
wall  
move-  
ments

material and domain magnetization can rotate. Discontinuities or imperfections in the material provide obstacles to domain wall movement. Thus, once the magnetizing field has driven the wall past an obstacle, the wall will not be able to return to its original position unless a reversed field is applied to drive it back again. The effect of these obstacles is, therefore, to increase the remanence. Conversely, in a pure, homogeneous material, in which there are few imperfections, it will be easy to magnetize the material to saturation with relatively low fields, and the remanent magnetization will be small; such characteristics are required in electromagnet applications.

**Demagnetization and magnetic anisotropy.** So far as domain rotation is concerned, there are two important factors to be considered, demagnetization and magnetic anisotropy (exhibition of different magnetic properties when measured along axes in different directions). The first of these concerns the shape of a magnetized specimen. Any magnet generates a magnetic field in the space surrounding it. The direction of the lines of force of this field, defined by the direction of the force exerted by the field on a (hypothetical) single magnetic north pole, is opposite to the direction of field used to magnetize it originally. Thus, every magnet exists in a self-generated field that has a direction such as to tend to demagnetize the specimen. This phenomenon is described by the demagnetizing factor. If the magnetic lines of force can be confined to the magnet and not allowed to escape into the surrounding medium, the demagnetizing effect will be absent. Thus a toroidal (ring-shaped) magnet, magnetized around its perimeter so that all the lines of force are closed loops within the material, will not try to demagnetize itself. For bar magnets, demagnetization can be minimized by keeping them in pairs, laid parallel with north and south poles adjacent and with a soft-iron keeper laid across each end.

The relevance of demagnetization to domain rotation arises from the fact that the demagnetizing field may be looked upon as a store of magnetic energy. Like all natural systems, the magnet, in the absence of constraints, will try to maintain its magnetization in a direction such as to minimize stored energy; *i.e.*, to make the demagnetizing field as small as possible. To rotate the magnetization away from this minimum-energy position requires work to be done to provide the increase in energy stored in the increased demagnetizing field. Thus, if an attempt is made to rotate the magnetization of a domain away from its natural minimum-energy position, the rotation can be said to be hindered in the sense that work must be done by an applied field to promote the rotation against the demagnetizing forces. This phenomenon is often called shape anisotropy because it arises from the domain's geometry which may, in turn, be determined by the overall shape of the specimen.

Similar minimum-energy considerations are involved in the second mechanism hindering domain rotation, namely magnetocrystalline anisotropy. It was first observed in 1847 that in crystals of magnetic material there appeared to exist preferred directions for the magnetization. This phenomenon has to do with the symmetry of the atomic arrangements in the crystal. For example, in iron, which has a cubic crystalline form, it is easier to magnetize the crystal along the directions of the edges of the cube than in any other direction. Thus the six cube-edge directions are easy directions of magnetization, and the magnetization of the crystal is termed anisotropic. In cobalt, which has a hexagonal, close-packed crystal structure, there is a single easy direction coinciding with the hexagonal axis. When the magnetization lies along an easy direction, the anisotropy energy is a minimum, and work must be done to rotate the magnetization away from this direction. This phenomenon is therefore another hindrance to domain rotation.

Magnetic anisotropy can also be induced by strain in a material. The magnetization tends to align itself in accordance with or perpendicular to the direction of the in-built strain. Some magnetic alloys also exhibit the phenomenon of induced magnetic anisotropy. If an external magnetic field is applied to the material while it is an-

nealed at a high temperature, an easy direction for magnetization is found to be induced in a direction coinciding with that of the applied field.

The above description explains why steel makes a better permanent magnet than does soft iron. The carbon in steel causes the precipitation of tiny crystallites of iron carbide in the iron that form what is called a second phase. The phase boundaries between the precipitate particles and the host iron form obstacles to domain wall movement, and thus the coercive force and remanence are raised compared with pure iron.

The best permanent magnet, however, would be one in which the domain walls were all locked permanently in position and the magnetizations of all the domains were aligned parallel to each other. This situation can be visualized as the result of assembling the magnet from a large number of particles having a high value of saturation magnetization, each of which is a single domain, each having a uniaxial anisotropy in the desired direction, and each aligned with its magnetization parallel to all the others. It is this model that has led to the dramatic improvement in permanent magnets in modern times.

#### MAGNETIC MATERIALS

**Powder magnets.** The problem of producing magnets composed of compacted powders is essentially that of controlling particle sizes so that they are small enough to comprise a single domain and yet not so small as to lose their ferromagnetic properties altogether. Broadly, two methods have been used; these are electrodeposition and the reduction of salts or oxides of the metal. All of the early work using these methods produced spheroidal particles, and so the advantage of shape anisotropy was not obtained. Magnets were produced by compression of the powders in a protective medium such as benzene, and the final magnetic properties of the material were determined largely by the degree of compression. The most successful of the earlier materials was an iron-cobalt alloy powder magnet. The electrodeposition method was later modified to produce elongated particles, which are compressed and molded in a high magnetic field that serves to align them. The advantage of this type of magnet is that it can readily be molded and machined into desired shapes.

The disadvantage of powder magnets is that when single-domain particles are packed together they are subject to strong magnetic interactions that reduce the coercive force and, to a lesser extent, the remanent magnetization. The nature of the interaction is essentially a reduction of a given particle's demagnetizing field caused by the presence of its neighbours, and the interaction limits the maximum values of  $H_c$  and  $(BH)_{max}$  that can be achieved.

More success has attended the development of magnetic alloys.

**Alloys. High anisotropy alloys.** The materials described above depend on shape for their large uniaxial anisotropy. Much work has also been done on materials having a large uniaxial magnetocrystalline anisotropy. Of these, the most successful have been cobalt-platinum (CoPt) and manganese-bismuth (MnBi) alloys.

Cobalt-platinum has a face-centred tetragonal crystal-line structure and can be prepared in powder form. The magnet is made by pressing and sintering (heating short of the melting point) the powder at about 1,000° C (1,800° F). Coercive forces of up to  $3.6 \times 10^5$  amperes per metre and  $(BH)_{max}$  of  $7.4 \times 10^4$  joules per cubic metre have been reported for these magnets. Industrial use is somewhat limited by the high price of platinum.

Manganese-bismuth alloy, with a 50-50 composition, has a uniaxial anisotropy similar to that of CoPt. Magnets made by compacting and sintering the powdered alloy in a strong field produce  $H_c$  values up to  $5.6 \times 10^5$  amperes per meter with  $B_c = 0.43$  webers per square metre and  $(BH)_{max} = 4.2 \times 10^4$  joules per cubic metre.

**Alnico alloys.** High coercive force will be obtained where domain wall motion can be inhibited. This condition can occur in an alloy in which two phases coexist, especially if one phase is a finely divided precipitate in a matrix of the other. Alloys containing the three elements iron, nickel, and aluminum show just such behaviour;

size

Preferred  
directions  
of  
magne-  
tization

and permanent magnet materials based on this system, with various additives, such as cobalt, copper, or titanium, are generally referred to as Alnico alloys. The addition of cobalt increases the  $(BH)_{max}$  value, and one of the earlier alloys had the composition 23 percent Ni, 10 percent Al, 12 percent Co, 5 percent Cu, balance Fe. This alloy was quenched (rapidly cooled) from a temperature of 1,300° C (2,400° F), producing a single-phase form of the material, and then annealed at 650° C (1,200° F) to promote precipitation of the second phase.  $(BH)_{max}$  of  $1.4 \times 10^4$  joules per cubic metre was obtained.

The property of those alloys having greatest technical significance is that of magnetic annealing. If heat treatment is carried out in a magnetic field, much improved values of  $H_c$  and  $(BH)_{max}$  are obtained. Heat treatment of an alloy with 14 percent Ni, 8.5 percent Al, 23 percent Co, 3 percent Cu, balance Fe, in a field of  $2.4 \times 10^7$  amperes per metre produces  $(BH)_{max} = 4.2 \times 10^4$  joules per cubic metre. The precipitated particles have cubic symmetry with the easy direction of magnetization along the cube edges. If the particles can be aligned with their edges parallel, an increased coercive force can be obtained. This property is achieved by a casting process in which the crystallites of the original single-phase material grow in aligned columnar form. The precipitate particles, produced by subsequent heat treatment, adopt the alignment of the matrix. One such alloy, marketed under the name Columax, has  $H_c = 6.7 \times 10^4$  amperes per cubic metre and  $(BH)_{max} = 6.6 \times 10^4$  joules per cubic metre.

Similar alloys with up to 4 percent titanium as an additional component are marketed under the name Ticonal, the crystal-oriented version of which is Ticonal XX. This material has  $(BH)_{max} = 9 \times 10^4$  joules per cubic metre,  $H_c = 10^5$  amperes per metre with  $B_r = 1.18$  webers per square metre.

None of these alloys is readily machinable and generally must be cast in their final shape.

**Rare-earth-cobalt alloys.** Isolated atoms of many elements have finite magnetic moments; that is, the atoms are themselves tiny magnets. When the atoms are brought together in the solid form of the element, however, most of them interact in such a way that their magnetism cancels out and the solid is not ferromagnetic. Only in iron, nickel, and cobalt, of the common elements, does the cancelling-out process leave an effective net magnetic moment per atom in the vicinity of room temperature and above. The unit in which this magnetic moment is measured is the Bohr magneton, symbolized by the Greek letter beta,  $\beta$ , which has the value  $1.165 \times 10^{-29}$  weber-metres (Wb-m). The atomic magnetic moments of iron, nickel, and cobalt are respectively  $2.22\beta$ ,  $0.606\beta$ , and  $1.716\beta$ . The only other ferromagnetic solid element that shows ferromagnetic behaviour at practical temperatures is the rare-earth element gadolinium. It has the large value of  $7.10\beta$  for the atomic magnetic moment, but unfortunately it loses its ferromagnetism at temperatures above 16° C (60° F) so that it is not of practical importance. Several of the rare-earth elements show ferromagnetic behaviour at extremely low temperatures, and many of them have large atomic moments. They are not, however, of great practical value at present.

Rare-earth-cobalt alloys form ferromagnetic materials, but most of them have practical disadvantages of one kind or another. Success was achieved in 1971 with the rare-earth metal samarium (Sm) alloyed with cobalt to form  $\text{SmCo}_5$ . This alloy has an exceptionally high magnetocrystalline anisotropy, which gives  $H_c = 6.4 \times 10^5$  amperes per metre and  $BH_{max} = 14.4 \times 10^4$  joules per metre with  $B_r = 0.87$  webers per square metre and is a very promising permanent-magnet material.

**Barium ferrites.** Barium ferrite, basically  $\text{BaO} \cdot 6\text{Fe}_2\text{O}_3$ , is a variation of the basic magnetic iron-oxide magnetite but has a hexagonal crystalline form. This configuration gives it a very high uniaxial magnetic anisotropy capable of producing high values of  $H_c$ . The powdered material can be magnetically aligned and then compacted and sintered. The temperature and duration of the sintering process determines the size of the crystallites and provides a means of tailoring the properties of the magnet.

For very small crystallites the coercive force is high and the remanence is in the region of half the saturation flux density. Larger crystallites give higher  $B_r$  but lower  $H_c$ . This material has been widely used in the television industry for focussing magnets for television tubes. The coercive force can be varied over the range  $3.1 \times 10^4$  to  $4 \times 10^5$  amperes per metre and values of  $(BH)_{max} = 2.8 \times 10^4$  joules per cubic metre are claimed for commercial materials.

A further development of commercial importance is to bond the powdered ferrite by a synthetic resin or rubber to give either individual moldings or extruded strips, or sheets, that are semiflexible and can be cut with knives. This material has been used as a combination gasket (to make airtight) and magnetic closure for refrigerator doors.

The characteristics and some trade names of materials in wide use in the early 1970s is given in Table 1.

for good permanent magnets. Such materials must be capable of being magnetized to a high value of flux density in relatively small magnetic fields and then must lose this magnetization completely on removal of the field. In terms of the hysteresis loop shown in Figure 1, such a material must have a narrow hysteresis loop (low  $H_c$ ) and reach high saturation values (high  $B_s$ ) with as low a remanence as possible (low  $B_r$ ). Further, because the area of the loop represents a loss of energy in the material as it is magnetized and demagnetized in each direction (the hysteresis loss), the smallest possible loop area is required.

In terms of the domain model, these conditions mean that there should be few or only small obstacles to domain wall movement and as little anisotropy as possible. These requirements call for homogeneous, single-phase alloys of low magnetocrystalline anisotropy. Further, to obtain high magnetization in low fields, the material must have a high relative permeability.

**Iron and silicon iron.** Because iron has the highest value of magnetic moment per atom of the three ferromagnetic metals, it remains the best material for applications where a high-saturation flux density is required. Extensive investigations have taken place to determine how to produce iron as free from imperfections as possible, in order to attain the easiest possible domain wall motion. The presence of such elements as carbon, sulfur, oxygen, and nitrogen, even in small amounts, is particularly harmful; and thus sheet materials used in electrical equipment have a total impurity content of less than 0.4 percent.

The guides to magnetic quality for permeable materials are the maximum relative permeability  $\mu_{RM}$  and the hysteresis loss  $W_H$  for alternating flux of a given amplitude of flux density  $\pm B_{max}$ . Typical values for commercially pure iron are  $\mu_{RM} = 5,000$ ,  $W_H = 70$  joules per cubic metre per hertz for  $B_{max} = 0.5$  webers per square metre. Laboratory production of iron with an impurity content of 0.04 percent gives  $\mu_{RM} = 280,000$  with  $W_H = 19$  joules per cubic metre per hertz for  $B_{max} = 1.4$  webers per square metre. The saturation flux density is in the region of 2.16 webers per square metre.

The addition of cobalt (Co) to iron (Fe) increases the saturation magnetization at the expense of a decrease in permeability. Commercial CoFe has a composition Co: 34.1 percent, Ni: 0.5 percent, C: 0.07 percent, Mn: 0.05 percent, balance Fe and gives a saturation magnetization of 2.36 webers per square metre.

Important advantages are obtained by alloying iron with a small amount (about 4 percent) of silicon. The added silicon reduces the magnetocrystalline anisotropy of the iron and hence its coercive force and hysteresis

loss. Although there is a reduction in the saturation flux density, this loss is outweighed by the other advantages, which include increased electrical resistivity. The latter is important in applications where the magnetic flux alternates because this induces eddy currents in the magnetic material. The lower the resistivity and the higher the frequency of the alternations, the higher are these currents. They produce a loss of energy by causing heating of the material and will be minimized, at a given frequency, by raising the resistivity of the material. A typical, hot-rolled silicon iron gives  $\mu_{RM} = 9,000$  with  $W_H = 25$  joules per cubic metre at  $B_{max} = 0.5$  webers per square metre.

By a suitable manufacturing process, silicon-iron sheet material can be produced with a high degree of preferred orientation of the crystallites. The material then has a preferred direction of magnetization, and in this direction high permeability and low loss are attained. Commercially produced material has about 3.2 percent silicon and is known as cold-reduced, grain-oriented silicon steel. This material gives  $\mu_{RM} = 70,000$  with  $W_H = 4.3$  joules per cubic metre per hertz at  $B_{max} = 0.5$  webers per square metre.

**Nickel-iron alloys.** Alloys of nickel and iron in various proportions are given the general name Permalloy. As the proportion of nickel varies downward, the saturation magnetization increases, reaching a maximum at about 50 percent, falling to zero at 27 percent nickel, then rising again toward the value for pure iron. The magnetocrystalline anisotropy also falls from the value for pure nickel to a very low value in the region of 80 percent nickel, rising only slowly thereafter. Highest value of permeability is at 78.5 percent nickel, which is called Permalloy A. The maximum relative permeability, which can reach a value in the region of 1,000,000 in carefully prepared Permalloy A, makes the alloy useful and superior to iron and silicon iron at low flux densities; but because of its lower value of saturation magnetization, this superiority only persists up to flux densities of 0.7 webers per square metre.

A range of commercially available permeable alloys with various additives is included in Table 2.

**Ferrites.** In addition to barium ferrite, which has a hexagonal crystal form, most of the ferrites of the general formula  $MeO \cdot Fe_2O_3$ , in which Me is a metal, are useful magnetically. They have a different crystalline form called spinel after the mineral spinel ( $MgAl_2O_4$ ), which crystallizes in the cubic system. All the spinel ferrites are soft magnetic materials; that is, they exhibit low coercive force and narrow hysteresis loops. Furthermore, they all have a high electrical resistivity and high relative

Permalloy

permeabilities, thus making them very suitable for use in high-frequency electronic equipment. Their saturation magnetization is, however, low, compared with the alloys, and this property limits their use in high-field, high-power transformers. They are hard, brittle, ceramic-like materials and are difficult to machine. Nevertheless, they are widely used, most importantly in computer memory stores (see also FERRITES).

#### ELECTROMAGNETS

Where controllable magnets are required, as for applications in which the magnetic flux is to be varied, reversed, or switched on and off, an electromagnet must be used. This device is made up of a coil of wire, through which electric current is passed. The coil is wrapped round the material to be magnetized in some suitable configuration. The engineering design of electromagnets is systematized by means of the concept of the magnetic circuit. In the magnetic circuit a magnetomotive force (mmf) is defined as the ampere-turns of the coil that generates the magnetic field to produce the magnetic flux in the circuit. Thus, if a coil of  $n$  turns per metre carries a current  $i$  amperes, the field inside the coil is  $ni$  amperes per metre and the mmf it generates is  $nil$  ampere turns, where  $l$  is the length of the coil. More conveniently, the mmf is  $Ni$ , where  $N$  is the total number of turns in the coil. The magnetic flux density  $B$  is the equivalent, in the magnetic circuit, of the current density in an electric circuit. In the magnetic circuit the magnetic equivalent to current is the total flux symbolized by the Greek letter phi,  $\phi$ , given by  $BA$ , where  $A$  is the cross-sectional area of the magnetic circuit. In an electric circuit the electromotive force (emf) is related to the current,  $i$ , in the circuit by  $\text{emf} = Ri$ , where  $R$  is the resistance of the circuit. In the magnetic circuit  $\text{mmf} = r\phi$ , where  $r$  is the reluctance of the magnetic circuit and is equivalent to resistance in the electric circuit. Reluctance is obtained by dividing the length of the magnetic path  $l$  by the permeability times the cross-sectional area  $A$ ; thus  $r = l/\mu A$ , the Greek letter mu,  $\mu$ , symbolizing the permeability of the medium forming the magnetic circuit. The units of reluctance are ampere-turns per weber. These concepts can be employed to calculate the reluctance of a magnetic circuit and thus the current required through a coil to force the desired flux through this circuit.

Several assumptions involved in this type of calculation, however, make it at best only an approximate guide to design. The effect of a permeable medium on a magnetic field can be visualized as being to crowd the magnetic lines of force into itself. Conversely, the lines of force passing from a region of high to one of low permeability tend to spread out, and this occurrence will take place at an air gap. Thus the flux density, which is proportional to the number of lines of force per unit area, will be reduced in the air gap by the lines bulging out, or fringing, at the sides of the gap. This effect will increase for longer gaps; rough corrections can be made for taking the fringing effect into account.

It has also been assumed that the magnetic field is entirely confined within the coil. In fact, there is always a certain amount of leakage flux, represented by magnetic lines of force around the outside of the coil, which does not contribute to the magnetization of the core. The leakage flux is generally small if the permeability of the magnetic core is high.

In practice, the permeability of a magnetic material is a function of the flux density in it. Thus, the calculation can only be done for a real material if the actual magnetization curve, or, more usefully, a graph of  $\mu$  against  $B$ , is available.

Finally, the design assumes that the magnetic core is not magnetized to saturation. If it were, the flux density could not be increased in the air gap in this design, no matter how much current were passed through the coil. These concepts will be expanded further in following sections on specific devices.

**Solenoids.** A solenoid is generally a long coil through which current is flowing, establishing a magnetic field. More narrowly, the name has come to refer to an electro-

mechanical device that produces a mechanical motion on being energized with an electric current. In its simplest form it consists of an iron frame enclosing the coil and a cylindrical plunger moving inside the coil, as shown in Figure 2. For an alternating current supply, the iron losses in a solid frame restrict the efficiency and a laminated frame is used, which is made up of a pile of thin sheets of iron cut to the appropriate shape and stacked with a layer of insulating varnish between each sheet. When the coil is energized, the plunger moves into the coil by virtue of the magnetic attraction between it and the frame until it makes contact with the frame.

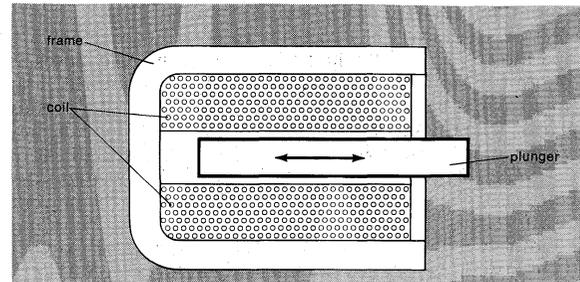

Figure 2: Elements of a solenoid.

Alternating current (ac) solenoids tend to be more powerful in the fully open position than direct current (dc) units. This result occurs because the initial current, high because of the inductance of the coil, is lowered by the air gap between the plunger and frame. As the solenoid closes, this air gap decreases, the inductance of the coil increases, and the alternating current through it falls. If an ac solenoid sticks in the open position the coil is likely to burn out.

When a solenoid is fully opened, it has a large air gap, and the high reluctance of this gap keeps the flux in the magnetic circuit low for a given mmf, and the force on the plunger is correspondingly low. As the plunger closes, the reluctance falls and the flux increases so that the force increases progressively. Manufacturers of solenoids provide force-stroke curves so that users can select the proper unit for their purpose. The curve can be modified by spring loading the plunger so that the force provided throughout the stroke may be matched to the particular mechanical load.

**Relays.** A relay is a device in which the solenoid principle is applied to opening and closing light-current electrical circuits. The same device applied in heavy-current circuits is called a contactor, or circuit breaker.

Because the amount of mechanical movement required is generally small, the solenoid plunger is usually stationary, and part of the frame is hinged to give the necessary movement. This arrangement is illustrated schematically in Figure 3. When the coil is energized, the hinged part of the frame is attracted to the solid iron core in the coil; this attraction pushes the contacts together. When the energizing current is removed, the hinged part is forced back to the open position by the springiness of the contact.

With the appearance of transistorized switching circuits, which use remarkably low power, a need arose for a relay that would operate reliably with a power of 100 to 300 milliwatts compared with four watts for the conven-

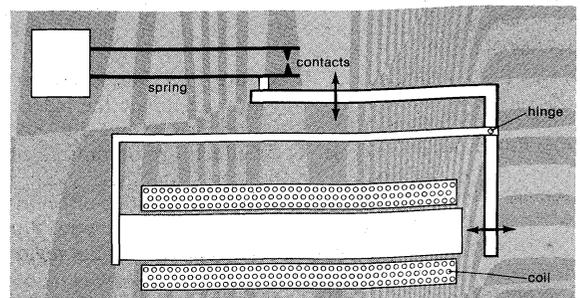

Figure 3: Elements of a relay.

The magnetic circuit

Permeability and flux density

The reed switch

tional relay. This need was met by the reed relay, or reed switch, shown in Figure 4. It consists of two flat blades of 50–50 nickel-iron alloy that overlap with a gap between them. When a magnetic field is applied along the length of the blades, opposite magnetic poles are induced in the overlapping parts, and they are attracted together, making electrical contact. On removal of the field, the springiness of the contact blade opens the contact. The overlap region is plated on each blade with gold to ensure good electrical contact, and the enclosing glass capsule is filled with dry nitrogen to prevent corrosion. The field required to operate the device is a function of the amount of overlap, and there is an optimum overlap corresponding to minimum required operating current.

Present reed switches used in telephone equipment are operated by up to 50 volts dc. Typically, the reed closes at 58 ampere-turns and releases at 15 ampere-turns, the hold current being 27 ampere-turns. The contact closes to give a stable contact resistance in two milliseconds, releases in 100 microseconds, and has a lifetime of more than 50,000,000 operations. Using a 35,000 turn coil the coil resistance is typically 18,600 ohms so that the current at 50 volts is 2.7 milliamperes. The minimum operating condition requires only about 1.7 milliamperes, so that the relay can be worked satisfactorily at lower voltage.

By the use of small, external, permanent magnets, reed switches can be made into latching relays that remain closed when the energizing field is removed. They can also be designed with three blades to give change-over contacts.

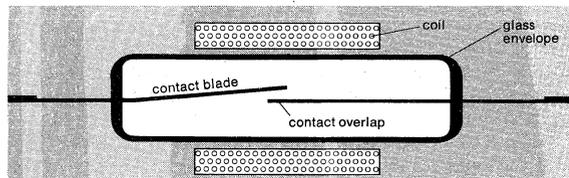

Figure 4: Elements of a reed relay.

**Design of large electromagnets.** Sooner or later almost every scientific research laboratory finds that it requires a facility for producing large magnetic fields. A number of advanced technologies likewise require large electromagnets; for example, a cyclotron, a device in which subatomic charged particles are accelerated by an alternating electric field in a constant magnetic field, needs a magnet to produce moderate fields but with a pole diameter that may be several metres. Some industries make use of large, high-power electromagnets for lifting purposes.

The design of large electromagnets in the past was more of an art than a science. Modern theoretical work has led to suitable approximations that allow magnet design to be carried out with the aid of some standard curves and a slide rule. For extremely high fields up to a flux density in an air gap of 25 webers per square metre, coils dissipating several megawatts of power are needed. By pulsing the current through the magnet coil with the aid of a controlled explosion, densities up to 1,400 webers per square metre have been produced experimentally. To put this high flux density in perspective, a one-ton laboratory electromagnet, with water-cooled coils passing a maximum current of about 30 amperes and with seven-inch diameter iron polefaces, could produce a density of about two webers per square metre across an air gap of two inches in length.

The basic principles of design are those discussed earlier. The difficulties arise in trying to estimate the magnitude of the fringing flux across the air gap and the leakage flux around the coils. Their effects are minimized by using a tapered shape for the cores and pole caps; a typical laboratory magnet is shown in Figure 5. Because soft iron saturates at 2.16 webers per square metre, flux densities in the air gap are generally limited to the region of 2.1 webers per square metre with iron magnets.

When designed for lifting or load-carrying purposes, an electromagnet may be required to have a single exposed

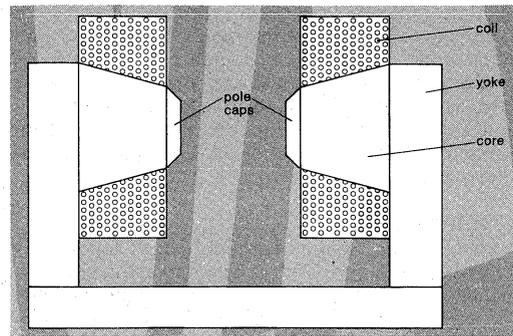

Figure 5: Elements of a typical electromagnet.

pole face to which the load to be carried will attach itself, and it will therefore have the shape of a bar magnet. The design is then dominated by the demagnetizing field. Suitably designed magnets can lift many times their own weight and are in general use in steelworks and scrap-yards.

Lifting magnets

#### GENERAL APPLICATIONS

There are many thousands of applications of magnets and electromagnets to electromagnetic devices and it would be impossible to cite all, or even a majority, of them. A few major areas of application and the principles of operation of some of the important devices in each area are given below.

**Communications.** Modern and future telephone systems will undoubtedly be based on the reed relay, together with sophisticated solid circuits for complex routing of connections. The telephone receiver is basically an electromagnet with a U-shaped yoke having coils wound on each leg of the U. Passage of the electrical signal through the coils causes magnetic attraction of a soft-iron diaphragm supported a small distance from the ends of the U. The diaphragm is deflected by an amount proportional to the magnitude of the current in the coil and generates sound waves as it moves back and forth. Improvement in magnetic materials has gradually increased the sensitivity of the telephone receiver, but the basic design has remained unchanged.

In modern, high-fidelity earphones the soft-iron diaphragm is replaced by a light, nonmagnetic diaphragm that carries a coil. The magnetic field is supplied by a small permanent magnet, generally a ferrite magnet. The current through the coil causes it to experience a force caused by the magnetic field. The force deflects the diaphragm by an amount proportional to the size of the current. This design permits an extremely small physical size because of the strength of modern permanent magnets.

The loudspeaker performs the same function as the earphone but is required to displace a larger volume of air. The diaphragm comprises a flexible cone of large area carrying a coil of fine wire on a small ring located at its apex. The ring lies between the poles of a powerful cylindrical permanent magnet. Audio frequency current through the coil causes deflection of the diaphragm, as in the earphone. Modern loudspeakers are much more sensitive and efficient than their predecessors because of the improvement in permanent magnet materials. The higher the flux density in the gap, the greater the sensitivity and the potential for fidelity of reproduction; modern loudspeakers use flux densities of up to one weber per square metre. Alloy magnets are usually used.

**Research.** Magnetic fields supply a powerful research tool without which modern physics could scarcely have grown to its present extent. A major area of application is in the interaction of magnetic fields and charged subatomic particles. A moving particle that carries a charge, such as an electron, can be regarded as an electric current and, like a current-carrying wire, experiences a force in a magnetic field. The direction of the force is perpendicular both to the direction of motion of the particle and to the magnetic field, so that the particle is deflected from its original path. This principle can be used to focus a stream of electrons into a narrow beam and to deflect the beam

Focussing a beam of electrons

by creating suitable magnetic fields, either from permanent magnets or from electromagnets. Every television receiver contains just such focussing and deflection systems to scan the face of the television tube with an electron beam.

In scientific applications the same principle is used in the electron microscope, in which the beam of electrons is passed through a series of magnetic "lenses," just as light is passed through glass lenses in a conventional microscope.

The cyclotron makes use of a magnetic field to cause charged particles to execute a circular path. On each traverse of the circle they are accelerated and finally acquire enormous kinetic energy (energy of motion). The cyclotron has been an important tool in nuclear research.

The same principle may be used to analyze materials in the mass spectrometer. The actual deflection of a moving charged particle in a magnetic field is determined by its charge, mass, and velocity. In a mass spectrometer the material under investigation is in the form of a gas of ionized particles that are accelerated by a fixed electric field. In passing through the magnetic field the particles are deflected by an amount determined by their mass, providing they all carry the same charge. By recording their arrival position at a fixed target, the mass of the particles can be deduced.

In the above description an applied voltage does work to accelerate the charged particles, and magnetic energy is expended in deflecting them. Suppose a high-velocity stream of ionized gas is produced by heating it to a high temperature (as, for example, in a jet engine) and "seeding" it with an ionizable molecule. As this ionized gas passes through a fixed magnetic field, the positive and negative ions will be deflected in opposite directions and, if they are collected on suitable electrodes, they will provide a potential difference capable of driving current around an external circuit. This is the principle of the magnetohydrodynamic (MHD) generator, which is believed to have an important future in power production (see also MAGNETOHYDRODYNAMIC DEVICES).

**Electrical industry.** It is no exaggeration to say that the whole of the electrical industry is founded on the generation and exploitation of magnetic fields. The electric motor is based on the force generated on a current-carrying conductor; the generator is based on the inverse effect that a conductor moving in a magnetic field has a current induced in it. In general, high-flux densities are required in the magnetic circuits of motors and generators, and this requirement has led to the use of soft iron or silicon-iron electromagnets as the source of magnetic fields in them. With the advent of modern permanent-magnet materials, however, small dc motors, in which the field is provided by permanent magnets, are finding wide applications, particularly in the toy industry.

Use of the motor principle in meters

The motor principle is also used in meters for measuring electric current. In the instrument, the design must be such that the force on the wire carrying the current to be measured is proportional to that current. In a typical design, a permanent magnet provides the field, and the pole pieces are shaped in such a way as to give a cylindrical air gap. Improved permanent magnets have led to improved instruments so that a reasonable robust meter can be made with a full-scale deflection corresponding to one microampere of current.

**Magnetic recording.** The principle of magnetic recording is to induce a permanent magnetization in a material by means of the signal to be recorded. The induced magnetization must be proportional to the amplitude of the signal and must remain in the material when the signal is removed. Thus, a magnetic material is required that has a high permeability, so that it will magnetize readily in a small field, a high remanent magnetization, so that the stored information can be easily "read," and not too high (but not too low) a coercive force, so that the stored information can be erased without great difficulty.

The most common type of magnetic recorder makes use of a magnetic tape. This passes at constant speed close to a recording head that may consist of a U-shaped magnet

yoke with coils wound on each limb. As the current in the coil varies in accordance with the audio-frequency signal to be recorded, a varying magnetization is induced in the tape. To play back the recorded information, the tape is passed through or near a coil so that the magnetic flux from the tape cuts the wires of the coil and induces an audio-frequency current in it. The tape may be erased by passing it through a recording head that carries a high-frequency signal, which has the effect of demagnetizing the tape.

The magnetic material used is a fine ferrite powder embedded in a plastic material comprising the tape. Manufacturers are very secretive about the precise materials and processes used in tape manufacture. A wide range of magnetic properties, however, can be obtained in the ferrites by varying the metal Me in the formula  $MeO \cdot Fe_2O_3$ . Further, control of coercive force is provided by the shape, size, and packing density of particles used. The ferrite is also a necessary choice because of its high resistivity. Metals and alloys would give high-eddy current losses and consequently poorer performance at the frequencies used (see also SOUND RECORDING AND REPRODUCING).

Computer information is in a particularly simple form for magnetic storage because it consists of a chain of electrical pulses of standard amplitude. Material requirements for the tape are not so stringent as for audio recording, the important feature being only that the tape should not demagnetize spontaneously; *i.e.*, it should have an adequate value of  $H_c$ . The most modern computers have replaced tape storage by disks of magnetic alloy that rotate under the recording head. Information can be stored at a higher density (bits per unit area) than in tape, and access to the information can be made faster by traversing the "read" head in a radial direction across the disks.

Ferrite materials have found an important application in the fast memory stores of computers. A spinel ferrite is formed into a small toroidal ring with the easy direction of magnetization around its periphery. A wire passing through its centre will generate a circular magnetic field when a current is passed through it; this current magnetizes the toroidal ring. On reversal of the current the magnetization will reverse in direction, so that the information is stored as, for example, clockwise magnetization for positive current and anticlockwise for negative. The two states correspond to the binary numbers 0 or 1 used in the computer language. The basic requirement is that the material should have a rectangular hysteresis loop in which  $B_r$  will be nearly equal to  $B_s$ , and that the magnetization should switch from one direction to the opposite direction when the coercive field is applied. It is often required that this switching should take place in  $1/10$  to  $1/100$  of a microsecond (a microsecond is  $1/1,000,000$  of a second). Such a system is called a ferrite core store and the ferrite rings are often less than one millimetre in diameter. The material most frequently used is a mixed magnesium-manganese ferrite typically having a threshold field for switching of 72 amperes per metre, a remanent flux density of 0.22 webers per square metre, and a saturation flux density of 0.95 webers per square metre. The initial relative permeability is 59.

Ferrite core store

An alternative device for a fast computer store is the magnetic thin film. If a ferromagnetic alloy is prepared in the form of a film in the thickness range 100–10,000 angstroms (an angstrom is  $10^{-10}$  metre), it can remain in a single domain state, with the magnetization everywhere in the same direction in the plane of the film. Furthermore, if the film is prepared in the presence of a magnetic field and the material used is a Permalloy, a uniaxial magnetic anisotropy is induced in it. The magnetization then has only two stable directions  $180^\circ$  apart, and it can be used in a way similar to the ferrite toroid in a computer store. Successful thin-film stores have employed cylindrical thin Permalloy films plated onto copper alloy wires (see also COMPUTERS).

## Magnoliales

Ever since the emergence of Darwin's evolutionary theories in 1859, botanists have attempted to classify the members of the plant kingdom according to their presumed natural relationships. During the first part of the 20th century, most "natural" systems of classification of the flowering plants (angiosperms) were based primarily on similarities or differences in gross morphological (structural) features, and the emphasis was placed on the reproductive structures; *i.e.*, the flowers. More recently, however, considerable data have accumulated from investigations of wood anatomy, vegetative nodal anatomy (*i.e.*, the manner in which vascular bundles depart from stems to enter leafstalks), pollen morphology, chromosome analysis, comparative biochemistry, floral anatomy, seedling development, and embryology, which, when considered as a whole, give a much more reliable picture of the true relationships within the flowering plants. Based on the totality of these features, most students of plant evolution now regard the Magnoliales order as including the most primitive components of the angiosperms.

Magnoliales is a plant order belonging to the dicotyledonous group of flowering plants (the dicots are roughly equivalent to broad-leaved plants as opposed to the monocots that have mostly parallel-veined leaves, grasses being a familiar example) and contains 8 families, 166 genera, and about 1,800 species, all of which are woody shrubs or trees. The 8 families of the Magnoliales order include the following: (1) Magnoliaceae with 12 genera and about 210 species; (2) Degeneriaceae with 1 genus and 1 species; (3) Himantandraceae with 1 genus and 4 species; (4) Eupomatiaceae with 1 genus and 2 species; (5) Annonaceae with 122 genera and about 1,100 species; (6) Canellaceae with 5 genera and about 9 species; (7) Myristicaceae with 16 genera and about 380 species; and (8) Winteraceae with 8 genera and 88 species. These estimates indicate that approximately 80 percent of the total genera (122 of 166) in this order and 60 percent of the species (1,100 of 1,794) are included in the pantropical (*i.e.*, found throughout the tropics) family Annonaceae. The next two largest families, Myristicaceae and Magnoliaceae, include about 32 percent of the species in the Magnoliales order, with the other five families comprising the remaining 8 percent. When this many small families are found to be classified together in the same order, it is usually assumed that they represent a group of

relic families that have evolved together slowly over a long period of time—a linear evolutionary derivation of one family directly from another should not be implied.

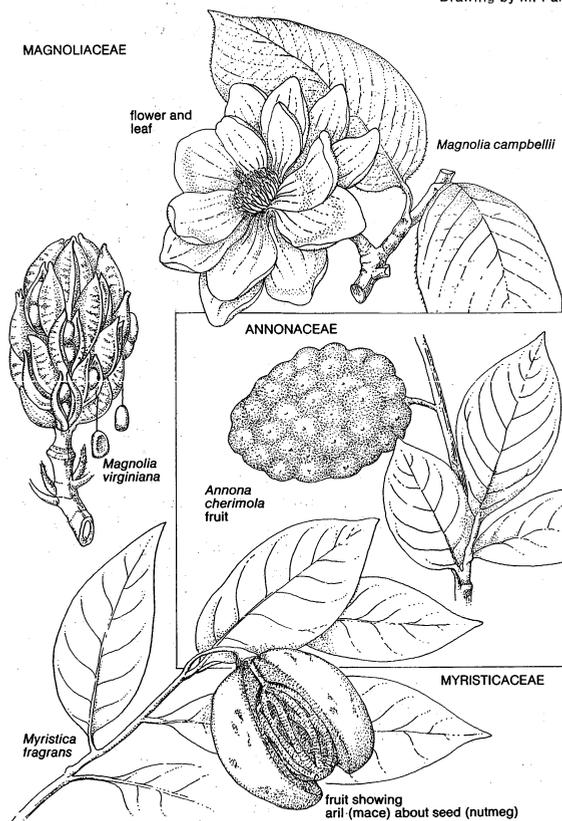

### GENERAL FEATURES

**Structural diversity and distribution.** All members of the order are woody; most are trees of small or intermediate size, though an exception occurs in the case of the tulip tree or tulip poplar, *Liriodendron tulipifera* (family Magnoliaceae), which reaches a height of over 150 feet (46 metres) and, in the Appalachian forests of the eastern United States, may have a base diameter of 10 feet.

Other tall trees are found in the genera *Mitrephora*, *Mezzettia*, and *Cananga* (all three of family Annonaceae) in the rain forests of Southeast Asia. The species of *Eupomatia* are shrubs, and many genera of the family Annonaceae are mostly shrubby, some being modified as climbers; *e.g.*, the genera *Ellipeia*, *Cyathostemma*, *Uvaria*, and *Phaeanthus*. Many species of Annonaceae are cauliflorous—*i.e.*, with flower buds formed from mature wood of the trunks and older branches; but the genus *Geanthemum* is unique in this order in that floral structures form on subterranean branches.

Growth forms and distributions

Drawing by M. Pahl

Representative plants from three of the largest families of the magnolia order.

Most Magnoliales are tropical in distribution, with the greatest speciation occurring in Southeast Asia and Africa. *Xylopia*, which includes about 160 species in the Annonaceae family, is the only genus in the order with pantropical distribution.

Genera with some temperate species include *Magnolia* and *Liriodendron* (Magnoliaceae family), with native species growing in China, Japan, and the eastern United States. Other temperate species include the papaw tree, *Asimina*, in the Annonaceae family, which extends northward into southern Ontario, Canada; *Eupomatia* from eastern Australia; and four genera of the Winteraceae family (*Drimys*, *Tasmannia*, *Pseudowintera*, and *Bubbia*) that range from eastern Australia and New Zealand to the southern Andes in Chile.

**Economic importance.** The wood of the tulip tree (*Liriodendron tulipifera*) sometimes referred to as Amer-

ican whitewood, is one of the most valuable timber products in the United States, where more than 800,000,000 board feet are cut each year. The wood is light yellow to tan, with a creamy white margin of sapwood. It is relatively soft, easily worked with tools, and takes paint well. Large, clear logs are well-suited to the manufacture of rotary-cut veneers, not only for furniture and cabinet-work, but also for berry and fruit boxes. Other uses are for millwork (sashes, doors, and blinds), hat blocks, and to a lesser extent, pulpwood for making paper (by the soda process).

The southern magnolia, or laurel magnolia (*Magnolia grandiflora*), has been called the most splendid ornamental tree in the American forests. The large, creamy-white flowers, together with dark green, lustrous, leathery leaves and reddish egg-shaped fruit with pendent scarlet seeds give it a striking appearance. The natural range of this stately tree (60 to 80 feet [18 to 24 metres] tall in the wild) is a strip about 100 miles (161 kilometres) wide from North Carolina, through northern Florida, along the Gulf Coast to eastern Texas. It is most abundant in Louisiana. A valuable ornamental, it is planted as far north as New Jersey on the Atlantic Coast of America and all the way to British Columbia on the Pacific Coast, where the winters are relatively mild. It also can be found in cultivation throughout most warm temperate regions of the world. Although its value as an ornamental far exceeds that as a timber producer, about 25,000,000 board feet are marketed annually in the southern United States. The majority of this wood is utilized in the manufacture of venetian blinds because of the wood's fine, uniform texture, hardness, and ability to resist warping.

The cucumber tree (*Magnolia acuminata*) reaches its greatest size (80 to 100 feet) in the narrow valleys of the Smoky Mountains of Tennessee and North Carolina. The fleshy fruit resembles a 2- to 3-inch-long cucumber, which gives the tree its popular name. The timber is not as durable as that of the related evergreen magnolia or tulip tree, but is marketed to make crates, boxes, cheap furniture, and interior flooring.

About 80 species of magnolia have been described; because of their showy flowers, which usually appear before their leaves in deciduous types, many are in cultivation in the north temperate parts of the world. Forty-six species and varieties are being grown at the Arnold Arboretum of Harvard University. The Morris Arboretum of the University of Pennsylvania has numerous American and Asiatic species, and the Royal Botanic Gardens, near London, has a magnificent living collection. Most American species have white to creamy-yellow flowers; many Asiatic species and their hybrids are characterized by pink to purplish-red flowers. A hybrid developed near Paris in 1820 is undoubtedly one of the most widely cultivated ornamentals—*M. soulangeana* is a large shrub or small tree of many varieties with large, cup-shaped, pinkish-purple flowers that appear early in the spring before the leaves. Some other well-known magnolia hybrids (indicated by the  $\times$ ) in cultivation are: *Magnolia loebneri* (*kobus*  $\times$  *stellata*); *M. thompsoniana* (*tripetala*  $\times$  *virginiana*); *M. watsonii* (*obovata*  $\times$  *sieboldii*); *M. proctoriana* (*salicifolia*  $\times$  *stellata*); and *M. veitchii* (*campbellii*  $\times$  *denudata*).

Another genus of the Magnoliaceae family that is widely cultivated in tropical regions is *Michelia*. Although the flowers are not as grandiose as those of the genus *Magnolia*, they more than make up this deficiency by their abundance and extreme fragrance. They also differ from the flowers of *Magnolia* in that they develop in dense clusters in the axils of leaves (the point at which the leaf stalk joins the branch), rather than singly at the ends of branches. The champac (*Michelia champaca*) is supposedly native to India, Assam, and Burma, but it has been in cultivation for so many centuries that its original natural range is difficult to determine. This tree is a handsome ornamental with evergreen leaves and profuse, highly scented yellow flowers that are the source of champak, an exotic East Indian perfume. In addition, the timber from this species has some local uses in making light furniture

and plywood. The banana shrub (*Michelia figo*) from southern China also is cultivated to some extent as a tropical ornamental with fragrant flowers.

Because the family Annonaceae is by far the largest in the Magnoliales order, it is not surprising that this group includes the most species that yield some type of economic product. Lancewood (*Oxandra lanceolata*) from northern South America and the West Indies, is undoubtedly the most important commercial timber source in this family. The wood is yellow to olive-yellow, hard, heavy (specific gravity 0.95), of fine texture, and with an extremely straight grain. These characteristics make the wood particularly suitable for use in scientific instruments, turnery (objects shaped by lathe), tool handles, and such sporting goods as billiard cues, archery bows, and fishing rods. Solera or Colombian lancewood (*Guatteria boyacana*) has most of the same properties and uses, but is not as well known in the timber trade. Yellowwood (*Enantia chlorantha*) from Liberia, Ivory Coast, and the Cameroons of West Africa produces a sulfurous yellow dye; the wood also is used locally to make unpainted furniture and veneers. Otu (*Cleistopholis patens*) yields a soft, light (specific gravity 0.40) wood from West Africa that finds some of the same uses as balsa wood—in buoys, life rafts, floats, etc. The fibrous inner bark is of some value for cordage and coarse netting.

*Polyalthia longifolia* is a tall, handsome tree with pendent linear leaves, which is cultivated in most parts of Ceylon and India as an avenue tree and around temples, where it has a religious significance. Although the wood is not very durable, it is utilized to some extent in making matches, boxes, and packing crates. Other woods of the Annonaceae family in India and Burma that have some commercial value are derived from the genera *Milusa*, *Sageraea*, *Mitrephora*, *Saccopetalum*, and *Cyathocalyx*. Because of their tough and elastic qualities, these woods are utilized in the manufacture of tool handles, wheel spokes, and sporting goods.

The wood of *Xylopia aethiopica* is quite flexible and has some local use in west central Africa for masts, boat paddles, and rudders. It has been described as termite-proof and, accordingly, is used for house posts and beams. The dried black fruits of this species are called guinea peppers and were once of commercial importance in Europe as a tangy condiment and drug. At present, the fruits are reportedly used by some African tribes as a cough medicine and purgative. The bark of several other *Xylopia* species from Brazil (*X. sericea*, *X. frutescens*, and *X. aromatica*) finds some local use in cordage and rough textiles.

The most widely known economic products of the Annonaceae family in the tropics are its edible fruits. One of the most important of these is the West Indian custard apple or bullock's heart (*Annona reticulata*). The latter common name is suggestive of the shape and general appearance of the fruits. When the fruit is ripe and the skin has begun to blacken, its white to cream-coloured flesh becomes sweet and aromatic, and resembles ice cream when chilled. It may be eaten with a spoon as a dessert. The sweetsop, or sugar apple (*Annona squamosa*), although native to northern South America, Central America and the Caribbean region, is even more widely cultivated and highly esteemed in India and Pakistan. The conical fruits break into segments when ripe and expose a cream-coloured sweet pulp in which dark brown glossy seeds are embedded. Among the natives of the tropics the sugar apple tree is of reputed medical value. Tea made from the roots is highly purgative, while that made from the leaves is mildly laxative and is also considered to have a general tonic effect on the digestive tract. Poultices of the leaves are used in dressing infected wounds.

The cherimoya is the fruit of a rather small tree, *Annona cherimola*, which is native to the cool (but frost-free) mountain valleys of Peru. Although it is grown in southern Florida, it does not produce fruit well there because of the high humidity; it is currently commercially grown on a small scale in southern California. The fruits, however, are quite perishable and ferment readily, and are thus shipped only to nearby markets. Like the

Magnolia trees in cultivation

Tropical edible fruits

sugar apple, it is now well-established in the Old World tropics. Although the ripe fruit does not break into segments when ripe the way that of the sugar apple does, the flesh is of a more creamy consistency and has fewer seeds. Under ideal conditions, the fruit may attain a large size, weighing up to 16 pounds. The soursop, or guanábana (*Annona muricata*), also is native to the American tropics, but is now general throughout the Old World tropics as well. In Cuba the fruit is a favourite and the tree may be found in almost every yard planting. The fruit is large (to 10 pounds), tapering, heart-shaped, and the green skin is covered with spiny protuberances. The aromatic flesh, white and somewhat fibrous, is strained to make custards and ice cream; the acidulous juice is usually extracted to make a refreshing drink, which has been described as a combination of the flavours of strawberries, pineapples, and cinnamon. The hybrid atemoya (*Annona squamosa* × *A. cherimola*) has been established in the Caribbean region; reputedly the fruit contains the best features of both parents. The alligator apple (*A. glabra*) grows plentifully in the Florida Everglades and on the Florida Keys, where its fruits have been described as "edible but not very palatable." The tree's prime use in Florida is as a rootstock in deep, sandy soils for the grafted custard apple and the sugar apple.

Other species of *Annona* that produce comparatively inferior fruit, but which are eaten locally, include: *A. montana*, the mountain soursop (West Indies and South America); *A. longiflora* (Mexico); *A. paludosa* (Brazil); *A. testudinea* (Honduras); *A. nutans* (Paraguay); *A. senegalensis* (East and West Africa); and *A. diversifolia*, the ilama, which was first cultivated long ago by the Aztecs of Mexico.

Two species of *Rollinia* (*R. mucosa* and *R. pulchrinervia*) have edible fruits that reach four inches (ten centimetres) in length and bear some resemblance to those of the soursop, except that the spines are softer and more blunt. *R. mucosa* is a large tree native to the West Indies and northern South America, whereas *R. pulchrinervia* is restricted in the wild state to the Amazon Basin. Both species are referred to by the common name biriba and both are widely cultivated, particularly throughout Brazil, for their delicious fruits.

The papaw (*Asimina triloba*) of eastern North America produces a fruit that is sometimes eaten. The fruits of this species show considerable variability in size, colour, and palatability. Two general types have been observed: (1) large, yellow-fruited, highly flavoured, and early ripening; and (2) relatively small, white-fleshed, mild flavoured, and late ripening. A number of selected clones (groups of plants of identical genetic makeup that are vegetative divisions of one plant), propagated by grafting, are in cultivation, principally in southern Pennsylvania, Ohio, Illinois, and Indiana (where the yellowish fruits are referred to as Indiana bananas). Sometimes an alcoholic beverage is made from the papaw.

Certain Asiatic species of *Polyalthia* (*P. cerasioides*, and *P. korinthii*), *Uvaria* (*U. burahol*, *U. dulcis*, and *U. heterophylla*), and *Artabotrys* produce edible fruit, as do African species of *Uvaria* (*U. chamae* and *U. globosa*).

The ylang-ylang tree (*Cananga odorata*) has its natural range from the tropical parts of eastern India through the Malaysian regions to the Philippines and northern Australia. The name means "flower of flowers" because the yellowish-green, bell-shaped flowers yield an exceedingly delicate and evanescent fragrance that is highly valued in the manufacture of perfumes. Ylang-ylang or cananga oil is derived by simple distillation from the petals of fully opened flowers. Although the tree blossoms throughout the year, the flowers picked in May or June yield the highest amounts of the cananga oil. Long known to the peoples of the Far East, this oil first reached Europe about 1864. Although the Philippines are probably the chief producers of ylang-ylang oil, some production also comes from Malaya, Java, the Mascarene Islands, and Madagascar. The related *Artabotrys odoratissimus* (climbing ylang-ylang) is cultivated in many tropical regions for the fragrance of its flowers, but the perfume has only localized uses.

In Ghana and the Ivory Coast regions of West Africa ethereal oils distilled from leaves of *Enneastemum capeus* are reportedly utilized in making perfume.

*Cymbopetalum penduliflorum* (Annonaceae family), a tree of Central America and Mexico, has flowers that, when crushed, yield an oil with a spicy odour similar to nutmeg or cubeb pepper, which has been used for several centuries to flavour chocolate and in cooking. According to one authority, this plant was called xochinacatzli—sacred ear flower of the Aztecs—because the inner petals bear some resemblance to human ears.

In the upper Amazon region, Indian tribes use an extract from the tree *Unonopsis veneficiorum* to tip their poison blowgun darts and arrows; this substance is said to have the same paralyzing effect on man and animals as that caused by curare poisons obtained from the genus *Strychnos* of the Loganiaceae family (order Gentianales).

*Monodora myristica* (family Annonaceae) is a large (up to 60 feet [18 metres] high) West African tree with big leaves and striking flowers; these features combine to make it an attractive ornamental in many tropical regions. Because the large ruminant (*i.e.*, folded in undulate fashion) seeds of this tree bear some resemblance to those of the true nutmeg (*Myristica*, family Myristicaceae), the tree is referred to as the Jamaica nutmeg or the calabash nutmeg. The latter name refers to the orange-sized fruit that encloses the seeds, and which has a superficial similarity to a gourd when dried. In West Africa the seeds are used to flavour cooking, as aromatic necklaces, in primitive medicinals, and (when pulverized) as a pomade.

Although many trees in the family Myristicaceae (nutmeg family) reach timber size, the wood is not of much value in world trade. Nevertheless, the following species from tropical regions of South and Central America find local uses in the manufacture of furniture, millwork, veneers, flooring, and general carpentry: *Dialyanthera otoba* (otobo), *Iryanthera lancifolia* (kirikawa), *Iryanthera sagotiana* (marakaipo), and *Virola koschyni* (banak). Wood of *Pycnanthus kombo* from West Africa is greyish-brown to pink, soft, and light (specific gravity 0.40), and is made into plywood for packing cases and low-grade interior woodwork. *Staudtia gabonensis* produces an orange to reddish-brown moderately hard and heavy (specific gravity 0.90) wood for cabinetry, tool handles, carving, and turnery in several West African countries. Chuglum (*Myristica irya*), from the Andaman Islands in the Bay of Bengal, yields light red to reddish-brown wood with darker streaks and high lustre, which is used to make musical instruments and furniture.

Both nutmeg and mace are obtained from the seeds of *Myristica fragrans*, a native of the Moluccas or Spice Islands in the Indonesian Archipelago, and is now grown in the tropics of both hemispheres. Although some of these spices are still exported from Indonesia, the greatest production today is in the British West Indies, principally the island of Grenada.

The nutmeg tree is a handsome evergreen with dark leaves and reaches a height of 30 to 60 feet (9 to 18 metres). The small, yellow, fleshy flowers are unisexual; *i.e.*, the male and female flowers are produced on separate trees. The ripe fruits are golden yellow and resemble apricots or pears. As the fruits dry out, they split open, revealing the single shiny brown seed covered with a bright red fleshy structure, called an aril. Inside the seeds are the kernels, which are the nutmegs of commerce; the aril is the source of mace. The pulverized seed finds much use for seasoning spiced fruits, sausages, pastries, puddings, egg nog, etc. Mace is one of the most delicately flavoured spices and is used in making pickles, ketchups, and sauces. Two oils are obtained from the seeds of *Myristica fragrans*, a volatile oil obtained by distillation, and a fixed oil obtained by subjecting the nutmegs to heat under pressure. The volatile oil contains myristic acid and a narcotic, myristicin; it is used medicinally as a carminative and as a flavouring agent in dentifrices tobacco, and perfumes. The fixed oil is known as nutmeg butter and is used in ointments and in candles.

Oils  
and  
perfumes

Products  
and uses  
of the  
nutmeg

The seeds of *Gymnacranthera farquhariana* have been used in India for candlemaking. Those of *Myristica malabarica* have been used for oil and for adulterating nutmegs; its aril is marketed as Bombay mace. *Myristica argentea*, the Papua or Macassar nutmeg, is also used in oils and soaps, but is useless as a spice. The seeds of *Viola surinamensis* are used to make a commercial wax.

The family Canellaceae is of relatively little economic importance. The leaves and bark of the wild cinnamon (*Canella alba*) from the West Indies still have some use as a condiment and for medicinal purposes. The small trees of this species are cultivated to a limited extent in southern Florida, as ornamentals prized for their reddish-purple flowers and blue-black berries. The scented wood of *Cinnamosma fragrans* is exported from Zanzibar to Bombay and Thailand where it is used for religious ceremonies. *Warburgia ugandensis* is a fairly important timber producer in Uganda; the bark is utilized as a purgative and the resin for cementing tool handles.

The sole economic product from the Winteraceae family is "Winter's bark" from *Drimys winteri* of South America; it still finds some use as an astringent and a stimulant.

**Distinguishing features.** As classified in this treatment, the eight families included in the Magnoliales order are believed to contain many more ancient and primitive structural features than can be found in any other order of flowering plants. Some of these features follow: vesselless woods in the Winteraceae family; *i.e.*, the water-conducting elements are all composed of primitive conducting cells called tracheids, such as those occurring in many ferns and some more primitive gymnosperms; flowers with numerous, spirally arranged, usually free parts on an elongated floral axis; the male organs or stamens often relatively broad and with pollen sacs embedded in their surfaces; the female organs or carpels often relatively unmodified from a leaflike structure; pollen grains usually with a single elongate germinal furrow such as that of the ancestral gymnosperm type; abundant ethereal oil cells in both floral and vegetative organs; and seeds bearing a small embryo embedded in copious endosperm (food storage tissue).

Pollination by beetles, believed to be a primitive condition among flowering plants, is normal for the Eupomatiaceae family and has been reported to occur commonly in many members of the Magnoliaceae, Winteraceae, and Annonaceae families. Ruminant endosperm—*i.e.*, endosperm that is fluted by the inward development of numerous ridges from the inner seed coat—is a normal feature in the Annonaceae, Myristicaceae, and Eupomatiaceae families, and at least one genus (*Cinnamosma*) in the family Canellaceae.

Since it is now recognized that evolution proceeds independently and at differing rates in both floral and vegetative organs, it is not to be expected that any one family in the magnolia order can be expected to contain only primitive characters in all their organs, and thus be selected as *the* most primitive. If the evolutionary significance of certain features is emphasized over several others, however, it is possible to suggest that either the Winteraceae or Magnoliaceae family is the most primitive living family of flowering plants.

#### EVOLUTION

**The fossil record.** Fossils representing four of the eight families of the Magnoliales order have been found. These include leaves ascribed to members of the Magnoliaceae family (*Magnolia* and *Liriodendron* from the Cretaceous Period of about 100,000,000 years ago and the Tertiary Period of about 60,000,000 years ago, and *Talauma* from the Tertiary, all of North America). Seeds (*Magnoliaespermum*) are recorded from the Tertiary brown coals of Germany, and pollen belonging to the family is widespread in the Lower Cretaceous and Tertiary deposits of both hemispheres. Fossil leaves and seeds of the Annonaceae family are known from the Cretaceous and Tertiary of both hemispheres. These have been assigned to about ten different modern genera. Seeds of the modern genus *Asimina* are known from the Tertiary brown coals of Germany, and petrified

woods (*Annonoxylon*) have been found in Tertiary deposits of North America and Austria. Fossil woods (*Myristicoxylon*) of the Myristicaceae family are known from the Tertiary of North Africa. The Winteraceae family is represented by fossil leaves (*Drimys*) from the Tertiary deposits of Australia, South America, and North America. The remaining four families have no fossil record.

Unfortunately, the fossil record is of little assistance in attempts to determine which group of flowering plants appeared first on earth. Although there are numerous scattered reports of putative angiosperm (flowering plant) fossils from pre-Cretaceous rocks—*i.e.*, deposits older than about 136,000,000 years—none of these finds has ever been indisputably accepted as belonging to the angiosperms. Indeed, possibly the best evidence is that the angiosperms arose rather suddenly during the Lower Cretaceous, about 120,000,000 years ago. Because these are the epochs when undoubted angiosperm pollen grains (which, due to the chemical nature of their coats, are extremely resistant to decay) first appeared in the fossil record, the pollen evidence is believed to be more reliable than that based on compressed leaves or leaf fragments. Nevertheless, in the absence of floral structures (which are only very rarely preserved as fossils) it is difficult to assign the Cretaceous fossils to modern families, let alone genera. Although numerous "species" of *Magnolia*, *Liriodendron*, *Drimys*, etc., have been described from leaf remains dating back to the Lower Cretaceous, only in rare instances have any of these identifications been validated by concomitant cuticular studies (*i.e.*, arrangement and types of cells on the outer cell layer of leaves), descriptions of wood anatomy, pollen morphology, fruits, or seeds preserved in the same sediments. Accordingly, most of the identifications of these supposed early remains of the Magnoliales order remain suspect. Although undoubted representatives of magnolialean families were present by the beginning of the Tertiary Period (approximately 63,000,000 years ago), so were numerous representatives of structurally much more highly evolved angiosperms; *e.g.*, the families Salicaceae (willows), Juglandaceae (walnuts), Fagaceae (oaks and beeches), and Moraceae (mulberries). Thus, the known fossil record cannot establish which angiosperm family is *the* most primitive.

#### CLASSIFICATION

**Distinguishing taxonomic features.** The features of most diagnostic value and for determining family relationships within the order include the presence or absence of stipules (leaflike appendages at the base of leafstalks); presence or degree of fusion of the carpels (simple pistil or seed-bearing organs); modification of perianth parts (tepals, the leaflike, showy parts of a flower) into sepals and petals; spiral or whorled arrangement of floral organs; free or connate (joined, fused together) stamens; pollen uniauritate (with a single aperture, or germ-pore) or modified; and rumination (folded, ridged pattern of growth) of endosperm.

#### Annotated classification.

##### ORDER MAGNOLIALES

Entirely woody group; flowers hypogynous; bisexual, rarely unisexual accompanied by reduction (*i.e.*, the "other" sex parts are "reduced"; they do not develop); acyclic to cyclic; perianth obvious, tepals may not be differentiated into sepals and petals; endosperm abundant; ethereal oil cells in all organs; pollen mostly uniauritate. Leaves alternate, simple. Eight families, 166 genera, and about 1,794 species. Mainly distributed throughout wet, tropical regions of the Old and New World, but with some temperate outliers.

##### Family Magnoliaceae

Trees or shrubs. Flowers terminal, except in *Michelia* and *Elmerrillia*, axillary. Leaves stipulate, evergreen, or deciduous, simple. Floral axis elongated and conelike. Tepals 6 to many, often in whorls of 3. Stamens numerous, arranged spirally. Carpels numerous to 2 with occasional species having one. Seeds numerous to 2 per carpel, often becoming pendent by the funicular threads from the ripe fruit. Pollen monocolpate (*i.e.*, with a single germinal aperture). Twelve genera and about 210 species. North America, West Indies, Central America to Brazil; also eastern Himalayas, southern India to

Primitive characteristics of the order

Problems in the fossil record

southern China, Manchuria, Japan, and Malaysia to New Guinea.

#### Family Degeneriaceae

Trees. Flowers solitary, subaxillary. Sepals 3, much smaller than the petals. Petals 12 to 18 in 3 to 5 whorls. Stamens 20 to 30 in 3 to 4 whorls, fleshy, flattened. Stamnodes 10 to 13. Carpel 1, ellipsoid, ventral margins incompletely sealed. Ovules numerous, biseriate (*i.e.*, in two rows). Fruit indehiscent (*i.e.*, does not split open along established sutures or joints). Embryo with 3 cotyledons. Pollen monocolpate. *Degeneria vitiensis*, the only species; Fiji Islands.

#### Family Himantandraceae

Trees with alternate leaves, margins entire. Flowers solitary or paired on short axillary branches, at first covered by 2 leathery, deciduous stipules. Petals 5 to 7, lanceolate (*i.e.*, lance-shaped), similar in size and shape to the numerous stamens. Carpels 6 to 10, free, but soon united into a globose fruit. Ovules solitary and pendulous from each carpel. Pollen monocolpate. Single genus *Himantandra* with 3 or 4 species. Malaya, Indonesia, New Guinea, and northern Australia.

#### Family Eupomatiaceae

Shrubs. Flowers perigynous, with undifferentiated perianth forming a deciduous calyptra on the rim of the expanded concave receptacle. Stamens numerous, reflexed, the inner ones sterile and petaloid forming a pseudoperianth that is basally connate (*i.e.*, fused together at the base). Styles absent. Ovules numerous, endosperm ruminant. Pollen biaperturate (*i.e.*, with two apertures or germination pores). Single genus (*Eupomatia*) with two species ranging from southern New Guinea to southeastern Australia.

#### Family Annonaceae

Trees, shrubs or lianas. Flowers usually bisexual, actinomorphic (*i.e.*, regular, radially symmetrical), hypogynous. Sepals usually 3, free or partly connate, slightly imbricate or valvate. Petals often 6 in two series. Stamens numerous, spirally arranged; anthers (*i.e.*, male sexual parts, the pollen-producing bodies) often overtopped by fleshy, truncate connective. Carpels numerous to few, free or rarely united into a 1-locular ovary. Seeds often arillate with copious ruminant endosperm. Pollen monocolpate or inaperturate. At least 122 genera and 1,100 species. Tropics of the world, except the genus *Asimina*, which ranges to southern Ontario in America.

#### Family Canellaceae

Trees, seldom shrubs. Flowers bisexual, actinomorphic, solitary, cymose or racemose. Perianth imbricate (*i.e.*, overlapping like shingles), often subtended by persistent bracts. Stamens up to 20, connate (fused) in a tube. Ovary superior, 1-loculate, placentation parietal. Fruit a berry with 2 or more seeds. Endosperm ruminant only in *Cinnamosma*. Pollen monocolpate. Five genera and 9 species. Southern Florida, West Indies to Brazil; Central and East Africa, the Malagasy Republic.

#### Family Myristicaceae

Trees, often large, evergreen. Reddish gum ("kino") and tanniferous tubules common in inner bark and wood. Flowers small, actinomorphic, dioecious (*i.e.*, male and female flowers are produced on separate plants), borne in fascicles or capitate. Petals absent. Calyx 3- to 5-lobed, funnel-shaped to globose, lobes valvate. Male flower with 2 to 30 stamens, filaments united into a column. Female flower with single superior ovary bearing 1 ovule. Fruit fleshy, often dehiscent by 2 valves. Seed with a thin or lacinate (*i.e.*, deeply dissected, lacinated, ragged) aril, often colored. Endosperm copious, ruminant. Pollen essentially monocolpate. Sixteen genera and about 380 species. Pantropical, often at lower elevations in rain forests.

#### Family Winteraceae

Trees or shrubs, woods lacking vessels (tracheids only). Flowers small, mostly cymose or fasciculate; bisexual or rarely polygamous (*i.e.*, separate male and female flowers but both produced on the same plant). Sepals 2 to 6, free and valvate or united (*Drimys*). Petals in 2 or more series, imbricate. Stamens several, hypogynous. Carpels many to one, free, seldom connate; ventral suture incompletely closed (*Tasmannia*). Fruit dehiscent or a berry. Pollen monoporate (*i.e.*, with one germination pore), shed in coherent tetrads (*i.e.*, groups of four that remain attached). Eight genera and 88 species. The Philippines, Borneo, New Guinea, New Caledonia to eastern Australia and New Zealand. Also, Mexico to Colombia, Brazil, Chile, and Argentina.

**Critical appraisal.** The classification presented here is a recent one that is gaining acceptance. By contrast, some authorities, in the treatment of the Magnoliales order, exclude four families recognized here (Eupomatiaceae, Annonaceae, Myristicaceae, and Degeneriaceae). Fur-

thermore, they place the monotypic genus *Degeneria* in the Winteraceae family, the Annonaceae and Eupomatiaceae together in an order Annonales, and the Myristicaceae family in the order Laurales. To the Magnoliales order of these treatments are added the families Illiciaceae, Schisandraceae, Lactoridaceae, Trochodendraceae, and Cercidiphyllaceae, which receive no treatment here. Other authorities take an even broader view of the Magnoliales order, not only including the eight families recognized here but also adding 11 other families, which, under the treatment presented here, appear in the orders Laurales and Illiciales. Although there are grounds for criticism of all of these systems, the system presented here, circumscribing a smaller group, is probably more natural, if for no other reason than the fact that fewer genera are included, thus there are fewer "odd" morphological features to confuse the picture.

**BIBLIOGRAPHY.** L. CONSTANCE, "The Systematics of the Angiosperms," in *A Century of Progress in the Natural Sciences, 1853-1953* (1955), an excellent review of the influence of research in various fields of botany on ideas concerning the phylogeny of the angiosperms; A. CRONQUIST, *The Evolution and Classification of Flowering Plants* (1968), a recent text outlining the salient features of a phylogenetic system based on all available information; A.J. EAMES, *Morphology of the Angiosperms* (1961), an advanced text describing the morphological and anatomical features of presumed evolutionary significance in the angiosperms—ch. 11 includes an excellent treatment of primitive families of dicotyledons and monocotyledons, as well as an extensive bibliography; J.E. HUTCHINSON, *The Families of Flowering Plants*, 2nd ed., vol. 1, *Dicotyledons* (1959), a delineation of his earlier (1926) system, based upon two parallel linear sequences of families—one basically woody (Lignosae) and the other fundamentally herbaceous (Herbaceae); A. TAKHTAJAN, *Flowering Plants: Origin and Dispersal* (1969; Eng. trans. from the 2nd Russian ed., 1961), remarkable coverage of the literature on this subject in all languages.

(J.E.Ca.)

## Mahārāshtra

India's third largest state in size and population, Mahārāshtra occupies a substantial portion of the Deccan Peninsula. It is triangular in shape, with a base running north-south for nearly 450 miles along the western shores of India and jutting out in a blunted apex toward the east about 500 miles away. It has an area of 118,637 square miles (307,269 square kilometres), and, early in the 1970s, had a population of over 50,000,000, thus taking up about one-tenth of India's land area and containing one-tenth of its population. It is bounded by the states of Gujarāt, Madhya Pradesh, Andhra Pradesh, and Mysore and the union territory of Goa, Daman, and Diu.

Mahārāshtra's capital, Bombay, is an island city, connected to the mainland by roads and railways. Apty called the gateway of India, it is one of India's biggest commercial and industrial centres and has played a significant role in the country's social and political life.

Mahārāshtra is one of the foremost states in agricultural and industrial production, in trade and transport, and also in the growth of education and culture. Its ancient culture, at one stage considerably obscured by the dominance of the British, survives largely through the medium of a strong literary heritage. A common Marathi literature (Marathi is the predominant language) has in fact played an important role in nurturing a sense of nationality and unity among the Maharashtrians.

**History.** The name Mahārāshtra first appeared in a 7th-century inscription and in the account of a contemporary Chinese traveller, Hsüan-tsang. It then denoted the western upland, which has since been continuously known as Mahārāshtra. The origin of the name is still controversial. One view, however, is that it is derived from the word *rathī* (chariot driver), which refers to the skillful builders and drivers of chariots who formed a fighting force (*mahārāthis*) and migrated southward, settling in the area occupied by the modern state. Their language, intermingled with the speech of the earlier Nāga settlers, became Mahārāṣṭrī, and this by the 8th century developed into Marathi. There was also a continuous influx of people from remote Greece and Central Asia.

Emergence  
of Marāthā  
culture

The people of this early period were separated among several Hindu kingdoms: Sātavāhana, Vākāṭaka, Kalacuri, Rāshtrakūṭa, Cālukya, and Yādavas. After 1307 there was a succession of Muslim dynasties. Persian, the court language of the Muslims, had a far-reaching effect on Marathi. By the mid-16th century Mahārāshtra was again fragmented among several independent rulers, who waged endless wars among themselves. It was in the midst of this chaos that a great leader, Chhatrapati Śivājī, was born. Śivājī (Shivaji) showed astonishing prowess by founding a large empire that shook Mughal rule to its foundations.

During the 18th century almost all western and central India, as well as large segments of the north and east, were brought under Marāthā suzerainty. It was this empire that succumbed to the British from the early 19th century on. When India became independent in 1947, the province, long known as Bombay Presidency, became Bombay state. The following year a number of former princely states (notably Baroda) were merged into the new state, and, on November 1, 1956, a major reorganization of the states of peninsular India resulted in the addition of large parts of the former Hyderābād and Madhya Pradesh. In the north, it now comprised most of the Gujarati-speaking peoples and, in the south, most of the Marathi-speaking. As a result of the demands of the two language groups, the state was split in two on May 1, 1960, with Gujarāt, in the north, and Mahārāshtra, in the south.

**The landscape.** *Relief and drainage.* Mahārāshtra presents an interesting range of physical diversity.

To the west is the narrow Konkan coastal lowland. This is widest near Bombay. Numerous minor hills dominate the relief. There are numerous small, swift, west-flowing streams, most of them less than 50 miles long. The biggest, Ulhās, rising in the Bhor Ghāt, joins the sea after an 80 mile course.

The  
Western  
Ghāts

The Western Ghāts (which are mountains at the western edge of the Deccan Plateau; *ghāt* means "step" in Hindi) run almost continuously 398 miles north-south, the foothills reaching to within three-four miles of the Arabian Sea. Elevations increase northward to peaks of some 4,430 feet. There are a few gaps through which roads and railroads link the coast with the interior. The eastern slopes of the Ghāts descend gently to the Deccan Plateau and are sculptured by the wide, mature valleys of the Krishna, Bhīma, and Godāvāri rivers.

Between Narmada Valley in the north, Krishna Basin in the south, and from the western coast as far east as Nāgpur, the Ghāts and the triangular plateau inland are covered with extensive lava outpourings called "traps." These reach a maximum thickness of 10,000 feet near Bombay. The differential erosion of lava has resulted in characteristic steplike slopes, uniform crest lines, and a table-top appearance of many hills.

East of Nāgpur, the Deccan Trap gives way to undulating uplands (890–1,080 feet high) underlain by ancient crystalline rocks. The Wardha-Wainganga Valley, part of the larger Godāvāri Basin, trends southward and abounds in lakes.

The lava rock breaks down into a heavy, black, fertile soil. Very old crystalline rocks in the Wardha-Wainganga Valley have been eroded into light-coloured, sandy soils. Saline soils in the river valleys are a result of heavy evaporation.

*Climate.* The climate is characteristically monsoonal, with local variations. India's southwest monsoon rains break on the Bombay coast usually on June 1st and last till September, during which period they account for 80 percent of the annual rainfall. Four seasons are normal: March–May (hot and dry) June–September (hot and wet); October–November (warm and moist); and December–February (cool and dry).

The Western Ghāts and the ranges on the northern borders greatly influence the climate and separate the wet Konkan Coast from the dry interior upland, called the Desh. Rainfall is very heavy in Konkan, averaging 100 inches, with some of the wettest spots recording 250 inches rapidly diminishing to one-tenth of this east of the

Ghāts. Rainfall increases again eastward, reaching 40–80 inches in the extreme east.

The coastal districts enjoy equable temperatures, monthly averages ranging, as at Bombay, only a few degrees above or below 80° F (27° C). A range of more than 13° F (7° C) between day and night temperatures is unusual. Towns such as Pune (Poona), high up on the plateau, benefit from cooler temperatures throughout the year but remain equable.

*Vegetation and animal life.* Forests cover less than one-fifth of Mahārāshtra and are confined to the Sahyādri Range, its transverse ranges, the Sātpura Range in the north, and the Chandrapur region in the east. On the coast and adjoining slopes, plant forms are rich with lofty trees, variegated shrubs, and mango and coconut trees. The forests yield teak, bamboo, myrabolan (for dyeing), and other woods.

Thorny, savanna-like vegetation occurs in areas of less than 30-inch rainfall, in upland Mahārāshtra.

Subtropical vegetation is found on higher plateaus having heavy rain and milder temperatures. Bamboo, chestnut, and magnolia are common. In the semiarid tracts, wild dates are found. Mangrove vegetation occurs in marshes and estuaries along the coast.

Wild animals include tigers, leopards, and even bison. There are several species of antelope. Striped hyena, wild hog, and sloth bear occur frequently. Monkeys and snakes are of many types. Game birds, the peacock, and ducks are numerous.

**Population.** *Ethnic patterns.* Mahārāshtra contains a mixture of races. Ethnically, it is a conglomeration of people—indigenous and immigrant. On the Sahyādri and Sātpura perches live some 2,400,000 Australoid aboriginals—Bhīls, Warlis, Gonds, Korkus, and Gowaris. They are dark, short statured, and have long heads and flat noses. Almost ubiquitous are Kunbī Marāthās—brown, medium-statured, and supposedly descendants of waves of settlers who came from the north around the beginning of the Christian Era. Through an agelong mixture of aboriginals and immigrants, many castes have developed, most of them in the east. The tall and fair Parsis form another group, having fled from Iran, in the 11th century, to safeguard their religion.

*Languages.* Marathi, the state language, is spoken by over 90 percent of the people. Other important languages are Gujarati, Hindi, Telugu, Kannada, Sindhi, Urdu, and English. Sindhi has spread in urban centres as a result of an influx of refugees after the 1947 partition. English is still used in universities, in administration, and in metropolitan cities. Urdu is spoken by Muslims everywhere. There are also many dialects, such as Konkani on the west coast and Gondi and Mundari in the eastern and northern forests.

Marathi is one of India's more developed languages. Despite various regional spoken forms, its written style is uniform.

*Religion.* A variety of faiths is found within Mahārāshtra. Hindus predominate (over 80 percent), followed by Muslims (8 percent) and Buddhists (7 percent). There are many Christians in the metropolitan cities. Parsis (a religious minority adhering to Zoroastrianism) are mainly confined to Bombay and its environs, though some are to be found in other cities. Other religious minorities include Jains and Sikhs, who are found in small numbers everywhere.

*Patterns of settlement.* In 1971, Mahārāshtra's 50,335,000 people lived in numerous villages, 289 towns (17 called cities and having over 100,000 people), and in the Bombay conurbation. Urban population was 31 percent compared to the average for India of 20 percent.

Greater Bombay's population of 5,969,000 reflects its industrial growth and commercial success. Textiles dominate, but engineering and chemical and pharmaceutical industries are catching up. Bombay is India's best equipped port and handles an enormous foreign trade. It is a centre of business, finance, and administration.

Nāgpur (city proper over 866,000), Pune (city proper over 853,000), and Sholāpur (city proper over 398,000)

Major  
urban  
centres

are other major cities. Its historical and cultural importance apart, Pune has developed many industries because of its proximity to Bombay. Nāgpur was once the capital of the Bhonsle kingdom and then, until 1956, of the erstwhile Madhya Pradesh. The city still enjoys status as Mahārāshtra's second capital. Nāgpur and Sholāpur have textile and other agriculturally based, market-oriented industries. Pune and Nāgpur are additionally important as educational centres. Of particular historical interest is the Mughal city of Aurangābād, which contains several forts and other historic buildings and which is in close proximity to the famous caves of Ajanta and Ellora.

**Administration and social conditions.** Mahārāshtra has had always three principal components: western Mahārāshtra, Vidarbha, and Marāthwādā. It is divided administratively into four divisions and 26 districts.

In common with other states, Mahārāshtra is administered by a governor and a council of ministers elected from members of the legislature and headed by the leader of the majority party.

Executive authority in the state is exercised by the cabinet in the name of the governor. The collector—responsible for collection of land revenue, special taxes, and for coordinating the work of other departments, is the key figure within the local administrative areas.

The judiciary is headed by the chief justice and a panel of judges and is based in Bombay, although there is also a bench at Nāgpur.

The legislature has two houses: Vidhan Parishad (legislative council) and Vidhan Sabha (legislative assembly). Both meet in Bombay and once annually in Nāgpur. Mahārāshtra is represented in the Lok Sabha and the Rajya Sabha (which are, respectively, the Lower and Upper Houses of the Indian parliament).

There is a Public Service Commission that selects candidates for appointment to all state services, largely by means of competitive examinations.

**Health services.** Health conditions improved greatly between 1947 and 1964. The death rate was reduced from 25 to 15 per 1000 and infant mortality from 162 to 91 per 1000. Life expectancy is approximately 50 years. While urban areas have one doctor for every 1,433 people, rural areas have only one for 19,393.

Medical colleges number 13, of which five are in Bombay and two in Pune. There are dental colleges in Bombay and Nāgpur. Indigenous medicine is taught at Ayurvedic colleges in Bombay and Nāgpur.

There are about 50,000 beds in 1,850 hospitals and dispensaries. Most district hospitals maintain nursing schools, and the state nursing service has over 2,500 members. Regional blood banks exist in Bombay, Pune, Aurangābād, and Nāgpur, and resuscitation centres are found in all districts. The state has three times received a national award for the best family-planning work. In Bombay the Haffkine Institute and the Indian Cancer Research Centre (located in the Tata Memorial Hospital) are well-known research centres.

**Welfare services.** Welfare activities are directed toward children, women, workers, and delinquent citizens but not as yet to the unemployed. A Children's Act takes care of youthful offenders, and remand homes do correctional work. About 20 state homes shelter women in distress. The aged have rest homes, and numerous hostels accommodate working women. Training facilities exist for the physically handicapped, and juvenile guidance centres function in slum areas.

**Education.** The average literacy percentage for Mahārāshtra is 39, as against the average for India of 30. Free compulsory education is provided for children between the ages of six and 14. During the decade 1955 to 1965 primary school enrollment increased by 80 percent and secondary school enrollment by 200 percent. Vocational and multipurpose high schools have also grown in importance.

There are six universities: two at Bombay, others at Nāgpur, Pune, Aurangābād, and Kolhāpur. Two others are projected—one in Vidarbha, the other in Khāndesh. There are also two agricultural universities and eight

engineering colleges. Various other colleges impart university level education.

**Economy.** Mahārāshtra's per capita income is 20 percent above the Indian average. Thirty-six percent of the state's income comes from primary-agricultural activities, 35 percent from commercial and administrative services, and 29 percent from mining and manufacturing.

**Agriculture.** Agriculture is the bulwark of Mahārāshtra economy, and the peasantry forms 64 percent of the population.

Recent progressive measures to combat food deficits include electrifying irrigation, the use of hybrid seeds, ultra-intensive cultivation, and offering incentives to the farmer. A major continuing problem, however, is water scarcity. Millet and pulses (edible seeds) dominate the cropped area. Rice grows where rainfall exceeds 100 centimetres, and wheat is a winter crop in fields that retain moisture. Rice and wheat together occupy 12 percent of the cropped area. Cotton and groundnuts are major crops in areas having 24–39 inches of rainfall. Irrigation dams in rain-shadow areas have resulted in a rich sugarcane crop. Mangoes, cashew nuts, bananas, and oranges are popular crops. Many problems relating to soil erosion, storage, transport, and marketing have yet to be overcome.

**Forestry, fisheries, and mineral reserves.** Forest products include timber, bamboo, sandalwood, and tendu leaves (for cheap cigarettes). Some 43,000 persons were thus employed early in the 1970s. The annual catch of fish is 171,000 tons, engaging 70,000 people.

Meagre mineral resources are found mostly in the eastern and, occasionally, in the western districts. Manganese, coal, iron ore, limestone, copper, bauxite, and common salt are extracted, providing employment for some 55,000 people.

Eastern Vidarbha districts are rich with reserves of coal, estimated at 5,000,000,000 tons. Mostly bituminous, it is used by railways and power stations.

Mahārāshtra produces both hydro-electricity and thermal electricity, the former in western areas, the latter in the east. There is also an atomic power station at Tārāpur, 70 miles north of Bombay.

**Manufacturing.** Fourteen percent of India's industrial units and 20 percent of its industrial workers are in Mahārāshtra, accounting for 24 percent of India's industrial output. The Bombay–Pune complex is the major industrial area; Nāgpur and Kolhāpur are also important.

The oldest and largest industry is the manufacture of cotton textiles. There are about 100 cotton mills and 240,000 textile workers in the state. Bombay, Nāgpur, and Sholāpur are the principal textile manufacturing centres.

Oil refining and petro-chemicals (Bombay) and the manufacture of such items as agricultural implements, electric and oil pumps, lathes, compressors, sugar-mill machinery, typewriters, refrigerators, and radio sets are assuming increasing importance. There is also an incipient automobile industry in Bombay.

**Transport and communications.** *Railways.* The foremost means of travel is a rail network focussing on Bombay. There is a total of 5,193 kilometres of track, both broad- and narrow-gauge. The nation's east–west and north–south trunk routes intersect between Nāgpur and Wardha.

Passenger amenities are increasing, with third class sleepers, diesel-electric engines, and air-conditioned coaches.

*Roads.* A 20-year plan inaugurated after independence provided for a major road within five miles of every village. Missing links on the 86 state highways were thus completed, and district roads developed in inaccessible areas. Five national highways (2,400 kilometres) connect the state with Delhi, Calcutta, Allāhābād, Hyderābād, and Bangalore.

The state transport corporation owns some 5,000 buses and carries 1,400,000 passengers daily over 5,000 routes. Recent innovations include luxury buses—including sleepers on interstate services—and a 50 percent discount for students. Special buses serve tourist, pilgrimage, and

Major  
crops

health resorts. Private motor vehicles number about 260,000.

Water transport plays a limited role in Mahārāshtra, although minor ports on the west coast handle some 1,500,000 passengers annually.

**Airways.** Daily air services connect Bombay with Pune, Nāgpur, Aurangābād, and Nāsik. Bombay is located on international air routes, and Nāgpur is the centre of India's airmail scheme.

**Communications.** More than 9,000 post and telegraph offices, 120,000 telephones, and five broadcasting stations make up the communications network. An international satellite communication centre has been commissioned at Arvi, near Pune.

**Cultural life.** Mahārāshtra is a distinct cultural region. Its long artistic tradition is manifested in the ancient cave paintings of Ajantā and Ellora, in medieval architectural masterpieces, in its classical and devotional music, and in its theatre. Pune, where numerous organizations sustain these great traditions, is the undisputed cultural capital. The Marathi stage is very active, plays being performed even in small communities.

Mahārāshtra's foremost diversion is *tamāshā*, combining music, drama, and dance. About seven artists form a *tamāshā* troupe. A female dancer is the central figure, a clown providing the humour.

Mahārāshtra has many festivals throughout the year: Holi is the spring festival and Ranga Panchami, which follows, is a riot of colours. The Dassera festival has a special significance, being the day on which Marāthā warriors started on their campaigns. Dīwālī, coming next, is a festival of lights and fireworks. Pola is a festival in which bullocks are given a holiday and decorated for a race. The Ganesh festival is by far the most popular in Mahārāshtra. Its public celebration was first sponsored by a nationalist political leader, B.G. Tilak. Muharram commemorates the great martyrs of Islām, although even Hindus participate. Unique to Mahārāshtra is the Hurda party, in which the farmer invites village folk to partake of fresh ears of jowar (Indian millet). Folk songs and traditional dances accompany all these celebrations.

**BIBLIOGRAPHY.** THE GOVERNMENT PUBLICITY DIRECTORATE, *Maharashtra* (1969), *Maharashtra at a Glance* (1969); and the BUREAU OF ECONOMICS AND STATISTICS publication *Statistical Abstract of Maharashtra* (annual), furnish reliable, up-to-date figures on the state. Much historical material may be found in G. YAZDANI (ed.), *The Early History of the Deccan*, 2 vol. (1960); and a brilliant socio-anthropological analysis of the population is I. KARVE, *Maharashtra Land and Its People* (1968). Resource potentials are discussed in the *Techno-Economic Survey of Maharashtra*, ed. by P.S. LOKANATHAN (1963). A good geographical account is C.B. JOSHI and B. ARUNACHALAM, *Maharashtra: A Regional Study* (1962).

## Mahāvīra

Vardhamāna, known as Mahāvīra, Great Hero, was the last patriarch of a line of 24 Tīrthaṅkaras (prophets, or, literally, Ford-Makers), most of them legendary, who founded Jainism, a religion concentrated mainly in western India and claiming approximately 2,600,000 followers in the 1971 census. Basing his doctrines on the teachings of the 23rd Tīrthaṅkara, Pārśvanātha, a 9th-century-BC teacher from Banaras (Vārānasi, Uttar Pradesh), Vardhamāna systematized earlier Jaina doctrines—along with metaphysical, mythological, and cosmological beliefs—and also established the rules and guidelines for the monks, nuns, laymen, and laywomen of the Jaina *saṅgha*, or religious order.

Born about 599 BC into a Kṣatriya (warrior caste) family, Vardhamāna grew up in Kṣatriyakunḍagrāma, a suburb of Vaiśālī (modern Basarh) in Magadha (Bihār state), the area of origin of both Jainism and Buddhism. His father was Siddhārtha, a ruler of the Nāta, or Jñātr, clan. According to one Jaina tradition his mother was named Devanandā and was a member of the Brahmin (priestly) caste; other traditions name her Trīśālā, Videhadinnā, or Priyakārīnī, and place her in the Kṣatriya caste.

The 6th century BC was a period of great intellectual,

Mahāvīra enthroned, miniature from the *Kalpa-sūtra*, 15th-century western Indian school. In the Freer Gallery of Art, Washington, D.C.

philosophical, religious, and social ferment in India, a period in which certain members of the Kṣatriya caste led a revolt against the Brahmins who used their positions as members of the highest caste to make demands upon the lower castes. In particular, the Brahmins demanded an increasingly large number of cattle as fees for the Vedic (ancient Aryan religious) *yajña*, or fire sacrifice. Because the strain of such demands on agriculture was intolerable to the food-producing and trading castes, attacks against animal sacrifice increased. The leaders of the anti-Brahmin sects came to be regarded as heretical. Mahāvīra and his younger contemporary Siddhārtha Gautama, the Buddha, were two of the greatest leaders in this revolt.

Though the traditions about the life of Mahāvīra vary according to the two Jaina sects (the Svetāmbaras, or White-Clad, and the Digambaras, or Sky-Clad), he apparently was reared in luxury, though as a younger son he could not inherit the leadership of the clan. At the age of 30 (569 BC), after he had married a lady of the Kṣatriya caste and had a daughter, he renounced the world and became a monk. According to legend, his parents had died by practicing the rite of *sallekhana*—i.e., voluntary self-starvation. Thus, when Mahāvīra joined the ascetic order of Pārśvanātha, to which his parents had belonged, self-denial was not foreign to him.

Perhaps beginning as a member of the order of Pārśvanātha, Mahāvīra used one garment for over a year, but later he went about naked and kept no possessions—not even a bowl for obtaining alms or drinking water. He allowed insects to crawl on his body and even bite him, bearing the pain with patience. People often shouted at him and hit him because of his uncouth and unsightly body. He meditated day and night and lived in various places—workshops, cremation and burial grounds, and at the foot of trees. Trying to avoid all sinful activity, he especially avoided injuring any kind of life, thus developing the doctrine of *ahimsā*, or nonviolence. He kept many fast periods and never ate anything that was expressly prepared for him. Though he wandered about continuously during most of the year, Mahāvīra spent the four months of the rainy season in villages and towns.

During his many wanderings he endured abusive language and physical injuries, always with patience and equanimity.

After 12 years of practicing such austerities, Mahāvīra attained, in 557 BC, *kevala-jñāna*, the highest knowledge. The school of Pārśvanātha apparently had been waning in appeal; Mahāvīra revived and reorganized Jaina doctrine and the *saṅgha*, thus being credited as the founder

Mahāvīra's  
renuncia-  
tion of  
the world

Artistic  
traditions

Social and  
religious  
influences  
on  
Mahāvīra

of Jainism. Though what he added to the teachings of Pārśvanātha is uncertain, his organization of the order and his rules for religious behaviour and practice became a landmark in Jaina history. Included in his teachings was a great interest in mathematics and the movements of celestial bodies. He taught that all that exists on earth and in other worlds is classified according to numerical categories, that objects are related to each other in a variety of ways, and that infinity and the indefiniteness of numbers are concepts significant to cosmology. In his concepts on geometry, Mahāvīra taught that lines are differentiated according to their straightness, curvature, and jaggedness and that figures are distinguished according to their angularity and curvature. Though his teachings contained philosophical complexities, he illustrated them by means of comparisons drawn from everyday life.

Mahāvīra also taught that a man can save his soul from the contamination of matter by practicing extreme asceticism and that he can maintain an austere life by practicing nonviolence toward all living creatures. This encouraged his followers to become strong advocates of vegetarianism, which in the course of time helped to bring about a virtual end to sacrificial killing in Indian rituals. His followers were aided in their quest for salvation by accepting the "five great vows" that have been attributed to Mahāvīra: renunciation of killing, speaking untruths, greed, sexual pleasure, and all attachments to living beings and non-living things. Mahāvīra's predecessor Pārśva preached only "four great vows."

Mahāvīra, also called Jina, or Conqueror (*i.e.*, conqueror of enemies such as attachment and greed) among other titles, died in 527 BC at Pāvā in northern Bihār state, leaving a group of followers who influenced Indian culture by their practice of nonviolence, which, in turn, has influenced reformers down to the 20th century.

**BIBLIOGRAPHY.** WALTER SCHUBRING, *Der Jinitismus in Der Religionen der Menschheit*, vol. 13, pp. 217–242 (1964; Eng. trans., *The Religion of the Jainas*, 1966), describes some important aspects of Mahāvīra's personality. MUNI NAGARAJA; *Contemporaneity and Chronology of Mahāvīra and Buddha* (1970), is a recent attempt, more convincing than earlier ones, at solving the problem of the chronology and contemporaneity of Buddha and Mahāvīra. HERMANN JACOBI'S English translation of Jaina Canonical texts *Ācārāṅga*, *Uttarādhyaṇa*, and the *Kalpa Sūtras*, entitled *Jaina Sūtras*, 2 vol. (1884–95, reprinted 1968), supplies the earliest Jaina accounts of Mahāvīra. B.C. LAW, *Mahavira, His Life and Teachings* (1937), is an authentic account appealing to both scholars and general readers.

(U.P.S.)

## Mahdī, al-

Known as al-Mahdī, or "The Divinely Guided One," Muḥammad Aḥmad ibn 'Abd Allāh created an Islāmic state extending from the Red Sea to Central Africa and founded a movement still influential in The Sudan.

Muḥammad Aḥmad was born on August 12, 1844, the son of a shipbuilder from the Dongola District of Nubia. Shortly after Muḥammad's birth, the family moved south to Karari, a river village near Khartoum. As a boy, Muḥammad developed a love of religious study. Instead of seeking an orthodox education, such as that offered at al-Azhar University in Cairo, and passing into the official hierarchy as a salaried judge or interpreter of Islāmic law, he remained in the Sudan. Increasingly, he tended to a more mystic interpretation of Islām, in the Sūfī tradition, through study of the Qur'ān—the sacred Muslim scripture—and the practice of self-denial under the discipline of a religious brotherhood. He joined the Sammānīyah order and grew to manhood in a wholly Sudanese religious setting, purposely separating himself from the official ruling class. By now the young man had begun to attract his own disciples and, in 1870, moved with them to a hermitage on Abā Island in the White Nile, 175 miles south of Khartoum. His highly emotional and intransigent religious observance brought him into conflict with his *skaykh* (teacher), whom he reproved for worldliness. The exasperated *skaykh* expelled him from the circle of his disciples, whereupon Muḥammad Aḥ-

mad, having vainly asked his teacher's pardon, joined the brotherhood of a rival *skaykh* within the same order.

The Sudan at this time was a dependency of Egypt, which was itself a province of the Ottoman Empire, and governed by the same multiracial, Turkish-speaking ruling class that governed Egypt. In appearance, education, and way of life the rulers contrasted starkly with their Sudanese subjects; and although the more assimilated higher officials and some of the chiefs of territories along the Nile who profited from their government connections were reconciled to the regime, the less privileged Sudanese were not. The situation was politically dangerous, for the discontented came from many different walks of life: taxpayers oppressed by fiscal injustices and enraged by the frequent floggings to which they were subject when tardy in their payments; slave traders aroused by the clumsy efforts of the government, which was hectored by the European powers, particularly Britain, to abolish the trade without delay; devout worshippers scandalized by the presence of non-Muslim Europeans as provincial governors and by their addiction to alcohol; peasants living by the Nile forced to tow government ships; warlike tribesmen, weary of the long years of enforced peace, spoiling for a fight—all these were potential enemies of the established order. It was Muḥammad Aḥmad who converted this diversified discontent into a unified movement that for a time would transcend tribalism and weld the faithful into an unconquerable military machine. Gradually, during 1880 and the first weeks of 1881, he became convinced that the entire ruling class had deserted the Islāmic faith and that the khedive, the viceroy of Egypt, was a puppet in the hands of unbelievers and thus unfit to rule over Muslims.

In March 1881 he revealed to his closest followers what he considered his divine mission—that God had appointed him to purify Islām and to destroy all governments that defiled it. On June 29 he publicly assumed the title of the Mahdī, who, according to a tradition cherished by the oppressed throughout Islāmic history, would appear to restore Islām.

The events that followed this announcement were among the most dramatic in the history of the Nile Valley. Within less than four years the Mahdī, who set out from Abā Island with a few followers armed with sticks and spears, ended by making himself master of almost all the territory formerly occupied by the Egyptian government, capturing an enormous booty of money, bullion, jewels, and military supplies—including Krupp artillery and Remington rifles.

By the end of 1883 the Mahdī's *anṣār* ("friends," a name first given to those people in the city of Medina who helped the prophet Muḥammad) had annihilated three Egyptian armies sent against them; the last, a force of 8,000 men with a huge camel train, commanded by Gen. William Hicks, was butchered almost to a man. El Obeid, the present-day al-Ubayyid, provincial capital of Kordofan, and Bara, a chief town of that province, fell after being besieged by the Mahdī. He now committed his first acts as the head of an armed theocracy on the march: taxes were collected, not as demanded by the Egyptians but as laid down by the Qur'ān. Already his fame had reached responsive ears in Arabia to the north and as far west as Bornu, now a province of northern Nigeria. A master of the art of putting his enemies always in the wrong, he supported his military operations by an intelligent and subtle propaganda. Counterpropaganda by the governor-general, 'Abd al-Qādir Pasha Ḥilmī, a man of great resource, and by the *'ulamā*, the learned men, of Khartoum who mocked the Mahdī's divine claims, failed miserably. The Mahdī's crowning victory was the capture of Khartoum, on January 26, 1885, after a resolute defense by its commander, Maj. Gen. Charles George Gordon, who, against the Mahdī's express order, was killed in the final assault. The Mahdī made a triumphal entry into the stricken city and led the prayers in the principal mosque. Even making allowance for the military weakness of Egypt, which during the crucial years 1881 and 1882 was torn by the nationalist revolt of Aḥmad 'Urābī Pasha, it was an astonishing feat.

The political background to his ascendancy

Capture of Khartoum

Religious  
empire

The withdrawal of the British expedition, which had failed to relieve Khartoum, left the Mahdī free to consolidate his religious empire. He abandoned Khartoum, still heavy with the stench of the dead, and set up his administrative centre at Omdurman, an expanded village of mud houses and grass-roofed huts on the left bank of the Nile, opposite Khartoum. The site of the new capital had two advantages: it was higher and better drained, hence healthier, than Khartoum, and, by governing from the exclusively Sudanese town of Omdurman, the Mahdī avoided the evil associations of the old capital. He directed every aspect of community and personal life by proclamations, sermons, warnings, and letters. In this endeavour he was helped by the capture, intact, of the government press and an abundance of stationery. But he confined himself to the enunciation of principles; most of the routine he left to his chief officers. The political institutions, as well as the nomenclature of his government, were based insofar as practicable on those of primitive Islām. In the manner of the prophet Muḥammad he appointed four caliphs, or deputies, to be the living successors of the four earliest caliphs in Islāmic history. Three of those appointed by the Mahdī were Sudanese, including the caliph 'Abd Allāh ibn Muḥammad, the Mahdī's most trusted counsellor and chief of staff; the fourth, Muḥammad al-Mahdī ibn as-Sanūsī, head of the Sanūsīyah order in the western desert, ignored the Mahdī's invitation. The Mahdī referred to himself as "the successor to the apostle of God"—that is, successor to the prophet Muḥammad but only in the sense of continuing his work.

The Mahdī's rule was brief. He was taken ill, possibly of typhus, and died in Omdurman on June 22, 1885, only 41 years old. At his wish his temporal functions were assumed by the caliph 'Abd Allāh. Over his grave the caliph built a domed tomb similar in architecture to those customarily built over the remains of the more venerated holy men. Partially destroyed by gunfire during the battle of Omdurman in 1898, it was later rebuilt by the Mahdī's son 'Abd ar-Raḥmān and the Mahdist community.

Personality  
and  
reputation

The Mahdī made a powerful impression on his Sudanese contemporaries, and the doubters were few. Recorded recollections are capricious, but most witnesses agreed on his medium-to-tall height; his austere frame which, according to some, fattened toward the end of his life; the soft voice that a sudden access of indignation could make terrible; the sympathetic, sensitive face; the large, piercing eyes. The pious were sure that in his person he conformed to all that was traditionally expected of a *mahdī*. Understandably, European captives drew a less favourable picture. There are no portraits; a photograph in a lithographed edition (Cairo, 1342 [1923–24]) of the Mahdī's *ar-rātib* (book of devotions) is unauthentic.

The Mahdī's reputation in Europe and America has changed with the times. To the British at the time of the Mahdist wars the Mahdī was the enemy whom they associated, though wrongly, with the killing of Gordon. The war correspondents generally reported him as an ogre, cruel when he was not lascivious; in their brash assurance they dubbed him the False Prophet and a dervish, a term that the Mahdī expressly repudiated. This caricature of the Mahdī was reflected in a bulky literature of unwitting misrepresentation involving authors as different as Rudyard Kipling and George Alfred Henty (Britain), Karl May (Germany), and Henryk Sienkiewicz (Poland), which distorted the Mahdī's image for an entire generation. Ironically, it was Gen. Horatio Herbert Kitchener's conquest of the Sudan in 1896–98 that first brought Mahdists and British officials together and fostered what was to become a growing interest among European and Sudanese scholars in the study of Mahdist documents in the original Arabic. Such studies have made possible a clearer view of this modern ascetic who changed the course of African history.

**BIBLIOGRAPHY.** F.R. WINGATE, *Mahdīism and the Egyptian Sudan* (1891, reprinted 1968); A.B. THEOBALD, *The Mahdiyya* (1951); P.M. HOLT, *The Mahdist State in the Sudan*, 2nd ed. (1970); B. FARWELL, *Prisoners of the Mahdī* (1967). The Mahdī's collected works in Arabic have been reprinted in a

series of volumes under the direction of Muḥammad Ibrāhīm Aḥmad Abū Salīm, director of the Sudan Government Central Archives, Khartoum.

(R.L.Hi.)

## Mahler, Gustav

The stature of Gustav Mahler, the last notable exponent of the Austro-German symphony, is as yet difficult to determine, because only since about 1960 has his music, widely rejected for 50 years after his death as an extravagant consummation of what was most extreme in Romanticism, found a substantial following. He is generally admitted to have been an important forerunner of 20th-century techniques of composition; but a more significant measure of his stature in his own right is the high opinion held of him by the widely differing composers who have acknowledged his influence, including Arnold Schoenberg, Dmitry Shostakovich, Benjamin Britten, Hans Werner Henze, and Luciano Berio. More significant still, perhaps, is the devotion to his art shown by several eminent conductors, such as Bruno Walter, Otto Klemperer, Rafael Kubelík, and Leonard Bernstein, coupled with the growing response of the public, which already, wherever Mahler's music is performed regularly, accords it a popularity commensurate with that of Beethoven and Tchaikovsky.

The Mansell Collection

Mahler.

**Childhood influences.** Born on July 7, 1860, Mahler was the son of an Austrian-Jewish tavern keeper living in the Bohemian village of Kališř (German Kalischt), in the southwestern corner of modern Czechoslovakia; a few months later the family moved to the nearby town of Jihlava (German Iglau), where Mahler spent his childhood and youth. These simple facts provide a first clue to his tormented personality: he was afflicted by racial tensions from the beginning of his life. As part of a German-speaking Austrian minority, he was an outsider among the indigenous Czech population and, as a Jew, an outsider among that Austrian minority; later, in Germany, he was an outsider as both an Austrian from Bohemia and a Jew.

Racial and  
religious  
tensions

Mahler's life was also complicated by the tension existing between his parents. His father, a self-educated man of fierce vitality, had married a delicate woman from a cultured family; and coming to resent her social superiority, he resorted to physically maltreating her. In consequence Mahler was alienated from his father and had a strong mother fixation, which even manifested itself physically: a slight limp was unconsciously copied in imitation of his mother's lameness. Furthermore, he inherited his mother's weak heart, which was to cause his death at the age of 50. Finally, there was a constant childhood background of illness and death among his 11 brothers and sisters.

This unsettling early background may explain the ner-

vous tension, the irony and skepticism, the obsession with death, and the unremitting quest to discover some meaning in life that was to pervade Mahler's life and music. But it does not explain the prodigious energy, intellectual power, and inflexibility of purpose that carried him to the heights as both a master conductor and a composer. The positive elements in his makeup stemmed no doubt from his father's side of the family, as did his great physical vitality. Despite his inherited heart trouble, he was an extremely active man—a ruthless musical director, a tireless swimmer, and an indefatigable mountain walker.

His musical talent revealed itself early and significantly. Around the age of four, fascinated by the military music at a nearby barracks and the folk music sung by the Czech working people, he reproduced both on the accordion and the piano and began composing pieces of his own. The military and popular styles, together with the sounds of nature, became main sources of his mature inspiration. At ten he made his debut as a pianist in Jihlava and at 15 was so proficient musically that he was accepted as a pupil at the Vienna Conservatory. After winning piano and composition prizes and leaving with a diploma, he supported himself by sporadic teaching while trying to win recognition as a composer. When he failed to win the Conservatory's Beethoven Prize for composition with his first significant work, the cantata *Das klagende Lied (The Song of Complaint)*, he turned to conducting for a more secure livelihood, reserving composition for the lengthy summer vacations.

The next 17 years saw his ascent to the very top of his chosen profession. From conducting musical farces in Austria, he rose through various provincial opera houses, including important engagements at Budapest and Hamburg, to become artistic director of the Vienna Court Opera in 1897, at the age of 37. As a conductor he had won general acclaim, but as a composer, during this first creative period, he immediately encountered the public's lack of comprehension that was to confront him for most of his career.

Since Mahler's conducting life centred in the traditional manner on the opera house, it is at first surprising that his whole mature output was entirely symphonic (his 40 songs are not true lieder but embryonic symphonic movements, some of which, in fact, provided a partial basis for the symphonies). But Mahler's unique aim, partially influenced by the school of Richard Wagner and Franz Liszt, was essentially autobiographical—the musical expression of a personal view of the world. And for this purpose, song and symphony were more appropriate than the dramatic medium of opera: song because of its inherent personal lyricism, and symphony (from the Wagner and Liszt point of view) because of its subjective expressive power.

**First period.** Each of Mahler's three creative periods produced a symphonic trilogy. The three symphonies of his first period were conceived on a programmatic basis (*i.e.*, founded on a nonmusical story or idea), the actual programs (later discarded) being concerned with establishing some ultimate ground for existence in a world dominated by pain, death, doubt, and despair. To this end, he followed the example of Beethoven's *Symphony No. 6 in F Major (Pastoral)* and Berlioz's *Symphonie fantastique* in building symphonies with more than the traditional four movements; that of Wagner's music-dramas in expanding the time span, enlarging the orchestral resources, and indulging in uninhibited emotional expression; that of Beethoven's *Symphony No. 9 in D Minor (Choral)* in introducing texts sung by soloists and chorus; and that of certain chamber works by Schubert in introducing music from his own songs (settings of poems from the German folk anthology *Des Knaben Wunderhorn [The Youth's Magic Horn]* or of poems by himself in a folk style).

These procedures, together with Mahler's own tense and rhetorical style, phenomenally vivid orchestration, and ironic use of popular-style music, resulted in three symphonies of unprecedentedly wide contrasts but unified by his unmistakable creative personality and his firm com-

mand of symphonic structure. The program of the purely orchestral *Symphony No. 1 in D Major* (one of the five movements of which was later discarded) is autobiographical of his youth: the joy of life becomes clouded over by an obsession with death in the macabre "Funeral March in the Manner of Callot" (basically a parody of popular music), which is eventually routed in the arduous and brilliant finale. The five-movement *Symphony No. 2* begins with the death obsession (the first movement's "funeral ceremony") and culminates in an avowal of the Christian belief in immortality (a huge finale portraying the Day of Judgment and ending with a setting of the 18th-century German writer Friedrich Klopstock's "Resurrection" ode involving soloists and chorus). The even vaster *Symphony No. 3*, also including a soloist and chorus, presents in six movements a Dionysiac vision of a great chain of being, moving from inanimate nature to human consciousness and the redeeming love of God.

The religious element in these works is highly significant. Mahler's disturbing early background, coupled with his lack of an inherited Jewish faith (his father was a freethinker), resulted in a state of metaphysical torment, which he resolved temporarily by identifying himself with Christianity. That this was a genuine impulse there can be no doubt, even if there was an element of expediency in his becoming baptized, early in 1897, because it made it easier for him to be appointed to the Vienna Opera post. The ten years there represent his more balanced middle period. His newfound faith and his new high office brought a full and confident maturity, which was further stabilized by his marriage in 1902 to Alma Maria Schindler, who bore him two daughters, in 1902 and 1904.

**Middle period.** As director of the Vienna Opera (and for a time of the Vienna Philharmonic Concerts), Mahler achieved an unprecedented standard of interpretation and performance, which proved an almost unapproachable model for those who followed him. A fanatical idealist, he drove himself and his artists with a ruthless energy that proved a continual inspiration and with a complete disregard for personal considerations that won him many enemies who worked for his dismissal. At this time too, he made a number of tours and became famous over much of Europe as a conductor. He continued his recently acquired habit of devoting his summer vacations, in the Austrian Alps, to composing; and since, in his case, this involved a ceaseless expenditure of spiritual and nervous energy, he thereby placed an intolerable double strain on his frail constitution.

Most of the works of this middle period reflect the fierce dynamism of Mahler's full maturity. An exception is *Symphony No. 4*, which is more of a pendant to the first period: conceived in six movements (two of which were eventually discarded), it has a *Wunderhorn* song finale for soprano, which was originally intended as a movement for *Symphony No. 3* and which evokes a naïve peasant conception of the Christian heaven. At the same time, in dispensing with an explicit program and a chorus and coming near to the normal orchestral symphony, it does foreshadow the middle-period trilogy, *Nos. 5, 6, and 7*. These are all purely orchestral, with a new, hard-edged, contrapuntal clarity of instrumentation, and devoid of programs altogether, yet each clearly embodies a spiritual conflict that reaches a conclusive resolution. *No. 5* and *No. 7* (both in five movements) move from darkness to light, though the light seems not the illumination of any afterlife but the sheer exhilaration of life on Earth. Between them stands the work Mahler regarded as his *Tragic Symphony*—the four-movement *No. 6 in A Minor*, which moves out of darkness only with difficulty, and then back into total night. From these three symphonies onward, he ceased to adapt his songs as whole sections or movements, but in each he introduced subtle allusions, either to his *Wunderhorn* songs or to his settings of poems by Friedrich Rückert, including the cycle *Kindertotenlieder (Songs on the Deaths of Children)*.

At the end of this period he composed his monumental *Symphony No. 8 in E Flat Major* for eight soloists, dou-

tion of  
*Symphony  
of a  
Thousand*

ble choir, and orchestra—a work known as the *Symphony of a Thousand*, owing to the large forces it requires, though Mahler gave it no such title. This stands apart, as a later reversion to the expansive metaphysical tendencies of the first period, and represents a consummation of them: the first continuously choral and orchestral symphony ever composed. It could be called at once a massive statement of human aspirations and a cry for illumination, from both the religious and the humanistic points of view. The first of its two parts, equivalent to a symphonic first movement, is a setting of the medieval Catholic Pentecost hymn *Veni Creator Spiritus*; part two, amalgamating the three movement-types of the traditional symphony, has for its text the mystical closing scene of Goethe's *Faust* drama (the scene of Faust's redemption). The work marked the climax of Mahler's confident maturity, since what followed was disaster—of which, he believed, he had had a premonition in composing his *Tragic Symphony, No. 6*. This work had revealed for the first time a superstitious element in his personality. The finale originally contained three climactic blows with a large hammer, representing "the three blows of fate which fall on a hero, the last one felling him as a tree is felled" (he subsequently removed the final blow from the score). Afterward he identified these as presaging the three blows that fell on himself in 1907, the last of which portended his own death: his resignation was demanded at the Vienna Opera, his three-year-old daughter Maria died, and a doctor diagnosed his fatal heart disease.

**Last period.** Thus began Mahler's last period, in which, at the age of 47, he became a wanderer again. He was obliged to make a new reputation for himself, as a conductor in the United States, directing performances at the Metropolitan Opera and becoming conductor of the Philharmonic Society of New York; yet he went back each summer to the Austrian countryside to compose his last works. He returned finally to Vienna, to die there, on May 18, 1911.

The three works comprising his last-period trilogy, none of which he ever heard, are *Das Lied von der Erde* (*The Song of the Earth*), *Symphony No. 9*, and *Symphony No. 10 in F Sharp Major*, left unfinished in the form of a comprehensive full-length sketch (though a full-length performing version has been made posthumously). The first of the three again revealed Mahler's superstition: beginning as a song cycle (to Chinese poems in German translations), it grew into "A Symphony for Tenor, Baritone (or Contralto) and Orchestra." Yet, he would not call it "Symphony No. 9," believing, on the analogy of Beethoven and Bruckner, that a ninth symphony must be its composer's last. When he afterward began the actual *No. 9*, he said, half jokingly, that the danger was over, since it was "really the tenth"; but in fact, that symphony became his last, and *No. 10* remained in sketch form when he died.

This last-period trilogy, Mahler's most profoundly personal achievement, marked an even more decisive break with the past than had the middle-period trilogy. It represents a threefold attempt to come to terms with modern man's fundamental problem—the reality of death, which in his case had effectively destroyed the religious faith he had opposed to death as an imagined event. *Das Lied von der Erde*—a six-movement "song-cycle symphony" as opposed to the two-part "oratorio symphony," *No. 8*—views the evanescence of all things human in veiled poetic terms—sardonic, wistful, and grief stricken by turns—until it finds a sad consolation in the beauty of the Earth that endures after the individual is no longer alive to see it.

Confron-  
tation  
with  
death  
in the  
*Ninth  
Symphony*

In the four-movement *No. 9*, purely orchestral, the confrontation with death becomes an anguished personal one, evoking horror and bitterness in Mahler's most modern and prophetic movement, the "Rondo-Burleske," and culminating in a finale of heartbroken resignation. The finales of both these works end with an extraordinary, long-drawn disintegration of the musical texture, suggesting dissolution; and the more extreme case in *No. 9* was for long thought to be Mahler's final comment on human

existence. Growing familiarity with the sketch of *No. 10*, however, has suggested that he broke through to a more positive attitude: its five movements deal with the same conflict as the two preceding works, but the resignation attained at the end of the finale is entirely serene and affirmative.

**Assessment.** Modern critical opinion recognizes Mahler's powerful influence during a period of musical transition. In his works may be found pervasive elements foreshadowing the radical methods employed in the 20th century: these elements include "progressive tonality" (ending a work in a different key from the initial one); dissolution of tonality (obscuring the perception of key through the constant use of chromaticism or harmonies not belonging to that key); a breakaway from harmony produced by the entire orchestra in favour of a contrapuntal texture (based on interwoven melodies) for groups of solo instruments within the full orchestra; the principal of continually varying themes rather than merely restating them; ironic quotation of popular styles and of sounds from everyday life (bird calls, bugle signals, etc.); and, on the other hand, a new way of formally unifying the symphony through the adoption of techniques subtly derived from Liszt's "cyclic" method (the carrying over of themes from one movement of a work to others).

In terms of the personal content of his art, it can be said of Mahler, more than of any other composer, that he lived out the spiritual torment of disinherited modern man in his art, and that the man is the music.

#### MAJOR WORKS

CANTATA: *Das klagende Lied* (completed 1880).

SYMPHONIES: *Symphony No. 1 in D Major* (1888; originally subtitled *Titan*); *Symphony No. 2*, with soprano, contralto, and chorus (1894; begins in C minor and ends in E flat major, popular title *Resurrection*); *Symphony No. 3 in D Major* (1896; often wrongly said to be in D minor, originally subtitled *Eine Sommernorgentraum*); *Symphony No. 4*, with soprano (1900; begins in G major and ends in E major, popularly called *Ode to Heavenly Joy*); *Symphony No. 5* (1902; begins in C sharp minor and ends in D major, popularly called *Giant*); *Symphony No. 6 in A Minor* (1904; popular title *Tragic*); *Symphony No. 7* (1905; begins in G minor and ends in C major, often wrongly said to be in E minor, popularly called *Song of the Night*); *Symphony No. 8 in E Flat Major*, for eight soloists, double chorus, and orchestra (1907; popular title *Symphony of a Thousand*); *Symphony, Das Lied von der Erde*, for tenor, baritone (or contralto), and orchestra (1908); *Symphony No. 9* (1910; begins in D major and ends in D flat major); *Symphony No. 10 in F Sharp Major* (full-length sketch only, realized in a performing version by D. Cooke).

SONGS: *Lieder und Gesänge aus der Jugendzeit*, 14 songs for voice and piano, mainly to poems from *Des Knaben Wunderhorn* (1880–88); *Lieder eines fahrenden Gesellen*, cycle of four songs for voice and orchestra to texts by the composer (1883–85); *Des Knaben Wunderhorn*, ten songs for voice and orchestra (1888–96); "Revelge" and "Der Tamboursg'ssell," two songs to poems from *Des Knaben Wunderhorn* (1899–1901); *Kindertotenlieder*, cycle of five songs to poems by Rückert (1901–04); *Fünf Lieder nach Rückert*, five songs to poems by Rückert (1901–04).

**BIBLIOGRAPHY.** A critical collected edition of Mahler's works is in the process of being published by the International Gustav Mahler Society of Vienna; the society possesses most of the autographs and issues a yearly bulletin. An irregular periodical, *Chord and Discord*, devoted to the study of Mahler and Bruckner, is issued by the Bruckner Society of America. The chief source book on the composer's life is that by his wife, ALMA MARIA MAHLER, *Gustav Mahler: Erinnerungen und Briefe* (1940; Eng. trans. rev. and enl. by D.C. MITCHELL, *Gustav Mahler: Memories and Letters*, 1968). Two important memoirs are B. WALTER, *Gustav Mahler* (1957; Eng. trans., 1958); and N. BAUCER-LECHNER, *Erinnerungen an Gustav Mahler* (1923); the only published volume of letters is *Briefe Gustav Mahlers* (1924). A first volume of a definitive biography (coupled with critical study) is D.C. MITCHELL, *Gustav Mahler: The Early Years* (1958); this, in conjunction with H.F. REDLICH, *Bruckner and Mahler*, 2nd ed. (1963), provides a large but not comprehensive bibliography. A notable critical study is D. NEWLIN, *Bruckner, Mahler, Schoenberg* (1947); P. BEKKER, *Gustav Mahlers Sinfonien* (1921), offers an exhaustive musical analysis of the symphonies.

(D.V.Co.)

## Maḥmūd of Ghazna

A 10th–11th-century ruler of the kingdom of Ghazna (modern Ghaznī), originally comprising modern Afghanistan and the northeastern part of modern Iran, Maḥmūd made his kingdom the centre of a vast empire including at its zenith Pakistan and most of Iran. Maḥmūd also established the Afghan city of Ghazna as a cultural centre that rivalled Baghdad, which was the metropolis of Islām.

Maḥmūd was born in 971, the son of Sebūktigin, a Turkish slave, who in 977 became ruler of Ghazna. When Maḥmūd ascended the throne in 998 at the age of 27, he already showed remarkable administrative ability and statesmanship.

Early years

At the time of his accession, Ghazna was a small kingdom, comprising modern Afghanistan and the northeastern portion of modern Iran. The young and ambitious Maḥmūd aspired to be a great monarch, and in more than 20 successful expeditions he amassed the wealth with which to lay the foundation of a vast empire that eventually included Kashmir, the Punjab, and a great part of Iran.

During the first two years of his reign Maḥmūd consolidated his position in Ghazna. Though an independent ruler, for political reasons he gave nominal allegiance to the 'Abbāsīd caliph in Baghdad, and the caliph, in return, recognized him as the legitimate ruler of the lands he occupied and encouraged him in his conquests.

Maḥmūd is said to have vowed to invade India once a year and, in fact, led about 17 such expeditions. The first large-scale campaign began in 1001 and the last ended in 1026. The first expeditions were aimed against the Punjab and northeastern India, while in his last campaign Maḥmūd reached Somnāth on the southern coast of Gujārāt.

His chief antagonist in northern India was Jaipāl, the ruler of the Punjab. When, in 1001, Maḥmūd marched on India at the head of 15,000 horse troops, Jaipāl met him with 12,000 horse troops, 30,000 foot soldiers, and 300 elephants. In a battle near Peshāwar the Indians, though superior in numbers and equipment, fell back under the onslaught of the Muslim horse, leaving behind 15,000 dead. After falling into the hands of the victors, Jaipāl, with 15 of his relatives and officers, was finally released. But the raja could not bear his defeat, and after abdicating in favour of his son, Ānandpāl, he mounted his own funeral pyre and perished in the flames.

Annexation of the Punjab

Ānandpāl appealed to the other Indians rajas for help. Some replied in person, others sent armies. The Indian women sold their jewels to finance a huge army. When, at last, in 1008, Maḥmūd met the formidable force thus raised, the two armies lay facing each other between Und and Peshāwar for 40 days. The Sultan finally succeeded in enticing the Indians to attack him. A force of 30,000 Khokars, a fierce, primitive tribe, charged both flanks of the Sultan's army with such ferocity that Maḥmūd was about to call a retreat. But at this critical moment Ānandpāl's elephant, panic-stricken, took flight. The Indians, believing that their leader was turning tail, fled from the battlefield strewn with their dead and dying. This momentous victory facilitated Maḥmūd's advance into the heart of India.

After annexing the Punjab, and returning with immense booty, the Sultan set about to transform Ghazna into a great centre of art and culture. He patronized scholars, established colleges, laid out gardens, and built mosques, palaces, and caravansaries. Maḥmūd's example was followed by his nobles and courtiers, and Ghazna soon transformed into the most brilliant cultural centre in Central Asia.

In 1024 the Sultan set out on his last famous expedition to the southern coast of Kāthiāwār along the Arabian Sea, where he sacked the city of Somnāth and its renowned Hindu temple. Maḥmūd returned home in 1026. The last years of his life he spent in fighting the Seljuq and other Central Asian tribes threatening his empire. He died in Ghazna in 1030.

Maḥmūd was the first to carry the banner of Islām into the heart of India. To some Muslim writers he was a

great champion of his faith, an inspired leader endowed with supernatural powers. Most Indian historians, on the other hand, emphasize his military exploits and depict him as "an insatiable invader and an intrepid marauder." Neither view is correct. In his Indian expeditions he kept his sights set mainly on the fabulous wealth of India stored in its temples. Though a zealous champion of Islām, he never treated his Indian subjects harshly nor did he ever impose the Islāmic religion on them. He maintained a large contingent of Hindu troops, commanded by their own countrymen, whom he employed with great success against his religionists in Central Asia. Conversion to Islām was never a condition of service in the Sultan's army.

Great as a warrior, the Sultan was no less eminent as a patron of art and literature. Attracted by his munificence and encouragement, many outstanding scholars settled in Ghazna, among them al-Bīrūnī, the mathematician, philosopher, astronomer, and Sanskrit scholar, and Ferdowsī, the Persian author of the great epic poem *Shāh-nāmeḥ*. Maḥmūd's conquest of northern India furthered the exchange of trade and ideas between the Indian subcontinent and the Muslim world. It helped to disseminate Indian culture in foreign lands. Similarly, Muslim culture, which by now had assimilated and developed the cultures of such ancient peoples as the Egyptians, the Greeks, the Romans, and the Syrians, found its way into India, and many Muslim scholars, writers, historians, and poets began to settle there.

**BIBLIOGRAPHY.** WOLSELEY HAIG in *The Cambridge History of India*, vol. 3 (1965), provides a reliable account of the Ghaznavid period. RAMESH MAJUMDAR *et al.*, *An Advanced History of India*, 3rd ed. (1967), includes a short sketch of this period. See also the relevant chapters in *A Cultural History of Afghanistan* by MOHAMMED ALI (1964); and S.M. IKRAM and PERCIVAL SPEAR, *The Cultural Heritage of Pakistan* (1955).

(M.A.L.)

## Maimonides, Moses

Moses Maimonides (Greek for Hebrew ben Maimon, "son of Maimon"), the foremost intellectual figure of medieval Judaism, made lasting contributions as a jurist, philosopher, and scientist. His epoch-making influence on Judaism extended also to the larger world. His philosophic work, after it was translated into Latin, influenced the great medieval Scholastic writers, and even later thinkers, such as Spinoza and Leibniz, found in his work a source for some of their ideas. His medical writings constitute a significant chapter in the history of medical science.

He was born in 1135 to a distinguished family in Córdoba (Cordova), Spain. The young Moses studied with his learned father, Maimon, and other masters and at an early age astonished his teachers by his remarkable depth and versatility. Before Moses reached his 13th birthday, his peaceful world was suddenly disturbed by the ravages of war and persecution.

Life

As part of Islāmic Spain, Córdoba accorded its citizens full religious freedom. But now the Islāmic Mediterranean world was shaken by a revolutionary and fanatical Islāmic sect, the Almohads (al-Muwahhidūn, "the Unitarians"), who captured Córdoba in 1148, leaving the Jewish community faced with the grim alternative of submitting to Islām or leaving the city. The Maimons temporized by practicing their Judaism in the privacy of their homes, while disguising their ways in public as far as possible to appear like Muslims. The Maimons remained in Córdoba for some 11 years, and Maimonides continued his education in Judaic studies as well as in the scientific disciplines in vogue at the time.

When the double life proved too irksome to maintain in Córdoba, the Maimon family finally left the city about 1159 to settle in Fez, Morocco. Although it was also under Almohad rule, Fez was presumably more promising than Córdoba, because there the Maimons would be strangers and their disguise would be more likely to go undetected. Moses continued his studies in his favourite subjects, rabbinics and Greek philosophy, and added medicine to them. Fez proved to be no more than a short

respite, however. In 1165 Rabbi Judah ibn Shoshan, with whom Moses had studied, was arrested as a practicing Jew and was found guilty and then executed. This was a sign to the Maimon family to move again, this time to Palestine, which was in a depressed economic state and could not offer them the basis of a livelihood. After a few months they moved again, now to Egypt, settling in Fostat, near Cairo. There Jews were free to practice their faith openly, though any Jew who had once submitted to Islām courted death if he relapsed to Judaism. Moses himself was once accused of being a renegade Muslim, but he was able to prove that he had never really adopted the faith of Islām and so was exonerated.

Though Egypt was a haven from harassment and persecution, Moses was soon assailed by personal problems. His father died shortly after the arrival in Egypt, and when his younger brother, David, a prosperous jewelry merchant, on whom Moses leaned for support, died in a shipwreck, taking the entire family fortune with him, Moses was left as the sole support of his family. He could not turn to the rabbinate because in those days the rabbinate was conceived of as a public service that did not offer its practitioners any remuneration. Pressed by economic necessity, Moses took advantage of his medical studies and became a practicing physician. His fame as a physician spread rapidly and he soon became the court physician to the sultan Saladin, the famous Muslim military leader, and to his son al-Afdal. He also continued a private practice and lectured before his fellow physicians at the state hospital. At the same time he became the leading member of the Jewish community, teaching in public and helping his people with various personal and communal problems.

Maimonides married late in life and was the father of a son, Abraham, who was to make his mark in his own right in the world of Jewish scholarship.

Works

The writings of Maimonides were prolific and varied. His earliest work, composed at the age of 16, was the *Millot ha-Higgayon* ("Treatise on Logical Terminology"), a study of various technical terms that were employed in logic and metaphysics. Another of his early works, like the work on logic written in Arabic, was the "Essay on the Calendar" (Hebrew title: *Ma'amar ha-'ibur*).

The first of Maimonides' major works, begun at the age of 23, was his commentary on the Mishna, *Kitāb al-Sirāj*, also written in Arabic. The Mishna is a compendium of decisions in Jewish law that date from earliest times to the 3rd century. Maimonides' commentary clarified individual words and phrases, frequently citing relevant information in archaeology, theology, or science. Possibly the work's most striking feature is a series of introductory essays dealing with general philosophical issues touched on in the Mishna. One of these essays summarizes the teachings of Judaism in a creed of Thirteen Articles of Faith.

He completed the commentary on the Mishna at the age of 33, after which he began his magnum opus, the code of Jewish law, on which he also laboured for ten years. Bearing the name of *Mishne Torah* ("The Torah Reviewed") and written in a lucid Hebrew style, the code offers a brilliant systematization of all Jewish law and doctrine. He wrote two other works in Jewish law of lesser scope: the *Sefer ha-mitzvot* ("The Book of Precepts"), a digest of law for the less sophisticated reader, written in Arabic; and the *Hilkhot ha-Yerushalmi* ("Laws of Jerusalem"), a digest of the laws in the Palestinian Talmud that was written in Hebrew.

His next major work, which he began in 1176 and on which he laboured for 15 years, was his classic in religious philosophy, the *Dalalat al-hā'irīn* (*The Guide of the Perplexed*), later known under its Hebrew title as the *More nevuḥhim*. A plea for what he called a more rational philosophy of Judaism, it constituted a major contribution to the accommodation between science, philosophy, and religion. It was written in Arabic and sent as a private communication to his favourite disciple, Joseph ibn Akin. The work was translated into Hebrew in Maimonides' lifetime and later into Latin. It was subsequent-

ly translated into most European languages and has exerted a marked influence on the history of religious thought.

Maimonides also wrote a number of minor works, occasional essays dealing with current problems that faced the Jewish community, and he maintained an extensive correspondence with scholars, students, and community leaders. Among his minor works those considered to be most important are *Iggeret Teman* (*Epistle to Yemen*), *Iggeret ha-shemad* or *Ma'amar Qiddush ha-Shem* ("Letter on Apostasy"), and *Iggeret le-qahal Marsilia* ("Letter on Astrology," or, literally, "Letter to the Community of Marseilles"). He also wrote a number of works dealing with medicine, including a popular miscellany of health rules, which he dedicated to the sultan, al-Afdal. A mid-20th-century historian, Waldemar Schweisheimer, has said of Maimonides' medical writings: "Maimonides' medical teachings are not antiquated at all. His writings, in fact, are in some respects astonishingly modern in tone and contents."

Maimonides complained often that the pressures of his many duties robbed him of peace and undermined his health. He died in 1204 and was buried in Tiberias, in the Holy Land, where his grave continues to be a shrine drawing a constant stream of pious pilgrims.

Maimonides' advanced views aroused opposition in his own lifetime, and this opposition continued after his death. In 1233 one zealot, Rabbi Solomon of Montpellier, in southern France, instigated the church authorities to burn *The Guide of the Perplexed* as a dangerously heretical book. But the controversy died down after some time, and Maimonides came to be recognized as a pillar of the traditional faith—his creed became part of the orthodox liturgy—as well as the greatest of the Jewish philosophers.

**BIBLIOGRAPHY.** MAIMONIDES' *Guide of the Perplexed*, ed. by SHLOMO PINES (1963), a new translation from the Arabic with an introduction and notes, and with an introductory essay by LEO STRAUSS, one of the leading authorities on Maimonides today; SALO BARON, "Moses Maimonides," in SIMON NOVECK (ed.), *Great Jewish Personalities in Ancient and Medieval Times* (1959), a succinct, popular essay by a noted historian, describing the essential facts in the life of Maimonides and a characterization of his major works, and (ed.), *Essays on Maimonides* (1941), a commemorative volume marking the 800th anniversary of the birthday of Maimonides, including an essay dealing with his medical writings; BEN ZION BOKSER, *Legacy of Maimonides*, rev. ed. (1962), an interpretation of the world outlook of Maimonides, with a brief biographical sketch; A. COHEN, *The Teachings of Maimonides* (1927), a brief biographical sketch, followed by selected passages from his legal and philosophical writing, arranged according to a conceptual framework; SOLOMON ZEITLIN, *Maimonides* (1935), a biography, with a detailed characterization of his major writings.

(B.Z.B.)

## Maine

Maine, the largest of the six New England states, lies at the northeastern tip of the contiguous United States. Its 33,215 square miles (86,027 square kilometres), including 2,295 square miles of water area, nearly one-half the total area of New England, are bounded on the northwest and northeast by the Canadian provinces of Quebec and New Brunswick, respectively, and on the west by New Hampshire. Its famed rocky coastline angles from southwest to northeast, along the Atlantic Ocean. Maine's capital has been Augusta since its admission, in 1820, as the 23rd state of the Union.

With a 1970 population of just under 1,000,000 persons, Maine is the most sparsely populated state east of the Mississippi River. More than 80 percent of its area is under forest cover. It is also, by most statistical measures, an economically depressed state; but the rugged beauty and challenge of its climate and landscape and the character of its people have given Maine an importance beyond its economic and political power. Limited economic growth, in fact, has contributed to the preservation of much of its natural appearance. Maine's economy remains largely dependent upon the extractive industries and the recreational opportunities associated with its sta-

Posthumous reputation

Location and general character

tus as a major U.S. vacationland, and the state epitomizes the increasingly difficult national choices between preservation of environmental quality or potential economic expansion. Politically, Maine was long regarded as a stronghold of the Republican Party, but it has been a two-party state in recent years. (For information on related topics, see the articles UNITED STATES; UNITED STATES, HISTORY OF THE; and NORTH AMERICA.)

#### THE HISTORY OF MAINE

Algonkian Indians were the earliest known settlers in Maine. Descended from Ice Age hunters, they lived along the river valleys and the coasts, hunting and fishing and planting crops. Few of them survived the arrival of the European settlers. But the earlier tribes are remembered in numerous place-names; in the sites of their camps and burial grounds; in ancient trails and water routes; in the use of the canoe, the snowshoe, and the toboggan; in corn, beans, and squash; and in the revived concern for man's relation with the natural environment.

**Explorations and disputes.** The first European explorations of Maine are shrouded in mystery. Evidence that the Norsemen landed on the coast is scant and disputed, and serious questions exist about some of the early British claims based on John Cabot's voyages in the late 1490s. Portuguese, Spanish, French, and English explorers did probe the islands, the bays, and the rivers of the "maine" throughout the 16th century; and by the first decade of the 17th century, summer fisheries had been established on some of the coastal islands and fur trade had begun with the Indians.

The French and English crowns claimed the same territory; and the area was an intermittent battleground between the English, the Indians, and the French from 1615 until 1675 and a constant battleground from that date until 1763, when the British conquered the French in eastern Canada.

Maine was given separate provincial status in New England under royal patents granted by Charles I. The Puritans of Massachusetts took over the territory when the proprietor, Sir Ferdinando Gorges, backed the losing side in the British Civil War. Frontier settlers in Maine chafed under Massachusetts rule; but the merchants of the coastal towns resisted the separation movement until the War of 1812, when popular resentment against the failure of the Massachusetts Commonwealth to protect the District of Maine against British raids tipped the scales in favour of separation. Maine entered the Union as a free state under the Missouri Compromise of 1820, offsetting the simultaneous admission of Missouri without restrictions on the ownership of slaves.

**Statehood.** Maine intrigued entrepreneurs, who hoped to make their fortune in furs, fisheries, timber, and land development. The first three proved to be lucrative for a few; but the climate, border troubles, and the knowledge of the more fertile land of the newer territories to the west curtailed settlement of the area before and after statehood. The greatest period of economic growth came between 1830 and 1860, when lumber, ice, granite, lime (extracted from limestone), and fishing and shipbuilding dominated the state's economy. Coastal communities flourished and railroads developed as Maine men and ships traded around the world.

The Civil War and the Industrial Revolution diverted men and capital from Maine in the last decades of the 19th century. Textiles and paper products became the primary sources of manufacturing employment, while fisheries and agriculture continued as important but uncertain sources of income. The details of economic activity changed during the first half of the 20th century, but the overall picture remained one of precarious prosperity and extreme susceptibility to swings in the national economy.

**Political development.** Maine's social and political history has been dominated by struggles against the adversity of frontier life and economic limitations, coupled with strong drives within the state for social reform, including world peace, antislavery, prohibition, and women's suffrage. Jeffersonian and Jacksonian Democrats held sway

from statehood until the rise of the Whigs and the emergence of the Republican Party. The Abolitionist movement gave the Republican Party its start in Maine in 1854, and the Grand Old Party dominated the state for almost a century. Democrats scored temporary gains in the elections of 1910 and 1912 and in the Depression elections of 1932 and 1934, but it was not until 1954 that sustained competition began to develop between the major parties.

#### THE NATURAL AND HUMAN LANDSCAPE

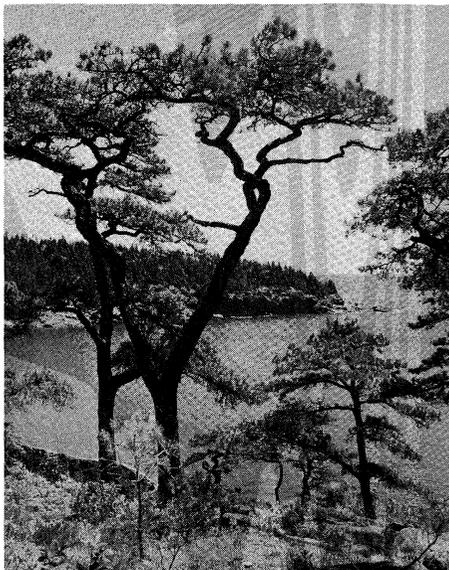

**The natural environment.** *Surface features.* The Appalachian Mountain chain extends into Maine from New Hampshire, terminating in Mt. Katahdin, at 5,268 feet (1,606 metres) the state's tallest peak. The western and northwestern borders adjoining New Hampshire and Quebec have the most rugged terrain, with numerous glacier-scoured peaks, lakes, and narrow valleys. South and east of the mountain areas lie rolling hills and smaller mountains and the broad river valleys of the Saco, the Androscoggin, the Kennebec, and the Penobscot. From Kittery, at the southern tip of the state, to Cape Elizabeth, just southwest of Portland, the state's largest city, long sand beaches are interrupted here and there by rocky promontories. North and east of Cape Elizabeth the coastline is a series of peninsulas, narrow estuaries, bays, fjords, and coves, once mountains and valleys that glaciers of the Ice Age pushed beneath the ocean. The Camden Hills and Mount Desert Island are the largest of the coastal mountains. The tides along this famous rockbound coast are among the strongest in the world, running between 12 and 24 feet. Off the coast lie about 1,200 islands, some no more than rocky ledges, others topped with trees and sheltering the homes of fishermen, lobstermen, and summer people. All told, the Maine coast—the bays, islands, and inlets washed by the tides—totals some 3,500 miles.

*Waters and soils.* Most of Maine's river systems flow from north to south. The St. John River and its principal tributary, the Allagash, are the major exceptions, flowing north and then east along the northern border of Maine and turning south through New Brunswick, Canada, to the sea. The state is dotted with 2,500 lakes and ponds, the largest of which is Moosehead Lake (120 square miles). Soils in southwestern Maine were formed primarily from granite; coastal, central, and eastern soils are composed of shale, sand, and limestone; while the soils of Aroostook County, in the northeast, which are among the most productive in the state, are largely composed of caribou loam.

*Climate.* Maine has three relatively well-defined climatic areas: southern interior, coastal, and northern. The southern and coastal regions are influenced by air masses from the south and west. North of the land dividing the St. John and Penobscot River basins, air masses moving down the St. Lawrence River basin tend to prevail. Mean annual temperatures range from 37° to 39° F (3° to 4° C) in the north and from 43° to 45° F (6° to 7° C) in the southern interior and coastal regions. Mean temperatures are about 62° F (17° C) throughout the state during the summer and 20° F (−7° C) during the winter. About 60 percent of the days are sunny, and annual precipitation averages 40 to 46 inches. Snowfall averages more than 100 inches in the northern area and the higher elevations.

*Vegetation and animal life.* Flora and fauna represent a combination of subarctic and Appalachian species. Forests include heavy stands of pine, spruce, and fir among the hardwoods. Among the fauna are the deer, moose, black bear, fox, lynx, hare, raccoon, porcupine, skunk, and woodchuck. Songbirds, lake birds, seabirds, and many game species abound throughout the state. Among the many aquatic species are the seal, whale, porpoise, lobster, shrimp, clam, haddock, cod, mackerel, Atlantic and landlocked salmon, and many freshwater game fishes.

**Patterns of human settlement.** *Traditional regions.* Coastal Maine is best known, from anecdotes and dialect stories, as the traditional home of the "Downeast Yankee." Many communities in that region, now relatively

#### Parks of Maine.

(Left) A. Devaney, Inc., (Right) Russ Kinne—Photo Researchers

isolated from the principal avenues of highway traffic, were once bustling centres of ocean commerce and river trade. Population movements have blurred some of the regional differences; but within the coastal region there are three areas, each with its own sense of identity. The southwestern coast, predominantly a resort area, extends from Kittery to the Portland metropolitan region on Casco Bay. The midcoast region, marked by a combination of fishing and maritime activities and vacation and retirement homes and resort centres, runs from Bath (long a shipbuilding centre) and the mouth of the Kennebec River to Belfast, on the western shore of Penobscot Bay. The eastern coastal region begins on the eastern shore of Penobscot Bay and ends at Calais, on the St. Croix River, at the New Brunswick border.

Central and southern Maine form a contiguous region covering the southern half of the state, from the New Hampshire border to the Penobscot River. It contains the bulk of the population and of its industrial and commercial activities. The western border areas of York, Cumberland, Oxford, and Franklin counties form a subregion, but increased mobility is eroding the distinctive community and speech patterns of those sections.

Aroostook County, a region by itself, is often referred to as "the" county. Central and southern Aroostook areas were settled by English and Irish immigrants whose speech patterns continue to resemble those of their neighbours across the border in New Brunswick more than they do the broad *a*'s and dropped *r*'s of the rest of Maine speech. The St. John Valley along the northern border of Aroostook County was settled by Acadians of French descent from Nova Scotia and New Brunswick. The communities of the valley retain their French character and speech.

*Rural and small-town life.* Maine's rocky terrain limited the size of farms in most areas of the state. With the exception of Aroostook County and a few broad valleys in the central region, fields are small and, in many cases, marked by old stone walls or separated by wooded lots.

Interior rural communities vary according to the terrain and their economic history. Some consist only of a crossroads settlement with a store, gas station, post office, and three or four homes; others have a church, school, a few stores, and small establishments clustered around a millsite; still others have the traditional village green, often with the typical white frame, single-spired New England church, as well as such social centres as a grange hall. Communities that prospered during the height of the lumber trade are marked, where the terrain permits, by broad avenues and imposing wooden homes.

Coastal communities are similar, with commercial areas on the waterfront and social, cultural, and residential centres on higher ground.

*Urban centres.* Maine's largest urban communities are Portland, Lewiston-Auburn, Bangor, Waterville, and Augusta. Portland is the centre of a metropolitan area (population about 107,000) spreading inland and around the harbour city, which lies on Casco Bay. It is the commercial and transportation hub of the state, whose economy has a growing and diversified industrial base, including paper manufacturing, steel fabrication, light manufacturing, and assembly. Bangor (about 33,000), an old lumbering town at the head of navigation on the Penobscot River, is the commercial centre for eastern and northern Maine. Augusta (about 22,000), the state capital, lies at the head of navigation on the Kennebec River. State government is the principal source of employment for the city, but it is also the site of textile, shoe, and paper industries.

The twin cities of Lewiston and Auburn form the second largest urban centre in the state (about 65,000). Long dependent on textile and shoe manufacturing, the two communities have pursued aggressive industrial development programs and now are diversified into electronics and light manufacturing. They also serve as a commercial and trade centre for the Androscoggin Valley and eastern Oxford County. Waterville (about 18,000), north of Augusta on the Kennebec, with its neighbouring communities of Winslow and Fairfield, is a pulp-and-paper and textile centre, a commercial and trade centre for the central and northern Kennebec Valley.

#### THE PEOPLE OF MAINE

*The mix of peoples.* The original "Downeast Yankees" were English-Scotch-Irish Protestant immigrants who made the most substantial and persistent early European settlements in Maine. They set the style of dour and taciturn industry and dry wit that is characteristic of Maine legends and stories. Their descendants dominated the political and economic life of the state during most of its development and still comprise its largest population group, particularly in the smaller communities and rural areas.

Contrary to popular impressions, however, Yankees are not the sole inhabitants of Maine. Two groups of French descent make up the second largest ethnic bloc. The Acadians, originally from Brittany and Normandy, were driven out of Nova Scotia in 1763 by the British; many of them settled in the St. John Valley, which now forms the northern border of Maine, while others made the long

trip to Louisiana. The later French-Canadian migration from Quebec province began with the growth of the lumber and textile industries following the Civil War. French is the primary language in much of the St. John Valley and the second language in Maine's industrial cities. Irish immigration began in the 18th century and continued into the 20th, and the Irish and the French make up the bulk of Maine's Roman Catholic population. French Huguenot and German settlements were made early near the coast. During the 1870s the state encouraged a Swedish settlement in Aroostook County as part of a program for agricultural development and population growth.

Among the relatively small population of the state, a number of ethnic groups of significant size are identifiable. Most of the remaining 2,200 members of the original American Indian population live on state reservations. The non-white population is less than one percent of the people.

**Demographic trends.** Maine's general population distribution still reflects the early patterns of settlement along the coast and the river valleys, with vast sections of the interior covered with forest and virtually uninhabited, except for occasional lumber encampments. Almost one-half of the population is concentrated in four southwestern counties: Androscoggin, Cumberland, Kennebec, and York. Slightly more than one-half of Maine's residents live in what are classified as urban places; but there are only three cities with 25,000 or more inhabitants (see above); about 30 percent live in communities of more than 10,000.

Between 1960 and 1970 Maine showed increasing evidence of suburban and exurban sprawl. The proportion of urban residents dropped slightly, and the central city areas of Portland, Auburn, and Bangor lost population. Lewiston's population increased by 975, but it had a net out-migration of 2,769 during the decade. Communities around those cities, and the rural areas beyond, had substantial population increases.

Two other demographic trends were noticeable between 1960 and 1970: the northern and eastern counties of Aroostook, Piscataquis, Penobscot, and Washington lost population, as did Oxford County on the western border, whereas the central, midcoast, and southern counties gained population; and the population flow from the huge metropolitan concentrations along the northeast coast spilled northward into southern Maine, where York County had the largest numerical and proportional growth in the state.

During the 1960s Maine suffered a net loss of 70,000 persons through emigration, about 7 percent of the 1960 population. The birthrate dropped from 24 per 1,000 inhabitants to 18 per 1,000, while the death rate remained constant. The drop in the birthrate was reflected in the sharp decline in the number of children under five years of age. The post-World War II baby boom can be measured in the larger number of residents between the ages of 15 and 25, and the birthrate decline that occurred during the Depression is visible in the smaller number of 30-to-40-year-old inhabitants.

The trends of the 1960s suggest that Maine's total population will continue to grow slowly. With the exception of those areas offering attractive and accessible recreational opportunities, Maine's rural areas in the central, eastern, and northern sections will continue to have problems of emigration; the midcoast, central, and southern industrial, commercial, and recreational areas, on the other hand, will feel increasing population pressures.

#### THE STATE'S ECONOMY

Maine's forest and waterpower resources invited exploitation through the early years of the Industrial Revolution, and skilled, low-cost manpower gave the state a longtime advantage in the textile and shoe industries. Those advantages faded as textile and shoe companies moved their operations to new factories in low-wage areas of the South and, more recently, overseas. Rich agricultural soils are scattered; and, with the exception of Aroostook County—where the potato is the main crop

—terrain and soil conditions make large-scale farming difficult. With the exception of lobster production, fishing is a marginal industry. As a result of these factors, Maine is a relatively poor state, with the lowest per capita income in New England.

Since 1955 the state government has promoted an active economic development program through the Department of Economic Development. The state-operated Maine Industrial Building Authority, the Maine Recreation Authority, and the privately sponsored Maine Development Credit Corporation have provided industrial and commercial loan guarantees. The state also has used the services and financial assistance of the federal Economic Development Administration and the Small Business Administration.

**Economic resources and components.** Maine's primary natural resources are timber, sand, gravel, limestone and building stone, fish, and shellfish. There are limited deposits of copper, zinc, feldspar, and semiprecious stones. Peat is mined for horticultural use. Soils and climate have contributed to the production of high-quality potatoes, apples, blueberries, and other fruits, and dairy products.

Manufactured products represent the largest component in the market value of Maine goods and services. Pulp and paper constitute the largest item in manufactured products, potatoes and poultry in farm income, and lobsters in the fishery industry. Tourists—attracted by Maine's picturesque lakes, streams, and coast and the opportunities for swimming, boating, fishing, hunting, hiking, and winter sports—account for a large portion of retail sales and service income.

**Electrical power.** About 60 percent of the electrical energy generated within the state of Maine is produced in steam plants, 38 percent at hydroelectric stations, and the remainder by diesel and gas-turbine units. Most of the state's potential hydroelectric sites have been developed. Notable exceptions are the sites of the proposed Dickey-Lincoln School project on the Upper St. John River and the proposed joint U.S.-Canada tidal power project on Passamaquoddy and Cobscook bays at the eastern end of the state. Both projects have been opposed by private utility companies and the St. John project by conservation groups as well. A consortium of Maine and other New England private power companies has undertaken the construction of a nuclear power plant at Wiscasset.

**Labour and management.** Relatively calm labour-management relations have prevailed in Maine in spite of the state's economic difficulties. Trade unions, strongest in the textile, shoe, and pulp-and-paper industries, have successfully fought off efforts to enact so-called right-to-work legislation. Chambers of commerce and trade associations are active in economic-development projects and state legislation. The principal employer organization is Associated Industries of Maine, which has concentrated most of its efforts on influencing state legislation affecting major industries.

**Continuing economic problems.** Maine's serious employment and income problems encourage a continued emphasis on industrial development. By the end of the 1960s there were signs of economic expansion, in part the result of population movements into the state from the south and in part the product of the state's economic development program. The latter developments, however, faced increased resistance from those who feared environmental degradation in the state. Proposed petroleum and petrochemical projects were the immediate focus of the controversy, but the conflict is certain to increase between those who want more jobs and higher income and those who want to preserve the existing attractiveness of Maine.

**Transportation.** Maine depends heavily on its 21,000 miles of roads for ground transportation. The 1,800 miles of railroad track carry freight but no longer carry passengers. Buses provide interstate, intrastate, and some suburban and urban passenger transportation. Portland and Searsport are the major seaports. State and private passenger and freight ferry services operate to many of the

State and private economic promotion

Population growth and migration

Hydroelectric production and potential

coastal islands; and Portland and Bar Harbor have ferry connections with Yarmouth, Nova Scotia. An airline operates from Presque Isle, Bangor, and Portland to points outside Maine; and commuter airlines provide intrastate and interstate service to other Maine communities. Some international nonscheduled air passenger and freight traffic is routed through Bangor International Airport.

#### ADMINISTRATION AND SOCIAL CONDITIONS

Executive,  
legis-  
lature,  
and  
judiciary

**Government and politics.** *The state level.* The constitution of the state, derived from that of the Commonwealth of Massachusetts, reflects the hangover of colonial suspicions toward royal governors. The governor is Maine's chief executive officer, but he is checked by a seven-member executive council elected biennially by the state legislature. Several constitutional officers, including the attorney general, the secretary of state, the auditor, and the state treasurer, are elected by the legislature, and, until 1971, state department heads, who must be confirmed by the council, were appointed for fixed terms. Repeated efforts to abolish the council have failed. But starting with the 1958 election, the governor's term was extended to four years, with a two-term limit; and in 1971 the legislature approved the consolidation of several departments and authorized the appointment of department heads whose terms coincided with that of the governor.

The legislature, which is comprised of a 151-member house and a 32-member senate, is elected every two years. The president of the senate is the constitutional successor to the governor. Maine has a three-tiered judicial branch, including district judges, a superior court, and a supreme court. Separate probate courts serve at the county level.

*Local government.* Maine's 16 counties traditionally have provided an administrative framework for the superior court system, law enforcement, land records, and probate practice and for some road maintenance and construction functions. Town government, with the annual town meeting and a board of selectmen, prevails in most communities. Twenty-one communities operate under city charters. Professional managers are used in most cities and in many towns.

*Finances.* Local communities depend for revenues on property, automobile excise, and poll taxes (the last a requirement for hunting, driving, and other licenses, not for voting), on state aid for education, roads, and welfare, and on federal grants-in-aid. State revenues are obtained from a corporate and personal income tax, inheritance tax, sales and use taxes, motor fuel taxes, tobacco and alcoholic beverage taxes, licenses and miscellaneous taxes, and federal grants-in-aid.

*Political life.* With the election of 1954, traditional Republican dominance in Maine's state offices and national representation ended. From 1954 through 1970, Democrats won six of the eight elections for governor, ten of the 22 elections for the U.S. House of Representatives, and three of the six elections for the U.S. Senate. During the same period, the Republicans controlled all but one state legislature. Registered Republicans narrowly outnumbered Democrats, and most elections turned upon the large percentage of independent voters. Party officials are elected in local caucuses and state conventions. Nominations for county and state offices are obtained through primary elections, but as of 1971 Maine had no presidential-preference primary.

**The social milieu.** *Education.* Local governments are responsible for public elementary and secondary education, under the general supervision of the state board of education. Most rural areas are now served by multicommunity school administrative districts. The state operates technical institutes for post-secondary-school vocational training. The University of Maine, established in 1865 in Orono as a college of agriculture and mechanic arts, has been reorganized into a nine-branch system and offers a broad range of undergraduate and graduate curricula. Private liberal arts colleges include Bowdoin (Brunswick; 1794), Bates (Lewiston; 1864), and Colby (Waterville; 1813).

*Welfare.* Maine's chronic economic problems are reflected in the high incidence of poverty, with about one-third of the state's population living below the poverty line as of 1970 according to the State Office of Economic Opportunity (though federal-government data show less than half this percentage). The largest proportion of poverty is found in the rural counties, particularly the eastern coastal counties and Aroostook County. Public awareness of Maine's poverty problems and of the particular difficulties faced by the state's Indian and black populations has led to more vigorous efforts by community action groups, civil rights organizations, and health and housing associations to improve economic opportunity and to deal with the related problems of housing, education, and health. Local communities provide some assistance to the poor, but most poverty assistance is administered by the State Department of Health and Welfare.

#### CULTURAL LIFE AND INSTITUTIONS

*Folk arts and artifacts.* In its culture, as in its social and economic development, Maine reveals the attributes of both a struggling frontier community and an eclectic society immersed in commerce with other cultures. Folktales, songs, local humour, and the short stories and poems of native authors are direct, earthy, and filled with a sense of the awkward absurdities of man's attempt to subdue nature.

Cultural  
heritage

The tools of the woodsman, farmer, and fisherman are clean and simple, as are the lines of country homes, meetinghouses, and working boats. The great mansions of the old seaports, among some of the finest memorials to an earlier America, are filled with chairs, tables, chests, books, prints, hangings, screens, pottery, and bric-a-brac gathered on the many voyages of Maine's seamen to Europe and Asia, as well as with examples of the shipbuilders' and sailors' arts of wood carving and scrimshaw. Maine has, in addition, the unique contributions of such groups as the Shakers and its own local versions of the Federal, Greek Revival, Gothic, and Victorian periods of American architecture.

In recent years Maine has had a revival in crafts production, including pottery, metalworking, block and silk-screen printing, weaving, furniture making, and carving. State agencies, historical societies, museums, and local associations are engaged in preserving historic sites and in the collection, preservation, and presentation of materials on Maine's heritage.

*Fine arts.* Maine has been, and continues to be, the birthplace or the permanent or seasonal home of well-known figures in the American arts. They include such writers as Henry Wadsworth Longfellow, Harriet Beecher Stowe, Sarah Orne Jewett, Edward Arlington Robinson, and Edna St. Vincent Millay; the painters Winslow Homer, John Marin, Edward Hopper, and Andrew Wyeth; and composer Walter Piston. Active cultural programs are sponsored by the state's colleges and universities, museums, community symphonies, workshops and camps, and the numerous summer theatres.

*Recreation.* Maine's special attractions include Acadia National Park on Mount Desert Island, the first national park east of the Mississippi River; Baxter State Park, a 200,000-acre wilderness area surrounding Mt. Katahdin; the 92-mile Allagash Wilderness Waterway; and more than 40 state parks and historic sites.

*The media.* One of the more important aspects of Maine's heritage is its long line of newspapers, dating back to the *Falmouth Gazette*, first published in 1785. Maine now has nine daily, more than 30 local weekly, and two statewide weekly newspapers and a number of special and general-purpose periodical publications. Twenty-seven communities have radio stations, and there are seven commercial television stations in the state. A four-station public television network serves more than 90 percent of the state's populated area.

#### PROBLEMS AND PROSPECTS

The people of Maine have long struggled with the pain of economic adversity, but they have enjoyed a challenging and stimulating environment. What was once merely

compensation for the rigours of their own lives now has become a major attraction for other Americans who are tired of the pressures and hazards of urban living. Maine's land and waters have become thereby more valuable and the prospects for higher income brighter—and the dangers to Maine's quality of life are greater. In the 1970s the citizens of the state were endeavouring to see whether they could achieve a balance between prosperity and those natural and human qualities that have made Maine unique in the nation.

**BIBLIOGRAPHY.** The most authoritative general history of Maine is still LOUIS C. HATCH (ed.), *Maine: A History*, 5 vol. (1919). RONALD F. BANKS (comp.), *A History of Maine: A Collection of Readings on the History of Maine, 1600-1970* (1969), provides a good sampling of contemporaneous sources. DORRIS A. ISAACSON (ed.), *Maine: A Guide Down-East*, 2nd ed. (1970), is a valuable introduction to contemporary Maine, with travel suggestions and bibliography. STANLEY B. ATTWOOD, *The Length and Breadth of Maine* (1946), is the authoritative work on Maine's geography and natural resources. The MAINE DEPARTMENT OF ECONOMIC DEVELOPMENT, *Maine Pocket Data Book: An Economic Analysis* (1970), is a useful collection of economic facts and analysis. The *Maine Register* (annual) is filled with facts and figures on elections, state government, organizations, and businesses. ISABELLE P. CONGDON, *Indian Tribes of Maine* (1961), is a good, brief account of Maine's Indians. PHILIP T. COOLIDGE, *History of the Maine Woods* (1963), is a social and economic history of a dominant part of Maine life. Among the books that give a flavour of Maine's folklore and cultural heritage are: ROBERT P. TRISTRAM COFFIN, *Lost Paradise: A Boyhood on a Maine Coast Farm* (1934); E.F. WILDER and G.A. MELLON (eds.), *Maine and Its Role in American Art, 1740-1963* (1963); FANNIE HARDY ECKSTORM and M.W. SMYTH (comps.), *Minstrelsy of Maine: Folk-Songs and Ballads of the Woods and the Coast* (1927); JOHN GOULD, *Last One In: Tales of a New England Boyhood* (1966); SARAH ORNE JEWETT, *The Country of the Pointed Firs* (1896; reprinted with other stories, 1956); and W. STORRS LEE (comp.), *Maine: A Literary Chronicle* (1968).

(E.S.M.)

## Maintenon, Madame de

The second wife of Louis XIV of France and untitled queen, Mme de Maintenon (*née* Françoise d'Aubigné) rose from an obscure and poor childhood to become the favourite and, later, the secret wife of the most powerful monarch of the 17th century.

**Early years** She was born at Niort, in Poitou, perhaps in the same prison where her father, Constant, was then incarcerated for debt; the infant was baptized as a Catholic on November 28, 1635. Constant, the son of Agrippa d'Aubigné, a great Huguenot soldier and companion of Henry IV as well as a poet, possessed neither his father's talents nor his virtues. His child, Françoise, received a Calvinist upbringing until the age of seven at the Château de Mursay, supervised by her aunt Villette, Agrippa's favourite daughter.

Constant was finally freed in 1645, and the Aubigné family embarked on a journey to the West Indies, for Constant believed he had been made governor of the island of Marie-Galante. The post was not vacant, however, and Constant returned to France, leaving his family in Martinique, where they were to remain for close to two years before being able to return. Constant died in France in 1647. Françoise was entrusted once more to her aunt Villette's care, but another aunt, Mme de Neuillant, a Catholic whose daughter was Françoise's godmother, claimed the child. Françoise was forced to go to this unknown relative, who raised the child sternly together with one of her own daughters.

When Françoise was 16, her mother died. Anxious to rid herself of the orphan, Mme de Neuillant arranged for her charge to live with the crippled author Paul Scarron, who was 25 years older than the girl. Françoise married him in 1652 and later said of this relationship: "I preferred to marry him rather than a convent." In addition to nursing the author, she also had to preside over his salon, where an extremely varied group was received. The marriage was probably unconsummated. The author of *Le Roman comique* was a rascal and although he may have formed his young wife intellectually, he also undoubtedly tried

Mme de Maintenon, portrait by Pierre Mignard, (1612-95). In the Louvre, Paris.

Giraudon

to corrupt her. Meanwhile, the men who frequented his salon did not hesitate to try their luck with his little wife, who skillfully practiced the art of flirtation until, at last, in 1660, she found herself a widow—free but without a sou. She was then 25 years old and beautiful. She was at first tempted to embark on a courtesan's life, but instead she took a room in a convent and, in this semi-retreat, lived the cultured and well-mannered life of a précieuse, zealous of her reputation. As the hostess of the Scarron salon, she had made powerful friends, with whose help she had obtained from Anne of Austria, the queen mother, an allowance of 2,000 pounds. Although later she was to be credited with many lovers, the widow remained discreet and was regarded as wise, rather devout, and even somewhat prudish.

In 1668 she was given a chance to improve her fortunes. One of her friends, the Marquise de Montespan, had become the King's mistress. Having supplanted the shy Louise de La Vallière, Mme de Montespan was soon to become pregnant. As she was already married and the king did not wish a scandal, he decided that the birth was to be kept secret. For this purpose he required a trustworthy person to receive and hide the child, a delicate task requiring both ability and discretion. Mme Scarron, displaying her prescience, agreed and thus began her surprising rise to power. She was born in March 1669 and was followed by many others. After the third, the family moved to a house in Paris, where the King made occasional visits and met the widow, then 36 years old. Louis XIV was three years younger than Mme Scarron.

The King recognized his illegitimate children by Mme de Montespan in December 1673. He gathered them around him, with their governess, at his residence in Saint-Germain. Thanks to the King's generosity, Mme Scarron was able to purchase the Château de Maintenon in December 1674. At the beginning of 1675, Louis XIV bestowed the title of her lands upon her. In December 1679, the Marquise de Maintenon was made second lady-in-waiting to the wife of the Dauphin. She was thus able to put aside her responsibilities for the royal children and to become independent from Mme de Montespan, with whom, for some time, she had been having a stormy relationship. After the Queen's death on July 30, 1683, Louis XIV was to have only one woman in his life: "la Scarron," as she was always called by her enemies. He married her, according to some, in October 1683 and according to others in April or May, 1697.

Some historians maintain that Louis XIV married Mme de Maintenon to consummate the relationship, while others believe that the King was only regularizing a liaison whose beginnings went back either to 1673 or 1678, but more likely to 1680. Whatever the date may have been, if the marriage took place in 1683, Louis XIV and his

Marriage  
to Louis  
XIV

companion had a union that lasted 32 years, 16 of them before 1700, the year in which Charles II, king of Spain, died. The latter having left his kingdom to the Duke of Anjou, Louis XIV's youngest son, France then found herself engaged in a deadly war, which was to mark the beginning of the reign's decline. The precise date of the marriage is only important for the determination of Mme de Maintenon's political role, for many have blamed her for Louis XIV's errors and faults. In reality, her influence was negligible prior to 1700 and quite prudent during the last 15 years of Louis XIV's reign. Mme de Maintenon did not have the smallest part in the Revocation of the Edict of Nantes in 1685, which denied all rights to Protestants in France. Indeed, the secret wife of Louis XIV was the only one to establish and maintain a climate of decency, dignity, and piety around her husband. Her role, all things considered, can be seen as beneficial, except for the Quietism affair, when she was to join forces with Bishop Jacques-Bénigne Bossuet in persecuting François de Salignac de la Mothe-Fénelon.

At Saint-Cyr, near Paris, she founded the Maison Royale de Saint-Louis (known simply as Saint-Cyr), an institution established for the education of impoverished young women of the nobility (1686). Racine's dramatic poem *Esther* was written for performance at the school. At first Saint-Cyr was considered fashionable. There Mme de Maintenon often sought to escape the restraints of the court and to put into practice the pedagogical talents she was convinced she possessed. To this day, many recognize that she did indeed have these talents. After the death of Louis XIV in 1715, his widow took ill and eventually died in her Saint-Cyr refuge. She survived him by four years, a stranger to the new era, and died on April 15, 1719.

Hated by some, revered by others, Mme de Maintenon never ceased to kindle violent emotions. To this day she is depicted in textbooks as greedy and evil, a narrow-minded bigot. It would be true to say that she was an ambitious woman who had an exceptional destiny, and did not do too badly with it. Her letters are still read with interest, and, in his exile at Saint Helena, Napoleon I professed to prefer them to those of Marquise de Sévigné.

**BIBLIOGRAPHY.** The most complete and one of the most recent studies, unfortunately not translated, is JEAN CORDELIER, *Madame de Maintenon, une femme au grand siècle* (1955), a tentative psychological explanation based on the factual and historical details known today. On the early years, EMILE MAGNE, *Scarron et son milieu*, 3rd ed. (1924), furnishes interesting details. MARCEL LANGLOIS, *Madame de Maintenon* (1932), is a slightly confused, but indispensable work in spite of the contradictions that reflect the mixed feelings of the author toward his heroine. Finally, basic to all serious study are the *Lettres* of Mme de Maintenon, published in four volumes by MARCEL LANGLOIS but incomplete (1935-39). Little has been published on the subject in English; however, MME SAINT-RENE TAILLANDIER, *Madame de Maintenon* (1920; Eng. trans., 1922), is worth reading.

## Malacca, Strait of

The Strait of Malacca extends from 6° N to 1° N, running between the Indonesian island of Sumatra to the west and West Malaysia and peninsular Thailand to the east. It has an area of 25,000 square miles (65,000 square kilometres). The strait, 500 miles (800 kilometres) in length, links the Indian Ocean with the South China Sea; its width varies from 155 miles (249 kilometres) in the north to 40 miles (64 kilometres) in the south. The strait derived its name from the trading port of Malacca—which was of importance in the 16th and 17th centuries—on the Malayan coast.

Lying on the shortest sea route between India and China, the strait, sometimes incorrectly called the "straits," is one of the most used shipping channels in the world. In early times, it helped to determine the direction of major Asian migrations of peoples through the Malayan archipelago. In the 2nd century AD, the Indianized trading kingdom of Lankasuka was based on the Malayan Peninsula shore of the strait, near Patani. The strait was later controlled successively by the Arabs; the Por-

tuguese, who established a base at Malacca, the trading port from which the strait took its name; the Dutch, who seized Malacca from the Portuguese in 1641; and the British, who took possession of the island of Penang at the northern entrance to the strait, and later, in 1819, secured Singapore in the south.

In 1826 further British holdings were added to create the Straits Settlements, a territory used to protect the British opium trade in the Orient. Pirates, who for centuries had hidden in the fringing mangrove swamps, meanwhile continued to menace shipping, using small boats of up to ten tons equipped with swivel guns. After 1837, when the first European armed steamers arrived in Southeast Asia, Anglo-Dutch forces undertook to suppress the pirates; and by 1860 the pirate strongholds had been eliminated.

In the south of the strait, water depths rarely exceed 120 feet (37 metres) and are usually about 90 feet (27 metres). Toward the northwest, the bottom gradually deepens until it reaches the 650-foot (200-metre) isobath (an imaginary line connecting all points of the same depth underwater) that marks the boundary of the Andaman Basin. Numerous islets, some fringed by reefs and sand ridges, trending northwestward for up to 30 miles (48 kilometres), hinder passage at the southern entrance to the strait. The ridges are identified as accumulations of material that have been brought down by rivers from Sumatra. Between the latitudes of Melaka (formerly Malacca) and of Port Swettenham, transverse sand dunes up to 50 feet (15 metres) high have been recorded. Many of these sand waves are asymmetrical, with steeper northern slopes. Former drainage channels are represented by valley relicts lying north off the Rokan River mouth and presumably by the 160-foot- (49-metre-) deep "hole" near Port Swettenham as well.

Geologically, the strait belongs to the Sunda Shelf, which was an extensive, low-relief land surface at the beginning of Quaternary time (about 2,500,000 years ago), and appears to have remained undisturbed by crustal movements since the Late Tertiary Period. Undeformed Quaternary terraces and a 10,000-year accumulation of peat deposit on the floor of the strait present absolute proofs of crustal stability during the most recent stage of earth's history. The strait attained its present configuration after having been inundated by the postglacial rise of the sea level resulting from the melting of land ice in higher latitudes.

Coastal swamps are common on both sides of the strait, and, in addition, at several localities in Sumatra and Malaya, hills composed of Tertiary or of Mesozoic rocks are present. Near large rivers, coastal accretion ranges from about 30 feet (9 metres) on the coast of Malaya, to about 650 feet (200 metres) annually on the east coast of Sumatra.

Various types of source rock, fluctuations of river discharge during the year, and longshore currents have produced extremely complex bottom deposits. The shallow waters are supersaturated with oxygen; pyrite (an iron sulfide that indicates reducing agents in the sediment) and glauconite (a green, pellet-like mineral of potassium iron silicate) are common within cavities of small organic remains. Decay of organic matter has probably caused these micro-reducing conditions.

The climate is hot and humid and is characterized by the northeast monsoon during the northern winter and the southwest monsoon during the northern summer. Mariners, from the earliest times, used the monsoonal wind system, scheduling their voyages to take advantage of the prevailing wind direction. The average annual rainfall varies between 76.4 inches (1,940.6 millimetres) and 101.4 inches (2,575.6 millimetres). During both monsoons the wind strength averages between 5 and 11 miles (8 and 18 kilometres) an hour. Throughout the year, the current flows northwest at rates of up to 1.7 miles (2.7 kilometres) an hour. During the earlier part of the southwest monsoon, southward currents may be evident. The net northward flow is indicated by the asymmetry of the transverse sand waves already mentioned and by the northward deflection of many river mouths on the

Climate

Malayan coast. Semidiurnal tides govern the larger part of the strait; flood currents run toward the southeast, while slightly stronger ebb currents at 21–40 inches (0.5–1.0 metres) per second flow in the opposite direction. On the Sumatran side, tidal ranges vary from 98 inches (2.5 metres) in the north to over 230 inches (5.8 metres) in the narrower southern portion. On the coast of Malaya, the tidal range averages 110 inches (2.8 metres). Surface temperatures are 30.5° C to 31° C in the east and may be as much as two degrees lower in the west. The annual variations are small and do not exceed two degrees. The bottom temperature is approximately 28° C in the region south of Pulau Pinang (formerly Penang Island); toward the north it decreases gradually to 12° C at the rim of the Andaman Basin. The close proximity of land and the occurrence of large rivers result in a low salinity.

The existence of oil wells in production on Sumatra's east coast, just off the Sunda Shelf region, has led a number of companies to prospect for petroleum in the strait. Prospects for the location of commercial tin placers off the Malayan coast are excellent.

In addition to its use as a waterway by other forms of shipping, the strait affords passage to giant oil tankers voyaging between the Middle East oil fields and ports in eastern Asia. Increasing traffic in the strait has led adjacent countries, as well as Japan, to chart the waterway in more detail.

**BIBLIOGRAPHY.** G.H. KELLER and A.F. RICHARDS, "Sediments of the Malacca Strait, Southeast Asia," *J. Sedim. Petrol.*, 37:102–127 (1967), an interpretation of new information on the marine geology of the strait with emphasis on bottom sediments; K. WYRTKI, *Physical Oceanography of the Southeast Asian Waters* (1961), comprehensive oceanographic information on the strait and adjacent seas.

## Malawi

A landlocked southeast African country of dramatic highlands and extensive lakes, Malawi occupies a narrow, curving strip of land along the Great Rift Valley. Stretching about 520 miles (837 kilometres) from north to south, it has a width varying from 5 to 100 miles and is bordered by the United Republic of Tanzania to the north, Mozambique to the east and south, and the Republic of Zambia to the west. Its total area of 45,747 square miles (118,485 square kilometres) includes some 9,400 square miles of lake surface dominated by the 8,900 square miles of Lake Nyasa (Lake Malawi). The federal capital was to be moved from Zomba (population about 20,000) to Lilongwe (population over 19,000).

Malawi's relatively young population of more than 4,550,000 is overwhelmingly engaged in subsistence agriculture. Most of the country's exports consist of the produce of large tea and tobacco plantations. The potential exploitation of natural resources is hindered by inaccessibility and the necessity of capital investment. The country is almost totally dependent upon Mozambique for access to the sea. Malawi attained independence on July 6, 1964, under the leadership of H. Kamuzu Banda, who became the republic's first president two years later. The leader of the Malawi Congress Party, Banda became president for life in 1971. (For coverage of associated physical features, see EAST AFRICAN LAKES and EAST AFRICAN MOUNTAINS; for historical aspects, see SOUTHERN AFRICA, HISTORY OF.)

**The natural environment.** While the landscape is highly varied, there are four basic regions—the Great Rift Valley, the central plateaus, the highlands, and the isolated mountains.

The Great Rift Valley—by far the dominant feature of the country—is a gigantic troughlike depression running throughout the country from north to south and containing Lake Nyasa and the Shire River valley. The lake's littoral, situated along the western and southern shores and ranging from 5 to 15 miles in width, covers about 8 percent of the total land area and is spotted with swamps and lagoons. The Shire Valley stretches some 250 miles from the southern end of Lake Nyasa at

Mangochi to Nsanje at the Mozambique border and contains Lake Malombe at its northern end. The Central Region plateaus rise to an altitude of between 2,500 and 4,500 feet and lie beyond the littoral to the west; they cover about three-quarters of the total land area. The highland areas are mainly isolated tracts that rise as much as 8,000 feet above sea level. They comprise the Nyika, Vipya, and Dowa highlands and Dedza-Kirk Mountain range in the north and west and the Shire Highlands in the south. The isolated massifs (mountain masses) of Mulanje (10,000 feet) and Zomba (6,500 feet) represent the fourth physical region. Surmounting the Shire Highlands, they fall away in the east, running down to the Lake Chilwa–Phalombe Plains.

**Drainage and soils.** The major drainage system is that of Lake Nyasa, which covers some 61,000 square miles and extends beyond the Malawi border. It is fed by the North and South Rukuru, Dwangwa, Lilongwe, and Bua rivers. The Shire River, the lake's only outlet, flows through adjacent Lake Malombe and receives a large seasonal inflow from several tributaries before joining the Zambezi River in Mozambique. A second drainage system is that of Lake Chilwa, the rivers of which flow from the Lake Chilwa–Phalombe Plains and the adjacent highlands. An enclosed lake, its waters become distinctly saline during the dry season.

**Rocks and soils.** The underlying rock throughout Malawi is of Precambrian age (4,600,000,000 to 570,000,000 years old) and consists of gneisses (coarse-grained, mineral-bearing rock), schists (coarse-grained, rock-bearing mica), granite, and syenite (a rock formed deep down under heat and pressure and containing alkaline minerals). Karoo formations—sedimentary rocks 345,000,000 to 190,000,000 years old, which cover much of Africa—occur less frequently in the lake basin and the Shire Valley. Later rock formations found in the Great Rift Valley contain reptile fossils and alkaline rocks.

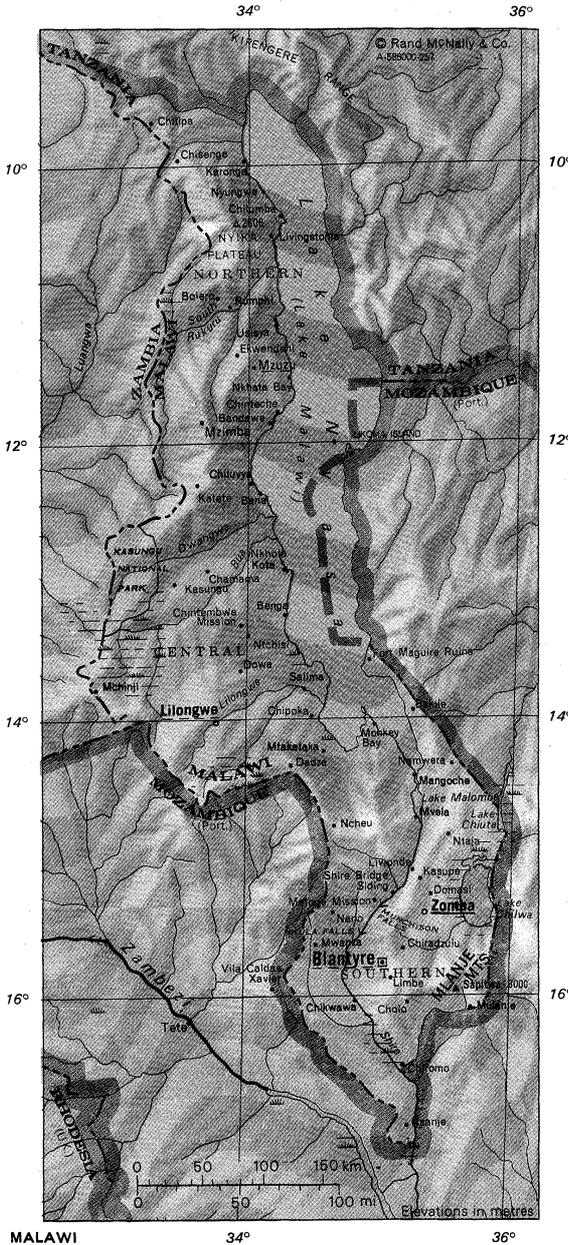

Soils, composed primarily of red earths, with brown soils and yellow gritty clays on the plateaus, are distributed in a complex pattern. Alluvial soils occur on the lakeshores and in the Shire Valley, while other soil types include hydromorphic (excessively moist) soils, black clays, and sandy dunes on the lakeshore.

**Climate.** There are two main seasons—the dry season from May to October and the wet season from November to April. Altitude has an important effect upon temperature as is clearly seen in comparison of the temperature of Nsanje (Port Herald) in the Shire River plain, which has a mean July temperature of 69° F (21° C) and an October mean of 84° F (29° C), and Dedza, which lies at an altitude of over 5,000 feet in the highlands of the Central Region and which has a July mean of 57° F (14° C) and an October mean of almost 69° F (21° C). On the Nyika Plateau in the Northern Region, at altitudes of about 8,000 feet, frosts are not uncommon in July. Annual rainfall is highest over parts of the northern highlands and on the Sapatwa Peak, of Mulanje Massif, where it is about 90 inches; it is lowest in the lower Shire Valley, where it ranges from 25 to 35 inches.

**Vegetation.** The natural vegetation pattern reflects diversities in altitude, soils, and climate. Various vegetation zones characterized by woodland, scrub, and grass may be distinguished. Savanna (grassy parkland) occurs in the dry lowland areas. Open woodland with bark cloth trees, or *miombo* (leguminous trees unsuitable for timber), is widespread on the infertile plateaus and escarpments. Woodland, with species of acacia tree, covers isolated, fertile plateau sites and river margins; grass-covered, broad depressions, called *madambo* (singular, *dambo*), dot the plateaus; grassland and evergreen forest are found in conjunction on the highlands and on the Mulanje and Zomba massifs. Swamp vegetation of reeds and matted grasses occurs on the edges of Lake Chilwa and along the lower Shire Valley. The vegetation is, however, being greatly altered by human settlement. Much of the original woodland has been cleared, and, at the same time, forests of softwoods are being planted in the highland areas. High population density and intensive cultivation of the Shire Highlands hinder

of paid employment. The larger settlements of the Lake Nyasa littoral originated as collection points for slaves and later developed as lakeside ports.

Improvements in communication and the sinking of wells in arid areas have permitted the establishment of new settlements in previously uninhabited areas. Architecture is also changing; the traditional round, mud-walled, grass-roofed hut is yielding its place to rectangular brick buildings with corrugated iron roofs.

Urban development began in the colonial era, with the arrival of missionaries, traders, administrators, and was further stimulated by the construction of the railway. The only true urban centres are Blantyre-Limbe, Zomba, and Lilongwe. Although some district centres and missionary stations have an urban appearance, they are closely associated with the rural settlements surrounding them. Blantyre, Malawi's industrial and commercial centre, is situated in a depression on the Shire Highlands at an altitude of about 3,400 feet. Zomba lies at the foot of Zomba Mountain and is purely of administrative origin. Farther north is Lilongwe, Malawi's future capital, which is the only urban centre in the Central and Northern regions.

**Ethnic, linguistic, and religious groups.** According to the official 1966 population census of Malawi, 99.5 percent of the country's population of 4,040,000 were Africans. The remainder were of Asian, European, or other origin. From 1945 to 1966, the population increased by nearly 100 percent, and it is estimated that it will double again by 1990.

Nine main groups are historically associated with modern Malawi—the Chewa, Nyanja, Lomwe, Yao, Tumbuka, Sena, Tonga, Ngoni, and Ngonde (Nkonde). All the African languages spoken belong to the Bantu language family. Although Chichewa and English are the official languages, English is understood by less than 10 percent of the population while Chichewa is spoken by more than 50 percent and understood by about 77 percent. Other important languages are Chilomwe, spoken by about 15 percent of the people; Chiyao, spoken by nearly as many; and Chitumbuka, spoken by 10 percent of the population.

The major religious groups are traditionalist, Christian, and Muslim. Although these groups appear to be approx-

Predominant languages

the natural regeneration process; wells have been sunk and rivers dammed to irrigate the dry grasslands for agriculture.

**Animal life.** Because of population pressures, game animals abound only in the game reserves, where antelope, buffalo, elephants, leopards, lions, rhinoceroses, and zebras occur; hippopotamuses live in Lake Nyasa. The waters of the lakes and rivers contain more than 200 species and 13 families of fish. The most common and commercially significant fish include the endemic tilapia, or *makumba* (nest-building freshwater fish); catfish, or *mlamba*; and minnows, or *matemba*. Birds, reptiles, and insects also occur in great variety.

**The landscape under human settlement.** A rural village—called a *mudzi*—is generally small. Organized around the extended family, its area is limited by the amount of water and arable land available in the vicinity. On the plateaus, which support the bulk of the population, the most common village sites are at the margins of *madambo*, which are usually contiguous with streams or rivers and are characterized by woodland, grassland, and fertile alluvial soils. In highland areas, scattered villages are located near perennial mountain streams and pockets of thin but arable land. Here, however, agriculture provides scant sustenance, and men often migrate in search

imately equal in number, their exact distribution is not known. In contrast to the other two, the traditionalist religious groups, variously called animist or nativist, lack any cohesive central organization.

**Demography.** No comprehensive data on birth and mortality rates are available, although there is an indication of high fertility. The median age of the population was only 18 years in 1966, indicating the relative youth of Malawi's inhabitants.

In 1968 Malawi had an average density of 118 persons per square mile. In the Northern Region the density was 48 per square mile, in the centre of the country it was 108 per square mile, and in the south it rose to 169 per square mile. This pattern reflects the preponderance of high, uninhabited plateaus and relatively inaccessible areas in the north. The figures, however, conceal marked local irregularities in distribution. Only about 5 percent of the total population was urban.

Total Malawi	36,324	94,079‡	4,039,583	4,530,000

\*Land areas only. The total area, including all major inland waters is 45,747 sq mi (118,484 sq km). †Includes figures for Mwanza district, which was created in 1970. ‡Figures do not add to total given due to rounding.  
Source: Official government figures.

As the population grows, bringing greater pressures on agriculturally productive areas, Malawians increasingly turn to emigration as a means of entering the money economy. In 1966, some 266,000 persons, excluding their dependents, were living outside the country. All but 14,000 of these were in Rhodesia, South Africa, and Zambia, where Malawi labour finds employment in the mines. Of that total, 26,000 were permanently settled, 178,000 intended to return, and the status of the remainder was unknown.

**The national economy.** Malawi is dependent on the export of primary agricultural products. National income data are often deficient because of the difficulty of evaluating subsistence output and the output of services. Malawi's economy is characterized by a relatively low income per capita, estimated to be about \$69 U.S. a year.

**Mineral resources.** Most of Malawi's mineral deposits are neither extensive enough for commercial exploitation nor easily accessible. Only a few have potential for future development. These include high-grade apatite (a calcium phosphate mineral used for making fertilizers), which occurs in about 3,000,000 tons of apatite-rich rock located near Lake Chilwa; bauxite deposits of about 65,000,000 tons on the Mulanje Massif; and cyanite (an

aluminum silicate mineral used for lining furnaces) on the Dedza-Kirk Range.

**Biological resources.** More than half of Malawi's total land area is suitable for cultivation. Some 3,200,000 acres are under field crops, with a further 1,000,000 acres lying fallow. Forests and woodlands cover nearly 9,000 square miles, of which almost 4,000 square miles are state-controlled forest reserves.

The lakes and rivers of Malawi provide a rich harvest of fish. The national herd of cattle is estimated to be about 510,000 head and grows at an average rate of 3 percent a year.

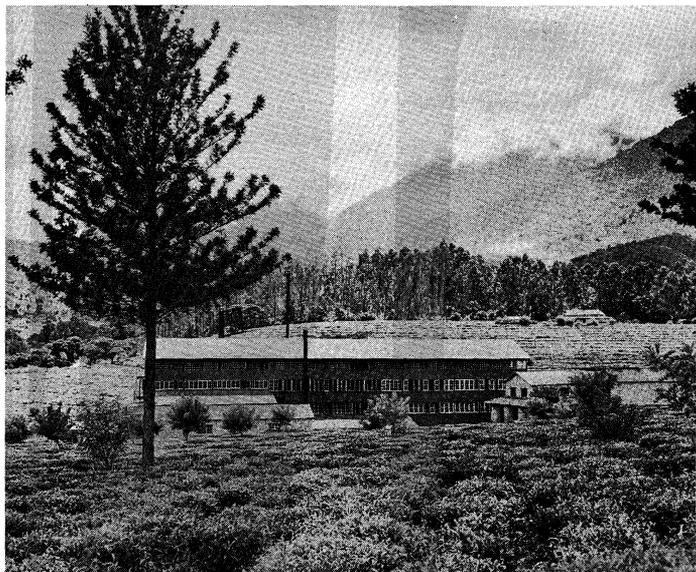

**Power and water.** Malawi has a vast water supply potential, although some areas have an inadequate amount of water. Most of the rivers are seasonal, but a few large ones, particularly the Shire River, have a considerable irrigation and generating potential. The total hydroelectric potential of the country is about 1,200 megawatts, of which 1,000 megawatts can be generated on the Shire alone. Present power demands, which represent less than 5 percent of potential capacity, are met by the Nkula Falls hydroelectric and diesel plants. The new 16-megawatt Tedzani Falls scheme (five miles downstream from Nkula) was scheduled for completion in 1973.

**Agriculture, fishing, and forestry.** The most important agricultural export products are tea and tobacco. Tea is grown on plantations on the Shire Highlands, and the industry employs the largest proportion of the country's labour force. Tobacco is raised largely on the Central Region plateau. Other important crops are maize (the major staple food), cotton, peanuts (groundnuts), cassava, sugar, coffee, and rice.

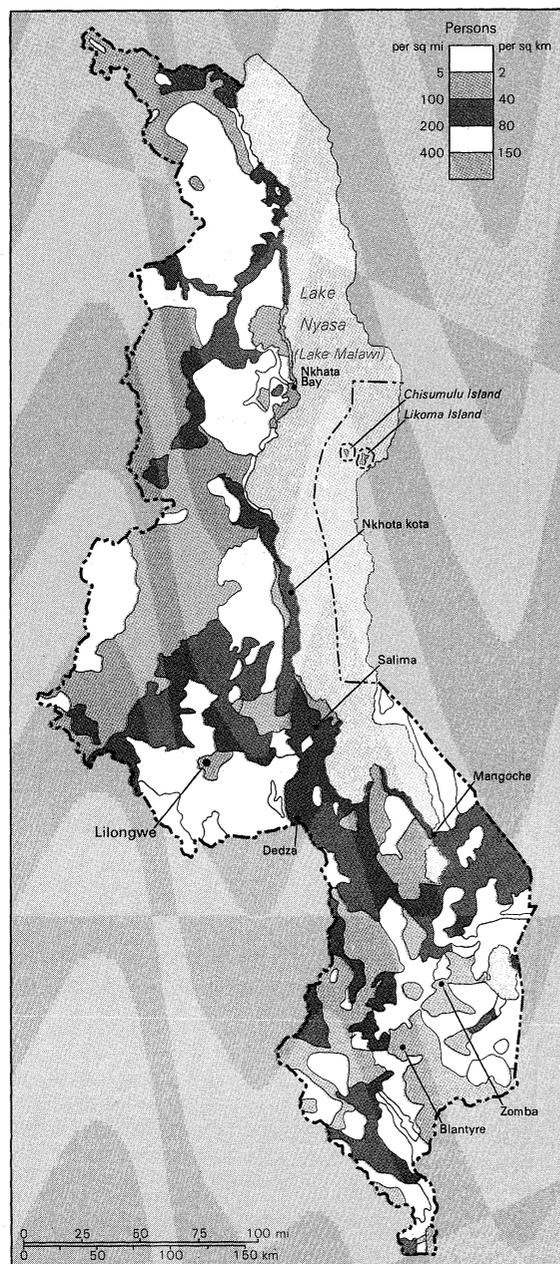

During the period from 1966 to 1968 the contribution of cash crops to the gross domestic product averaged about 15 percent a year, while that of subsistence agriculture averaged about 35 percent. The principal cash crops are marketed by the Agricultural Development and Marketing Corporation; there are also more than 100 cooperative societies that purchase and also market produce.

The amount of fish landed in 1970—mainly from Lake Nyasa—totalled almost 34,000 tons; this amount is likely to increase with the recent rise in the water level of Lake Chilwa, which had previously shown signs of drying up. Sales of forestry products yielded about \$500,000 U.S. in 1968; more than 60,000 acres of the Vipya Highlands are being afforested with softwood. Sawnpoles, posts, and manufactured wooden items are produced largely for the domestic market. There are small forestry exports to Denmark and Zambia, but Malawi is a net importer of wood and wood products.

**Manufacturing.** The rapid growth in the number of local industries has been sufficient for Malawi to satisfy

A tea estate in Malawi.

Population density of Malawi.

Adapted from *Malawi Population Census 1966: Final Report*

The growth of manufacturing industries

its domestic need for products such as cotton textiles, sugar, radios, hoes, and shoes, all of which previously had to be imported. The main demand for electric power is in the industrial areas of the Southern Region, where electricity consumption has more than trebled since 1964. Manufacturing—together with mining and quarrying of clay, granite, limestone, and marble for building and construction—contributed about 15 percent of the gross domestic product a year in the late 1960s. Mining may expand as a result of surveys of the bauxite deposits on the Mulanje Massif and of other minerals in promising areas. In addition, it is expected that the Vipya pulpwood afforestation scheme will form the basis for a pulp and paper industry.

**Foreign trade.** About 95 percent of Malawi's exports are derived from agriculture. An export drive in the late 1960s, however, led to an increase in exports of manufactured products to neighbouring countries. The United Kingdom continues to provide Malawi's largest market. Zambia, Rhodesia, and the United States are also important customers. Sales to South Africa, West Germany, and the Netherlands have also increased.

**Financial services.** Malawi's decimal currency, introduced in February 1971, consists of the kwacha, which is divided into 100 tambala (0.84 kwacha = \$1 U.S.; 2 kwachas = £1 sterling as of the beginning of April, 1971). There are two commercial banks—the National Bank of Malawi and the Commercial Bank of Malawi. The Reserve Bank of Malawi is the central bank of the country. Other financial institutions include the Post Office Savings Bank, the New Building Society, and finance houses. Among the several insurance companies, only one is locally based.

**The public and private sectors.** In the early 1970s the government's economic policy was anti-inflationary, arising from the need to reduce the deficit in public expenditure and to maintain the level of foreign-exchange reserves. In budgetary policies maximum restraint, consistent with development needs and planned reduction of grants-in-aid from the United Kingdom, was exercised. Estimated expenditure on the recurrent budget for 1970 to 1971 was 47,755,000 kwachas, some 12 percent higher than in 1969. Of the total, over 39,819,000 kwachas were raised from various taxes and departmental receipts; the balance is represented in grants (mainly from the United Kingdom).

The main emphasis continues to be directed toward fostering economic growth through agricultural export production and the completion of investment projects, while at the same time maintaining a satisfactory external balance. The Malawi development program is concerned with the public sector only insofar as it does not interfere with the private sector. Priority is given to transport, agriculture, education, and housing.

The development expenditure of the government and public corporations, derived mainly from external borrowing, was more than 28,500,000 kwachas in 1970. This figure represents a substantial increase over the 1969 amount of 16,000,000 kwachas.

**Taxation, trade unions, and employer associations.** A minimum annual tax of 3.50 kwachas is payable by all men over 18 years of age unless they are liable to other taxes. Employed men and women who earn up to 900 kwachas a year pay a graduated tax, and those with higher incomes pay an income tax. Local companies pay taxes at the rate of 40 percent of chargeable income, and companies incorporated outside of Malawi pay an additional 5 percent. Tax allowances are, however, offered as an incentive to investment.

There is no sizable industrial labour force in Malawi. Some 20 trade unions and employer associations are connected with such enterprises as the tea plantations, the building and construction industry, road transport, and railways. The Ministry of Labour plays a significant role in maintaining good relations between employers and employees.

**Contemporary economic policies.** The agricultural sector provides the greatest potential for increasing Malawi's national income. Consequently, the government seeks to strengthen it by encouraging integrated land use, higher crop yields, and irrigation schemes. The quality and output of subsistence agriculture is being improved by means of advisory services and educational programs. In addition, the Malawi Young Pioneers, a national youth movement, trains over 2,000 young men and women yearly in techniques of rural development.

Both higher incomes in the rural areas and continued public expenditure are likely to increase the purchasing power of the public as a whole, thus providing a stimulus for further industrial development. The government continues to promote the establishment of manufacturing industries, thus reducing reliance on expensive imported goods, and so strengthening the balance of payments situation, at the same time increasing employment opportunities.

The government, however, does not itself engage in industrial enterprise or nationalize private concerns. Through the Malawi Development Corporation, its own agency in the private sector, the government ensures local participation in agricultural, commercial, and industrial enterprises.

Promoting higher crop yields

Any forecast of economic conditions in a country like Malawi is subject to the qualification that crop yields—hence, exports and the whole economy—are liable to be affected by weather conditions. This was demonstrated in 1968 when a poor harvest of marketable crops combined with devaluation resulted in a low growth rate. Between 1964 and 1969, however, the growth of the economy as a whole averaged about 5½ percent a year.

**Transportation.** The Malawi government has made substantial investments in developing its transport system. Located within the east central region of Africa, Malawi has road connections to Chipata on the Zambian border; to Salisbury, Rhodesia, via Mwanza and Tete; and to several points on the Mozambique border. In addition, there are two rail links to ports on the Mozambique coast and several air routes to east, central, and southern Africa.

**Road and rail network.** The backbone of the road system is represented by a road running from Blantyre in the south to Lilongwe in the west. A new lakeshore highway, roughly parallel to the inland highway from Mangochi to Karanga, was due for completion in the early 1970s. By 1970 the country had over 6,700 miles of roads, including over 460 miles of paved roads and over 520 miles of gravelled roads.

Of Malawi's two railway links to the sea, the first stretches more than 500 miles from Salima near the southwest shore of Lake Nyasa to the port of Beira on the Mozambique coast. The second railroad joins the Salima-Blantyre line at Nkaya Junction to the south of Balaka and travels due east to link with the Mozambique Railways system at Nova Freixo, from where it continues to the port of Nacala.

**Lake transport.** Lake Nyasa has long been used as a means of inexpensive transportation. Of the rivers, only the Shire is navigable, all other streams being broken by rapids and cataracts. A passenger and cargo service that operates on the lake is linked to Chipoka railway junction about 20 miles south of Salima. The main ports on the lake are Monkey Bay, Nkhotakota, Nkhata Bay, and Likoma Island.

**Air services.** Air Malawi, the national airline, operates services from the main airport at Chileka, 11 miles from Blantyre, to Lusaka, Zambia; Salisbury, Rhodesia; Beira, Mozambique; Johannesburg, South Africa; and Nairobi, Kenya.

**Administration and social conditions.** Under the republican constitution of Malawi promulgated in July 1966, Parliament is composed of a president, who is head of state and government and of the National Assembly. The cabinet is appointed by the president. The original number of 50 elected members of the assembly was raised to 60 in November 1969. In addition, the president can appoint no more than 15 nominated members.

The central government is composed of 14 ministries. For purposes of administration, the country is divided into 24 administrative districts. The local government system consists of district councils, the city council of Blantyre, the municipality of Lilongwe, and six town councils.

Since August 1961, when the first general elections were held, Malawi has been a de facto one-party state. This situation was formalized in the constitution of 1966 which recognizes the Malawi Congress Party—led by Pres. H. Kamuzu Banda—as the country's sole political organization.

#### Elections

Elections for the presidency and the assembly are held every five years, the first general election since Malawi became a republic being held in 1971. For purposes of the election, the presidential candidate is nominated by an electoral college composed of party officials at the national, regional, and district levels; the League of Malawi Women; the League of Malawi Youth; members of Parliament; recognized chiefs; and all chairmen of district councils. In 1971, Banda was elected president for life. Candidates for the National Assembly may stand for election only after their nomination by the district party conferences.

There is an annual party convention, the composition of

which is similar to that of the electoral college. The convention, in conjunction with the national executive of the party, establishes guidelines for national policies.

The judiciary is based upon the system prevailing in the British colonial era and Malawi traditional law. It consists of a High Court, a Supreme Court of Appeal, magistrates' courts, and traditional courts. In 1969 an important change was made in the jurisdiction of the traditional courts, as a result of which criminal cases involving witchcraft or local superstition, for which the death penalty can be imposed, are now tried in the traditional courts instead of the High Court. The minister of justice has the power to direct a particular case or group of cases to a particular court; cases tried in the traditional courts can be appealed to the National Traditional Court of Appeal. The Ministry of Justice is also responsible for legal aid to the needy and for drafting new legislation.

Armed forces, known as the Malawi Rifles, under the authority of the president as commander in chief, are stationed in Zomba and Mzuzu. Police service is provided by the Malawi Police Force, which has three divisional headquarters, each responsible for a number of districts.

Like most new states, Malawi has relatively low standards of living and limited resources with which to improve them. The majority of the people are subsistence farmers. Over 250,000 persons work for wages in Malawi, in addition to a further 200,000, most of whom are migrant workers, who are employed in neighbouring countries.

There are eight major public and private hospitals and several district hospitals and clinics, including Zomba Mental Hospital and Kochira Leprosarium. Among diseases, the most common are malaria, bilharzia (a water-borne parasite), and trachoma (an eye disease). The main emphasis of the health services is unavoidably on curative medicine. Government agencies and voluntary organizations do, however, provide some health services designed to prevent disease.

The community development program fosters the well-being of the people and seeks to help increase agricultural output. A national training centre at Magomero provides training facilities for community workers, local government personnel, and local leaders.

An acute shortage of housing has existed for several years in urban areas. The Malawi Housing Corporation has, however, launched a 3,000,000-kwacha project to help meet the need by building more than 1,000 houses.

Elementary education in the primary schools is provided by local education authorities. Post-primary education comprises a four-year secondary school course that can lead to a university education. There are also institutions for teacher training and for technical and vocational training. Because of limited resources, only about 35 percent of the school-age population is enrolled in schools. The Malawi Correspondence College caters to more than 16,000 students. In view of its central importance, agriculture is the focal point in the curricula of most primary and secondary schools and teacher-training colleges.

The University of Malawi, founded in 1965, has five constituent colleges and a total enrollment of about 900 students.

**Cultural life and institutions.** Though under the impact of modernization, Malawi's traditional culture is characterized by both continuity and change. The country is one of the least urbanized in Africa. Despite the geographical mobility of many Malawians, who are prepared to work for a time in the urban centres of central and southern Africa, the traditional life of the village has remained largely intact.

One of the most distinctive features of Malawi culture is the enormous variety of traditional songs and dances that use the drum as the major musical instrument. Among the most notable of these dances are *ingoma* and *gule wa mkulu* for men, and *chimali* and *visekese* for women. There are various traditional arts and crafts, including sculpture in wood and ivory. There are two museums—The Museum of Malawi in Blantyre and a smaller one in Mangochi. While various cultural activities are organized by the Kwacha National Cultural Centre

in Blantyre, radio has proved to be the most effective means of bringing traditional and modern plays to the rural population.

There are two main newspapers, both published twice a week in Blantyre-Limbe—*The Malawi News*, issued in both Chichewa and English, and *The Times*, published in English. *The African* of Lilongwe is bilingual and is issued fortnightly. There are also four monthly publications, one quarterly, and the biannual *Society of Malawi Journal*.

The Malawi Broadcasting Corporation, a statutory body, operates a radio service from Ngumbe Estate, near Blantyre. Programs are broadcast in both Chichewa and English.

**Prospects for the future.** Since it gained independence in 1964, Malawi has enjoyed a large measure of national unity and political stability. This circumstance has helped to create a climate conducive to economic advancement. Developments in communications and administrative services as well as improvements in agricultural productivity have contributed to an economic growth rate that has averaged more than 5 percent per year since the middle 1960s.

Malawi maintains diplomatic relations with various African countries, including the white-ruled regimes in southern Africa, with which it has close historical and economic links. Although opposed to the "apartheid" system of South Africa, its relations with that country are based on the doctrine of the sovereignty of states rather than of violent confrontation. Malawi's cooperative stance toward South Africa, while economically beneficial, may provide an alternative strategy for the solution of racial problems in southern Africa.

**BIBLIOGRAPHY.** The most extensive bibliography on Malawi is E.E. BROWN, C.A. FISCHER, and J.B. WEBSTER (comps.), *A Bibliography of Malawi* (1965). The following works are especially recommended: W.J. BARBER, *The Economy of British Central Africa* (1961); D.G. BETTISON, *The Demographic Structure of Seventeen Villages in the Peri-urban Area of Blantyre-Limbe, Nyasaland* (1958), rather dated; B. BINNS, *A First Checklist of the Herbaceous Flora of Malawi* (1968); E. DEAN, *The Supply Responses of African Farmers: Theory and Measurement in Malawi* (1966); F. and L.O. DOTSON, *The Indian Minority of Zambia, Rhodesia and Malawi* (1968); W.J.C. GERKE and C.J. VILJOEN, *Master Plan for Lilongwe: The Capital City of Malawi* (1968), an example of urban design, land use, and traffic planning in the context of traditional Malawi life; MALAWI GOVERNMENT, DEPARTMENT OF CENSUS AND STATISTICS, *Malawi Population Census 1966: Final Report* (1969), includes many detailed tables; J.G. PIKE, *Malawi: A Political and Economic History* (1968), covers the period up to 1965, and with G.T. RIMMINGTON, *Malawi: A Geographical Study* (1965), the most comprehensive study on the physical, historical, social, and economic geography of Malawi to date; F.E. READ, *Malawi, Land of Progress: A Comprehensive Survey*, 2 vol. (1967-69), general information on the people, economy, communications, tourism, and development projects; R.H.N. SMITHERS, *The Mammals of Rhodesia, Zambia and Malawi: A Handbook* (1966); M.M. STEWART, *Amphibians of Malawi* (1967); C.S. STRONG and D. GIBB, *A Geography of Rhodesia, Zambia and Malawi* (1966), largely an introductory text. The ECONOMIST INTELLIGENCE UNIT, *Quarterly Economic Review of Rhodesia, Zambia and Malawi*, has current data on the state of the economy, compiled from official documents and reports.

(Z.D.K.)

## Malaya, History of

Malaya has been inhabited for at least 6,000 years. Archaeologists have unearthed evidence of several Stone Age cultures as well as an early Bronze Age civilization. These probably existed contemporaneously with more advanced settlements stimulated by the arrival of Indian adventurers beginning in the 2nd century BC.

**Rise of Indianized states.** The Malay Peninsula, and indeed most of Southeast Asia, experienced over 1,000 years of Indian or Indianized influence. Indian blood and Indian culture blended with indigenous elements to produce an amalgam, which found political expression in the creation of a number of states and several great empires. Lacking the fertile plains of Java or Cambodia, the peninsula was unable to support a great empire. Although

knowledge is scanty and is based largely on Chinese written sources, it does appear that at least 30 small states, nearly all along the east coast, flourished during this millennium. These included Tun Sun, in the northeastern part of the peninsula, where in the 3rd century AD there were more than 500 Indian merchants and priests. Ch'ih't'u ("Red Land," *Tanah Merah* in Malay) may have been established in the 6th century on either the Kelantan or Trengganu River. The most important of the Indianized states was Lankasuka, whose control extended at times across the whole northern part of the peninsula. The most significant complex of Indianized temple ruins in Malaya, on the slopes of Kedah Peak opposite Penang Island (now Pulau Pinang), was at one time part of this state. Kedah, the name of a modern Malay state, was once thought to be Kalah, described by Arab sailors of the 9th through the 14th centuries. This state, it is now thought, was north of the peninsula, in present-day Thailand.

These small states, now long forgotten, have left a living legacy, traces of which are to be found even in the political structure of modern Malaysia. In religion, too, traces of Hinduism and Buddhism persist in the ritual, language, and practice of the Malay Muslims. A similar influence is seen in many of the arts and crafts still flourishing on the peninsula.

Much of the influence was imposed not directly from India but by the great Indianized empires of Southeast Asia. The small peninsula states, it would appear, were usually under the hegemony of one or the other of these empires, either in Siam (Thailand) or Cambodia to the north or Sumatra and Java to the south. On Singapore Island, for example, Tumasik, an Indianized settlement, owed allegiance in the 14th century first to Sumatra—West Malaya, under Srivijaya; then to Majapahit, the great Javanese empire; and finally to Siam, with its capital at Ayutthaya. Paramesvara, Tumasik's Sumatran ruler near the end of the 14th century, unsuccessfully attempted to win independence for Tumasik from Ayutthaya. Tumasik was sacked, but Paramesvara found refuge at Malacca (now Melaka), at that time a small fishing village, where he established himself as ruler c. 1400.

**Advent of Islām.** From this precarious beginning, Malacca rose during the 15th century to become a political power of the first rank, the most important commercial mart in Southeast Asia, and the main centre for the diffusion of Islām. A fortunate set of circumstances combined to permit this. Soon after he won control of Malacca, Paramesvara secured the support of China. Chinese settlers at that time were beginning to move into the *Nanyang* ("South Seas"), or general Southeast Asian region. The Chinese admiral Cheng Ho called at Malacca in 1409 and again in 1414. In return for annual tribute, twice taken to Peking by Paramesvara himself, the Chinese emperor promised his protection to Malacca. For some decades, China's guardianship deterred other Southeast Asian states, notably Siam, from crushing Paramesvara's settlement and permitted it to develop. Its location, in addition, was attractive to traders from India, Arabia, China, and the Indonesian islands as a central, independent meeting place not for the purchase of Malaccan goods, of which there were few, but for barter and exchange. A good government and a sensible nonrestrictive policy encouraged the traders to settle and to frequent the peaceful bay in increasing numbers. The fishing village thus grew into a bustling and famous city where many of the commodities of Asia were traded.

Malacca's most important role, however, was not commercial but religious. It replaced Sumatran ports as the main centre for the transmission of Islām throughout Southeast Asia. Originally disseminated by peddlers and traders from east Bengal and other areas of the Indian subcontinent, Islām had secured a toehold in north Sumatra and east Malaya during the 14th century or earlier. With the growth of Malacca in the 15th century, however, the new faith was conveyed most effectively along Malaccan trade routes by missionaries and merchants. The ancient Hindu beliefs survived only on Bali; elsewhere the courts and the peoples accepted the new faith and helped it to spread, for the most part as a major movement for

Indian  
influence

Emergence  
of Malacca

peace, to the coastal areas of West Irian and the Philippines.

On the Malay Peninsula itself, the spread of Islām was linked closely to the territorial expansion of the Malacca sultanate, which began during the reign of Muzaffar Shah (1446–59), Paramesvara's grandson. In 1456 Muzaffar Shah appointed an outstanding man, Tun Perak, as *bendahara* ("prime minister"). In that year, also, Tun Perak became the saviour of Malacca, defeating the Siamese in a fierce naval battle off South Johore. For some 40 years (1456–1498), although he never became sultan, he was the effective ruler of Malacca and promoted its expansion. The state of Perak already had become Muslim and in 1460 became a part of Malacca; Pahang, a tributary of Siam, was conquered. Islām followed and moved north to Trengganu. South Malaya also was made part of the growing sultanate. The river states in Sumatra that had been commercially linked to Malacca were acquired in 1477. In 1474 Kedah, Malaya's one granary of importance, also received a Muslim sultan.

**Early European intrusions.** Long before the end of the 15th century the fame of Malacca had reached Europe, attracting those interested in the spice trade. The Portuguese, who for a century had been dedicated to the national endeavour of reaching the Orient by sea, arrived at Malacca in 1509. It was the beginning, as one Asian historian has called it, of "the Vasco da Gama Era," the period of European dominance in Asia. Although the Portuguese and subsequently the Dutch did not exert the dominance exercised by the British in the 19th century, the European intrusion of the 16th century was, nevertheless, the beginning of a political movement that grew in strength for over 400 years and has only just ended.

In 1511 Malacca was captured by a Portuguese fleet led by Afonso de Albuquerque. Along with the Moluccas (Maluku) and Goa (in India), it became one of Portugal's major trading outposts in Asia. The Portuguese were, however, few in number, and although they retained defensive possession of Malacca until 1641, Malaya was more deeply influenced in the 16th century by Aceh, an aggressive state in Sumatra.

Malacca Empire in 1500.

When the Achinese first attacked Malacca in 1537, the city was saved by its new stone fort. Subsequent assaults came in 1539, 1547, 1568, 1570, and 1573. Aceh's target was not merely Malacca but all the Malay states as well. The story is complex and confused, for the allies of one decade were often the enemy in the next. The Malay states and the Portuguese sometimes fought one another, sometimes joined together. Aceh remained the aggressor until well into the 17th century. By that time the few hundred Portuguese at Malacca were a spent force. They

had to face a new opponent, the Dutch, who had secured a base in 1596 on Java. In 1607 the Dutch allied themselves with Aceh, while the Portuguese in Malacca joined with Johore. The Achinese sacked Johore, 1613–1615; Pahang in 1617; Kedah in 1619; and Perak in 1620. Aceh thus secured for 20 years an unquestioned suzerainty over the Malay states.

In Java the Dutch, in the meantime, had grown steadily in strength. They began actively meddling in the affairs of the Malay states in 1633, when they laid siege to Malacca. Year after year the few Portuguese waited in vain for relief, surrendering finally in 1641. Malacca had become a moribund town, its bustle and importance long vanished. Despite all efforts by the Dutch to revive the port and to channel the trade in tin from the west Malay states to it, Malacca never recovered its earlier glory.

**The Minangkabau and the Bugis.** The last 50 years of the 17th century witnessed the migration of many Minangkabau people from Sumatra. These sturdy agriculturalists settled in south Malaya, which until then had been virtually unpopulated. They brought with them an almost uniquely matrilineal outlook by which property and authority descended through the female. Their leader was freely elected (their method of election has served as the basic model for selecting the ruler of modern Malaysia), and in the late 18th century, they formed a confederation of small states, which came to be known as *Negri Sembilan*, or "Nine States."

During the 18th century the Dutch found that profits from dealings with Malacca could not compare with the benefits to be derived from trade with Java and the Spice Islands. Malacca was therefore neglected, a situation that permitted large-scale penetration of Malaya by the "Norseman of the East," the Bugis rovers from the Celebes (or Sulawesi). Just as the well-governed state of Normandy arose as the Norseman's contribution to Atlantic civilization, so are Selangor and Johore perhaps the best examples of Bugis occupation and organization in Southeast Asia. Hardly a member of the Johore civil service today does not have Bugis blood in his veins, and Johore's independent progress in the 19th and 20th centuries is attributable largely to the migrations of the 18th century. Although the Bugis had traded for many centuries on the Java Sea, they did not begin to settle in the relatively weak Malay Peninsula until the late 17th century. In Selangor they established their ruler as sultan as early as 1700. The Bugis leader, Raja Haji, seized Perak and sacked Alor Star, capital of Kedah, in 1770. By that time the Bugis had developed a new trading centre south of Singapore, in the Rhio (Riau) archipelago, where a policy of free trade and peaceful government attracted Asian and European merchants. Malacca was nearly captured by the Bugis in 1784.

Dutch influence in the Malay Peninsula was weakened not only by the Bugis invasions but also by the arrival of the British. Seeking a source for goods to be sold in China, the East India Company acquired Penang Island in 1786. In 1795 the British captured Malacca, and in 1819 Sir Thomas Stamford Raffles established a settlement on Singapore Island. Britain's entrenched position was clarified beyond dispute by the Anglo-Dutch treaty of 1824. Malacca, Singapore, and Penang Island, the three "Straits Settlements," came under the direct control of the British Colonial Office in 1867. Singapore, a free port, grew rapidly.

With the opening of the Suez Canal in late 1869, the full effect of European technological superiority swept over Southeast Asia. The Malay states were little prepared. With the exception of Johore, which was effectively ruled by Abubakar, the states were generally poorly administered and failed to cope with their mounting problems, chief of which was the steady immigration of Chinese in search of tin. From the mid-19th century to the present, the Chinese and the Malays have been two elements of an inadequately integrated community, prone to racial clashes and communal disorder. The clashes, which included disputes between rival Chinese groups on the newly discovered tin fields of Perak, became sufficient in 1874 to provoke British intervention.

This intervention by a European power into the internal

The Dutch

The Bugis

Chinese immigration

affairs of weak Asian states was at first crude. Malay reaction saw the murder of J.W.W. Birch, the first British resident (chief officer) in Perak (1875). Lack of understanding and incompetence also characterized the first British residents in Selangor and Sungei Ujong, one of the Negri Sembilan. They were followed, however, by more talented men. Frederick Weld (1823–91) expanded the policy of intervention to encompass all the Negri Sembilan and Pahang on the east coast. He selected competent officers to work as residents in the various states. Among these was Frank Swettenham, resident in Selangor, whose service in the Malay Peninsula culminated in his appointment as first resident general, when the four states of Perak, Selangor, Negri Sembilan, and Pahang were brought together in a federation in 1896, with Kuala Lumpur as its capital. The other sultanates in the peninsula were also induced to accept British officers as residents or “advisers” but managed to avoid joining the federation. They saw too great a loss of individuality and control despite the British policy of preserving the sultanates, the Muslim faith, and the Malay way of life. Between 1902 and 1909 Trengganu, Kelantan, and Kedah were extricated from the Siamese sphere of influence. In the south, Johore accepted a British adviser in 1914.

**The genesis of the modern state of Malaya.** British political control over the whole peninsula radically transformed Malaya economically and socially. As with the Romans in Britain, the British in Malaya devoted much attention to transport. Railways appeared, first from the coast to the tin fields, and then north to south down the peninsula until connections with Singapore were completed in 1924. A road network was constructed and paved to withstand the rains. Penang (Pinang), Singapore, Port Swettenham, and other ports were enlarged, improved, and given constant attention by the British.

Tin and rubber industries

Development of transport facilities assisted in the rapid growth of the important tin and rubber industries. During the 19th century technological developments in the U.S. and Europe created an ever increasing demand for tin. Though the Malays were indifferent to the opportunities created by this demand, thousands of Chinese migrated to Malaya during the second half of the 19th century to develop tin mining and manufacture. Vast new deposits were found, and the industry remained in Chinese hands through the 19th century. The Chinese, however, lacked capital and technological knowledge. Their open-cut, intensive labour methods of mining were replaced by the mining dredge introduced by British-financed companies in the early 20th century. Two major tin smelters were established at Penang and Singapore, and “Straits tin” became known throughout the world. The tax on the tin export became one of the two main sources of revenue for Malaya; the other was a similar levy on rubber.

The first strain of rubber, introduced from Ceylon in the 1870s, had proved unsuccessful. The planters grew coffee until the development in the 1890s of a superior strain of rubber by H.N. Ridley, the director of the Singapore Botanical Gardens. From 1896 through the early 20th century, funds from British financiers provided for the clearing of thousands of acres of virgin jungle and the establishment of new rubber plantations. Rubber production was increased also with the allotment of acreage to individual Malay and Chinese “small holders.”

Whereas Chinese immigrants had been attracted in great numbers by the tin industries of Perak and Selangor in central Malaya, thousands of south Indians from 1880 through 1920 moved to the west coast of Malaya to work on the rubber estates. A plural society was thus created and was maintained largely by the educational system. One school system taught Malay to the Malays. A network of missionary schools used English to teach the Christian Chinese, Indians, and Malays. Still other schools, financed by Chinese and supported by the Chinese Communist and Kuomintang parties, instructed Chinese residents in Chinese. The status quo of the plural society, preserved by Britain, was unchallenged until 1941. The few attempts toward self-government were discouraged.

In the field of public health, the British eliminated the

scourge of malaria. Beriberi and other previously incurable diseases also were eliminated.

By the close of 1941 the relations among East Asian nations had reached a critical stage. Locked in a struggle with China since 1937, and increasingly desperate for raw materials such as oil, Japan faced an embargo on raw materials from her major supplier, the U.S. To reach the oil and rubber of Java, Japan had to neutralize the great British naval base on Singapore Island. Attacks on Pearl Harbor on December 7, 1941, and on the Philippines on December 10 eliminated the U.S. presence in the Pacific, at least for several decisive months. On December 8 the Japanese had invaded Malaya and then headed south to Singapore.

Japanese invasion and occupation

The campaign was the greatest disaster the British had experienced since Cornwallis' surrender at Yorktown; the Japanese victory was complete. Singapore was captured within 70 days. Within three days Japanese aircraft had sunk the major British battleships “Prince of Wales” and “Repulse.” Within a week they had swept the skies clear of the antiquated British aircraft. The troops of General Yamashita outfought and outmanoeuvred Gen. A.E. Percival and his British, Indian, Australian, and Malay troops. The Japanese scored further successes at Jitra in north Kedah, Dec. 11–12, 1942, and at Slim River in Perak on Jan. 7, 1943. Singapore fell on February 15. The Japanese lost 15,000 men. The total loss to the British Commonwealth was approximately 166,600 men.

From 1942 to 1945, when the first swift Japanese success turned to a slow, stubborn retreat, the people of Malaya received markedly different treatment from their Japanese overlords. The Malays were employed in posts of responsibility, and the Indians were assisted in forming an Indian national army to free India from British rule. The Chinese, however, were persecuted and brutally treated. Many fled into the jungle to join the Communist-organized Malayan People's Anti-Japanese Army (MPAJA).

Following the expulsion of the Japanese and the return of British rule in late 1945, an attempt by London to organize Malaya into one state deeply offended the Malays, who prized their treaty arrangements with Britain and were determined not to become a mere colony. A tremendous upsurge of Malay political feeling, led by Dato Onn Bin Jaafar, resulted in the creation in 1946 of the United Malays National Organization (UMNO). In 1948 a federation joining the Malay Peninsula and Penang was formed.

Birth of Malayan nationalism

In 1948 the Malayan Communist Party (MCP), formed before the war among the Chinese community, rose in armed revolt and opposed the British from enclaves in the jungle. An Emergency was proclaimed, as Britain endeavoured to suppress the MCP and MPAJA by military means and by eliminating the political causes of their agitation. These aims finally were achieved by Gerald Templer, who arrived in 1952. Templer invigorated military measures already planned, and, as high commissioner, encouraged the attainment of *merdeka* (“independence”) through political cooperation among the races. Under a new leader, Tunku Abdul Rahman, the UMNO in 1952 joined with the Malayan Chinese Association (MCA), led by Tan Cheng Lock and his son Tan Siew Sin. Both parties were anti-Communist and anticolonial. In the national election of 1955 the UMNO-MCA Alliance, led by Abdul Rahman, captured 51 of 52 seats. Britain responded by relinquishing its powers in Malaya. On Aug. 31, 1957, Malaya secured its *merdeka*, and the Emergency period ended three years later.

**Independence and the federation of Malaysia.** Postwar Malaya has been marked above all by the political drive of the Malays, expressed through UMNO. Only by associating with this powerful organization and its leader, Tunku Abdul Rahman, were other elements in the community able to achieve some of their goals. Malay dominance has caused bitterness, and racial antagonism found expression in the Kuala Lumpur riots of May 13, 1969. Tun Abdul Razak succeeded the Tunku in 1970.

Singapore secured full self-government in 1959. Its leader, Lee Kuan Yew, immediately pressed for “independence through merger” with Malaya. Singapore shared

Conflict with Singapore

much with the peninsula, and Lee felt that its future could be assured only by uniting with the mainland. Tunku Abdul Rahman, who became Malaya's first chief minister in 1955, agreed to the merger in order to forestall the growth of Communist influence among Singapore's Chinese population. To offset the inclusion of the 1,000,000 Chinese of Singapore, however, Malaya suggested in 1961 that Sarawak and Sabah (North Borneo), the other British colonies in Southeast Asia, also join with Malaya and Singapore in the merger. After considerable discussion, and increasing opposition from the Philippines and Indonesia, the four states established a new, independent federation of Malaysia on Sept. 16, 1963. (August 31, the date of Malaya's founding in 1957, remains the national day.)

Within two years, however, although Malaysia was able to withstand the external pressures of Indonesian armed opposition and "confrontation," internal disagreements worsened between Kuala Lumpur and Singapore. Abdul Rahman believed that civil war was imminent, and Malay political supremacy seemed challenged. On Aug. 9, 1965, Singapore was separated from Malaysia and established as an independent republic. (For Malaysian physical features and government see the article MALAYSIA.)

(K.G.T.)

## Malaysia

The federation of Malaysia in Southeast Asia is composed of two regions—West Malaysia, on the Malay Peninsula, and East Malaysia, consisting of the territories of Sarawak and Sabah on the island of Borneo. It has a total land area of 127,316 square miles (333,403 square kilometres) and a population of nearly 10,500,000.

West Malaysia has an area of about 51,000 square miles and occupies most of the Malay Peninsula south of latitude 6°40' N. To the north it is bordered by Thailand, with which it shares a 300-mile land boundary. To the south, its nearest neighbour is the island republic of Singapore, with which it is connected by a causeway; to the southwest, across the Strait of Malacca, is the Indonesian island of Sumatra. East Malaysia, consisting of Sarawak and Sabah (formerly North Borneo), is separated from West Malaysia by some 400 miles of the South China Sea. Sarawak, with an area of 48,050 square miles, and Sabah, with an area of 28,460 square miles, occupy most of the northwestern coastal part of the large island of Borneo. Both these territories share common land boundaries with each other and with the Indonesian provinces of Borneo (Kalimantan). Embedded within Sarawak is the small enclave of Brunei (*q.v.*), a sultanate still under British protection, politically separate from Malaysia.

Malaysia, a member of the Commonwealth of Nations, represents the political marriage of territories formerly under British rule. When it was established on Sept. 16, 1963, Malaysia was composed of Malaya (now West Malaysia), Singapore, Sarawak, and Sabah. In August 1965 Singapore (*q.v.*) left the federation and became an independent republic. (For a detailed discussion of associated physical features, see the articles CHINA SEA; and MALACCA, STRAIT OF; for historical aspects, see the article MALAYA, HISTORY OF.)

While not large by Asian standards, Malaysia is never-

theless one of the richest countries in the region. It occupies a focal position in Southeast Asia, commanding one of the major sea-lanes of the world, the Strait of Malacca. Malaysia is also unique in that it is the only country that has territory on both the mainland and insular regions of Southeast Asia. The physical separation between mainland Malaysia and insular Malaysia (Sarawak and Sabah), however, inevitably poses problems of communication. The fragmentation between West and East Malaysia is not only physical in nature. Wide disparities and differences exist as well in the degree of development and in the living standards of the population.

Malaysia inherited many long-standing problems from its colonial past. Politically the country was faced with the tasks, first of instilling a polyglot society with a sense of common identity and national purpose and, second, of resolving the tensions arising from inequalities of political and economic conditions. Economically, difficulties have included a high population growth rate (which poses the related problems of finding productive employment for an expanding labour force and of at least maintaining, if not raising, living standards); an inordinate dependence on rubber and tin production; disparities in income between rural and urban peoples and between ethnic groups; and a shortage of skilled manpower.

### THE LANDSCAPE (WEST MALAYSIA)

**The physical landscape.** The Malay Peninsula is a long, narrow strip of mountainous land extending southward from Burma and Thailand. West Malaysia occupies the granite, and the remainder is covered by alluvium (deposited material). More than half of the land area is over 500 feet above sea level. Topographically, the country is dominated by its mountainous core, which consists of a number of roughly parallel mountain ranges aligned along the longitudinal grain of the peninsula. The most prominent of these is the Main Range, which has elevations of over 3,000 feet, peaks of over 7,000 feet, and is about 300 miles long. Limestone hills, with their characteristically steep, whitish-gray sides, stunted vegetation, solution caves (*i.e.*, caves eaten out by the dissolving action of water), and subterranean passages, are distinctive landmarks in central and north West Malaysia. Bordering the mountainous core are the coastal lowlands, which are 10 to 50 miles wide along the western coast of the peninsula but which are narrower and discontinuous along the eastern coast. Settlement and development have taken place primarily along the western coast.

The peninsula is drained by an intricate network of rivers and streams. The largest river—the Sungai Pahang—is only 270 miles long. The year-round rainfall results in perennial streamflow, but the volume of water transported fluctuates considerably because of the localized and torrential nature of the rainfall. In the western part of the peninsula such heavy falls may occur at any time of year, but in the eastern part they are more likely to occur during the northeast monsoon winds that blow from November to March. Prolonged rains often cause floods, especially in areas where the natural regimes of the rivers have been disrupted by uncontrolled mining or agricultural activities in the past.

The Malay Peninsula has an equatorial climate, but its narrowness and configuration—a central mountainous core with flat flanking coastal plains—facilitate the inland penetration of maritime climatic influences. In addition, monsoonal effects further modify the climate. The country is influenced by eight or nine major airstreams, flowing from the northeast, south, and west; the advance and retreat of these are responsible for the division of the climatic year into four seasons. These are (1) the northeast monsoon (from November or December until March), (2) the first intermonsoon period (from March to April or May), (3) the southwest monsoon (from June to October), (4) the second intermonsoon period (from October

Mountain ranges

Penang, Malaysia.  
T. Kautsch—Publix

to November). The onset and termination of the monsoons are not sharply defined.

The mean annual rainfall is about 100 inches. The driest location, in Kuala Kelawang (formerly Jelebu), about 30 miles east of Kuala Lumpur, receives about 65 inches of rain a year; while the wettest, Maxwell's Hill, about 25 miles northwest of Ipoh, receives 200 inches. Temperatures are uniformly high throughout the year, averaging 78° to 82° F (25° to 28° C) for most lowland areas. Relative humidities are also persistently high, averaging from 82 to 86 percent. The climate, in consequence, tends to be hot and humid.

#### Soils

The soils of the peninsula have been exposed for an extremely long time to intense tropical weathering, with the result that most of their plant nutrients have been leached out. The soils are typically strongly acid and coarse textured; deficient in nitrogen, phosphorus, potassium, and magnesium; and have low amounts of organic matter. Only 11 percent of the soils of West Malaysia are fertile, and of this over half are either of low or of below average fertility. Regular applications of fertilizers are therefore necessary for sustained crop yields. On slopes, such additional measures as the building of contour embankments or the planting of protective cover crops are also needed to minimize soil erosion.

The characteristic vegetation of the peninsula is the dense, evergreen rain forest—the climax vegetation of the hot, wet tropics. Rain forest still covers nearly 60 percent of the total land area; a further 9 percent is under swamp forest. The flora of the Malayan rain forest is among the richest in the world. There are about 8,000 species of flowering plants, of which at least 2,500 are trees. An acre of forest may have as many as 100 different species of trees, as well as shrubs, herbs, lianas (creepers), and epiphytes (plants that grow nonparasitically upon others, deriving nourishment from the atmosphere). The forest canopy is so dense that little sunlight can penetrate it. As a result, the undergrowth is usually poorly developed and—contrary to popular belief—is not impenetrable. Much of the original rain forest has been destroyed by wind and lightning storms, by aborigines clearing it for temporary agricultural use, or by clearances made for agricultural or commercial purposes. When such cleared land is subsequently abandoned, coarse grassland, scrub, and secondary forest develop. These types of vegetation comprise about 7 percent of the total land area.

The forests and scrubland is inhabited by a large vari-

ety of animal life. Mammals include the elephant, the tiger, the magnificent seladang (or Malayan gaur, a massive wild ox), the Sumatran rhinoceros, the tapir (a hoofed and snouted quadruped), the wild pig, and many species of deer, including the *pelandok*, or mousedeer (a small, deerlike ruminant). Crocodiles, monitor lizards, cobras, and king cobras are also indigenous to the country, while the green sea turtle and the giant leathery turtle nest regularly on the beaches of the east coast.

**The landscape under human settlement.** West Malaysian settlements range from the rudimentary settlements of the aborigines to modern cities. This complexity and variety reflects in part the range of economic activities, in part the cultural diversity of the inhabitants, and in part the long history of settlement in the peninsula. The first settlers were small groups of aborigines, who were later followed by peoples of Malay stock and, in recent times, by immigrants from China and India.

The Malays are predominantly a rural people. Their settlements are similar in appearance and pattern to those of their rural counterparts elsewhere in Southeast Asia. The basic unit is the *kampung* (village, or community of houses), composed of dwellings on stilts, which are commonly erected beside rivers, canals, beaches, roads, and footpaths. The houses are usually built of wood and a thatched roofing called *atap*, woven from the leaves of the nipa palm (a species also used for basketry). Each house is surrounded by trees bearing coconuts, bananas, papayas, and other fruits. The four main types of Malay settlements—fishing villages, paddy (rice-field) villages, cash-crop villages, and mixed-crop villages—despite their variations, all conform to the same basic pattern.

Most other rural settlements are associated with peoples who have settled in the country within the last 150 years. The earliest of these were the mining camps, which sprang up in the tin fields on the west of the peninsula. Some of these have since grown into large towns, but others—especially in the Kinta Valley—still remain small. The British introduced the plantation system of agriculture, and the subsequent cultivation of rubber and of the oil palm has changed the face of rural West Malaysia, bringing to the landscape the plantation, or estate, settlement. This is usually a group of buildings composed of the processing factory and storehouse, the labourers' quarters, and the manager's house.

The most recent settlement type is the New Village, which originally was simply a group of buildings occupy-

Types of  
rural  
settlement

ing a defensive site enclosed with barbed wire near a road. A total of about 550 New Villages were established between 1948 and 1960, during the Emergency, the formal name for the period when the administration was engaged in suppressing the Communist guerrilla uprising. They were part of a plan to resettle rural dwellers in easily defended positions, so as to prevent contact between them and the armed Communists. With the end of the Emergency in 1960, some of the New Villages were abandoned and have since disappeared. Most of them, however, took root and have now become permanent settlements. With their barbed-wire fences dismantled, they differ little from other small towns.

The cities and large towns were built up during the colonial and postcolonial periods and are distributed mainly along the tin and rubber belt on the west of the peninsula. There are at least 230 small towns with a population of 2,000 or more and over 80 with a population of 5,000 or more. The towns are associated with mining, purchasing, processing, distributing, exporting, or administrative functions, although each town usually performs not one but several of them. Some towns are located at coastal or riverine sites, emphasizing the early importance of water transport; more recently built towns are in inland areas served by road, rail, and air transport. About two-thirds of the urban population is Chinese, while Indians and Pakistanis constitute another 10 percent. Malays form only some 22 percent of the urban population, but the proportion of them is increasing.

Except for the new satellite towns such as Petaling Jaya (outside Kuala Lumpur), the towns of West Malaysia are unplanned, having grown up around pre-urban nuclei. Urban land use is generally mixed, and buildings are put to multiple uses. Streets, built for a more leisurely era, are narrow and often congested. In the larger centres, such as Kuala Lumpur, Ipoh, and Pinang, distinct central business districts, similar to those in Western cities, have emerged. These are characterized by heavy population and traffic densities, high land values, and a concentration of shopping, banking, insurance, entertainment, and other facilities.

#### THE LANDSCAPE (EAST MALAYSIA)

**The physical landscape.** East Malaysia is an elongated strip of land approximately 670 miles long, with a maximum width of about 160 miles. The coastline of 1,400 miles is paralleled inland by a 900-mile land boundary with Kalimantan (Indonesian Borneo). For most of its length the relief is composed of three topographic features. First, there is the flat coastal plain, which in Sarawak, where the coastline is regular, averages 20 to 40 miles in width. In Sabah, where the coastline is rugged and deeply indented, it is only 10 to 20 miles in width. Inland from the coastal plain is the second topographic feature—the hill and valley region. This is generally below 1,000 feet in altitude, but isolated groups of hills reach heights of 2,500 feet or more. The terrain in this region is usually very irregular, with steep-sided hills and narrow valleys. The mountainous backbone that forms the divide between East Malaysia and Kalimantan is the third topographic feature. This backbone is both higher and nearer the coast in Sabah than it is in Sarawak. It is composed of an ill-defined complex of plateaus, ravines, gorges, and mountain ranges, all of which have been cut by erosion. The summits of the ranges are between 4,000 and 7,000 feet. Mt. Kinabalu (13,455 feet), the highest peak in the whole of the Malay Archipelago, towers above this mountain complex; no other peak in the country reaches 8,000 feet in height.

As in West Malaysia, the drainage pattern is set by the interior highlands, which also form the watershed between East Malaysia and Kalimantan. The rivers are perennial because of the year-round rainfall. They form a dense network of drainage lines covering all parts of the country. The longest river in Sarawak—the Rajang—is 350 miles long and is navigable by shallow-draft boats for about 160 miles from its mouth; its counterpart in Sabah—the Kinabatangan—is of comparable length but is only navigable to about 120 miles from its mouth.

The rivers are all of importance as they provide a means of communication between the coast and the interior. Settlement has also taken place along the rivers, as it did on the peninsula in an earlier period.

Both continental and insular Malaysia are in the same latitudes and are influenced by similar airstreams. They consequently experience similarly high temperatures and humidities, heavy rainfall, and a climatic year patterned around the northeast and southwest monsoons. In coastal areas in East Malaysia, minimum temperatures range from 72° to 76° F (22° to 25° C) and maximum temperatures from 88° to 92° F (31° to 33° C); temperatures are lower in the interior because of higher altitudes. As on the peninsula, rainfall variations are pronounced. Mean annual rainfall in Sabah varies from 60 inches to 120 inches, while most parts of Sarawak receive between 100 to 160 inches. The northeast monsoon brings heavy rain and rough seas to the exposed coasts of southwest Sarawak and north and northeast Sabah. The southwest monsoon, however, affects mainly the southwest coastal belt of Sabah. Floods are common, especially along the west coast of Sabah. Neither mainland nor insular Malaysia is in the typhoon belt, but their coasts

**MALAYSIA**

Size of symbol indicates relative size of town • ○ ◻ ◼

Elevations in metres

are occasionally subject to the heavy rainstorms associated with squalls.

The soils of East Malaysia, like those of the peninsula, developed under intensive tropical weathering conditions over a long period. They are consequently heavily leached and are generally poor in plant nutrients. When exposed, the organic matter in such soils is rapidly oxidized, and the soils consequently become even poorer. Soil erosion is always a danger on sloping land. In such an environment, agricultural development poses considerable problems. Generally speaking, soil conditions in Sarawak and Sabah do not differ greatly from those in West Malaysia. Of these three territories, only Sabah has appreciable areas of fertile soils. These are found in particular on the Semporna peninsula, where the parent material from which the soil is formed is composed of basic volcanic rocks.

Forest areas

Large expanses of East Malaysia—77 percent of the total land area in Sarawak and 78 percent in Sabah—are still covered by dense, evergreen rain forest. Soil type, location, and altitude produce distinctive vegetation zones, varying from tidal swamp forest on the coast, to freshwater and peat swamp forest on the ill-drained parts of the coastal plains, to lowland rain forest on the well-drained parts of the coastal plains and foothills up to an altitude of about 2,000 feet, to submontane and montane (lower mountain-type) forest above that altitude. The highly leached and sandy soils of parts of central Sarawak and the coast support an open, heathlike forest, known locally as *kerangas* forest. Large expanses of the forested land, especially in the upland areas, have been cleared for shifting cultivation, and the original forests have given way to scrub and savanna.

Animal life in East Malaysia is even more varied than it is on the peninsula. In addition to the peninsula species, East Malaysia is also the home of the fast-disappearing orangutan ape, the rhinoceros, the honey bear, and the unique proboscis monkey—a reddish tree-living species. There are also millions of cave swifts, whose nests are regularly collected and sold as the main ingredient of bird's nest soup.

**The landscape under human settlement.** About 85 percent of the population of East Malaysia is still rural, and it is in the rural areas that the greatest variety of settlement types is encountered. This variety is a direct reflection of the almost bewildering ethnic complexity of the population and of the fact that indigenous as well as immigrant groups are settled in the rural areas. The indigenous ethnic groups, such as the Sea Dayaks (Ibans), Land Dayaks, Kenyahs, Kayans, and Muruts, are thinly scattered in the foothill country and, to some extent, in the coastal lowlands as well. They are primarily shifting cultivators and live in locations on or near the banks of rivers. Their characteristic dwelling is the longhouse, more commonly found in Sarawak than in Sabah. Each longhouse is raised on stilts and is composed of a number of rooms, known as *bileks*; each *bilek* houses a family. A longhouse can grow by accretions of related families, and an Iban longhouse may in time reach a length of 50 *bileks*. Some groups, such as the Melanaus of Sarawak and the Dusuns of Sabah, have abandoned the longhouse settlement form, adopting instead the individual dwelling of the Malays.

The Malays and Melanaus of East Malaysia share many common characteristics with their rural counterparts on the peninsula. They are a riverine and coastal people, with an economy based on agriculture and fishing. They live in *kampongs* set in the midst of coconut, mangrove, or other swamp trees. Their houses are invariably built on stilts. The Melanaus specialize in sago production; their *kampongs* are built in the large deltaic swamp region between Bintulu and Rajang. The rural Chinese in Sarawak have settled in the region between the coast and the uplands, usually in homesteads strung along both sides of the roads. They grow cash crops such as rubber, pepper, fruits, and vegetables in small holdings. Their houses are commonly built at ground level and are thus easily distinguishable from the stilt-raised dwellings of the Dayaks and Malays.

Urbanization in East Malaysia has proceeded neither fast nor far. Only 15 percent of the total population live in towns of 3,000 or more people. Only six towns have a population of over 10,000—Kuching, Sibul, and Miri in Sarawak, and Sandakan, Kota Kinabalu, and Tawau in Sabah. As on the peninsula, the urban population is predominantly Chinese. The large towns are invariably located on coastal or riverine sites. The layout and appearance of these towns are markedly similar: a wharf area; rows of Chinese shop-houses in the central business districts; more substantial buildings in the governmental administrative area; and one or more timber and *atap kampongs* built on the river banks.

Principal towns

#### PEOPLE AND POPULATION

The total population of Malaysia enumerated at the 1970 census was 10,452,000: 8,801,000 in West Malaysia, 977,000 in Sarawak, 656,000 in Sabah, and 18,000 transients and others. The population exhibits great ethnic, linguistic, cultural, and religious diversity. Important differences exist between the indigenous and immigrant peoples, as well as among the indigenous peoples themselves, and between the Muslims, Buddhists, Christians, and tribes adhering to traditional religions.

**Groups historically associated with contemporary West Malaysia.** The Malay Peninsula, situated at one of the great maritime crossroads of the world, has been the meeting place of peoples from other parts of mainland, as well as insular, Asia. As a result, the population shows the ethnographic complexity typical of Southeast Asia as a whole. In essence there are four groups of people—the aborigines, the Malays, the Chinese, and the Indians and Pakistanis.

Numerically the least important of these four, the aborigines can be divided ethnically into three groups: the Jakun, who speak an archaic Malay, and the Semang and Senoi, who speak languages of the Mon-Khmer language family. They are primarily adherents of traditional religions, but a number have been converted to Islām.

The Malays originated from different parts of the peninsula and the Malay Archipelago. They comprise 50 percent of the total population and are politically the most important group. They share with each other a common culture, speak a common Austronesian language, Bahasa Malaysia, which is the national language, and are firm adherents of the Muslim religion. Adherence to Islām is, indeed, regarded as one of the most important factors distinguishing a Malay from a non-Malay; the number of Malays who are not Muslim is negligible. Minor differences in dialect, culture, and physical characteristics are noticeable among the Malays living in the south in Johor state, on the east coast in the states of Kelantan and Terengganu, and on the west coast in the states of Negeri Sembilan, Perak, Kedah, and Perlis.

The Chinese, who make up 36 percent of the peninsular population, were originally from the provinces of southeastern China and are ethnically homogeneous. They are, however, less homogeneous than the Malays in language and religion. The peoples of southeastern China comprise several different tribes, each with its own spoken language. Oral communication between two Chinese may thus sometimes depend on Mandarin Chinese, English, or Malay. A minority, the Baba Chinese, speak a Malay patois, although otherwise they remain Chinese in customs, manners, and habit. The most important cultural and linguistic Chinese groups are the Hokkien, from Fukien Province; the Cantonese, from the Canton region of Kwangtung Province; the Hakka, from the area between Canton and Swatow; the Tiechui, from the Swatow region of Kwangtung Province; the Hainanese, from the island of Hainan; the Kwongsai, or Kwangsi, from Kwangsi Province; and the Hokchui, from the hinterlands of Fukien Province. The Chinese do not have a dominant religion; most of them, while subscribing to the Confucian code of moral behaviour, are either Buddhists or Taoists. A small minority have become Christians.

Origins of the Chinese population

The peoples from the Indian subcontinent—the Indians, Pakistanis, and Ceylonese—constitute about 11 percent of the population of West Malaysia. Linguistically, they

can be subdivided into speakers of Dravidian languages (Tamil, Telugu, Malayalam *et al.*) and speakers of Indo-European languages (Punjabi, Bengali, Pashto, and Sinhalese). Numerically, the Tamil speakers are the largest group. Most of the Indians and Ceylonese are Hindus, while the Pakistanis are predominantly Muslim. Some Indians have been converted to Christianity. The Sikhs, from the Punjab, speak their own language and also adhere to their own religion, Sikhism.

The population also includes small numbers of Europeans and Americans, Eurasians, Arabs, and Thai.

**West Malaysian demography.** Vital statistics of West Malaysia indicate several perceptible trends in health and sanitation conditions. The average life expectancy has increased significantly in recent decades and now stands in the 60s. Crude death rates among all races dropped from about 12 per 1,000 in the late 1950s to about 7 per 1,000 in the late 1960s. Due to better health services and a more general acceptance of the methods of modern medicine, mortality rates are lower in the towns and cities. Since the Chinese are usually urban dwellers, their crude death rates have always been lower than those for the country as a whole, while the essentially rural Malays have death rates above the national average.

Crude birth rates have declined significantly only in the last decade or so. The trend toward lower birth rates is most evident among the Chinese. The rates among the Malays are higher, while those of the Indians and Pakistanis are slightly lower than those for the country as a whole. Over the years the rate of population growth has slowed down, and the average annual population increase due to the excess of births over deaths has dropped progressively from a peak of 3.5 percent in 1956 to 2.76 percent in 1968.

The movement of vast numbers of peoples in and out of the country, which occurred in the earlier years of West Malaysia's history, ended before World War II. A series of laws passed since 1945, and particularly after the political separation from Singapore in 1965, severely restrict the entry of immigrants from all countries. Migratory surpluses are consequently no longer significant as a cause of population growth, amounting to less than 70,000 in the decade of the 1960s.

Restrictions on immigration

in the Kelantan and Terengganu river deltas in the north-east of the peninsula. The remainder of the peninsula—the interior uplands and most of the east—is sparsely populated except in towns and cities and along the main rivers, roads, and railways. Approximately one-third of the population lives in towns with a population of 5,000 and over. There are over 80 such towns, and two-thirds of them are located in the tin and rubber belt.

The peninsula has a high rate of population growth, averaging about 3 percent per annum. Such a growth rate has hindered development. There are, however, indications that the rate of population growth may be slowing down. A recent survey found that within the decade 1956 to 1965 fertility among the Chinese declined by about a quarter, among the Indians by over 20 percent, and among the Malays by 13 percent.

**Groups historically associated with contemporary East Malaysia.** The population of East Malaysia is ethnographically even more complex. Although recent censuses have tended to oversimplify, listing 8 main ethnic groupings in Sarawak and 7 in Sabah, there are in fact 25 ethnic groups in Sarawak and 26 in Sabah, not counting minor tribal groups. In order of numerical importance, the main ethnic groups in Sarawak are the Chinese, one-third of the total population; various speakers of mutually unintelligible Austronesian languages including the Sea Dayaks or Ibans (under 30%); the Malays (under 20%); the Land Dayaks (under 10%); the Melanaus (about 5%); and other minor races (about 5%).

Ethnic diversity

The Chinese of Sarawak, drawn from the southeastern provinces of China, share common regional origins with the Chinese of West Malaysia, but the relative importance of each dialect group is different. Thus the Hakka and Foochow (Hokchiu) groups, who are less numerous than the Cantonese and Hokkien in West Malaysia, are the dominant linguistic groups and together comprise two-thirds of the Chinese population. The other important dialect groups are the Hokkien, the Cantonese, the Tiechiu, the Henghua, and the Hainanese. As in West Malaysia, the Chinese of Sarawak practice Buddhism, Taoism, and Confucianism. Only a few are Christians.

The Ibans are the largest and most important indigenous group in Sarawak. Their origins are obscure. Until fairly recently they were headhunters. They are a homogeneous people speaking a language described as a kind of pre-Islamic Sumatran Malay. Most of them are longhouse dwellers, practicing shifting cultivation in the interior uplands. They have a distinctive culture, in which religion plays an important part; nearly every activity is influenced or governed by animist beliefs.

The Malays of Sarawak are a heterogeneous group of people, among whom only a few are of immigrant West Malaysian origin. Most are the descendants of indigenous peoples who were converted to Islām and adopted the Malay way of life some time during a period of perhaps the past 500 years. Although ethnically diverse, they are culturally homogeneous, speaking a common language and professing the Muslim faith.

The Land Dayaks live in hill country; most of them are found in the First Division. (Sarawak is divided into five divisions; these administrative units were created at different stages in the historical growth of Sarawak as a political entity.) Although all are of the same ethnic group, they speak five different but related dialects that are, nevertheless, to some extent mutually intelligible. The majority of Land Dayaks are adherents of traditional religions, but in recent years Christian missionaries have made some converts among them.

The Land Dayaks

The Melanaus differ ethnically from the Sarawak Malays, being shorter, broader shouldered, and of a lighter complexion. Their dialects, which are distinct from Malay, do not differ sufficiently to constitute a barrier to communication. Three-quarters of the Melanau population are Muslims; the rest, except for a small number of Christians, follow traditional religions. Other indigenous peoples—Kenyahs, Kayans, Kedayans, Muruts, Kelabit, Bisayas, Punans, and others—contribute much to the ethnic and cultural diversity of East Malaysia.

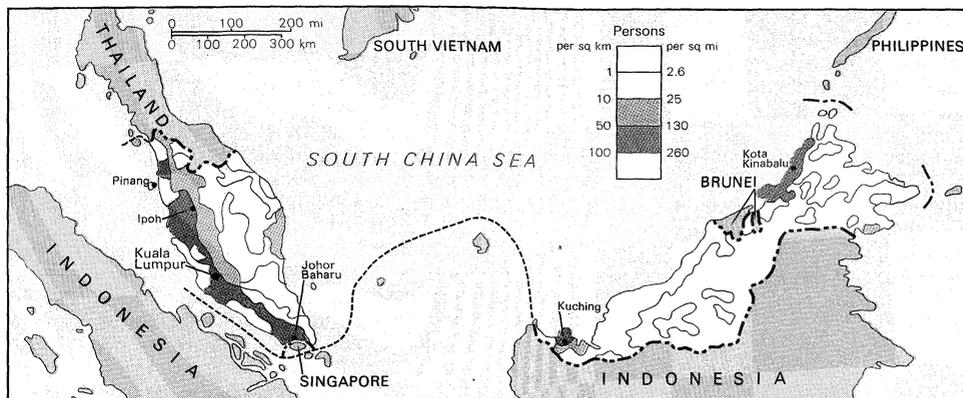

Sabah also has a kaleidoscopic mixture of peoples. Of

†Sabah and Sarawak had 1960 census. ‡No census total for Malaysia can be given because the census of Sabah, Sarawak, and West Malaysia took place at different dates. §Total is revised and includes 18,000 transients and others.  
Source: Official government figures.

The pattern of population distribution consists of two areas of high population densities and one area of low density. The major area of population concentration is the tin and rubber belt, a belt 25 to 75 miles wide extending along the west of the peninsula from Perlis to Johor. Within this area, which comprises only 30 percent of the total land area, live three-quarters of the total population. Another 12 percent of the population is distributed

Population density of Malaysia.

the total population of 656,000, 30 percent are Dusuns (or Kadazans); 22 percent, Chinese; over 10 percent, Orang Lauts (Bajaus); almost 5 percent, Muruts; and under 20 percent is composed of such indigenous peoples as the Brunei Malays, Kedayan, Orang Sungei, Bisaya, Sulu, Tidong, and Sino-Native. Europeans, Eurasians, Malays, Indonesians, Filipinos, and Indians and Pakistanis comprise the remainder.

The Dusuns are composed of a number of tribes, each speaking a dialect that the others can understand. About a quarter of the Dusun population are Christians, about 7 percent are Muslims, and the remainder are animists. More than half of the Chinese are Hakka-speaking; the other important Chinese dialect groups are Cantonese, Hokkien, Tiechiu, and Hainanese. The Bajaus are not a cohesive community, being split into two main groups—the sedentary agriculturists, who have settled on the north coast, and those who live by the sea on the east coast. Most are Muslims, but not all of them can communicate with each other. The Muruts of Sabah are ethnically different from the Muruts of Sarawak, being descended from the same stock as the Dusuns. They are shifting cultivators. Although they are divided into subtribes, their languages are mutually intelligible. Although most follow traditional religions, approximately one-fourth are Christian.

**East Malaysian demography.** The vital statistics of East Malaysia indicate that the population is increasing at an unprecedentedly rapid rate, due to increasing fertility and declining mortality. The crude birth rates of all the major ethnic groups in Sarawak and Sabah have increased steadily since 1945. The crude birth rate in both Sarawak and Sabah averages about 48 per 1,000. The crude death rates for both have fallen progressively over the last decade or so and stand at about 12 per 1,000.

Before the war there was a free flow of people to and from East Malaysia, so that the rate of population growth, although slow, was nevertheless greatly influenced by the net surplus from migration. Today neither immigration nor emigration is any longer significant as a cause of population changes. The rates of population growth in East Malaysia have nevertheless increased remarkably in recent years, averaging about 3.5 percent per annum. As in West Malaysia, this high growth rate is due almost entirely to the natural increase of population, owing little to immigration.

The population of East Malaysia is concentrated along the coasts and the rivers; the interior highlands are sparsely inhabited. Overall densities are extremely low: only 20 per square mile in Sarawak and 22 per square mile in Sabah. In Sarawak the heavy concentration of people in the southwest makes this region the most important in the country. Outside this region, every district except Miri Urban has a population density below the average. In Sabah the population is similarly clustered on the coast, but riverine settlements are less important than in Sarawak. Half of the population is distributed in the narrow west coastal zone or in Sandakan, the former capital. Large parts of the interior and of the east coast are thinly populated.

East Malaysia is still a sparsely settled land, with population densities far below the 173 persons per square mile in West Malaysia. East Malaysia can therefore afford to maintain its present high rates of population growth, as well as absorb some of West Malaysia's population in future years.

#### THE NATIONAL ECONOMY

Malaysia, the third richest country in Asia, is surpassed in wealth only by Japan and Singapore. The monetary unit is the Malaysian dollar. The country is the world's largest producer of two primary products: rubber and tin, and second to Nigeria in palm oil. Its economy, compared with those of most developing countries, is relatively advanced in terms of infrastructural facilities (roads, water supplies, electricity, etc.), institutional patterns, commercial and financial patterns, and management, professional, and administrative skills.

**Natural resources.** The mineral resources of Malaysia include tin, iron ore, bauxite (from which aluminum is made), coal, gold, china clay (kaolin), monazite (the principal ore of thorium, a malleable, radioactive metallic element), ilmenite (a common black mineral), columbite (a black crystalline mineral, the principal ore of niobium, used in making steel alloys), manganese, tantalite (a mineral used to make tantalum, a metallic element resistant to corrosion), wolframite (an important ore of tungsten, a metallic element with a high melting point), and zircon (the chief ore of zirconium, a metallic element, used in steel metallurgy) in West Malaysia; antimony (a brittle, lustrous, white metallic element, used in alloys), mercury, gold, coal, petroleum, bauxite, phosphate, and glass sand in Sarawak; and gold, coal, manganese, and copper in Sabah. Except for tin, iron ore, bauxite, petroleum, and copper, however, most of the minerals are of minor economic importance. In Sabah only copper is of importance.

Tin is by far the most important mineral in Malaysia. Found in 9 of the 11 West Malaysian states, it is distributed in two belts—western and eastern. The western tin belt runs along the flanks of the Main Range and along either side of the subsidiary granite ranges to the west of the Main Range. The less continuous, and also less rich, eastern tin belt runs from southern Terengganu to eastern Johor. Recent investigations indicate that there are 1,000,000,000 cubic yards of tin in the Malay Reservations (*i.e.*, lands set aside by law for the use of Malays and which cannot be sold to others). The search for new fields has been extended to the offshore areas of the western peninsula. Iron ore deposits along the eastern and western peninsula have been largely mined out.

Petroleum is found only in Sarawak, but offshore prospecting is being carried out in Sarawak, in Sabah, and in West Malaysia. The only oil field in Sarawak is at Miri in the Fourth Division, but in 1968 an offshore deposit was discovered in the state. Output of crude oil increased very rapidly between 1967 and 1970, reaching a total of 6,558,800 U.S. barrels in 1970.

The main biological resources of Malaysia are its forests and its fisheries. The extensive areas still under rain forest

Population growth

Tin

in both West and East Malaysia are a source of various forest products used by the indigenous peoples, as well as of timber, charcoal, firewood, poles, resins, gums, and rattans, which are produced both for local consumption and for export. In recent years the exploitation of the timber resources has intensified; timber is Malaysia's third largest foreign exchange earner, after rubber and tin.

The shallow seas off the coasts of Malaysia are the principal fishing grounds. In general the nutrient level, and hence the productivity of these seas, is low, the richer portions being those fertilized by drainage waters from the land. The annual output of the fishermen who use traditional techniques and who fish in inshore waters is low. The increased use of motorized boats has extended the range of the fishermen, enabling them to tap richer offshore fishing grounds.

Hydro-  
electric  
potential

The power resources of Malaysia include coal, peat, wood, petroleum, and hydroelectricity. Although proved reserves of coal and peat exist, they are not economic to mine and therefore remain only of potential use. Wood and charcoal have been the traditional domestic fuels, but in the urban areas they are rapidly being displaced by bottled gas. No hydroelectric power is generated in East Malaysia, but, as on the peninsula, the abundant rainfall and steep gradients of the rivers in the interior highlands offer a good hydroelectric potential. The main hydroelectric schemes in operation in West Malaysia are at Cameron Highlands, at Batang Padang, and at Chenderoh (on the Perak River); in addition there are small plants at Ulu Langat, Sempang, and Rahman. The petroleum resources of Sarawak do not constitute a major source of fuel oil. For power generation, therefore, Malaysia continues to depend primarily on imported fuel oil.

**Sources of national income.** Agriculture, forestry, fishing, and mining together constitute the most important sector of the Malaysian economy, contributing more than 90 percent of the value of all exports. Slightly more than half of the work force of West Malaysia and about 80 percent of the work force in Sarawak and Sabah are engaged in these pursuits. The majority of the population continues to depend upon agriculture for a livelihood. Agriculture contributes about 30 percent of the total gross national product (GNP). About 6 percent of the land area in Sarawak, 3 percent in Sabah, and 21 percent in West Malaysia is under cultivation. The most important cash crops are rubber (the country's main foreign exchange earner), oil palm, and coconut. The main food crop is rice (called *padi* in Malay), which ranks second only to rubber in terms of the amount of land and labour devoted to its production. Cultivation systems range from the traditional shifting cultivation, still commonly practiced in East Malaysia, to the most modern forms of plantation agriculture.

Most of the land area in Malaysia, as we have seen, is still covered by forest. Forestry has assumed increased importance in recent years because of the rapid expansion of the timber industry. The sustained export demand for tropical timber has stimulated the opening up of new forest areas for timber exploitation. The output of timber has also increased as a result of the clearance of large areas of forest for land development. Timber has become Malaysia's third most important product.

Similar progress has occurred in the fishing industry. Total fish landings trebled between the late 1950s and the late '60s. The long coastlines provide Malaysian fishermen with easy access to the surrounding seas, although most of them still confine their fishing to the over-exploited shallow inshore waters. In the last decade, however, the greater use of trawlers and mechanized fishing boats has allowed the fish resources of the offshore grounds to be tapped.

Mining  
exports

The mining industry contributes about one-quarter of the total export receipts. The main minerals produced are tin, iron ore, bauxite, and petroleum. West Malaysia is the world's largest producer of tin, but intensive exploitation over the past century has led to a steady depletion of known deposits, and the tin industry is consequently searching for new deposits off the coast of the western

peninsula, as well as in Malay Reservations. The output of iron ore is also dropping due to the gradual working out of high-grade deposits. Bauxite production declined after the closure of the Sarawak mine in 1965, but an increased output from the mines in southeastern Johor had restored production to the 1,000,000-ton level by 1969. Sarawak is the only state which has petroleum resources. The first offshore well began production in Sarawak in 1968; prospecting for offshore deposits has been extended to Sabah and West Malaysia. A large deposit of copper has been discovered near Mt. Kinabalu, to be mined by a Japanese company.

Most of Malaysia's manufacturing plants are located on the peninsula. The contribution of the manufacturing sector of the economy rose from about 9 percent of the gross domestic product in 1960 to about 12 percent in 1970. Malaysia is attempting to broaden its economic base by industrialization. Efforts have been directed mainly at the production of hitherto imported consumer goods, and the range of manufacturing is also being widened to include production for export. Governmental efforts to promote industrialization include the granting of favoured treatment, including tax holidays, for selected industries; the establishment of tariff barriers for the protection of the home market; the establishment of institutions to promote industrial development; and the development of 17 industrial estates—12 in West Malaysia, 3 in Sabah, and 2 in Sarawak.

The services sector of the economy has maintained a steady growth rate over the last decade, now accounting for about half of the gross domestic product (GDP). In West Malaysia more than 30 percent of the labour force is engaged in service industries. The highest growth rates have been in electricity, water and sanitary services, banking, insurance and real estate, transport and communications, public administration and defense, and public services such as schools and hospitals.

A high percentage of Malaysia's exports is made up of raw materials. Five commodities—tin, rubber, timber, palm oil, and iron ore—account for about three-quarters of the total value of all exports. The three most important imports are food, manufactured goods and machinery, and transport equipment, which together constitute about two-thirds of the total value of all imports.

**Management of the economy.** The free enterprise system introduced during the British colonial era has been modified since independence. The government has embarked upon a program of planned economic development that aims at raising living standards of the population in general and of the economically weaker communities in particular. The program, however, encourages the continued participation of the private sector. Direct governmental participation is limited to the development of such infrastructural facilities as transport, public utilities, drainage and irrigation works, agricultural settlement schemes, and industrial estates, as well as of social and administrative services. The First Malaysia Development Plan, which covered the period from 1966 to 1970, was supported by both public and private investment programs.

Systems of public finance—auditing and organization of accounts, parliamentary control, and revenue collection—are based on British principles. The fiscal system—rather than being employed to manipulate the pace of economic activity, the level of employment, or price levels—is basically a mechanism for raising revenue for governmental expenditure. Heavy dependence is placed on customs and excise duties for revenue collection, while income and other direct taxes provide a comparatively small proportion of the total yield, even though in recent years higher incomes and improved methods of tax collection have increased the yield. The government is attempting, meanwhile, to distribute the tax burden equitably, by such means as sliding income tax scales, higher duties on luxury goods, and lower duties on essential commodities.

The economy of Malaysia relies heavily on a few raw materials for export. More than half the total labour force is engaged in primary production. There is a contin-

Economic  
develop-  
ment

ued dependence on imports for many manufactured goods, and the industrial sector is still insignificant. By the standards of other developing countries in Asia, Malaysia's economy is nevertheless relatively advanced, varied, and complex. The component states of Malaysia are, however, in widely different stages of economic development. West Malaysia, contributing nearly 90 per cent of the total GNP, is clearly the dominant economic partner, with Sarawak and Sabah lagging far behind.

Economically, Malaysia faces the necessity of maintaining a steady rate of economic growth despite a rapid population increase. Unemployment is growing, standing at nearly 8 percent of the total labour force of 3,200,000 in 1970. Underemployment, also, while its extent has not been accurately assessed, is widespread, especially in the agricultural sector. Most of the unemployed are in West Malaysia; Sabah, on the other hand, is short of manpower. In Sarawak, population pressure has already led to land exhaustion and to soil erosion in many areas of shifting cultivation.

In order to reduce its vulnerability to world market fluctuations, Malaysia has to diversify its economy and at the same time raise standards of living, especially in its depressed areas—in the eastern side of the peninsula and in the interior parts of Sarawak and Sabah.

#### TRANSPORTATION

The transport network in West Malaysia is well developed, especially in the tin and rubber belt. Both Sarawak and Sabah, however, have poor transport facilities, relying primarily on river transport for movement between the coast and the interior.

The road network in West Malaysia is considered the best in Southeast Asia. There are over 10,000 miles of road, almost all of which are hard-surfaced. The network will be further extended with the completion of the 185-mile East-West Highway, linking Kota Baharu on the east coast to Butterworth on the west via Gerik, and the 89-mile Southern Pahang road, which will open up the Pahang-Tenggara region. The road networks in Sarawak and Sabah are still skeletal in pattern, though many miles of road were added in the 1960s. There are about 1,000 miles of road in Sarawak and over 1,700 miles in Sabah. Only 200 or 300 miles in each territory are bitumen-surfaced; the rest are of poor quality.

The rail transport system is only well developed on the peninsula. Sarawak has no railway and Sabah has only a short line linking Kota Kinabalu to Beaufort, Tenom, and Melalap. Because of competition from road transport, the Malayan Railway has been operating at a loss and a reorganization has been recommended.

Traditionally, transport in both East and West Malaysia has been by water. River transport, however, is no longer important in West Malaysia except on parts of the east coast, but in East Malaysia it continues to play a major role. On the rivers of Sarawak and Sabah, which link the interior and the coast, almost all settlements are riverine and many are only accessible by water. Due to the long coastlines, the coastal and sea transport systems of Malaysia are of great importance. Over the years a number of coastal and river ports have been established at strategic locations—Pinang and Port Swettenham in West Malaysia; and Kuching, Sibul, Labuan, Kota Kinabalu, Sandakan, and Tawau in East Malaysia. Traffic at these ports has grown at a rate of between 5 and 10 percent a year.

Air transport has grown even more rapidly, with passenger traffic increasing at the rate of about 20 percent a year. The rate of increase was higher in East Malaysia, internally as well as externally, because in West Malaysia other modes of transport are available. Regular internal services fly between Kuala Lumpur, Kuching, and Kota Kinabalu and also link the component states of Malaysia. Malaysia-Singapore Airlines, the jointly owned local airline, now operates international services in the Pacific region in addition to its internal operations, using jet and propjet aircraft.

#### ADMINISTRATION AND SOCIAL CONDITIONS

**The structure of government.** Malaysia is a federal constitutional monarchy with a nonpolitical head of

state (the *yang di-pertuan agong*—a title meaning literally “the supreme ruler”—who is elected from among the rulers or sultans of the nine Malay states for a five-year term of office), a legislature composed of two houses, or dewan (the Senate, or Dewan Negara, meaning “National Hall,” and the House of Representatives, or Dewan Ra'ayat, meaning “Hall of the People”), a prime minister and cabinet, an independent judiciary, and a neutral civil service. The federal parliament is the supreme legislative body of the country. It also controls the finances of the government. A bill passed by both houses and sanctioned by the *yang di-pertuan agong* becomes a federal law.

The House of Representatives functions in a similar manner to the British House of Commons. It has a membership of 144, of which 104 are from West Malaysia, 24 from Sarawak, and 16 from Sabah. Members are elected to office from single-member constituencies on the basis of a simple majority. The term of office of a member is five years. The Senate has a membership of 58, of which 32 are appointed by the *yang di-pertuan agong* on the recommendation of the prime minister. The 26 elected members are made up of 2 representatives from each of the legislative assemblies of the 13 component states. Voting in either house is by a simple majority, but amendments to the constitution require a two-thirds majority.

The *yang di-pertuan agong* appoints the prime minister, who must be a citizen in law as well as a member of the House of Representatives. On the advice of the prime minister, the *yang di-pertuan agong* then appoints the other ministers who make up the cabinet. The number of ministers is not fixed, but all must be members of the federal parliament.

The powers of the federal parliament are relatively wide and include the authority to legislate in matters concerned with defense, external affairs, internal security, the administration of justice, and citizenship. The state legislatures of the 13 component states, however, retain responsibility for matters pertaining to Islamic law and for matters pertaining to personal and family laws affecting those of the Islamic faith, as well as for land laws. The constitution also provides that some items may be dealt with either by the federal or by the state legislature.

Each of the 13 states of Malaysia has its own written constitution and its own legislative assembly. Each state also has an executive council collectively responsible to the legislative assembly and headed by a chief minister in Pinang, Melaka, Sarawak, and Sabah and by a *mentri besar* (literally, “chief minister”) in the nine other Malay states. These nine Malay states have hereditary rulers, who are entitled sultans in Johor, Kedah, Kelantan, Pahang, Perak, Selangor, and Terengganu; the raja (king) in Perlis; and the *yang di-pertuan besar* (literally, “the chief ruler”) in Negeri Sembilan. The heads of the other states are appointed to office. They are known as governors in Melaka, Pinang, and Sarawak, while in Sabah the head of state is known as the *yang di-pertuan negara*. The ruler or governor of a state acts on the advice of the state government.

The constitution provides for parliamentary elections, and for elections to state legislatures, to be held at least every five years. General elections were held in May 1969, but balloting was abandoned in East Malaysia after postelection racial riots broke out in Kuala Lumpur. A halt to party politics was ordered by the emergency government (National Operations Council), which then took over the government. Elections were subsequently held in East Malaysia in July 1970. A coalition, the Alliance Government (see Table 2), was then returned to power. With the possible support of the five SUPP (Sarawak United People's Party) representatives, the Alliance Government could command a two-thirds majority in the House of Representatives, which would permit amendments to the constitution.

The constitution of the federation of Malaysia, which is the supreme law of the country, provides that the judicial power of the federation shall be vested in the High Court of West Malaysia and the High Court in East Malaysia and also in subordinate courts. Above the High

Courts is the Federal Court, with jurisdiction to hear and determine appeals from decisions by any High Court. The supreme head of the judiciary is the lord president of the Federal Court.

Each High Court consists of a chief justice and a number of other judges—12 in West Malaysia and 4 in East Malaysia. The High Court has unlimited criminal and civil jurisdiction and may pass any sentence allowed by law. Below the High Court are the subordinate courts, which consist of the Sessions Courts and the Magistrates' Courts. Both these lower courts have criminal and civil jurisdiction—criminal cases coming before one or the other court depending upon the seriousness of the offense and civil cases depending upon the sum involved. In addition, there are religious courts in those Malay states that are established under Islamic law. These courts are governed by state and not federal legislation.

**The armed forces and police.** The Malaysian armed forces have increased in strength and capability since the formation of Malaysia in 1963. After the withdrawal of British military forces from Malaysia and Singapore at the end of 1971, a five-power defence agreement between Malaysia, Singapore, New Zealand, Australia, and Britain was concluded to ensure defence against external aggression. In the early 1970s Malaysia was engaged in internal security operations against guerrilla forces of the Malaysian Communist Party on the West Malaysia–Thai border, as well as against the clandestine Communist organization in Sarawak; the requirement that all young persons register for a national service draft to combat the guerillas was, however, ended in 1972.

The armed forces, consisting of the army, the navy, and the air force, total nearly 48,000 men (1970). The army, which is the most experienced and the largest of the three, consists of 18 infantry battalions, 2 reconnaissance regiments, 1 squadron of scout cars, 2 artillery regiments, and various supporting arms. In addition to some 38,000 men in the regular army, the ground forces also include 23,000 men in the Police Field Force and 45,000 men in the reserves. The Royal Malaysian Navy has a strength of 4,000 men and a complement of 2 frigates, 8 minesweepers, 4 fast patrol boats, and 24 other patrol boats. The emphasis is on speed and manoeuvrability for the purpose of defending the long, indented coastlines and narrow waters of Malaysia against intruders and pirates. The Royal Malaysian Air Force has 3,000 men and 30 combat aircraft (10 Sabre and 20 Tebuan jet aircraft), as well as 27 transport aircraft and a number of helicopters.

The states of Malaysia inherited from their common colonial past an internal security system based on the British model. The police force is well trained and combats not only crime but also subversive activities, including armed Communist insurrection.

**Social conditions.** The education system has been expanded to help to develop skills, to rectify the educational

imbalance between urban and rural areas, and to foster greater national unity. Public expenditure on education increased from about 3 percent to over 6 percent of the national income in the past decade.

**Education.** Governmental policy is to provide nine years of education to any child who desires it. Enrollment in primary schools on the peninsula has increased by almost 40 percent in the past decade. In Sarawak in recent years, the rate of enrollment has increased even more sharply. In Sabah it more than doubled between 1960 and 1967 alone. Considerable progress has also been achieved at the secondary level, although about 90 percent of the total enrollment is in West Malaysia. Institutions of higher learning include three universities—the University of Malaya, the University of Penang, and the National University of Malaysia (Universiti Kebangsaan Malaysia)—as well as the Mari Institute of Technology, the Federal Technical College, the College of Agriculture, and a large number of teacher-training colleges and vocational training centres.

**Health.** The general level of health has improved in the last decade. The country is free from many of the diseases that plague tropical countries, but diseases borne by carriers, such as malaria, are still a problem in rural areas. Health conditions and health facilities vary among the component states, being better in West Malaysia than in the states of Borneo. One indicator of this difference is that the doctor-to-population ratio is one to 4,000 in West Malaysia, one to 9,000 in Sabah, and one to 14,000 in Sarawak. Within each state, health services are better in the towns and cities than in the rural areas. Segments of the rural population continue to rely on traditional rather than modern medicine for treatment. Most of the modern health services are provided by the government. Welfare services are, however, provided by both government and voluntary agencies and include relief programs for the needy, the aged, and the handicapped.

**Housing.** The multicultural character of the population of Malaysia is visibly reflected in the great variety of types of houses to be seen, which range from the longhouses and stilt houses of the rural peoples to examples of modern architecture in the cities. There is an abundance of forest-derived building material in the rural areas, so that no statistically measurable housing problem is evident, even though some of the dwellings in the more remote areas are often only temporary shelters. In the larger towns and cities, however, slums are common. A governmental housing authority was to be established to plan the rehousing of slum dwellers.

**Wages and cost of living.** As large numbers of people, especially in Sarawak and Sabah, live by hunting, gathering, fishing, and simple agriculture, wage earners form only part of the total economically active population. Because of the increasing pressure of population on the land, however, there is a growing tendency for the male labour force to seek wage employment. A major problem is, nevertheless, the shortage of skilled labour, even though high wages are offered for such labour in industrial occupations. Wages in tin mines are higher than those on the plantations. Average monthly earnings of an unskilled labourer in a tin mine may be two to three times more than the earnings of a weeder on a rubber, oil palm, coconut, or tea plantation.

The value of real wages is difficult to estimate in the absence of indexes showing the relationship between wages and cost of living. In West Malaysia, wages appeared to have risen steadily in the 1960s, especially in the tin mines and on the plantations, and to have outpaced rises in the cost of living. The cost-of-living index, for example, only rose from 100 in the base year 1963 to 110 in 1972.

#### CULTURAL LIFE AND INSTITUTIONS

Malaysia, with its complexity of peoples and cultures, is a melting pot of several important cultural traditions, stemming from the Malay Archipelago as well as from China, India, the Middle East, and the West. Malay culture and Bornean culture are indigenous to the area. In the first one and a half millennia AD, indigenous Malay culture in the Malay Peninsula and in other parts of Southeast Asia

was strongly marked by pre-Islāmic Indian and early Islāmic influences. Indian contact with the Malay Peninsula extended over a period from about the 4th century AD to the late 14th century, exerting a profound influence upon religion (through Hinduism and Buddhism), art, and literature. Islām, introduced to Malacca (now Melaka) in the 15th century, soon became the dominant religion of the Malays. The introduction of Western cultural influences in the 19th century affected many aspects of Malay life, especially in technology, law, social organization, and economics.

Contemporary Malay culture is thus multifaceted, consisting of many strands—animistic, early Hindu, early and modern Islāmic, and, especially in the cities, Western. The collective pattern thus established is distinct from other cultures and recognizably Malay.

Unlike the early Chinese traders who settled in Malacca and Penang and were partially assimilated (at least to the extent of adopting the Malay language), the Chinese who emigrated to the Malay Peninsula in the late 19th and early 20th centuries in large numbers were usually transients who established self-contained communities. Chinese cultural influence has consequently been minimal. The Chinese immigrants themselves, moreover, did not form a homogeneous group. Their culture in Malaysia today has its roots in the culture and civilization of prerevolutionary China, with modifications brought about by local circumstances and environment.

The Indians are either immigrants or descendants of immigrants, most of whom originally came as labourers to work in the coffee and rubber plantations. Like the Chinese, they too, until World War II, were mainly transients, living in closed communities and remaining virtually unassimilated.

The communities of Malaysia have all been affected by past British colonial rule and present Western modernizing influences. Western cultural influence has been greatest in education and institutional forms. Traditions and cultural institutions have been least affected in the rural areas—in eastern West Malaysia and in the interior of East Malaysia—while the cities have been the focus of the most rapid cultural changes.

Art forms Within Malaysian societies, external cultural influences have made the least impact in music, dancing, literature, and the decorative arts. In East Malaysia, the indigenous cultural background includes no written history or literature; architecture is little developed; and the principal art forms are dancing and handicrafts, represented notably by the textiles handwoven by the Punan tribe, cloth made by the Bajau people, patterned rattan mats and basketwork, and wood carvings. Particularly on the peninsula, the artistic manifestations of Malay culture are mainly in literature, music, dancing, and the decorative arts. Painting and sculpture are poorly developed, primarily because Islām does not encourage the representation of the human form. Distinctive and colourful examples of the Malay decorative arts include batik cloth (cloth hand dyed by using a special technique), silverware, the hand-made *kris* (a short sword or heavy dagger with a wavy blade), wood carving, and basketwork. Malaysian Chinese culture is derived from Chinese civilization and is represented by literature, drama, music, painting, and architecture. In recent years some Malaysian artists, of Malay, Chinese, and Indian origin, have also begun to produce new art forms, especially in painting and architecture, that represent a new synthesis that is distinctively Malaysian in character.

**Press and broadcasting.** The cultural diversity of Malaysia is illustrated by the fact that newspapers, 48 (in 1969) in number, are published in 6 languages—Malay, Chinese, English, Tamil, Punjabi, and Kadazan—while Radio Malaysia broadcasts in 16 languages and dialects. The newspapers are all privately owned and vary greatly in circulation, quality of reporting, and news coverage. Among the educated groups, the press is the principal source of information. In remote rural areas, especially among illiterate groups, the radio is relied upon. Television is, however, the most popular medium among all language groups.

#### PROSPECTS FOR THE FUTURE

Malaysia is a federation of disparate ethnic, economic, and political components. The federation has faced difficulties and problems from the moment of its inception in 1963. The most intractable of these problems—the strained relations between West Malaysia and Singapore—was solved by a political separation. Other problems, however, no less serious, remain. Racial riots of May 1969, between the Malays and the Chinese, which led to the suspension of parliamentary rule for 21 months, were an indication of the underlying tension stemming from ethnic imbalances. Other imbalances exist—between West and East Malaysia, between urban and rural areas, and between the modern and traditional. The fact that East Malaysia takes less than 5 percent of West Malaysia's exports and supplies only 0.5 percent of its imports indicates the need for closer economic integration between the component states. Malaysia also faces the threat of armed Communism on the Thai and Sarawak borders. Within the country itself, however, the fundamental problem remains that of correcting ethnic disparities in income while fostering the growth of a Malaysian consciousness and sense of identity among the people.

(O.J.B.)

#### Malformation, Biological

The processes of development are regulated in such a way that few malformed organisms are found. Those that do appear may, when properly studied, shed light on normal development. The science of teratology—a branch of morphology or embryology—is concerned with the study of these structural deviations from the normal, whether in animals or plants.

In general, abnormalities can be traced to deviations from the normal course of development, often in very early embryonic stages. Such deviations may be caused by abnormal (mutant) genes, by environmental conditions, by infection, by drugs, and, perhaps most frequently, by interactions between these sets of causes. A general interpretation has been that one factor in many cases is re-

duction of the rate of development, the kind and degree of deformity depending upon the stage at which the retardation occurs. This interpretation is supported by the results of descriptive studies of anomalies, and especially by evidence from experimental teratology.

#### ANIMAL MALFORMATIONS

Among the newborn young and embryos of man and most other species of animals are found occasional individuals who are malformed in whole or in part. The most grossly abnormal of these have been referred to from ancient times as monsters, probably because the birth of one was thought to signify something monstrous or portentous; the less severely malformed are usually known as abnormalities or anomalies.

The origin of malformations

Monsters have been regarded by primitive peoples as of supernatural origin. The birth of a malformed individual was often attributed, before the rise of modern science, to intercourse between human beings and devils or animals. The mythical beings that appear in the folklore of many peoples—races of dwarfs and giants, of sirens, mermaids, and men with a single median eye (cyclops) or leg (skia-pods)—were probably suggested by observations of malformed humans. Giants and dwarfs were often classed as monsters, probably because of the prominent places they occupied in mythology.

The objective study of malformations began with the English physiologist William Harvey (1651), who correctly attributed them to deviations from the normal course of embryonic development. Systematic scientific study, however, had to await the pioneer work of the French anatomists Étienne and Isidore Geoffroy Saint-Hilaire. Their *Traité de Teratologie* (1836), which laid the basis for the science of teratology, still remains a valuable source of information. Recent improvements in understanding have come from the application of experimental analytical methods and from increased knowledge of the mechanisms of inheritance—*e.g.*, from genetics.

In man certain gross defects in babies at birth have been shown to be associated with effects acting through the mother in early pregnancy: gross defects of eyes and ears caused by infection of the mother with rubella (German measles); and microcephalic idiocy with diagnostic use of X-rays on the mother. The latter observations have been confirmed by animal experimentation. It has been established that higher rates of congenital malformations occur in areas of higher natural radioactivity. The effect may be induced by fallout from atomic explosions.

The teratogenic action of many drugs has been tragically dramatized. The appearance of an alarming number of deformed, basically limbless infants, especially in Germany, in the late 1950s and early 1960s, was traced to the ingestion by pregnant women of the sedative thalidomide (known under many trade names). This drug adversely influences the developing fetus; it appears to interfere with development only in the first seven weeks of pregnancy. Hallucinogenic drugs, such as LSD, (lysergic acid diethylamide) are suspected of damaging chromosomes and their use could result in defective offspring.

According to form, two main classes of malformations may be recognized: those with defective or excessive growth in a single body, and those with partial or complete doubling of the body on one of its axes.

**Repetition or deficiency of parts.** *Somatic characters.* Repetition or deficiency of single parts, such as fingers or toes (polydactyly, hypodactyly, brachydactyly), is a frequent anomaly in man and other mammals. In many analyzed cases it has been shown to result from the inheritance of an abnormal gene that produces a localized disturbance of a growth process in the embryo. In the rabbit a recessive gene for brachydactyly (short digits) causes a localized breakdown of circulation in the developing limb bud of the embryo, followed by necrosis (tissue death) and healing.

Absence or abnormality of whole limbs is less common and includes, besides clubfoot, the so-called congenital amputations once thought to be caused by the strangulation of a limb by a fold of embryonic membrane (amnion). It is probable that internal abnormalities of the

bone are more frequent causes of such amputations than are strangulations. Cases are recorded of human identical twins in which both members have the same type of limb abnormality, suggesting a hereditary predisposition to this type of malformation. Besides malformed individuals with rudimentary limbs (phocomelus; having "seal-like limbs"), others have incomplete or underdeveloped extremities (hemimelus, micromelus, ectromelus).

A rare type of malformation, but one that has always attracted special interest, occurs when the lower extremities are more or less united, as in the mythical figures of sirens or mermaids. Such sirenoid individuals may have a single foot (uromelus), or limbs fused throughout their length with no separate feet (sirenomelus or symmelus).

Absence of the brain at birth (anencephaly); an abnormally small brain and head (microcephaly); and enlargement of the brain and head, sometimes to prodigious dimensions due to dilation of the ventricles by fluid (hydrocephaly), are frequent congenital defects in man. In some cases they have been traced to defective genes, although they may also arise from accidental or traumatic processes during embryonic development. Occasionally, malformed persons are found in which a part of the brain protrudes through the cranium as an encephalocele. An extreme variant of this type is pseudencephaly, in which the whole brain is everted and rests upon the top of the cranium like a wig.

Defects of the brain and head of man

Cyclopic malformations with a single median eye occur rarely in man and other animals. More frequent anomalies are anophthalmia (absence of eyes) and microphthalmia (abnormally small eyes), both occasionally the result of abnormal heredity. Defective closure of lines of junction in the embryo produces malformations such as cleft palate, in which the ventral laminae of the palate have failed to fuse, and harelip, in which the median nasal and maxillary processes fail to unite. A frequent abnormality in human infants is spina bifida, in which the spine fails to close over and a gap is left in the vertebral column. These conditions are inherited, albeit somewhat irregularly, in man.

*Sexual anomalies.* In man and other vertebrates, male and female individuals usually have distinctive characters in addition to the primary one of producing either sperm or eggs. Individuals with both male and female functions are known as hermaphrodites. While this is the normal condition in some lower animals and in many flowering plants, it is so rare in mammals as to be regarded as anomalous. Individuals with mixtures of male and female characters (usually sterile) are known as intersexes. In man there occur two rare conditions that, according to recent evidence, represent partial sex reversal. Individuals with Klinefelter's syndrome are apparent males who produce no sperm. Many cases have been shown to have two X-chromosomes (the usual state determining femaleness) with an additional Y-chromosome (which carries genetic factors for maleness). Individuals with Turner's syndrome are apparent females without functional ovaries. The cases analyzed have only one X-chromosome (like the normal male with one X- and one Y-chromosome). These anomalies are clearly caused by disturbances in the mechanism for sex determination.

*Complex syndromes.* A remarkable feature of malformations in vertebrates including man is the association of multiple abnormalities in complex syndromes. Thus, in man harelip, spina bifida, hydrocephalus, and polydactyly may be found in the same individual; acrocephalosyndactyly (an egg- or dome-shaped skull and partial or complete fusion of digits in both hands and feet) often occurs with harelip, contractures, spina bifida, and mental abnormalities.

In man, individuals afflicted with mongolism, also known as Down's syndrome, have facial and bodily characters that permit diagnosis at or even before birth. Mongols have 47 instead of the normal 46 chromosomes. The extra chromosome is apparently responsible for the abnormal condition.

**Doubling of parts.** Individuals partially or wholly double, but joined together, are represented by the rare occurrence in man of Siamese twins, so-called from a

Siamese  
twins

famous Siamese pair exhibited for many years in the 19th century. The condition consists of identical twins joined by a bridge of tissue through which the circulatory systems communicate. Such twins probably arise by the incomplete separation of a single fertilized egg into two parts; the experimental production of such double individuals in newts has been accomplished by constricting the egg in the two-cell stage.

In man, partially double symmetrical malformations are found. They vary from those with a single head but with neck, trunk, and limbs doubled, through those with two heads and a single trunk, to others with head, shoulders, and arms doubled, but with one trunk and one pair of legs. Such double malformations probably arise following the less complete separation of the halves of the early embryo or partial separation at later stages. A rare type is one in which there is a Janus head, two faces on a single head and body. Janus malformations have been produced experimentally in amphibian embryos by a variety of treatments in early stages. A group of cases in which the hinder end of the body was doubled from the sacrum back has been found in one strain of mice and appears to be due to abnormal heredity. Doubling of whole limbs in amphibia has been produced experimentally by injuring the limb rudiment at an early, sensitive stage. (L.C.D.)

#### PLANT MALFORMATIONS

Monstrosities, freaks, and other malformations have interested botanists for many years. There are numerous categories of such growth abnormalities in plants, and these are often related only loosely or not at all to one another.

**Exaggerated growth.** Sometimes divergence from the normal represents merely a quantitative change, which is evidenced by a harmonious but exaggerated manifestation of the normal developmental processes. This is well illustrated in the so-called *bakanae*, or foolish seedling disease, of rice. The *bakanae* disease is caused by the fungus *Gibberella fujikuroi*. Diseased plants are often conspicuous in a field because of their extreme height and pale, spindly appearance. This exaggerated growth response was found to be due to specific substances, known as gibberellins, which were produced by the fungus. Evidence is now available to indicate that gibberellins, also produced by higher plant species, participate directly as an essential growth-regulating system in all higher plant species. The gibberellins of either fungal or higher plant origin stimulate the normal development of certain genetic dwarfs of maize and peas, which cannot themselves produce the gibberellins in amounts sufficient for their normal development.

A common deformity of tobacco, called frenching, occurs in most tobacco-growing regions of the world. The advanced state of this condition is characterized by a cessation of terminal bud and stem growth. When dominance of the stem tips is lost, the buds in the axils of the leaves develop, and unusually large numbers of leaves (as many as 300) appear on a plant. The leaves are characteristically sword- or string-shaped because of the failure of the leaf blades to develop. Such plants have the appearance of a rosette. Although the cause of frenching has not yet been unequivocally established, it is thought to be due to a toxic substance produced by the nonpathogenic soil bacterium *Bacillus cereus*.

**Alteration of floral parts.** Under the stimulus of pathogenic organisms of the most diverse kinds, the sepals, petals, stamens, or pistils of a flower may be transformed into structures that are very different in appearance from those found normally. Certain viruses can cause enlargement of the leaflike flower parts (sepals) surrounding the base of a blossom in plants of the nightshade family. The tomato big-bud virus appears to affect the sepals of the tomato flower rather specifically. These structures enlarge greatly under the influence of the virus and fuse to form huge bladderlike structures that may be ten times or more the normal size. In the Madagascar periwinkle (*Vinca rosea*), however, viruses of this type bring about a green coloring in the petals, stamens, and styles; nor-

mally the petals are pink and the stamens and styles whitish: There is in this instance a retrograde development of floral parts into foliage leaves. (Findings such as these are of interest to the morphologist because they support the contention that the flower should be regarded as a modified leafy branch.)

**Translocation of organs.** Plant organs may arise in unusual places as a result of the infection by certain types of pathogenic agents. The carrot-yellows virus, for example, stimulates production of aerial tubers in the axils of the leaves of potato plants. Large numbers of adventitious roots (arising in abnormal places) appear on the stems of tomato plants infected with the bacteria *Pseudomonas solanacearum* and *Agrobacterium tumefaciens* as well as the *Fusarium* wilt fungus and the cranberry false-blossom virus.

An extreme example of adventitious shoot formation is found in *Begonia phyllomaniaca* after shock. In this instance, small plantlets develop spontaneously in incredible numbers from the superficial cell layers of the leaf blades, petioles, and stems. The adventitious shoots do not arise from preformed buds but develop from cells at the base of hairs and especially from certain glands present in great numbers in young stems and leaves of this species. Although these plantlets develop a vascular system of their own, the vast majority never succeed in connecting that system with the vascular system of the host. They must therefore be regarded not as branches but rather as independent organisms.

**Witches'-brooms.** Witches'-brooms, or hexenbesens, are closely grouped, many-branched structures commonly found on a number of species of trees and shrubs and caused by certain fungi. Witches'-brooms live a more or less independent existence, despite the fact that they are derived from the tissues of the host. In accordance with their independence, the witches'-brooms tend to break away from the normal correlations of the parent plant. Instead of branching out horizontally, the brooms stand as more or less erect clusters of branches. Witches'-brooms do not as a rule flower, and the vegetative buds may open several weeks earlier in the spring than do those present on healthy branches, indicating further the independence of these structures from normal controls.

Similar structures occur in certain plant species after virus infection. These appear to result from the excessive stimulation and development of secondary shoots. The witches'-broom virus in potato, for example, causes the infected plant to produce numerous buds on the above-ground stems of potato plants. Long, slender stolons resembling aerial roots that are covered with hairs develop from these adventitious buds.

**Fasciation.** This condition is best placed in that category of teratological abnormalities known as monstrosities. Fasciation is a term that has been used to describe a series of abnormal growth phenomena resulting from many different causes, all of which result in flattening of the main axis of the plant. Although a ribbonlike expansion of the stem is often the most striking feature of this condition, all parts of the plant may be affected. As fasciation develops, the growing point of the plant becomes broader; the unregulated tissue growth results in significant increases in the weight and volume of the plant. The apical growing point becomes linear and comblike in some instances or develops numerous growing points, producing a witches'-broom effect. In still other instances, the growing points may be coiled and resemble a ram's horn, or they may be fused and highly distorted into a grotesque tangle of coils. Fasciations found in plants such as the common cockscomb (*Celosia argentea cristata*) and in cacti are highly prized by gardeners.

There seems little doubt that nutritional changes due to disturbances in the growth-hormone relationships in a plant play an important role in fasciation. It has been suggested that maldistribution of growth hormones in the plant is also a cause of these abnormalities. (A.C.Br.)

## Mali

The Republic of Mali (in French, the République du Mali) is a landlocked state in central West Africa. Bounded north by Algeria, west by Mauritania and Senegal, south by Guinea and the Ivory Coast, and east by Upper Volta and Niger, it covers an area of 479,000 square miles (1,240,000 square kilometres). Mali's sparsely distributed population was about 5,000,000 in the early 1970s. Bamako is the national capital. As a part of French West Africa from 1898 to its independence in 1960, it was known as the French Sudan. Its current name, taken at the time of independence, is derived from the Mali Empire of the Upper and Middle Niger and ruled by the Mandingo (Malinke) from the 13th to the 16th century.

Mali is basically an agricultural country. Although its development has been hindered by the nature of the Sahara, which occupies about half its territory, the country nevertheless benefits from the advantages conferred by the waters of the Niger and Sénégal rivers and their tributaries: almost all of the population lives in the southern river basins, where diverse crops are cultivated. Most agricultural activity, however, is at the subsistence level, and the few cash crops grown are subject to the fluctuations of the world market. Industrial development is minimal and is largely confined to food processing. Despite its poverty, the country has long functioned as a crossroads between North and West Africa and has developed a rich cultural tradition. (For history, see WEST AFRICA, HISTORY OF. For related physical features see NIGER RIVER; SENEGAL RIVER; and SAHARA.)

### THE LANDSCAPE

**The natural environment.** *Relief.* Mali's landscape is largely flat and monotonous. Two basic relief features can be distinguished—plateaus and plains. The highland regions are localized and discontinuous.

The plateaus of the south and southwest (extensions of the Fouta Djallon highlands of Guinea and the Guinea Highlands of Guinea and the Ivory Coast) lie between about 1,000 and 1,600 feet above sea level but attain heights approaching 2,000 feet in the Mandingue Plateau near Bamako and more than 2,100 feet at Satadouougou. Composed mainly of sandstone, the plateaus are deeply incised by the Sénégal and Niger rivers and their tributaries. The plateau edges often take the form of precipitous cliffs, and their surfaces are cut by deep river valleys and waterfalls.

The plateaus of the southeast and east, also extensions of the Guinea Highlands, are a series of small, broken hills. Altitudes in the southeast range between almost 1,000 feet in the region of Sikasso and 1,739 feet (530 metres) at Mt. Mina. East of the Niger River the Dogon Plateau descends gently westward to the river valley but ends in abrupt cliffs on the southeast. These cliffs reach an altitude approaching 3,300 feet at Bandiagara.

The only marked relief feature in the north is the Adrar des Iforas. An extension of the mountainous Hoggar re-

gion of the Sahara, this heavily eroded sandstone plateau rises to altitudes of between 1,300 and 1,600 feet.

Northern and central Mali are composed of the plains of the Niger River basin and of the Sahara. In the north are the vast plains of the Tanezrouft and Taoudenni, which are covered with sand dunes and with areas of shifting sand known as ergs. In the central region are the alluvial plains of Meriyé and Azaouak.

*Drainage.* The drainage system is composed of the Sénégal and Niger rivers and their tributaries. The Sénégal River flows in a northwesterly direction across Mali for 560 miles on its course to the Atlantic Ocean. Its main headwaters—the Bafing and the Bakoye (Bakhoy) rivers—rise in the Fouta Djallon and join at Bafoulabé to form the Sénégal. The river then flows to the west across the plateau region, where it is broken by falls at Gouina and Férou. Between Kayes and the Senegalese border it receives the Kolimbiné and Karakoro rivers on the right and the Falémé—its major tributary—on the left. A tropical river, the Sénégal experiences seasonal flow. The waters are low in April and May and are high between July and October. Floods occur during the first two months of the high-water period.

For 1,010 miles, nearly one-third of its total length, the Niger River flows through Mali. Rising in the Fouta Djallon, the river is of significant size by the time it enters Mali near Banankoro. It flows to the northeast across the Mandingue Plateau, where it is broken by falls at Sotuba. Reaching Koulikoro, it spreads out in a wide valley and flows majestically to its confluence with the Banifing River at Mopti. The Niger then forms an interior delta because the land is flat and the river's descent almost nonexistent. The river breaks down into a network of branches and lakes as it continues northward. The lakes include those of Débo, Fati, Télé, and Faguibine. At Bourèrè the Niger makes a great bend to the south, known as the Niger Bend, and flows past Gao and Ansongo to the Niger border at Labbezanga.

The Niger also flows intermittently. High waters occur on the Upper Niger from July to October, at the delta from September to November, and at the bend from December to January. Periodic floods and the rich alluvial soils in the central delta make the Niger Valley an important agricultural region.

*Soils.* The soils are generally poor. In the south, ferruginous (iron-bearing) soils are shallow and form a hard, red crust because of intense evaporation. Along the southern edge of the Sahara, the brown and reddish soils are only slightly transformed into crust because of the lack of water and chemical decomposition. The desert region is composed of sand, rock, and gravel.

*Climate.* Mali lies within the intertropical zone and has a hot, dry climate. The sun is at its zenith throughout most of the year. In general, there are two distinct seasons, the dry and the wet. The dry season, from November to June, is marked by low humidity and high temperatures and is influenced by the *alize* and harmattan winds. The *alize*, from the northeast from December to February, causes a relatively cold spell, with temperatures averaging 77° F (25° C). From March to June, the dry, hot harmattan blows from the east and sweeps the overheated soil into dusty whirlwinds. The wind causes temperatures between 104° and 113° F.

During the rainy season from June to October, the monsoon wind blows from the southwest. Preceded by large, black clouds, the tornado-like rainstorms are accompanied by lightning and thunder. Temperatures lessen somewhat in August, when most of the rainfall occurs.

The country can be divided into three climatic zones—the Sudanic, the Sahelian, and the desert zones. Sudanic climate occurs in almost one-third of the country, from the southern border to latitude 15° north. It is characterized by an annual rainfall of between 20 and 51 inches and average temperatures of between 75° and 86° F (24° and 30° C). The Sahel, or the area bordering on the Sahara, receives between eight and 20 inches of rain a year and has average temperatures between 73° and 97° F (23° and 36° C). In the Sahara, temperatures during the day range from 117° to 140° F (47° to 60° C), while

The Niger River

The plateaus and the plains

Climatic zones

at night the temperature drops to between 39° to 41° F (4° to 5° C). The scanty annual rainfall of less than seven inches is rare and irregular, and some years are rainless.

**Vegetation and animal life.** There are two main vegetational zones that correspond to the climatic regions of the Sudan and the Sahel. In the Sudanic zone there are localized forest corridors along the Guinean border and the river valleys. The rest of the area is covered with savanna (open grassland and scattered trees). The trees include the nere, or twoball nitta tree (*Parkia biglobosa*), the karite (*Butyrospermum parkii*), the cailcedra (Senegal khaya; *Khaya senegalensis*), and the kapioka. The incidence of trees decreases to the north as the Sudanic zone merges with the Sahel. The Sahel is characterized by steppe vegetation; drought-resistant trees such as the baobab, the doum palm, and palmyra are found. These trees also disappear to the north, however, where short, thorny plants such as the mimosa, the acacia, and cram-cram (a member of the grass family) occur. All vegetation gradually disappears as one enters the Sahara region.

The animal life of the Sudan and of the Sahel is rich and varied. Large, herbivorous mammals include the gazelle, the antelope, the giraffe, and the elephant. The main carnivores are lions, panthers, and hyenas. Crocodiles and hippopotamuses inhabit the rivers, and there is a wide variety of monkeys, snakes, and birds (including the ostrich). There is a national park along the Baoulé River in the west and an animal reserve between Ansongo and Ménako in the east.

**Traditional regions.** Mali is traditionally divided into the nomadic region of the Sahel and the Sahara and the agricultural region of the Sudanic zone.

**The landscape under human settlement.** About 90 percent of the population is rural. The rural population lives in thatched dwellings grouped together in villages of between 150 and 600 inhabitants. The villages are surrounded by cultivated fields and grazing lands. The older towns, such as Djénné, Tombouctou (Timbuktu), Gao, and Ségou, are built in the characteristic Sudanese style of architecture. The newer towns, such as Bamako, Kayes, San, and Kati, consist of a central business district, around which African residential districts are grouped. The houses are built of a mixture of earth and cement.

#### PEOPLE AND POPULATION

**Population groups.** *Ethnic groups.* What is known as the "white" population includes nomadic groups of Berbers (including the important Berber subgroup of the Tuareg [Touareg]) and the Arab-Berber group known as the Moors. These groups live in the Sahelian zone and north of the Niger Bend.

The black population is composed of numerous agricultural groups, some of whom are descended from the peoples of the ancient empires of Ghana, Mali, and Songhai. The largest group are the Bambara, who number about 1,200,000 and live along the Upper Niger River. The Soninke, or Sarakole, number about 350,000; they are descended from the founders of the Ghana Empire and live in the western Sahelian zone. The 250,000 Malinke (Mandingo), bearers of the heritage of the Mali Empire, live in the southwest, while the 250,000 Songhai are settled in the Niger Valley from Djénné to Ansongo. The Dogon, who number about 180,000, live in the plateau region around Bandiagara. The Voltaic group includes the Bwa, or Bobo (70,000), the Senoufo, (about 180,000), and the Minianka (about 160,000). They occupy the east and southeast.

The Fulani, or Peul (numbering about 400,000), are nomadic pastoralists of the Sahel and Macina. Other ethnic groups of note include the Tukulors (Toucouleurs), the Kasonke (70,000), the Bozo (85,000), and the Somono.

**Linguistic groups.** French is the official national language. There are several indigenous languages and dialects, which roughly correspond to either ethnic groups or regions. The most important is the Mande group, which includes Bambara (spoken by 60 percent of the population), Malinke, Kasonke, and Wasulunka (Ouassoulou).

Soninke and Dogon are also related to Bambara; Dogon includes many dialects. The related but autonomous languages of the Voltaic peoples are Bwa, Senoufo, and Minianka. The Fulani and Tukulor speak Fulah (Peul), and Songhaic is spoken all along the Niger Bend. The Tuareg have retained their ancient Berber language and written script, *tifinagh*, which is related to that of ancient Libya. The Moors speak Arabic.

**Religious groups.** There are three main religions. Islam is practiced by 65 percent of the population, animism, by about 30 percent, and Christianity, by 2 percent. Islamization dates back to the 11th century and has eclipsed traditional animism among the Soninke, Songhai, Tukulor, Moors, Tuareg, and Fulani. Animism continues as the religion of the Voltaic peoples, the Malinke, and the Bambara.

**Demography.** *General distribution.* In 1969 Mali had an estimated population of 4,929,000. Because half of the country consists of uninhabited desert, the estimated average population density of ten persons per square mile is misleading. Densities ranged between 39 and 65 persons per square mile in the Niger Valley. In the less populated areas of the west and east, densities ranged from 23 persons per square mile at Niore to ten persons at Gao and three persons at Tombouctou.

†Estimate based on results of a sample survey; probably including an allowance of 209,000 for nomad population and about 33,000 for persons in the zone controlled by Niger Office, not covered by survey.  
Source: Official government figures; UN.

Only 10 percent of the population lived in urban areas in 1969. Bamako, with a population of 189,000, was the largest town. Other towns with populations of more than 20,000 were Mopti (34,000), Ségou (32,000), Kayes (30,000), and Sikasso (23,000).

In 1969 there were 15,000 more women than men. Almost 3,000,000 people, or 60 percent of the population, were less than 20 years of age; only about 3 percent of the Malians were over 60.

**Birth rates and death rates.** In 1969 the annual birth rate stood at 60 per 1,000 persons and the death rate at 30 per 1,000. These figures represented an annual growth of 30 per 1,000, a rate which would double the population in 20 years. The infant mortality rate, although reduced by improved medical and sanitary facilities, was almost 250 per 1,000.

**Migration patterns.** There is a constant movement of young people from the countryside to the towns, especially to Bamako. Some of the migrants return home for the planting season (May to November), but most remain in the urban areas. Employment opportunities are limited, and most of the migrants live on the income of friends and relatives.

Some Malian workers, especially members of the Soninke group, emigrate to France and other western European countries. Malian traders are found in the Ivory Coast, Liberia, and central Africa. There are also "colonies" of Malians in the Ivory Coast and Senegal whose members have adopted the nationality of their host country. The previous immigration into Mali of merchants from Libya, Syria, and Morocco has almost ceased.

#### THE NATIONAL ECONOMY

**The extent and distribution of resources.** *Mineral resources.* Iron is the most widespread mineral resource.

Found almost everywhere, its reserves are estimated at 1,000,000,000 tons. Bauxite deposits of about 800,000,000 tons are located near Kayes and on the Mandingue Plateau. There are approximately 3,500,000 tons of manganese, and the phosphate deposits in the Ansongo region are estimated at 20,000,000 tons.

There are important deposits of gold near Bambouk, on the Mandingue Plateau, and in the Adrar des Iforas. Lithium (a soft, silver-white, metallic element, the lightest of all metals) has been discovered near Kayes and Bougouni, and there are uranium deposits in the Adrar. There are also traces of tungsten, tin, lead, copper, and zinc, as well as deposits of salt, marble, kaolin (china clay), and limestone.

**Biological resources.** Vegetation resources are limited and are not conducive to forestry activities. The fish of the country's rivers and lakes, however, form the basis of a growing fishing and fish-processing industry. Wild animals are not economically significant.

**Power resources.** There are extensive possibilities for the production of hydroelectric power on the Sénégal and Niger rivers, as well as on some of their tributaries.

**Sources of national income.** *Agriculture and fishing.* Subsistence and commercial agriculture are the bases of the Malian economy. More than 90 percent of the working population are engaged in subsistence agriculture, and the government supports the development of commercial products. Areas of cultivation are located in the Sudanese and Sahelian zones; the most important agricultural area is the inland Niger Delta. Crops such as millet, rice, wheat, and maize, as well as potatoes, yams, and cassava, are the main subsistence crops. Cotton and peanuts (groundnuts) are the important commercial crops; sugarcane, tobacco, and tea are also grown for market. Market gardens produce a variety of vegetables and fruits, including cabbages, turnips, carrots, beans, tomatoes, bananas, mangoes, and oranges.

The major areas for the raising of livestock are the Sahel and the area around Macina. There are more than 5,000,000 head of cattle and about 12,000,000 sheep and goats in the country.

Mali is the third largest producer of fish in West Africa after Morocco and Senegal, with about 29,000 fishermen producing an annual catch of about 100,000 tons. After processing (drying and smoking), about 20 percent of the annual catch is exported.

**Mining and quarrying.** Although mineral resources are extensive, the mining industry is minimal. The only exploited deposits are those of salt (at Taoudenni), marble and kaolin (at Bafoulabé), and limestone (at Diamou).

**Manufacturing.** Most industrial enterprises engage in the processing of food products. There are several rice mills, flour mills, and cotton gins. The oil and soap factory of Koulikoro satisfies domestic demands for its products. There are breweries, a tannery, and a refrigerated slaughterhouse at Bamako; fruit-preservation plants at Baguinéda; a sugar refinery at Dougabougou; and cigarette and match factories at Djoliba.

The Malian Company of Textiles (Comatex) produces cotton fibre and unprinted cloth, while the Textile Industry of Mali (Itema) manufactures printed cloth and blankets. A cement factory at Diamou is a basic industry. There are also shops for the construction of autocycles, the repair of machinery, and the assembly of radios.

Handicrafts are important, and the Malians are noted for their clothing, pottery, shoes, baskets, and wood carvings.

**Energy.** Electricity is largely produced in thermal-power stations. There are eight thermal stations, located in Bamako and other large towns. Hydroelectric power is produced at the Sotuba and Markala dams on the Niger River and at the Felou Dam on the Sénégal River. These thermal and hydroelectric stations produced about 40,000,000 kilowatt-hours of electricity in 1970. The construction of dams at Gouina on the Sénégal and at Sélingué on the Sankarani is planned. The possibility of producing solar energy is also under investigation.

**Financial services.** The Central Bank of Mali, managed equally by Mali and France, controls the nation's

credit and the exchange rate between the Mali franc (the monetary unit of the country) and the French franc. The Development Bank of Mali finances development projects, while the Malian Bank of Credit and Deposits and the French-owned West African International Bank carry out credit and depository functions. Several French insurance companies maintain offices in Bamako.

**Foreign trade.** The most important export items are cotton, peanuts, live animals, and dried and smoked fish. Mali's major customers include the Ivory Coast, Senegal, and France. Imports consist largely of textiles, sugar, automobiles, iron and steel, and petroleum. The major sources of imports are France, the Soviet Union, the Ivory Coast, China, and Senegal. Foreign trade is entirely controlled by the Malian Society of Import and Export (Somix) and operates at a deficit. Mali is a member of the Organisation pour la Mise en Valeur du Fleuve Sénégal (Organization for the Development of the Sénégal River), which also includes Senegal and Mauritania. Despite strict customs controls, smuggling—especially of cattle and fish—is considerable.

**Management of the economy.** *The public and private sectors.* At the time of independence in 1960, the government adopted a policy of Socialism. State companies and rural cooperative societies were organized to regulate both the production and the distribution of goods. Since the military coup d'état in 1968, Socialist policy has been mitigated by the encouragement of private business.

**Taxation and foreign aid.** Direct taxes include an income tax on salaries and a uniform per capita tax on those individuals who do not participate in the money economy. Most of the government's revenue is derived from indirect taxes, such as customs duties and commercial taxes.

Bilateral external aid is provided largely by China, the Soviet Union, and France. International aid is granted by such organizations as the United Nations, the FED (Fonds Européen de Développement, or European Development Fund), and the United Nations Development Programme (UNDP).

**Trade unions.** Trade unions were abolished by the military government in 1970.

**Contemporary economic policies.** Economic development is centred upon increased agricultural production and the creation of small industrial firms for the processing of agricultural products. Since 1967, when Mali rejoined the French franc zone, French businesses and advisers have become increasingly active. Private commerce is encouraged, and domestic investments in social services have been reduced.

**Problems and prospects.** The main economic problem is posed by a growing national debt. Imports continue to outdistance exports, while the export of agricultural products is dependent upon fluctuating world prices. There is a need to reduce reliance upon foreign aid and to make the internal civil administration more effective.

**Transportation.** Mali's transportation systems are concentrated in the Sudanic and Sahelian regions. Because Mali is landlocked, its major transport routes connect with those of neighbouring countries and their ports to provide it with outlets to the sea.

**Roads.** In 1971 there were about 7,500 miles of roads of which almost 5,000 were all-weather roads, and over 700 miles were paved. There are two main axes of paved roads radiating from Bamako. The road from Bamako to Bougouni and Sikasso connects with the Ivory Coast road running to the port of Abidjan. The second main road runs through Bamako, Ségou, San, Mopti, Gao, and Ansongo to the border with Niger.

**Railways.** The one railroad track runs for 400 miles from Koulikoro, a short distance northeast of Bamako, northwestward to Diboli, on the Senegal border, where it connects with the Senegalese railway to Dakar. Another railway line is planned to link Bamako with the Guinean railway, which runs to Conakry.

**River transport.** The Sénégal River is navigable from July to October from Kayes in the west of the country down to Saint-Louis, Senegal, at the river's mouth. The Niger River is navigable throughout its length in Mali

Mali's

Socialism

Agricultural  
products

Industries  
and handi-  
crafts

Inland  
water-  
ways

from July to January. The Banifing River is navigable for 186 miles.

**Air transport.** A national airline, Air Mali, operates both domestic and international flights. The main airport is at Bamako, and another is being built at Ségou. There are domestic air routes to Ségou, Mopti, Goundam, Tombouctou, Gao, Kayes, and Nioro. Bamako is also linked by air to France, Morocco, and other West African nations.

#### ADMINISTRATION AND SOCIAL CONDITIONS

**Structure of the government.** *Constitutional framework.* Upon independence in 1960, a constitution was granted that guaranteed parliamentary democracy through universal suffrage and provided for an elected National Assembly; the provisions of the constitution were, however, not fully implemented. The military government that took power in 1968 suspended the constitution and forbade all political activity. Since then the country has been ruled by the Military Committee for National Liberation (CMLN).

**Local government.** The country is divided into the six regions of Kayes, Bamako, Sikasso, Ségou, Mopti, and Gao. Each of the regions is further divided into administrative units called *cercles*, which are in turn subdivided into smaller units called *arrondissements*. Each region is administered by a governor, who coordinates the activities of the *cercles* and implements economic policy. The *cercles*, directed by commanding officers, provide nuclei for the major government services; their various headquarters provide focal points for the health service, the army, the police, local courts, and other government agencies. The *arrondissement* is the basic administrative unit, and its centre usually houses a school and a dispensary. It is composed of several villages, which are headed by chiefs and elected village councils. The urban areas (or *communes*) are administered by delegates of the military committee.

**Justice.** At the head of the judicial system, the Supreme Court exercises both judicial and administrative powers; it is the court of first and last resort in matters concerning the government. The Court of Appeal, located in Bamako, tries all cases on appeal from ordinary tribunals. There are more than 50 tribunals and more than 70 magistrates. Justices of the peace have full powers to judge ordinary civil, commercial, and financial cases; they sit in the headquarters of the *cercles* and also travel to the major towns of the *arrondissements*.

Since 1960 there has been a determined attempt to mold the judicial system to the contemporary needs of the population. New law codes have liberated women from traditional restraints, defined the rights and duties of citizens, and modified the penal procedure.

**The army.** The army consists of 3,000 men. Its officers come from the former French colonial army or else were trained either in the Soviet Union or at Mali's École Interarme at Kati. Recruitment is by enlistment or by conscription (military service is compulsory in principle). Garrisons are located throughout the country, and the army is well equipped with Soviet arms, including jet fighter planes and tanks.

**Administration. Education.** French is the only language of instruction. In 1968 to 1969 about 22 percent of school-age children attended school. Primary and secondary education are combined in the nine-year curriculum of the *cycle fondamental* ("fundamental educational level"). The general secondary school, or *lycée*, provides the last three years of traditional secondary education. Higher education—geared directly to the needs of the government—is obtained in state colleges. These colleges include teacher-training colleges, a college of administration, an engineering institute, a polytechnic institute, and a school of medical assistants. Many of Mali's university students study abroad, especially in France, the Soviet Union, and Senegal.

**Health and welfare services.** In 1968 there were two national hospitals (at Bamako and Kati), six regional hospitals, more than 40 medical centres, 60 maternity centres, and 300 dispensaries. There were also infectious

disease and leprosy centres. There are not enough trained medical personnel to meet Mali's needs.

A Secretariat for Social Affairs is charged with improving the conditions of women, children, and invalids. There are more than 50 social centres, located throughout the country; they offer public-health information and provide day nurseries. There is no national social security fund. A Service for Family Allowances, however, makes loans to workers and issues pensions to retired people.

**Police services.** The National Gendarmerie maintains brigades in the *cercles*, and there are policemen in all the towns. The head of national security and the general staff of the gendarmerie are responsible to the Ministry of Internal Affairs, as well as to the armed forces.

**Social conditions.** *Wages and the cost of living.* Inflation has plagued the economy since independence and even more so since the devaluation of the Mali franc in 1967. Wages, however, have not risen as the cost of living continues to rise.

**Social and economic divisions.** Mali contains two distinct, stratified societies. About 90 percent of the population belong to traditional social groups, which have inherited hierarchical social structures. These groups consist of nobles, vassals, and members of various castes, all of whom acquired their status by birth.

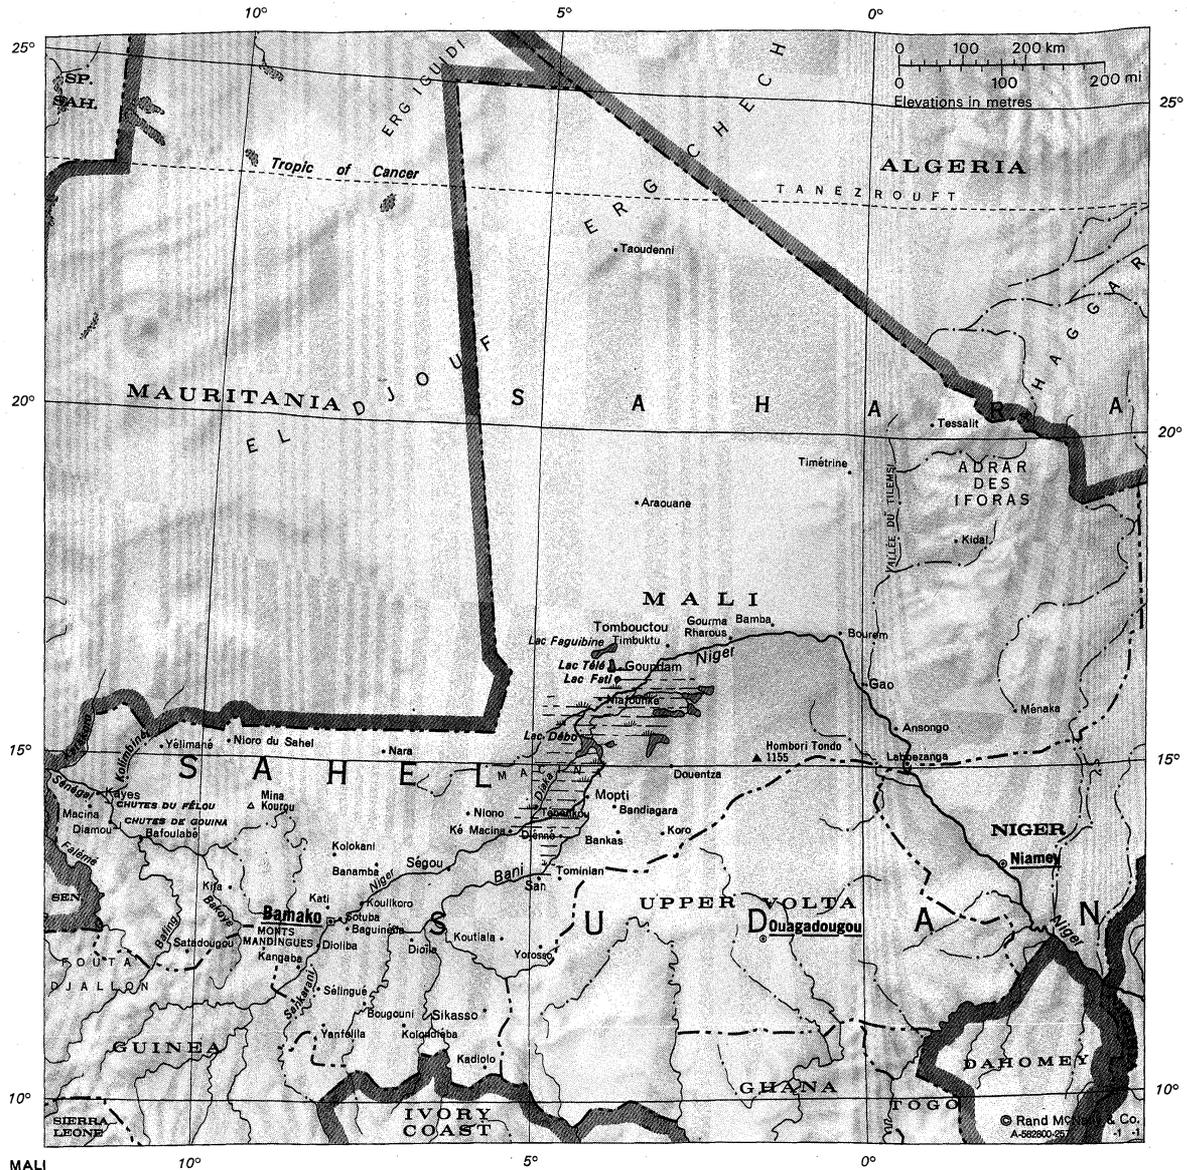

The second Malian society is formed by the urban population. Privileged groups are the educated government officials and the traders. The middle socioeconomic group is composed of civil servants and industrial workers. The lowest group is made up of the unemployed.

#### CULTURAL LIFE AND INSTITUTIONS

Mali is one of the cultural crossroads of West Africa. Situated between the Arab world to the north and the black African nations to the south, it has for centuries been a cultural meeting place. The mixture of both worlds has produced an original Sudanic culture that is

The judicial system

Rural and urban society

MALI

diversified according to the various ethnic groups and regions that compose it.

**Cultural expression.** Music and dancing are the most common cultural activities; they form an especially rich heritage among the Malinke and Songhai peoples. The Bambara and the Voltaic groups excel in the creation of wood carvings of masks, statues, stools, and objects used in animist worship. The *tiewara*, or gazelle mask, of the Bambara is remarkable for its fineness of line.

Architecture is well developed in the Niger Valley. The Sudanic style finds typical expression in the storied houses and mosques of Djénné and Tombouctou.

Localized handicrafts include jewelry making by the Mandingo people, leatherworking around the Niger Bend, the weaving of geometrical designs into cotton cloth, and the carving of statues for the tourist trade.

**Cultural institutions.** The Musée de l'Institut de Recherches et de Documentation at Bamako contains collections of art from most of the country's regions. The National Archives of Mali, the National Library, and the Institute of Human Sciences are also located in Bamako, as also is the Municipal Library. The Centre of Arab Documentation is located in Tombouctou, and there is a French Centre of Documentation in Bamako. The Library of the Office of Niger in Ségou contains information on agriculture, irrigation, and general science.

The government promotes the expansion of popular culture through the Committee of Youth and Sports. Youth

associations organize sports, theatrical, musical, and dancing activities in every important town. Cultural competitions are presented in Bamako during the biennial Youth Week. The Malian Ballet Troupe performs throughout the world. Artists are trained at the National Institute of Arts and at the Artisan Centre of Bamako.

**Press and broadcasting.** The press and the broadcasting services are controlled by the government. *L'Essor* (apart from the *Journal Officiel* the country's only newspaper), is published as both a weekly and a daily. Radio Mali broadcasts from Bamako in French, English, Bambara, and several other local languages. There are no television services.

#### FUTURE PROSPECTS

Since 1968 the military government, which attempts to combine socialist and liberal principles, has attempted to encourage the development of Mali's economy. The main agency responsible for stimulating agricultural development is the Niger Office, although commercial crops such as cotton, sugar, and tobacco, as well as rice, are being grown by using the waters of the Sénégal River. It is anticipated that the Kayes region, which possesses important mineral reserves, including bauxite, will be the focus of future industrialization and hydroelectric development. The major economic problems confronting Mali in the early 1970s were the lack of capital investment and a well-developed transportation system.

## Malinowski, Bronisław

Internationally recognized as a founder of social anthropology, Bronisław Malinowski was one of the most significant teachers and writers in the discipline in the first half of the 20th century. Developing the concept of culture as an expression of the totality of human achievement, he examined a wide range of cultural aspects and institutions, challenging existing propositions on kinship and marriage, exchange, law, myth, and ritual. Using what he termed the functional method, he trained and inspired most of the distinguished social anthropologists who began their work from Great Britain and the Commonwealth in the interwar period.

By courtesy of the Polish Library, London

Malinowski.

By the breadth of his interests and his sheer intellectual power, he also attracted the attention of prominent scientists in other disciplines, such as linguistics and psychology, and collaborated or debated with them. With a keen sense of the significance of anthropology as an analytical tool and a source of information in the study of practical problems of social relations, he participated vigorously in educational programs for administrators, missionaries, and social workers. Malinowski is thus one of the greatest historical figures in securing public recognition of the significance of anthropology in the modern world.

Bronisław Kasper Malinowski was born on April 7, 1884, in Cracow, a former capital of Poland. His father, Lucjan, a professor of Slavic philology at the Jagiellonian University in Cracow, was a linguist of some reputation who had studied Polish dialect and folklore in Silesia. His mother, Józefa, née Łącka, of a moderately wealthy land-owning family, was highly cultured and a good linguist. Early afflicted by the ill health that dogged him throughout life, in his teens Malinowski travelled extensively in the Mediterranean region with his mother, who was by then widowed. Although his early education was conducted largely at home, he subsequently attended the Jagiellonian University, completing his doctorate in 1908, with highest grade honours in philosophy, with physics and mathematics as subsidiaries. Happening upon Sir James Frazer's *Golden Bough*, an encyclopaedic treatment of religious and magical practices, Malinowski was enthralled and long afterward traced his enthusiasm for anthropology to it. After contact with the newer psychologies and economics in Leipzig, he came in 1910 to the

London School of Economics and Political Science, where anthropology had been recently established as a discipline.

For the next quarter-century Malinowski's career was oriented toward London. A prolific writer, he soon published reinterpretations of Australian Aboriginal data from literature then very popular in anthropological circles. These gained him a reputation and promoted his plans for field research, and in 1914 he was able to go to New Guinea. Six months' work among the Mailu on the south coast produced a monograph that, while lacking theoretical development, was sufficient—along with his study of the Australian family—to earn him a doctor of science (D.Sc.) degree from London in 1916. When he moved to the nearby Trobriand Islands, where he worked for two years in 1915–16 and 1917–18, Malinowski's talents flowered. Living in a tent among the people, speaking the vernacular fluently, recording "texts" freely on the scene of action as well as in set interviews, and observing reactions with an acute clinical eye, Malinowski was able to present a dynamic picture of social institutions that clearly separated ideal norms from actual behaviour. In later publications on ceremonial exchange, on agricultural economics, on sex, marriage, and family life, on primitive law and custom, on magic and myth, he drew heavily on his Trobriand data in putting forward theoretical propositions of basic significance and stimulus in the development of social anthropology. Yet, while very rewarding, his field experience had its strains. Writing in Polish for his own private record, Malinowski kept field diaries in which he exposed very frankly his problems of isolation and of his relations with New Guinea people.

In 1919 Malinowski married Elsie Rosaline Masson, daughter of Sir David Orme Masson, professor of chemistry in the University of Melbourne; they had three daughters, Józefa, Wanda, and Helena. Mrs. Malinowski died in 1935 after a long illness.

After living in the Canary Islands and southern France, Malinowski returned in 1924 to the University of London as reader in anthropology; he became professor in 1927. As one of the intellectually most vigorous social scientists of his day, Malinowski had a stimulating and wide influence. His seminars were famous. Conversant with continental European social theory and especially acknowledging his debt to Émile Durkheim, Marcel Mauss, and others of the French sociological school, he rejected their abstract notions of society in favour of an approach that focussed more on the individual—an approach that seemed to him more realistic. His functional theory, as he himself explained,

insists . . . upon the principle that in every type of civilisation, every custom, material object, idea and belief fulfils some vital function, has some task to accomplish, represents an indispensable part within a working whole. ("Anthropology," in *Encyclopaedia Britannica*, 13th ed., suppl., p. 133.)

Only by understanding such functions and interrelations, he held, can an anthropologist understand a culture.

Convinced of the value of functional anthropology as an aid to understanding problems of social life, he was active in sponsoring studies of social and cultural change. In the 1930s he became much interested in Africa; was closely associated with the International African Institute; visited students working among Bemba, Swazi, and other tribes in eastern and southern Africa; and wrote the introduction to Jomo Kenyatta's book *Facing Mount Kenya* (1938), prepared as a diploma thesis under his supervision. (Kenyatta became president of Kenya in 1964.)

In 1938 Malinowski went on sabbatical leave to the United States—which he had already visited in 1926 on a Laura Spelman Rockefeller Memorial Fellowship, in 1933 as a lecturer at Cornell University, and in 1936 as recipient of an honorary doctor of science degree at the Harvard University tercentenary celebrations. When World War II was declared, being by age and temperament unsuited for direct participation in the war effort, he became Bishop Museum Visiting Professor of Anthropology at Yale University, then accepted a tenured

In the  
Trobriand  
Islands

Functional-  
ism

appointment there. He died unexpectedly, of a heart attack, in New Haven on May 16, 1942. His teaching career during those last years had been less remarkable than before, but he had been able to study peasant markets in Mexico in 1940 and 1941 and had plans for a study of social change in Mexican-Indian communities. A great believer in freedom, he had also been actively identified with the Polish cause in the war. In 1940 Malinowski had married again, to Anna Valetta Hayman-Joyce, an artist who paints under the name Valetta Swann and who assisted him in his Mexican studies and was primarily responsible for the publication of his *Scientific Theory of Culture* (1944) and other posthumous works.

#### MAJOR WORKS

*The Family Among the Australian Aborigines* (1913); *The Natives of Mailu* (1915); *Argonauts of the Western Pacific* (1922); *Myth in Primitive Psychology* (1926); *Crime and Custom in Savage Society* (1926); *The Father in Primitive Psychology* (1927); *Sex and Repression in Savage Society* (1927); *The Sexual Life of Savages in North-Western Melanesia* (1929); *Coral Gardens and Their Magic*, 2 vol. (1935); *The Foundations of Faith and Morals* (1936); posthumously published works include *A Scientific Theory of Culture* (1944); *Freedom and Civilization* (1944); *The Dynamics of Culture Change* (1945); *Magic, Science and Religion and Other Essays* (1948). *A Diary in the Strict Sense of the Term* (1967) is a translation of private field diaries kept in Polish during 1914–15 and 1917–18.

### Mallarmé, Stéphane

The latter part of the 19th century in France, even more than the earlier part, was a period of change and experimentation in the arts, and among the writers, painters, and musicians who extended the boundaries within which their predecessors had been confined Stéphane Mallarmé holds a high place. In terms of mere size, his achievement is relatively slight—one slim volume of poetry, a brief and obscure work enigmatically called *Un Coup de dés jamais n'abolira le hasard*, a dozen prose poems, some occasional verse, a number of short essays, and a few translations—yet the audacity of what he attempted to do, and in some measure succeeded in doing, as regards both the form and the content of poetry has ensured his reputation as one of the most remarkable figures in the history of French literature.

Mallarmé was born in Paris on March 18, 1842. He enjoyed the sheltered security of family life for only five brief years, until the early death of his mother in August 1847. This traumatic experience was echoed 10 years later by the death of his younger sister Maria, in August 1857, and by that of his father in 1863. These tragic events would seem to explain much of the longing Mallarmé expressed, from the very beginning of his poetic career, to turn away from the harsh world of reality in search of another world; and the fact that this remained the enduring theme of his poetry may be explained by the comparative harshness with which adult life continued to treat him. After spending the latter part of 1862 and the early months of 1863 in London so as to acquire a knowledge of English, he began a lifelong career as a schoolteacher, first in provincial schools (Tournon, Besançon, and Avignon) and later in Paris. He was not naturally gifted in this profession, however, and found the work decidedly uncongenial. Furthermore, his financial situation was by no means comfortable, particularly after his marriage in 1863 and after the birth of his chil-

dren, Geneviève (in 1864) and Anatole (in 1871). To try and improve matters he engaged in part-time activities, such as editing a magazine for a few months at the end of 1874, writing a school textbook in 1877, and translating another one in 1880. In October 1879, after a six-months illness, his son Anatole died.

Archives Photographiques

Mallarmé, 1891.

Despite these trials and tribulations, Mallarmé made steady progress with his parallel career as a poet. His early poems, which he began contributing to magazines in 1862, were influenced by Charles Baudelaire, whose recently published *Fleurs du mal* were largely concerned with the theme of escape from reality, a theme by which Mallarmé was already becoming obsessed. But Baudelaire's escapism had been of an essentially emotional and sensual kind—a vague dream of tropical islands and peaceful landscapes where all would be "*luxe, calme et volupté*." Mallarmé was of a much more intellectual bent, and his determination to analyze the nature of the ideal world and its relationship with reality is reflected in the two dramatic poems he began to write in 1864 and 1864, *Hérodiade* and *L'Après-midi d'un faune*, the latter being the work that inspired Claude Debussy to compose his celebrated *Prélude* a quarter of a century later.

By 1868 Mallarmé had come to the conclusion that although nothing lies beyond reality, within this nothingness lie the essences of perfect forms. The poet's task is to perceive and crystallize these essences. In so doing, the poet becomes more than a mere descriptive versifier, transposing into poetic form an already existent reality; he becomes a veritable God, creating something from nothing, conjuring up for the reader, as Mallarmé himself put it, "*l'absente de tous bouquets*"—the ideal flower that is absent from all real bouquets. But to crystallize the essences of things in this way, to create the notion of floweriness, rather than to describe an actual flower, demands an extremely subtle and complex use of all the resources of language, and Mallarmé devoted himself during the rest of his life to putting his theories into practice in what he called his *Grand Oeuvre*, or *Le Livre*. He never came near to completing this work, however, and the few preparatory notes that have survived give little or no idea of what the end result might have been.

On the other hand, Mallarmé did complete a number of poems related to his projected *Grand Oeuvre*, both in their themes and in their extremely evocative use of language. Among these are several elegies, the principal ones being to Baudelaire, Edgar Allan Poe, Richard Wagner, and the French poets Théophile Gautier and Paul Verlaine, that Mallarmé was commissioned to write at various times in his career. He no doubt agreed to do them because the traditional theme of the elegy—the man is dead but he lives on in his work—is clearly linked to the poet's own belief that, although beyond reality there is nothing, poetry has the power to transcend this annihilation. In a second group of poems, also written at various times in his career, Mallarmé wrote about poetry itself, reflecting evocatively on his aims and achievements.

Poetics

Sonnets to  
Méry  
Laurent

Among these poems are the enigmatically entitled "Prose (pour des Esseintes)," and the sonnets "Le vierge, le vivace, et le bel aujourd'hui," "Ses purs ongles très haut dédiant leur onyx," and "À la nue accablante tu."

In addition to these two categories of poems related to his *Grand Oeuvre*, he also wrote some poems that run counter to his obsession with the ideal world, though they, too, display that magical use of language of which Mallarmé had made himself such a master. These are the dozen or so sonnets he addressed to his mistress, Méry Laurent, between 1884 and 1890, in which he expressed his supreme satisfaction with reality, especially in "Quelle soie aux baumes de temps," "Victorieusement fui le suicide beau," and "Le chevelure vol d'une flamme." At that time, life was becoming much happier for him, not only because of this liaison but also because his inclusion in the series of articles entitled *Les Poètes maudits* published by Verlaine in 1883 and the praise lavished upon him by J. K. Huysmans in his novel *A Rebours* led to his wide recognition as the most eminent poet of the day. A series of celebrated Tuesday evening meetings at his tiny flat in Paris were attended by well-known writers, painters, and musicians of the time, who were eager to sit at the feet of the master and listen to him expound his ideas. All this perhaps decreased his need to seek refuge in an ideal world, and in *Un coup de dés jamais n'abolira le hasard*, the work that appeared in 1897, the year before his death, he found consolation in the thoughts first that, even if he had completed his *Grand Oeuvre*, it might have been ignored by the public, and, second, that through what he considered his minor works and his discussions about his ideas, he had met with some measure of success in giving poetry a truly creative function.

Mallarmé died on September 9, 1898, at his cottage at Valvins, a village on the Seine near Fontainebleau, his main residence after retirement.

#### MAJOR WORKS

**POETRY:** A number of poems contributed to various magazines from 1862 onward and to two volumes (1866, 1869) of the anthology *Le Parnasse Contemporain; Poésies* (1887), a collection of 35 poems selected by Mallarmé; *Album de vers et de prose* (1887), a selection of nine poems from *Poésies; Vers et prose* (1893), an expansion of the above to include 21 poems; *Poésies*, 2nd enl. ed. (1899), in which Mallarmé incorporated about a dozen additional poems—published six months after the poet's death.

**PROSE POEMS:** Various prose poems contained in the collections *Album de vers et de prose* (1887), *Pages* (1891), and *Vers et prose* (1893); *Un Coup de dés jamais n'abolira le hasard*, published in the review *Cosmopolis* (1897).

**CRITICISM:** *Divagations* (1897), a collection of articles on such contemporaries as Verlaine, Villiers de l'Isle-Adam, and Wagner and a number of essays on literary matters.

**OTHER WORKS:** *La Dernière Mode* (1874), eight issues of a fashion magazine; *Les Mots anglais* (1877), a study of English vocabulary; *Les Dieux antiques* (1880), a study of mythology.

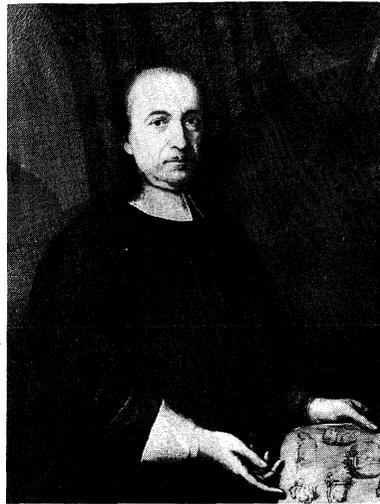

**BIBLIOGRAPHY.** STEPHANE MALLARME, *Oeuvres complètes*, ed. by HENRI MONDOR and G. JEAN-AUBRY (1945), has been reprinted many times since it was first published. *Poésies* (1970) is the latest version of the edition prepared by Mallarmé himself, to which various poems that have come to light over the intervening years have been added, along with a selection of the poet's occasional verse. *Mallarmé*, ed. with an introduction and plain prose translations by ANTHONY HARTLEY (1965), is a bilingual edition containing the *Poésies*, the occasional verse, the prose poems, some essays, and *Un Coup de dés*; Mallarmé's condensed and complex language responds badly to literal translation, and the renderings in this edition are sometimes meaningless and occasionally incorrect. The *Correspondance*, vol. 1, 1862-1871, has been edited by HENRI MONDOR and J.P. RICHARD; vol. 2, 1871-1885, and vol. 3, 1886-1899, by HENRI MONDOR and L.J. AUSTIN (1959-69). HENRI MONDOR, *Vie de Mallarmé* (1941-42), is the standard biography of Mallarmé, based on the vast amount of manuscript material collected by the author. A.R. CHISHOLM, *Mallarmé's "Grand Oeuvre"* (1962), is a useful introduction (in English) to Mallarmé's work. GUY MICHAUD, *Mallarmé* (1953; Eng. trans., 1965); C. CHADWICK, *Mallarmé, sa pensée dans sa poésie* (1962); and P.O. WALZER, *Essai sur Stéphane Mallarmé* (1963), are among the best short studies.

(C.Ch.)

## Malpighi, Marcello

A physician and biologist, Marcello Malpighi pioneered the use of the microscope in the study of the fine structure of plants and animals. Through his patient and systematic observations of structures never before seen, he brought about a re-examination of ancient concepts concerning the organization of living things. After Malpighi, microscopic anatomy became a prerequisite for advances in physiology, embryology, and practical medicine.

Fotofast

Malpighi, painting attributed to the School of Bologna, 17th century. In the Putti Collection, Rizzoli Institute, Bologna, Italy.

Malpighi was born on March 10, 1628, in Crevalcore, near Bologna, Italy. Little is known of his childhood and youth except that his father began his education in "grammatical studies," and that he entered the University of Bologna in 1646. Both parents died when he was 21, but he was able, nevertheless, to continue his studies. Despite opposition from the university authorities because he was non-Bolognese by birth, in 1653 he was granted doctorates in both medicine and philosophy and appointed as a teacher, whereupon he immediately dedicated himself to further study in anatomy and medicine.

In 1656, Ferdinand II of Tuscany invited him to the professorship of theoretical medicine at the University of Pisa. There Malpighi began his lifelong friendship with Giovanni Borelli, mathematician and naturalist, who was a prominent supporter of the Accademia del Cimento, one of the first scientific societies. Malpighi questioned the prevailing medical teachings at Pisa, tried experiments on colour changes in blood, and attempted to recast anatomical, physiological, and medical problems of the day. Family responsibilities and poor health prompted Malpighi's return in 1659 to Bologna, where he continued to teach and do research with his microscopes. In 1661 he identified and described the pulmonary and capillary network connecting small arteries with small veins, one of the most important discoveries in the history of science. Malpighi's views evoked increasing controversy and dissent, mainly from envy, jealousy, and lack of understanding on the part of his colleagues.

Hindered by the hostile environment of Bologna, Malpighi accepted (November 1662) a professorship in medicine at the University of Messina in Sicily, on the recommendation there of Borelli, who was investigating the effects of physical forces on animal functions. Malpighi was also welcomed by Viscount Francavilla, a patron of science and a former student, whose hospitality encouraged him in furthering his career. Malpighi pursued his microscopic studies while teaching and practicing medicine. He identified the taste buds and regarded them as terminations of nerves, described the minute structure of the brain, optic nerve, and fat reservoirs, and in 1666 was the first to see the red blood cells and to attribute the colour of blood to them. Again, his research

Early  
life

Work at  
Messina

and teaching aroused envy and controversy among his colleagues.

After four years at Messina, Malpighi returned in January 1667 to Bologna, where, during his medical practice, he studied the microscopic subdivisions of specific living organs, such as the liver, brain, spleen, and kidneys, and of bone and the deeper layers of the skin that now bear his name. Impressed by the minute structures he observed under the microscope, he concluded that most living materials are glandular in organization, that even the largest organs are composed of minute glands, and that these glands exist solely for the separation or for the mixture of juices.

Malpighi's work at Messina attracted the attention of the Royal Society in London, whose secretary, Henry Oldenburg, extended him an invitation in 1668 to correspond with him. Malpighi's work was thereafter published periodically in the form of letters in the *Philosophical Transactions* of the Royal Society. In 1669 Malpighi was named an honorary member, the first such recognition given to an Italian. From then on, all his works were published in London.

At the peak of his fame, Malpighi could have left his tiring medical practice and research to accept one of the many highly remunerative positions offered to him. Instead, he chose to continue his general practice and professorship. These years at Bologna marked the climax of his career, when he marked out large areas of microscopy. Malpighi conducted many studies of insect larvae—establishing, in so doing, the basis for their future study—the most important of which was his investigation in 1669 of the structure and development of the silkworm. In his historic work in 1673 on the embryology of the chick, in which he discovered the aortic arches, neural folds, and somites, he generally followed William Harvey's views on development, though Malpighi probably concluded that the embryo is preformed in the egg after fertilization. He also made extensive comparative studies in 1675–79 of the microscopic anatomy of several different plants and saw an analogy between plant and animal organization.

During the last decade of his life Malpighi was beset by personal tragedy, declining health, and the climax of opposition to him. In 1684 his villa was burned, his apparatus and microscopes shattered, and his papers, books, and manuscripts destroyed. Most probably as a compensatory move when opposition mounted against his views, and in recognition of his stature, Pope Innocent XII invited him to Rome in 1691 as papal archiater, or personal physician, such a nomination constituting a great honour. In Rome he was further honoured by being named a count, he was elected to the College of Doctors of Medicine, his name was placed in the Roman Patriciate Roll, and he was given the title of honorary valet.

Malpighi may be regarded as the first histologist. For almost 40 years he used the microscope to describe the major types of plant and animal structures, and in so doing marked out for future generations of biologists many major areas of research in botany, embryology, human anatomy, and pathology. Just as Galileo had applied the new technical achievement of the optical lens to vistas beyond the earth, Malpighi extended its use to the intricate organization of living things, hitherto unimagined, below the level of unaided sight. Moreover, his lifework brought into question the prevailing concepts of body function. When, for example, he found that the blood passed through the capillaries, it meant that Harvey was right, that blood was not transformed into flesh in the periphery, as the ancients thought. He was vigorously denounced by his enemies, who failed to see how his many discoveries, such as the renal glomeruli, urinary tubules, dermal papillae, taste buds, and the glandular components of the liver, could possibly improve medical practice. The conflict between ancient ideas and modern discoveries continued throughout the 17th century. Although Malpighi could not say what new remedies might come from his discoveries, he was convinced that microscopic anatomy, by showing the minute construction of living things, called into question the value of old medi-

cine. He provided the anatomical basis for the eventual understanding of human physiological exchanges.

Malpighi died of apoplexy in Rome on November 29, 1694. In accordance with his will, his body underwent an autopsy. He was temporarily buried in SS. Vincent and Anastasius Church, and in 1695 he was reinterred in SS. Gregorio and Siro Church, Bologna, as his will had stipulated.

**BIBLIOGRAPHY.** The definitive study of Malpighi is HOWARD ADELMANN, *Marcello Malpighi and the Evolution of Embryology*, 5 vol. (1966). It contains a complete biography of Malpighi, translations from the Latin of Malpighi's chief works with Latin on facing pages, colour reproductions of Malpighi's illustrations, and detailed essays on structure based on embryologists of the 17th, 18th, and 19th centuries with extensive translations from French, German, and Latin. ETTORE TOFFOLETTO, *Discorso sul Malpighi* (1965), provides a critical analysis (in Italian) of Malpighi both as a man and a scientist.

(E.T./A.I.R.)

## Malraux, André

A major novelist of the 20th century who also distinguished himself in archaeology, philosophy of art, and, notably, political action, André Georges Malraux could be recognized on his own admission as a man driven simultaneously by two "demons": history and art. His novels—first classed as adventure stories and for a long time regarded as disparate—reveal a unity in which the expressive forces of both an exceptional "witness of his time" and a humanist are conjoined. Born with the 20th century in 1901, Malraux identified the stages of development not only of his own country but also of the world in his novels, breaking with those preceding generations of French writers who had confined themselves within their own frontiers.

Bruno Barbey—Magnum

Malraux, 1967.

Malraux was born in Paris on November 3, 1901, of a well-to-do family. The details of his early life and education are obscure.

At the age of 21 he left France accompanied by Clara Goldschmidt, whom he had married shortly before, in search of an Indochinese temple, Banteay Srei, of whose discovery he had read in an archaeological bulletin. Plunging into the Cambodian forest—following an itinerary he was later to call the royal road (*la voie royale*)—he reached the temple, which was not then being considered for restoration. He had some bas-reliefs removed from it and took them back to Phnom Penh, the capital of Cambodia. Arrested at once and sentenced to imprisonment, he appealed to Paris and was released. But his true and historic rendezvous with the Far East was already approaching. As revolution stirred in Southeast Asia and China and the old order began to topple, Malraux organized the Young Annam League (the precursor of the Viet Minh, or Viet Nam League for Independence), became a leader writer and pamphleteer, and founded a newspaper, *L'Indochine Enchaînée* ("Indochina in Chains"). Crossing to China Malraux met—or

First  
revolution-  
ary role

Height  
of his  
career

at least allowed it to be believed that he met—Mikhail Markovich Borodin, the Russian Communist adviser to Sun Yat-sen and then to Chiang Kai-shek, who sensed the revolutionary future of China and already foresaw the difference between Mao Tse-tung's armed peasant revolution and Soviet orthodoxy.

Malraux was to return to the Far East several times. In 1929 he made important discoveries of Greco-Buddhist art in Afghanistan and Iran. In 1934 he flew over the Rub' al-Khali in Arabia and discovered what may have been the site of the Queen of Sheba's legendary city. After his second return from Indochina in 1926 he published *La Tentation de l'Occident (The Temptation of the West)*, in which he vainly tried to interpret to the two civilizations—Western and Eastern—that which the other had to offer. With his novels *Les Conquérants (The Conquerors)*, published in 1928, *La Voie royale (The Royal Way)*, published in 1930, and *La Condition humaine (Man's Fate)* in 1933 (awarded the Prix Goncourt), he became a literary but not a politico-philosophical success. For though he captivated Paris with his exceptional intelligence, lyrical prose, astonishing memory, and breadth of knowledge, it was not generally appreciated that his true life was elsewhere than in the salons or on the committee of *La Nouvelle Revue Française* or at literary congresses.

History, however, beckoned Malraux again. As Fascism, in the shape of Nazism, rose in the 1930s, he recognized its threat and presided over committees pressing for the liberation of the international Communists Ernst Thälmann and Georgi Dimitrov from their imprisonment under the Nazis. He simultaneously eschewed a rigid Marxism, participated in the Ligue Nationale contre l'Antisémitisme, and in 1935—before the world in general had learned that concentration camps existed—published *Le Temps du mépris (Days of Contempt)*—which critics inappropriately judged “exotic.” At the same time he began to write his *Psychologie de l'art (The Psychology of Art)*, an activity that bore a relationship to his other interests, for to Malraux aesthetic ideas, like the philosophy of action expressed in his own novels, would always be part of man's eternal questioning of destiny and his response to it.

On the second day of the Spanish Civil War, Malraux crossed the Pyrenees and organized in a single week an international air squadron, becoming its colonel. After several missions to the Madrid front, he visited the United States in order to collect money for medical assistance to Spain. His masterpiece *L'Espoir (Man's Hope)*, based on his experiences in Spain, was published in 1937. A motion picture that he produced and directed in Barcelona in 1938 was not shown in France until after the country's liberation at the end of World War II.

When World War II broke out and the Soviet Union's alliance with Germany shattered once and for all the old dream of a Communist International through which the whole world might be Communized, Malraux enlisted as a private soldier in a tank unit. He was captured but escaped to the free zone of France, where he joined the resistance movement under the name of “Berger”—a name he later gave the hero of his unfinished novel *La Lutte avec l'ange* (“The Battle with the Angel”). His life in the French underground movement began in the Corrèze département in south central France. He was shot and captured (1944) by the Germans and made to undergo a mock execution; on his liberation by the Forces Françaises de l'Intérieur, he formed the Alsace-Lorraine brigade, which he commanded during the 1st French Army's campaign against Strasbourg in Alsace. During this time of trial his ideas underwent a change, and he was able to rediscover a sense of national unity and a new promise held out by Western culture.

On the Alsatian front he met Gen. Charles de Gaulle, with whom his destiny was thenceforth to be linked. He was appointed temporary minister of information (November 1945–January 1946) in de Gaulle's first government. He then followed de Gaulle into retirement, from which he emerged to deliver brilliant speeches as a national delegate to the Gaullist Rassemblement du Peuple

Français, or RPF (French People's Rally). Withdrawing to his villa at Boulogne in northern France, he devoted himself to his monumental meditation on art. As a kind of preface to the historical role he would soon play as minister of cultural affairs, *Les Voix du silence (The Voices of Silence)*, published in 1951, sounded the notes of the first universal humanism, that of the brotherhood of works of art, through which man inherits all that is noble in the world and on whose defiance of death the foundation of his true greatness is laid.

Though he had already experienced private adventures in mass revolutions and gone through the throes of a heroic national struggle to arrive at his humanist philosophy, it was not until de Gaulle summoned him to ministerial office in 1958 that Malraux was to experience power. For 10 years he was minister of cultural affairs and the intimate friend of de Gaulle. But his grand designs were limited by the means at his disposal, and, despite a promising beginning, he was less effective than might have been expected. Those works published after he quit the political scene tell much of what Malraux described as the “historical state of grace” that he recognized at that time in France: in *Les Chênes qu'on abat (Felled Oaks)*, which tells of his last conversation with de Gaulle, and likewise in *Oraisons funèbres* (“Funeral Orations”), in which his principal ministerial themes are set out and his preoccupation with death is clearly evident. That preoccupation was explored still further in *Lazare* (1974).

André Malraux was that rare being who lived his own legend and whose life reflected his works. His *Antimémoires* (1967), the only autobiography that Malraux considered essential, has no hint of the traditions of autobiography or of confession. It records nothing of the tragic events of his own life. He makes no mention of the death of Josette Clotis, mother of his two sons, nor of their death in an automobile accident. His brother Roland's imprisonment by the Germans and death are completely ignored. The *Antimémoires* belong both to his legend and to the resurrected past in which “adventure begins by a sense of estrangement, the experience of which will eventually make of the adventurer, a madman, king, or recluse.” After the death of his companion the novelist Louise de Vilmorin, André Malraux lived and worked in solitude at Verrières-le-Buisson, near Paris. He died on November 23, 1976, and was buried at Verrières-le-Buisson.

#### MAJOR WORKS

NOVELS: *Les Conquérants* (1928; *The Conquerors*, 1929); *La Voie royale* (1930; *The Royal Way*, 1935; and in *Antimémoires*, 1968); *La Condition humaine* (1933; *Man's Fate*, 1934); *Le Temps du mépris* (1935; *Days of Contempt*, British title; *Days of Wrath*, U.S. title, 1936); *L'Espoir* (1937; *Days of Hope*, British title; *Man's Hope*, U.S. title, 1938); *Les Noyers de l'Altenburg*, first pub. as *La Lutte avec l'ange* (1943); *The Walnut Trees of Altenburg*, 1952; and in *Antimémoires*).

WRITING ON ART: *Esquisse d'une psychologie du cinéma* (1946); *Psychologie de l'art*, 3 vol. (1947–49; *The Psychology of Art*, 1949); *Saturne, essai sur Goya* (1950; Eng. trans. 1957); *Les Voix du silence* (1951; *The Voices of Silence*, 1953); *Le Musée imaginaire de la sculpture mondiale*, 3 vol. (1952–54; *Museum Without Walls*, 1967).

OTHER WORKS: *La Tentation de l'Occident* (1926; *The Temptation of the West*, first trans. in 1961, also trans. in *Antimémoires*); *Antimémoires* (1967; *Antimemoirs*, 1968); *Les Chênes qu'on abat* (1971; *Felled Oaks*, U.S. title; *Fallen Oaks*, British title, 1972), autobiography; *Oraisons funèbres* (1971), speeches.

BIBLIOGRAPHY. Critical studies of Malraux's works (in French) include: GAETAN PICON, *Malraux par lui-même* (1953), with annotations to the subject; ANDRE and JEAN BRINCOURT, *Les Oeuvres et les lumières* (1955); PIERRE DE BOISDEFRE, *André Malraux*, 6th ed. (1963); and ANDRE BRINCOURT, *André Malraux ou le temps du silence* (1966). English-language works particularly recommended are: R.W.B. LEWIS (ed.), *Malraux* (1964), a collection of essays representing international contemporary critical opinion; W.M. FROHOCK, *André Malraux and the Tragic Imagination* (1952), an important study of the writer by a leading American critic of modern French literature; DENIS BOAK, *André Malraux* (1968), by a more severe critic who finds much preten-

Political activities in the 1930s

Participation in the French underground

Minister of cultural affairs

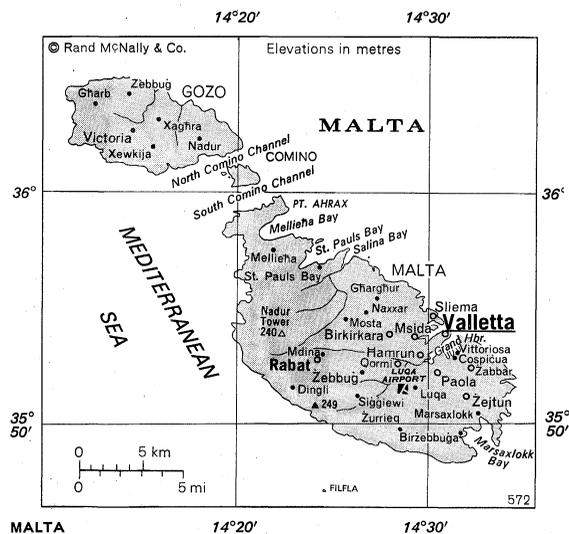

tiousness in the writer's work: JOSEPH FRANK, *The Widening Gyre* (1963), a lucid exposition of Malraux's artistry and personal philosophy; VICTOR H. BROMBERT, *The Intellectual Hero* (1961); and CHARLES D. BLEND, *André Malraux: Tragic Humanist* (1963), two works that concentrate on the philosophy that underlies the novels.

Literary portraits of the man include: CLAUDE MAURIAC, *Malraux; ou, le mal du héros* (1946); ROGER STEPHANE, *Portrait de l'aventurier* (1950); WALTER G. LANGLOIS, *André Malraux: The Indochina Adventure* (1966); CLARA MALRAUX, *Le Bruit de nos pas*, 3 vol. (1963–69) a candid account of Malraux by his estranged wife; VIOLET M. HORVATH, *André Malraux: The Human Adventure* (1969); and PIERRE GALANTE, *Malraux, quel roman que sa vie* (1971; Eng. trans., *Malraux*, 1971).

(An.Br.)

## Malta

An independent parliamentary state, Malta consists of a small but strategically important group of islands in the central Mediterranean Sea. Throughout a long and turbulent history, the little archipelago has played a vital role in the struggles of a succession of powers for domination of the Mediterranean and in the interplay between emerging Europe and the older cultures of Africa and the Near East. As a result, Maltese society was molded by many centuries of foreign rule, with influences ranging from Arab to Norman. The withdrawal of British military and naval personnel from its famous Dockyard—associated with the achievement of independence from the U.K. in 1964—created economic and political problems. The Malta of the 1970s continues to face major problems of economic development and diversification, while its traditional social order, in which the Roman Catholic Church has played a powerful role, faces challenges from trade unionists and political movements seeking a more egalitarian society.

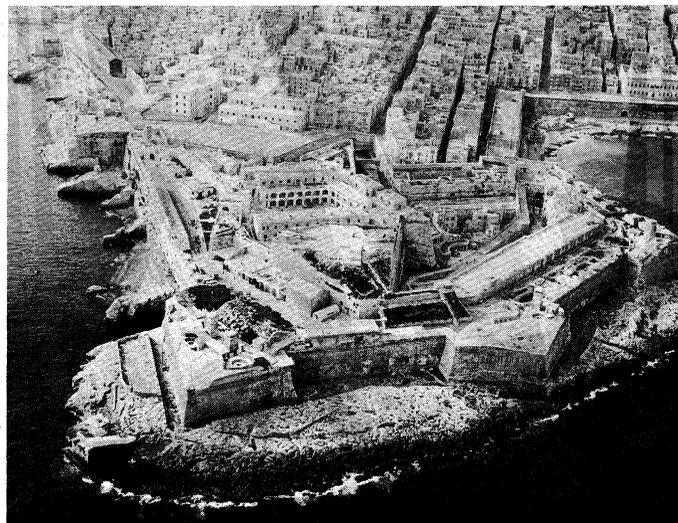

There are five islands—Malta, the largest; Gozo; Comino; and uninhabited Cominotto and Filfla—lying some 58 miles south of Sicily, 220 miles north of Libya, and about 180 miles east of Tunisia, at the eastern end of that constricted portion of the Mediterranean Sea separating Italy from the African coast. The islands cover a combined land area of about 122 square miles (316 square kilometres) and supported a population of just over 322,000 in 1971. Valletta is the capital, although Sliema is the largest city. (For a related physical feature, see MEDITERRANEAN SEA; for related history, see CRUSADES; MONASTICISM.)

**History.** The earliest archaeological remains date from about 3800 BC. Neolithic farmers lived in caves like those at Ghar Dalam or villages, like Skorba, and produced pottery that seems to be related to that of contemporary eastern Sicily. An elaborate cult of the dead of Stone Age or Copper Age culture evolved about 2400 BC. Initially centring around rock-cut collective tombs

such as those at Ggantija and Hagar Qim, it culminated—probably through contacts with the cultures of the Cyclades and Mycenae—in the unique underground burial chamber (hypogeum) at Hal Saffieni. This culture came to a sudden end at about 2000 BC, possibly as a result of invasions. The culture which replaced it, of southern Italian flavour, is evidenced today only by fragmentary remains. Bronze Age tools and weapons have been found at Borg in-Nadur and Tarxien Cemetery, while Iron Age relics from about 1200 to 800 BC include cart ruts at Bingemma.

Authenticated News

Aerial view of Valletta with Ft. St. Elmo at the extremity of the promontory, flanked by Grand and Marsamxett harbours.

Between the 8th and 6th centuries BC contact was made with Semitic cultures. Evidence is scanty, however, and a few inscriptions found on Malta constitute the only indication of a Phoenician presence. There is more substantial proof of the Carthaginian presence in the 6th century BC; coins, inscriptions, and several Punic-type rock tombs have been found. It is certain that in 218 BC Malta came under Roman political control. Originally part of the Praetorship of Sicily, the islands were subsequently given the status of municipium and were thus allowed to coin their own money, send ambassadors to Rome, and control domestic affairs. According to tradition, St. Paul was shipwrecked in Malta in AD 60 and began to convert the inhabitants. The Maltese have been Christians uninterruptedly since that time.

With the division of the Roman Empire, in AD 395, Malta was given to the eastern portion dominated by Constantinople. Until the 15th century, it followed the more immediate fortunes of nearby Sicily, being ruled successively by Arabs (who left a strong effect on the language), Normans (who advanced the legal and governmental structures), and a succession of feudal lords. In 1530, however, it was ceded to the Order of the Hospital of St. John of Jerusalem (the Knights Hospitallers), a religious and military order of the Roman Catholic Church. Malta became a fortress and, under the Knights' Grand Master, Jean de La Valette, successfully withstood the Ottoman siege of 1565. The new captial city of Valletta became a town of splendid palaces and unparalleled fortifications. Growing in power and wealth—due mainly to their maritime adventures against the Turks—the Knights left the island an architectural and artistic legacy. Although there was little economic and social contact between them and the Maltese, they managed to imprint their cosmopolitan character on Malta and its inhabitants.

In 1798, Napoleon Bonaparte captured the island, but the French presence was short-lived, and the Treaty of Amiens returned the island to the Knights in 1802. The Maltese protested and acknowledged Great Britain's sovereignty, subject to certain conditions incorporated in a Declara-

British  
rule

tion of Rights. The constitutional change was ratified by the Treaty of Paris in 1814.

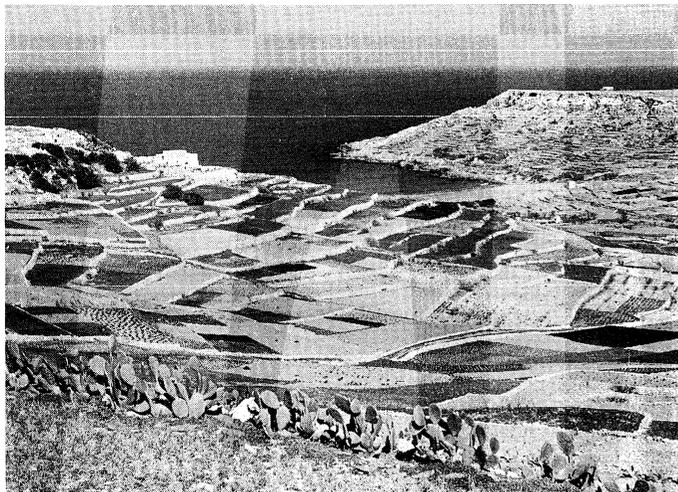

Malta's political status under Britain underwent a series of vicissitudes in which successively constitutions were granted, suspended, and revoked. The economy became a function of British demands for Malta's military facilities, and the Dockyard developed into the economic mainstay.

The island flourished during the Crimean War and was favourably affected by the opening of the Suez Canal in 1869. Self-government was granted in 1921 on a dyarchical basis whereby Britain shared power and responsibility with Maltese ministers who were elected by the legislature. But the battle over the relative roles of the English, Italian, and Maltese languages took its toll and in 1936 the islands reverted to a strictly colonial regime in which full power rested in the hands of the governor. During World War II, the islands repelled the Axis powers against severe odds, having been one of the most heavily bombed targets of that conflict. As a result, it was awarded the George Cross, Britain's highest civilian decoration. Self-government was granted in 1947, revoked in 1959, and then restored in 1962. Malta finally achieved independence within the British Commonwealth on September 21, 1964.

**The landscape.** *Relief.* The main physical characteristic of Malta Island is a well-defined escarpment that bisects it along the Victoria Lines Fault running along the whole breadth of the island from Ra's Ir-Raheb to the coast northeast of Gharghur. The highest areas are coralline limestone uplands that comprise a triangular plateau to the west. The uplands are separated from the surrounding areas by blue clay slopes, while undercliff areas are found where the coralline plateau has fallen and forms a subordinate surface between the sea and the original shore.

Limestone  
and coral

Blau—Camera Press—Publix

Limestone rock and terraced plots, where shallow soil is held together by rubble walls, on the island of Malta.

To the north the escarpment is occasionally abrupt and broken by deep embayments. To the south, however, the plateaus gradually descend from a height of 600–800 feet into undulating areas of globigerina (derived from marine protozoa) limestone less than 400 feet high. On the west there are deeply incised valleys and undercliff areas, while on the east there are several valleys descending to the central plains.

The west coast of Malta presents a high, bold, and generally harbourless face. On the east, however, a tongue of high ground known as Mt. Sceberras separates the bays of Marsamxett and Grand Harbour. These deepwater harbours contribute to the strategic importance of Malta, because there are relatively few of them in the Mediterranean. The bays are associated with nine seasonal creeks that include those of Sliema, Lazzaretto, Msida, and Marsa. The northern shore is again bare and craggy, charac-

terized by its coves and hills, which are separated by fertile lowlands.

In Gozo, the landscape is characterized by a broken coralline plateau to the north and by low-lying globigerina limestone plains and hills to the south.

Malta possesses favourable conditions for the percolation and underground storage of water. The impermeable blue clays provide two distinct water tables between the limestone formations. The principal source for the public supply of water has been the main sea-level water table. In the absence of permanent streams or lakes and given a considerable loss of rainfall, the water supply has often been a problem. A seawater distillation power plant, however, is now coming into operation.

Shortage  
of fresh  
water

*Soils.* Maltese soils are mainly young or immature and thin. By law, when soils are removed from construction sites, they must be taken to agricultural areas, and level stretches in quarries are often covered with carted soil. Organic refuse from the towns is also used. Consequently, the soils are unusual and are partly a manufactured medium.

*Climate.* The climate is typically Mediterranean, with hot, dry summers, warm and sporadically wet autumns, and short, cool winters with adequate rainfall. Nearly three-fourths of the precipitation falls between October and March; and June, July, and August are normally quite dry.

The temperature is very stable, the annual mean being 64° F (18° C) and the monthly averages ranging from 53° F (12° C) to 77° F (25° C). Winds are strong and frequent; the most common are the cool northwesterly (the *Majjistral*), the dry northeasterly (the *Grigal*), and the hot humid southeasterly (the *Xlokk*). The relative humidity is consistently high and rarely falls below 40 percent.

*Vegetation and animal life.* While wild vegetation is sparse, there is an abundance of cultivated potatoes, *sulla* (a leguminous fodder crop), onions, tomatoes, and vines. The great variety of trees includes the carob, fig, and chaste. The developed seashore vegetation includes golden and rock samphires, sea campion, spurge, saltwort, and marram grass.

Typical of the few native mammals are the hedgehog, the least weasel, the water and the white-toothed shrews, and the pipistrel and other bats. Rats, mice, and some rabbits are also found. Resident birds include the spectacled and Sardinian warblers, the Manx and Cory's shearwaters, and the blue rock thrush. Linnets, tree and Spanish sparrows, buntings, rock doves, and several kinds of owls also form breeding populations, while birds of passage include ospreys, rollers, swallows, cuckoos, bee-eaters, and vultures. Common insects are beetles, grasshoppers, flies, mosquitoes, moths, bees, wasps, cockroaches, ants, and several species of butterflies. Ladybirds migrate from Sicily.

*Human settlement.* Until the mid-19th century, the Maltese lived in the relative seclusion of the fields that, as they became increasingly fragmented, accentuated the individuality of the farming community. The *zuntier*, or church square, was the traditional focus of village life. With the growth of the Dockyard complex in the latter part of the 1800s, new settlements appeared around Grand Harbour, and the Sliema metropolitan region developed in the 20th century into the most fashionable part of Malta. The advent of industrial estates near major villages has somewhat stemmed the exodus from the rural areas. Higher living standards and expatriate residents are now giving rise to residential developments in several hitherto forsaken areas such as Kappara and the Gardens.

New  
towns

Gozo conserves its own rural character. The architecture of the new development at *ta' Cenc* successfully blends with the island's natural beauty and is architecturally stimulating.

*Population.* The islands' ethnic and linguistic composition reflects the heritage of many rulers. A European atmosphere predominates as a result of close association particularly with southern Europe. About 95 percent of the islanders are Maltese-born, about 2 percent are En-

glish, and slightly more than 1 percent are Italian. During the 20th century, the increasing rate of Anglo-Maltese marriages has added a new dimension to the ethnic structure of the population.

	area		population*	
	sq mi	sq km	1967 census	1971 estimate
<b>Census regions†</b>

Total Malta	122	316	314,000	322,000

\*De jure. †Malta has no first-order political subdivisions. Data are presented according to census regions.  
Source: Official government figures.

After reaching a peak of 329,000 in 1962, the population has been fluctuating. In the early 1970s, it numbered just over 322,000 at a density of 2,600 per square mile. This decrease is attributable to a high rate of migration; lower birth, fertility, and mortality rates; and the loss of British personnel as the naval base operations are slowed down. The crude birthrate now numbers 16 births per 1,000, the fertility rate is 154 per 1,000, and the mortality rate is 9.4 per 1,000.

The age pyramid has a somewhat narrow base. The largest age group—those under the age of 15—numbers 28 percent of the total population. Those between the ages of 25 and 49 represent over 29 percent and those over 60 represent 13 percent. The aging trend within the population is enhanced by a life expectancy of 69 years for men and 72 for women and the existence of slightly more women than men.

Maltese—the medium of daily conversation—is a distinct language that resulted from the interaction and fusion of North African Arabic and a Sicilian form of Italian. It is the only Semitic language that is officially written in Latin script; it became an official language of Malta in 1934. English is the other official language and is the medium of instruction. Italian was the language of church and government until 1934, and consequently it is still understood by a sizable sector of the island's population.

Relations  
of state  
and church

Although Roman Catholicism is the state religion, there is full freedom for all religious beliefs. The islands are an independent province of the Church, with two dioceses at Malta and Gozo and five bishops. There are two Roman Catholic cathedrals at Mdina (Notabile) and Valletta, and an Anglican cathedral at Valletta.

**The economy.** Malta's only mineral resource is the globigerina limestone that is used as building stone. Its other assets are its deep harbours, an adaptable, skilled labour force, and a strategic position as both a fuelling centre and a military and naval base. The economy, therefore, has been artificial and determined by the vicissitudes of war and peace in the Mediterranean. In the 1950s Britain began the retrenchment of its naval and military forces on Malta, a move that necessitated a drastic diversification of the economy. Between 1959 and 1971, a series of five-year plans was supported by government grants, loans, and other fiscal incentives, to encourage private investment mainly in the areas of manufacturing and tourism. These incentives were subsequently drastically altered in the hope of attracting large-scale industry from all over the world but particularly from Europe. Offshore drilling for oil was also initiated to help bolster the Maltese economy.

New  
industries

**Industry and tourism.** Since the decline of the labour force in the Dockyard, the majority of labour is now engaged in manufacturing industries. New development is concentrated in manufactures—brewing, textiles, and consumer goods—and the encouragement of the tourist trade. The influx of tourists and some immigration

spurred a construction boom in the late 1960s based on hotels and housing. The traditional manufacture of lace and silver filigree continues.

**Agriculture and fishing.** Agricultural development is hampered by infertile soils and the lack of adequate water supplies, and large amounts of food and beverages are imported. Most farming is carried out on small terraced strips of land that preclude the introduction of large-scale mechanization. The major crops are grains, vegetables, fruit, and fodder for domestic consumption, and early potatoes, tomatoes, and onions for export. Cattle and goats are also important.

Fishing is seasonal and undeveloped. The 930 fishing boats are small and are affected by weather conditions. The fish population off the island is quite sparse, and during the summer months small lamps are used by fishermen to attract the fish.

**Finance.** The Central Bank and the Malta Development Corporation were both founded in 1968. Between 1964 and 1971 the United Kingdom provided some financial assistance in the form of loans and grants intended to blunt the economic effects of the withdrawal of British military personnel and to finance the conversion of the Dockyard. In 1972 Malta concluded a new seven-year agreement with Britain to increase considerably payments to Malta for the use of military facilities. Malta also obtained both grants and loans from a number of other countries.

In 1968 Malta joined the International Monetary Fund. In 1971 the island entered into a special trade relationship with the European Economic Community (EEC), a relationship that was subsequently revised with the aim of rendering it more favourable to Malta at a delicate stage of economic development.

**Transportation.** The road system connects all towns and villages and includes a coast road, a panoramic road, and a regional road, which connects Msida to the coast road via St. Andrews. Bus services radiating from Valletta provide cheap and frequent internal transportation. Taxis are abundant, and there is one private automobile for every nine people. Several daily sailings connect Malta and Gozo, and there is a regular ferry and special car-ferry service between Malta and Sicily. Scheduled airlines connect Malta with Britain, Italy, and North Africa; and, by the early 1970s, the desire to attract new tourists had led to efforts to establish direct links with other parts of Europe.

**Administration.** Under the 1964 Independence Constitution Malta is a constitutional monarchy and parliamentary state within the British Commonwealth: its head of state is a Maltese governor general appointed by, and representing, the British crown. Parliament, with a statutory life of five years, is basically derived from the British model. Local features include a single chamber with 55 members while election is by proportional representation from 10 electoral divisions. The governor general acts on the advice of the Cabinet, which is composed of the prime minister and eight other members and is collectively responsible to Parliament. There is no municipal government in the islands, but Gozo has a measure of local authority.

Maltese law, which was codified mainly between the period of 1854 to 1873, is largely based on the Code Napoléon and Napoleonic law. Procedural common law and some commercial and maritime affairs are regulated by English principles, but judiciary precedent is not binding. Maltese is the language of the courts. Civil and criminal jurisdiction is almost exclusively vested in the Superior Courts and the Courts of Magistrates. The chief justice and seven judges are appointed from the Maltese population by the governor general on the advice of the prime minister, and their duties are apportioned throughout the court system. Nine professional magistrates sit in the lower courts.

The  
judicial  
system

Between 1964 and 1972 Malta's main defense dispositions were those contained in a 1964 Anglo-Maltese defense agreement with the United Kingdom guaranteeing mutual assistance. The island subsequently followed a policy of nonalignment and has its own regular land

force headed by a Maltese brigadier. It also has a part-time territorial army.

**Social conditions.** There is no national full health scheme, but district medical services are available for the needy. Fees for treatment in public hospitals are reduced or waived according to the patient's financial status, and private hospitalization is also available. In 1956, social insurance was introduced covering employees over 14 years of age and self-employed and nonemployed persons between 19 years and pension age (63 years for men, 60 years for women). The program provides modest cash benefits for sickness, unemployment, invalidism, widowhood, orphanhood, and accident or disease resulting from employment. Supplementary schemes for medical assistance, age and blindness pensions, and family welfare services are also provided. Housing is a major problem, with overcrowding obtaining in 18 percent of the private dwellings.

Homes for the local population are still scarce, and the government is embarking on a sizable scheme to provide apartments and individual homes on a rental basis. The Socialist administration of the early 1970s planned considerable improvements in social services and social security.

**Education and cultural life.** The educational system, traditionally influenced by the Roman Catholic Church, is molded on the British pattern. Compulsory education for children between the ages of 6 and 14 was introduced in 1946, and secondary education for all in 1970. There are free government-run primary schools in all towns and villages and free grammar schools prepare students for university entrance. In addition, there are also a number of private schools that are run mainly by various religious groups.

Higher education is available at the teacher-training colleges, the Malta College of Arts, Science, and Technology, and the Royal University of Malta. Founded as a Jesuit college in 1592, the university became a public institution in 1769. It is an autonomous body with seven faculties—law, theology, arts, science, medicine, dentistry, and architecture and engineering.

Folk traditions in Malta have evolved mainly around the festa to celebrate the patron saint of a village, marked by processions and fireworks. Good Friday is also celebrated with colourful processions in several villages. *Imnarija*, which takes place on June 29, is the principal folk festival; it is highlighted by folk-singing (*ghana*) contests and fried-rabbit picnics at Buskett. The annual Carnival is celebrated at Valletta with vigorous dancing displays that include the *Parata* and *Il-Maltija*, the Maltese national dance.

Apart from its unique Neolithic ruins, Malta contains important examples of its flourishing architectural school of the 17th and 18th centuries. It was essentially Classical with a balanced overlay of Baroque decorations. The Italian artists Caravaggio and Preti spent several years in Malta, the latter's most important paintings embellishing many of Malta's churches.

In the 20th century, a vernacular architecture has been developed by Richard England and others. The composer Charles Camilleri has interwoven folk themes into his works, while Maltese literature has been enriched by the poetry of the late national bard, Dun Karm. There is an interesting theatrical upsurge with Francis Ebejer emerging as a brilliant playwright.

**The future.** In the years ahead, Malta's main task will be to balance economic and social development. Greater diversification will be necessary in tourism and in industry, while evolving industrial relations necessitate the wider participation of workers in management. Through fiscal measures and the provision of equal opportunities in employment and education, the imbalances evident in the local economic and social structure are giving way to a more egalitarian society.

## Malthus, Thomas Robert

Thomas Robert Malthus, English economist and pioneer in modern population study, is best known today for his theory, first stated in 1798, that the growth of population always tends to outrun growth of production, so that poverty is therefore man's most inescapable fate. For a century his theory was used by economists and policy makers to justify laissez-faire and oppose efforts toward social or economic reform.

Malthus, engraving after a portrait by J. Linnell, 1833.

**Early life.** Malthus was born near Dorking, Surrey, on February 14, 1766. His family was prosperous, and his father, a personal friend of the philosopher and skeptic David Hume, was an ardent disciple of Jean-Jacques Rousseau, whose book *Émile* may have been the source of the elder Malthus' liberal ideas about educating his son. The young Malthus was educated largely at home until

his admission to Jesus College, Cambridge, in 1784. There he studied a wide range of subjects and took prizes in Latin and Greek, graduating in 1788. He took his master of arts degree in 1791, was elected a fellow of Jesus College in 1793, and took holy orders in 1797. He wrote a pamphlet in 1796 called "The Crisis" (not published), which, among other things, took a favourable view of newly proposed poor laws, which were to set up workhouses for the poor. This was a view that ran somewhat counter to his views on poverty and population published two years later.

The opinions and teachings that Malthus developed reflect largely a reaction, amiably conducted, to his father's views and to the doctrines of the French Revolution and its supporters. The English radical philosopher William Godwin, for example, was being widely read for such works as *Political Justice* (1793), which took for granted the perfectibility of mankind and foresaw a millennium in which rational men would live prosperously and harmoniously without laws and institutions. Unlike Godwin (or, earlier, Rousseau), who viewed human affairs from a theoretical standpoint, Malthus was essentially an empiricist, and he began from the harsh realities of his time. His reaction developed in the tradition of British economics, which would today be called sociological.

*Essay on  
Population*

In 1798 he published anonymously the first edition of *An Essay on the Principle of Population as it affects the Future Improvement of Society, with Remarks on the Speculations of Mr. Godwin, M. Condorcet, and other Writers*. The work received wide notice. Briefly, crudely, yet strikingly, Malthus argued that infinite human hopes for social happiness must be vain, for population will always tend to outrun the growth of production. The increase of population will take place, if unchecked, in a geometrical progression, while the means of subsistence will increase in only an arithmetical progression. Population will always expand to the limit of subsistence and will be held there by famine, war, and ill health. "Vice" (which included, for Malthus, contraception), "misery," and "self-restraint" alone could check this excessive growth.

Malthus was an economic pessimist, viewing poverty as man's inescapable lot. The argument in this first edition is essentially abstract and analytical. To the subsequent edition of 1803, which expanded the long pamphlet of 1798 into a longer book, part of the information for which he had gathered by reading more economic and population literature and part of which he absorbed on trips to Germany, Sweden, Norway, Finland, Russia, France, and Switzerland in the intervening years, Malthus added much factual material and illustration to his thesis. At no point, even up to the final and massive sixth edition of 1826, did he ever adequately set out his premises or examine their logical status. Nor did he handle his factual and statistical materials with much critical or statistical rigour, even though during his lifetime the sophistication of statisticians was developing remarkably in both continental Europe and Great Britain. A remark by Kingsley Davis, a United States student of population, that Malthus' theories, apparently founded on so extensive an empirical base, are yet at their weakest with respect to empiricism and at their strongest as a tight and elegant theoretical formulation, has much truth in it as both praise and blame. For better or worse, the Malthusian theory of population was, nevertheless, incorporated into current theoretical systems of economics. It acted as a brake on economic optimism, helped to justify a theory of wages that made the minimum cost of subsistence of the wage earner a standard of judgment, and discouraged traditional forms of charity.

The immediate influence of the Malthusian theory of population on social policy was very great. It had been believed that fertility itself added to national wealth; the poor laws perhaps encouraged large families by their doles. If they had "never existed," wrote Malthus, "though there might have been a few more instances of severe distress, the aggregate mass of happiness among the common people would have been much greater than it is at present." These laws limited the mobility of la-

bour, he said, and encouraged fecundity and should be abolished. For the most unfortunate it might be licit to establish workhouses, not "comfortable asylums," but they should be places in which "fare should be hard" and "severe distress . . . find some alleviation."

**Life at Haileybury and world fame.** In 1804 Malthus married Harriet Eckersall and in 1805 became professor of history and political economy at the East India Company's college at Haileybury, Hertfordshire. It was the first time in Great Britain that the words political economy had been used to designate an academic office. He lived quietly at Haileybury for the remainder of his life, except for a visit to Ireland in 1817 and a trip to the Continent in 1825, for his own and his wife's health. In 1811 he met and became close friends with the economist David Ricardo.

Meanwhile, he continued publishing a variety of pamphlets and tracts on economics. In them he approached the problem of what determines price with a less rigorous analysis than Ricardo and in terms of an institutionally determined "effective demand," a phrase that he invented. In 1820 in his summary *Principles of Political Economy Considered with a View to Their Practical Application*, he went so far as to propose public works and private luxury investment, as palliatives for economic distress, that would increase effective demand and prosperity. He went further and criticized thrift as a virtue knowing no limit; to the contrary, he argued, "the principles of saving, pushed to excess, would destroy the motive to production." To maximize wealth, a nation had to balance "the power to produce and the will to consume." In fact, Malthus, as an economist concerned with what he called the problem of "gluts" or, as they would be called today, the problems of slump and depression, can be said to have anticipated the economic discoveries of John Maynard Keynes in the 1930s.

In 1819 Malthus was elected a fellow of the Royal Society; in 1821 he became a member of the Political Economy Club, the number of which included Ricardo and James Mill, and in 1824 he was elected one of the ten royal associates of the Royal Society of Literature. Malthus was one of the cofounders, in 1834, of the Statistical Society of London. In 1833 he was elected to the French Académie des Sciences Morales et Politiques and to the Royal Academy of Berlin. During these later years, though he wrote various papers, he never added substantially to what he had gathered in *Essay on Population* and *Principles of Political Economy*. Malthus died on December 23, 1834, and was buried in the Abbey Church, at Bath.

**BIBLIOGRAPHY.** W. OTTER, "Memoir," preface to the 2nd ed. of the *Principles of Political Economy* (1836), is still a basis for any biography. J. RONAR, *Malthus and His Work* (1885, reprinted and expanded 1924), is the major work of 19th-century scholarship, illuminated by very wide learning. JOHN MAYNARD KEYNES, "Robert Malthus: The First of the Cambridge Economists," in *Essays in Biography* (1933, new ed., 1957), is charming and of great importance in the rehabilitation of Malthus as a major economic theorist. D.V. GLASS (ed.), *Introduction to Malthus* (1953), contains "A Summary View of the Principles of Population" and an important letter on the Poor Laws by Malthus, in addition to a very full bibliography on the Malthusian question in the 19th century and three useful essays discussing Malthus in historical perspective. A. FLEW, "The Structure of Malthus' Population Theory," *Australasian Journal of Philosophy*, 35:1-20 (1957), and the same author's edited version of Malthus' *An Essay on the Principle of Population* (1970), were contributed by a critic and philosopher who has brought both logical rigour and sympathy to the clarification of Malthus' analysis so that no more favourable case can be made for the Malthusian theory of population in modern terms. P.M. HAUSER and O.D. DUNCAN (eds.), *The Study of Population: An Inventory and Appraisal* (1959), though already partly out of date, is a most useful single introduction to modern population studies so far as the issues raised by Malthus are alive in the late 20th century. K. SMITH, *The Malthusian Controversy* (1951); and D.E.C. EVERSLEY, *Social Theories of Fertility and the Malthusian Debate* (1959), are two admirable and scholarly discussions of all the issues surrounding the Malthusian population theory in its long history.

of  
Political  
Economy*

## Malvales

Malvales, the mallow order, is a relatively small order of flowering plants (in the class Dicotyledoneae) containing nine families and about 3,000 species, most of which are woody plants, though some are herbaceous. The order is found throughout the world, except in the Arctic, in nearly all types of habitats, especially in the warm temperate and tropical regions.

A number of plants in this order are economically or aesthetically important; for example, the cotton genus (*Gossypium*), the source of chocolate (*Theobroma cacao*), and plants cultivated for their beautiful flowers (*Hibiscus*, *Althaea*, and others).

Fruits of a large number of species of the Sterculiaceae family are rich in caffeine and those of *Theobroma cacao* also contain the alkaloid theobromine. West African kola nuts from species of the genus *Cola* also contain the heart-stimulating glucoside kolanin. In addition, alkaloids have been detected in numerous other species, including *Waltheria indica* (family Sterculiaceae), several species of *Elaeocarpus* and *Sloanea* (Elaeocarpaceae), a number of genera of the family Malvaceae, and *Corchorus* and *Grewia* (Tiliaceae).

### GENERAL FEATURES

**Size range and diversity of structure.** The life-forms exhibited by plants in the order Malvales are diverse, including plants with a size range from small herbs to large trees. None, however, is parasitic or normally epiphytic (not rooted in soil but living among tree branches), nor are there any particularly succulent species. In the family Bombacaceae the trees often develop swollen trunks, a feature particularly well exemplified in the baobab (*Adansonia digitata*) of tropical Africa (with related species in the Malagasy Republic and one in northwest Australia), a tree noted not for its height but for its remarkable girth, which may reach nine metres (about 30 feet) in diameter.

**Importance to man.** *Ochroma pyramidale* (family Bombacaceae) is the source of balsa wood, the lightest of all timbers. The trees are natives of the area from Mexico to Bolivia, in Brazil, and in the Antilles.

*Ceiba pentandra* (Bombacaceae), the silk-cotton, or kapok, tree, is a widely buttressed tree up to 60 metres (200 feet) high, native to tropical America but now widely distributed throughout the tropics. Kapok, the resilient water-resistant hairs from the fruit capsules, is used for upholstery, lifesaving equipment, quilts, and other products. *Bombax ceiba*, the cotton tree of tropical Asia, produces an inferior kapok.

*Durio zibethinus* (Bombacaceae), a large buttressed tree native perhaps in Sumatra and Borneo, is now cultivated and often naturalized throughout tropical Southeast Asia for its fruit, the durian, which is famous for its delicate flavour but disagreeable odour.

The family Elaeocarpaceae contains no plants of great economic importance, although a few are sometimes grown for their horticultural merit; for example, *Muntingia calabura*, often cultivated, and naturalized in parts of Florida. Other horticultural plants include species of *Elaeocarpus* and *Crinodendron*, especially *C. hookeriana*, a native of Chile, the lantern tree. The fruits of *Aristolelia macqui*, the macqui, are eaten in Chile.

*Abutilon theophrasti* (Malvaceae) is cultivated in northern China for its bast fibres, Chinese jute, which are used to make ropes, twine, and other fibre products.

*Althaea rosea* (Malvaceae), the hollyhock, a native of the eastern Mediterranean region, is widely cultivated in temperate gardens. The well-known *Hibiscus rosa-sinensis* (Malvaceae) is grown throughout the tropics for its flamboyant flowers. *H. esculentus* (also known as *Abelmoschus esculentus*), okra, is widely cultivated in tropical regions for its edible, mucilaginous, immature fruits, much used in soups. *H. sabdariffa*, the roselle, is used for its sweet calyx or as a potherb.

Cotton is obtained from species of the genus *Gossypium* (Malvaceae) and consists of the hairs that have developed on the seeds. In addition, cottonseed oil is extracted from the seeds themselves and cottonseed-oil

cake, the residue, is used to feed cattle. There are about 20 wild species of *Gossypium*, perhaps three in Australia, seven in Africa and Southwest Asia, and eight in the Americas. All of them are lintless; that is, the individual seed hairs, even when well-developed, are without convolutions. They are perennial shrubs that occur naturally in open habitats of dry regions of the tropics and subtropics, especially on banks of creeks or stream beds that are dry during most of the year. Such habitats are preferred because the seedlings are highly susceptible to competition from other plants. The domesticated cottons, two species, bear seeds with lint that may be spun. They have double the number of chromosomes found in the wild species and arose by hybridization some time in the past between Old and New World species. At first perennial, they later developed an annual habit, as shown in the modern races.

The genus *Cola* (Sterculiaceae), *C. nitida* and *C. acuminata* especially, is the source of kola nuts. These two species are forest trees native to West Africa, and there they are often cultivated beyond the area of their natural distribution. Kola nuts constitute an important article of trade in West Africa and are a rich source of caffeine. They also contain the glucoside kolanin and when chewed confer considerable ability to withstand fatigue.

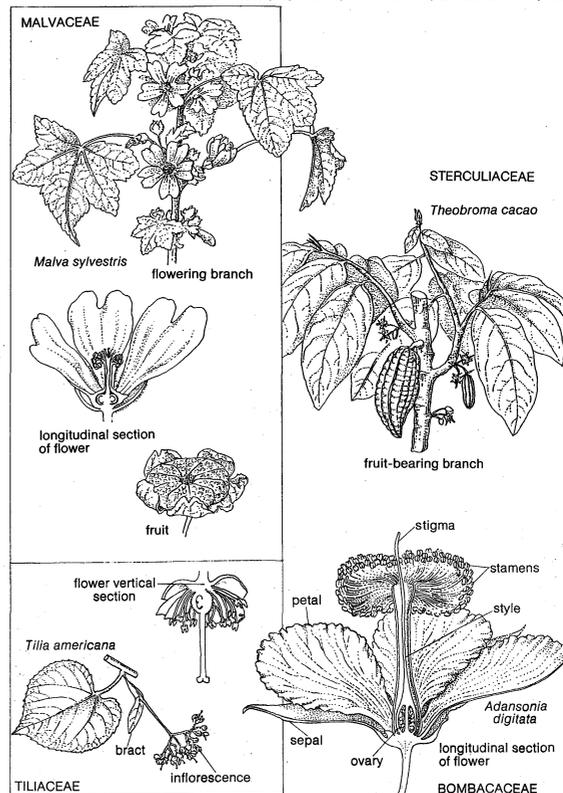

The species *Theobroma cacao* (Sterculiaceae), cacao, is one of about 22 species in the genus and is native from the central part of the Amazon Basin and Guyana westward and northward to southern Mexico. Its fruits are the source of cocoa, chocolate, and cocoa butter. There are two main types of cocoa trees, their distributions separated by the Isthmus of Panama. The subspecies *cacao*, from Mexico and Central America, corresponds to the "Criollo" cultivars, while the subspecies *T. cacao sphaerocarpum* of South America contains the "Forastero" varieties. The large, tough, berrylike fruits containing the seeds, or beans as they are called, are often borne directly on the tree trunks. Cocoa butter is obtained from the beans by pressing and cocoa by roasting them.

The genus *Tilia* (Tiliaceae), the lindens or limes (not to be confused with the unrelated tropical limes, *Citrus aurantifolia* [family Rutaceae, order Rutales]), particular-

Drawing by M. Pahl based on (Tiliaceae) G.H.M. Lawrence, *Taxonomy of Flowering Plants* (1951); Macmillan & Co., and (others) H. Baillon, *The Natural History of Plants*, vol. 4 (1875); L. Reeve & Co., Ltd.

Representative plants and structures from four of the largest families of the order Malvales.

ly *T. americana* and *T. × europaea*, are valuable as timber trees and for the fibre below the bark, the bast fibre, which is much used in country districts. The nectar secreted at the base of the sepals in the sweetly scented flowers has been much sought after by bees and produces highly prized honey.

*Corchorus capsularis* and *C. olitorius* (Tiliaceae) constitute the chief source of jute or gunny and—especially *C. capsularis*—are much cultivated in India and Bangladesh and, to a lesser extent, elsewhere. The plants form sparsely branched annuals up to about three metres (ten feet) high. When ready, the stems are cut, retted in water, and the fibre extracted by beating. The leaves and young shoots are also eaten as a vegetable or potherb; *C. olitorius* has been cultivated for this purpose from ancient times, especially in Egypt. The seeds, however, are poisonous and contain glycosides of the type found in the genus *Digitalis* (family Scrophulariaceae, order Scrophulariales).

#### NATURAL HISTORY

**Pollination.** Although little is known about the majority of the genera and several of the families in this order, it appears that the flowers, with their bright colours and nectaries, are generally adapted to pollination by insects or birds. A number are pollinated by bats, especially in the family Bombacaceae. Wind pollination is rare and perhaps of only secondary importance. Flowers are commonly protandrous; that is, the male stamens develop and mature before the styles (female structures that receive the pollen) of the same flower, an adaptation that favours cross-pollination. In some weedy species in the family Malvaceae, however, the styles eventually bend over to touch the withered stamens, still bearing some pollen, and effect self-pollination, thus ensuring fertilization in case pollen from some other source has failed to reach the styles.

In the African genus *Sparmannia*, the showy flowers contain numerous fertile and sterile stamens that are sensitive to touch; they bend outward from the centre when stimulated, presumably to aid pollination.

Insect  
pollination

Elaborate adaptations to insect pollination are found in many members of the family Sterculiaceae. The flowers of the genus *Abroma* are a good example of "lantern-flowers," which have small "windows" in the petals that permit light to shine through, thus attracting insects. In many genera, especially *Sterculia* itself, dark-purple or chocolate-coloured flowers with a fetid odour attract flies. *Theobroma cacao*, the source of cacao and of chocolate, is pollinated by diverse types of small insects; thrips, ants, midges, and aphids have been recorded.

Pollination by hummingbirds, sunbirds, and others is widespread in many tropical species. The red flowers of *Malvaviscus*, which have a relatively narrow tube formed by the overlapping petals and have protruding stamens and styles, are an excellent example of adaptation to pollination by hummingbirds.

*Hibiscadelphus*, a rare native Hawaiian genus, two of four species of which are already extinct, is adapted to bird pollination. Here the natural pollinating bird may be extinct or nearing extinction too, and hand-pollination by man of the few remaining trees is necessary to ensure a good seed set.

Pollination by bats is widespread in the family Bombacaceae. In the genus *Adansonia*, for example, the drab-coloured flowers with their numerous stamens hang down below the foliage where bats can easily reach them. This association of characters is typical of flowers adapted to pollination by bats. Bat pollination has also been recorded for *Ochroma*, *Ceiba*, and *Durio* (of the family Bombacaceae).

**Seed dispersal.** Methods of seed dispersal are not particularly remarkable in the order Malvales. Fruits usually take the form of dry capsules or schizocarps (fruits that separate into pieces at maturity), which are sometimes hooked for dispersal by attachment to animals' coats. Drupes (stone-seeded fruits) and berries also occur; the latter are large and leathery, as in the genus *Theobroma*, or juicy, as in *Malvaviscus*.

#### FORM AND FUNCTION

**Distinguishing characteristics.** The family Bombacaceae is distinguished by a combination of characters of which the most diagnostic is perhaps the unilocular (single-chambered) anther containing smooth pollen, which distinguishes it from the very closely related family Malvaceae.

The diagnostic characters of the family Elaeocarpaceae include flowers without an epicalyx (a series of bracts close to, and resembling, the sepals), petals that are often characteristically fringed or divided at their ends, and anthers that usually open by two apical pores (small openings in the end of the pollen sac).

The family Malvaceae is identified by the characteristic combination of a united column of stamens with unilocular anthers containing spiny pollen grains, especially when combined with the possession of an epicalyx and petals convoluted in the bud.

The Huaceae is a small and little-known family in which the petals are stalked and more or less persistent. There is a single basal ovule in the genus *Hua* and six in *Afrostryrax*; the seeds in both genera smell strongly of onions.

The family Rhopalocarpaceae (Sphaerosepalaceae) has flowers with imbricate (overlapping) petals densely streaked with short resinous lines, and the numerous stamens are dotted as well.

The family Sarcolaenaceae (Chlaenaceae) has flowers with large petals, that are convolute in the bud, similar to those of many other members of the order Malvales. The stamens are usually numerous and are borne inside a disk or a cupular ring of staminodes (sterile stamens). The fruit is often surrounded by lignified (woody) bracts.

The family Tiliaceae has flowers of a somewhat generalized type for the order, with five valvate (*i.e.*, touching edge to edge in the bud; not overlapped) sepals, five convolute, imbricate, or valvate petals, usually numerous stamens that are free or united into groups, a superior ovary of united carpels, and seeds with endosperm (a starchy nutrient tissue for the developing embryo).

The family Scytopetalaceae has leaves that lack stipules (basal appendages) and that are often asymmetrical at the base. In the flower the valvate petals are either reflexed at anthesis (flower opening) or do not separate but fall as an entire cap when the flower opens. The seeds are sometimes covered with agglutinated mucilaginous hairs.

The family Sterculiaceae has leaves that are often digitately divided. The flowers are sometimes unisexual and may be without petals, the stamens are free or united into a column, and the pollen is nonspiny.

Anatomical characters indicate a very close affinity between the families Malvaceae, Bombacaceae, Sterculiaceae, and Tiliaceae, and, to a slightly lesser degree, the family Elaeocarpaceae. Mucilage cells are found in the tissues of all five of these families, and mucilage cavities and canals are found in the tissues of most of them. Pericyclic fibre bundles are characteristic of most families in the order. Many of these fibres are of great economic importance—*e.g.*, jute and various hemps.

The presence of stellate hairs (hairs branched in a star-like pattern) on leaves and young stems is often characteristic, especially of the families Malvaceae, Bombacaceae, Sterculiaceae, and Tiliaceae.

**Pollen.** Pollen grains in the order Malvales are generally three-pored (tricolpate), often with the pores sunken or sometimes with several apertures. In shape, the pollen grains are generally more or less flattened spheres. The surface is generally ridged, but in the family Malvaceae the grains are characteristically spiny. In fact, one of the factors that helps to place the genera around *Hibiscus* and *Gossypium* in the Malvaceae rather than in the Bombacaceae (in which, on fruit characters, they have been classified by some authorities) is their possession of spiny pollen.

Nonspiny pollen of a basically similar kind is common to members of the families Tiliaceae, Bombacaceae, Sterculiaceae, and Scytopetalaceae. The pollen of the Elaeocarpaceae is somewhat like that of the Tiliaceae but much smaller; however, grains that are very similar indeed are

Basis of  
relationships  
between  
families

found in the family Flacourtiaceae of the order Violales, the group suggested by some as being the nearest family outside the order Malvales.

The pollen of the family Sarcocaulaceae is somewhat remarkable and has been investigated in detail. In all of the genera of that family the grains are united in firm tetrads (groups of four), sometimes with individual grains more or less degenerate and therefore smaller than the others. At first sight they appear quite dissimilar from any others in the order Malvales, yet the fine reticulations of the surface pattern show some affinity with the family Tiliaceae.

#### EVOLUTION

The earliest fossil remains, the petrified wood *Hibiscoxylon niloticum*, recognizable as belonging to the order Malvales date from Cretaceous deposits (about 100,000,000 years ago) in Egypt. Elsewhere, leaf impressions resembling the present-day genus *Sterculia* have been recorded from the Upper Cretaceous.

Fossil record

From the Eocene (about 50,000,000 years ago) numerous leaves and some fruits have been recognized as belonging to families in the order Malvales. A species of *Echinocarpus* (Elaeocarpaceae), for example, has been described from fruits in southern England, but other remains, not attributable to present-day genera, have been given fossil names—e.g., *Sphinxia* (Sterculiaceae), and *Cantitilia* (Tiliaceae). From later Tertiary beds (about 20,000,000 years old, or less) numerous Malvacean fossils have been reported from many different parts of the world, including Europe, North and South America, Central and eastern Asia, and Australia. Leaf remains have been attributed to several modern genera—e.g., *Elaeocarpus*, *Vallea*, and *Sloanea* (Elaeocarpaceae); *Bombax* and *Hampea* (Bombacaceae); *Sterculia*, *Byttneria*, *Pterospermum*, *Melochia*, and *Theobroma* (Sterculiaceae). From the Pliocene (about 5,000,000 years ago) even more numerous and recognizable leaf and fruit remains are recorded.

Fossil pollen attributed to the genus *Tilia* has been recorded from as far back as the Upper Cretaceous Period (about 65,000,000 years ago), and Bombacaceae-like pollen from Upper Cretaceous or Early Tertiary deposits in Brazil.

##### Annotated classification.

#### ORDER MALVALES

Trees, shrubs, or herbs, often with mucilaginous juice and fibrous stems. Leaves alternate, rarely opposite, usually with stipules. Flowers cyclical (rarely having the carpels more or less spirally arranged); hermaphroditic, sometimes unisexual. Calyx and corolla members usually 5-merous (present in groups of 5), usually distinct, rarely lacking petals, regular, rarely somewhat bilaterally symmetrical; epicalyx often present; sepals usually valvate; petals mostly convoluted in bud, sometimes imbricate or valvate. Stamens usually numerous, free, or shortly connate at the base into 5–10 bundles, or united into a staminal column surrounding the style. Carpels 2 to many, united, superior, rarely inferior, with 1 to many axile, rarely parietal (attached to ovary wall) ovules. Fruit various, seeds usually with some endosperm. Nine families, about 240 genera, and 3,000 species.

##### Family Bombacaceae

Trees, often large with thick trunks. Leaves simple or palmate, alternate, often containing mucilage cells. Flowers bisexual, often large, usually regular. Calyx valvate, often with an epicalyx. Petals 5, often large, sometimes absent, convoluted in the bud. Stamens 5 to numerous, free or united into a tube; anthers usually unilocular. Ovary superior, of 2–5 united carpels; style simple, capitate or lobed. Fruit a capsule, sometimes indehiscent; seeds with little or no endosperm, often surrounded by hairs from the inner wall of the capsule. About 20 genera and 180 species with worldwide distribution in the tropics, especially of the New World.

##### Family Elaeocarpaceae

Trees and shrubs. Leaves simple, alternate or opposite, without mucilage cells. Flowers usually bisexual and regular. Calyx valvate without an epicalyx. Petals 4 or 5, usually free, sometimes absent, often much divided at their ends, usually valvate, imbricate, never convoluted, in bud. Stamens numerous, free, arising from a disk that is sometimes developed into an an-

drophore (a structure bearing the male flower parts); anthers bilocular, usually opening by 2 apical pores. Ovary superior, with 2 to many (rarely 1) united carpels; style simple, often lobed at its apex. Fruit a capsule or drupe; seeds with abundant endosperm. About 10 genera and 350 species of wide distribution in the tropics and subtropics, centred in western Melanesia and South America but absent from continental Africa.

##### Family Huaceae

Trees. Leaves simple, entire, and stipulate. Flowers bisexual, regular, and small. Calyx of 3–5 valvate lobes. Petals 4–5 free, in *Hua* with a slender claw, induplicate-valvate in the bud, more or less persistent. Stamens 10, free, in one series; anthers with 4 locules, the 2 lower smaller than the upper. Ovary superior, of 5 united carpels but 1-locular; style simple; ovules 1 on a basal placenta in *Hua*, 6 basal ovules in *Afrostryax*. Fruit relatively large, a 1-seeded capsule, dehiscent from the apex (*Hua*) or indehiscent (*Afrostryax*); seed with copious endosperm smelling of onions in both genera. One genus, *Hua*, with 2 species or, according to some authorities, the family also contains the genus *Afrostryax* with 5 species. Distributed in tropical Africa.

##### Family Malvaceae

Herbs or shrubs, rarely small trees. Leaves stipulate, alternate, simple or variously lobed, especially palmately so, mucilage cells present, also in the stem tissue. Flowers usually bisexual, regular, usually 5-merous. Calyx valvate, frequently with an epicalyx. Petals 5, free, although appearing united at the base due to junction with the filament bases, often individually asymmetrical, convoluted in bud. Stamens numerous due to branching of the inner whorl (the outer whorl usually absent), all united below to form a tube joined to the petals and surrounding the style; anthers unilocular (each consisting of half an anther by division), opening longitudinally; pollen spiny. Ovary superior with 1 to many, commonly 5, united carpels (in a few genera the several carpels are arranged in a spiral cluster); style branched above with the same number or, more rarely, twice as many branches as carpels. Fruit a dry capsule or a schizocarp (rarely in *Malvaviscus* a berry); seeds usually with a little endosperm or with none. About 75 genera and 1,000 species with wide distribution throughout the world, except in the Arctic.

##### Family Rhopalocarpaceae

Trees and shrubs. Leaves alternate, simple, with stipules partially encircling the stem and leaving a prominent scar on falling. Flowers bisexual, regular. Calyx of 4 (rarely 3 + 3) unequal, strongly imbricate lobes. Petals 4 (rarely 3) unequal, imbricate in the bud, densely streaked with short resinous lines. Stamens numerous, more or less connate at the base, resin dotted; anthers small, bilocular; within the stamens a large cupular disk. Ovary superior of 2 (rarely 3) united carpels; style simple, geniculate, with an entire stigma. Fruit 1- (rarely 2-) seeded, globose, densely muricate; seed large with abundant endosperm and a minute embryo. Two genera and 14 species, known only from the Malagasy Republic.

##### Family Sarcocaulaceae

Trees and shrubs. Leaves alternate, simple, with stipules that are often large, mucilaginous cells present. Flowers bisexual, regular. Calyx of 3–5 equal or unequal, imbricate lobes. Petals 5–6, large, convolute in bud. Stamens numerous (rarely 5 or 10) sometimes fasciculate, arising inside a disk or cupular ring of staminodes (sterile stamens); anthers bilocular, dehiscent longitudinally. Ovary superior, of 1–5 united carpels; style usually thick, more or less elongated, usually with a lobed stigma. Fruit a capsule with several-seeded locules, or 1-seeded and indehiscent; often surrounded by lignified bracts; seed with endosperm. Eight genera and about 30 species, known only from the Malagasy Republic.

##### Family Scytopetalaceae

Trees or shrubs. Leaves simple, alternate, often asymmetrical at their bases, without stipules. Flowers bisexual, regular. Calyx of 3–4 united persistent lobes, often petaloid or cuplike. Petals 3–16, valvate in bud, free and reflexed at anthesis or not separating and falling as an entire cap, sometimes thick in texture. Stamens numerous in 3–6 series, free or sometimes connate below; anthers bilocular, often opening by an apical pore. Ovary of 3–8 superior united carpels, the locules sometimes incomplete in the upper portion; style simple with a small stigma. Fruit usually a tardily dehiscent capsule, often woody; seeds with copious endosperm, sometimes covered with agglutinated mucilaginous hairs. Five genera and about 20 species, native to tropical Africa.

##### Family Sterculiaceae

Trees, shrubs, or herbs. Leaves simple or digitately divided, alternate, stipulate, often containing mucilage. Flowers unisexual or bisexual, usually regular. Calyx of 3–5 united, valvate sepals, without an epicalyx. Petals 5, in some genera of-

ten absent or small, convoluted. Stamens 5–45 in 2 whorls, the outer sometimes staminoidal or absent, the inner often branched, free or more or less united into a tube; anthers bilocular, pollen smooth. Ovary superior, usually of 5, sometimes 1–4 or 10–12 united carpels; style simple and lobed, rarely divided to the base. Fruit various, often a schizocarp; seed with or without endosperm. About 65 genera and 1,000 species, found chiefly in the tropics and subtropics.

#### Family Tiliaceae

Trees and shrubs, rarely herbs. Leaves simple, alternate, stipulate. Flowers usually bisexual, regular. Calyx of 5 sepals, free or united, valvate, sometimes with an epicalyx. Petals 5, rarely apetalous, convolute, imbricate or valvate in bud. Stamens usually numerous, inserted at the base of the petals or on an androphore, free or united into 5 or 10 groups; anthers bilocular, dehiscing by a longitudinal slit or an apical pore. Ovary superior with 2 to numerous united carpels; style simple with a capitate or lobed stigma. Fruit a capsule or schizocarp, rarely baccate; seed with endosperm. About 50 genera and 450 species, of which only the genera *Tilia* (50 species mainly in northern temperate areas) and *Entelea* (New Zealand, 1 species) are temperate in distribution. The remainder are tropical, especially centred in Southeast Asia and in Brazil.

**Critical appraisal.** All recent classifications agree on the close relationship between the families Bombacaceae, Malvaceae, Sterculiaceae, and Tiliaceae although a few authorities maintain two related orders, the Tiliales and Malvales, the latter containing only the family Malvaceae. Careful revisionary work on the order is highly desirable, and it should consider recent evidence from cytology, pollen studies, etc., and may perhaps lead to some rearrangements of a few genera among these families. The family Elaeocarpaceae, which is retained by some workers within the Tiliaceae, is separable from this close group on a number of characters and appears to be the most primitive family in the order, with a more generalized flower structure and a more primitive wood anatomy. A relationship with the family Flacourtiaceae (order Violales) is postulated by most authorities and supported by evidence from both floral and pollen-grain morphology.

Uncertain relationships of smaller families

The families included here in the order Malvales follow a recent classification system. Knowledge of the four smaller families is still inadequate. They are all confined to Africa, and two of them, the Rhopalocarpaceae and Sarcocaulaceae, are restricted to the Malagasy Republic. Some authorities classify them in an order called the Ochanales. All four are little represented in collections, and, for most of them, knowledge of their comparative anatomy, pollen morphology and comparative biochemistry is meagre or nonexistent. Clearly, they are less closely related to the larger families of the order, and even the inclusion here of the family Huaceae is somewhat speculative. Some evidence of affinity exists, but more work is required to support it or to point to true affinities.

## Mamlüks

The use of Mamlüks (Mamelukes; slaves; literally, "owned men," or men of slave origin) as a major component of Muslim armies became a distinct feature of Islāmic civilization as early as the 9th century AD. The practice was begun in Baghdad by the 'Abbāsīd caliph al-Mu'tasim (833–842), and it soon spread throughout the Muslim world with the formation of slave armies by almost every Muslim dynasty of the Middle Ages, from the Ghaznavids of Afghanistan in the east to the Umayyads of Spain in the west. Moreover, the political result was almost invariably the same: the slaves exploited the military power vested in

Formation of slave armies

them to seize control over the legitimate political authorities, often only briefly but sometimes for astonishingly long periods of time. Thus, soon after al-Mu'tasim's reign the caliphate itself fell victim to the Turkish Mamlük generals, who were able to depose or murder caliphs almost with impunity. Although the caliphate was maintained as a symbol of legitimate authority, the actual power was wielded by the Mamlük generals; and by the 13th century, Mamlüks had succeeded in establishing dynasties of their own, both in Egypt and in India, in which the sultans were necessarily men of slave origin or the heirs of such men.

Undoubtedly the leniency recommended by Islām in the treatment of slaves helps explain the universal acceptance of a slave-based military and political institution. Both the origin and pervasiveness of such an institution, however, should be sought in the evolution of Muslim armies. Muslim rulers inevitably found the original components of their armies, whether basically tribal or regional in character, to be unreliable as loyal and effective fighting forces. Therefore, to augment or replace these components, the rulers resorted to forming corps of slaves, acquired either by purchase or capture, whose loyalty was ensured by the fact that their very existence was dependent on their owners. All too frequently, however, the loyalty of the troops was directed toward their commanders, also Mamlüks, whose power the ruler could offset only by purchasing more and more contingents of Mamlüks and thereby providing a force strong enough to usurp the power of the state.

#### THE MAMLUK DYNASTY (1250–1517)

**History.** This process of usurping power is epitomized by and culminated in the establishment of the Mamlük dynasty, which ruled Egypt and Syria from 1250 to 1517 and whose descendants survived in Egypt as an important political force during the Ottoman occupation (1517–1798). The Kurdish general Saladin, who captured control of Egypt in 1169, followed what by then constituted a tradition in Muslim military practice by including a slave corps in his army in addition to Kurdish, Arab, Turkmen, and other free elements. This practice was also followed by his successors, the Ayyūbids, and was intensified when individual members of the royal family attempted to build up their own power in order to defend, or to capture, the throne of Egypt and Syria. Al-Malik aṣ-Ṣāliḥ Ayyūb (1240–49) is reputed to have been the largest purchaser of slaves, chiefly Turkish, as a means of protecting his sultanate both from Ayyūbid rivals and from the crusaders. Upon his death in 1249 a scramble for his throne ensued, in the course of which the Mamlük generals murdered his heir and eventually succeeded in establishing one of their own number as sultan. Thenceforth, for more than 250 years, Egypt and Syria were ruled by Mamlüks or sons of Mamlüks.

Establishment of the Mamlük dynasty

Historians have traditionally broken the era of Mamlük rule into two periods—one covering 1250–1382, the other, 1382–1517. Western historians persist in calling the former the "Baḥrī" period and the latter the "Burjī," because of the political dominance of the regiments known by these names during the respective times. More meaningfully, however, the contemporary Muslim historians referred to the same divisions as the "Turkish" and "Circassian" periods in order to call attention to the change in ethnic origin of the majority of Mamlüks, which occurred and persisted after the accession of Barqūq in 1382, and to the effects that this change had on the fortunes of the state.

There is universal agreement among historians that the Mamlük state reached its height under the Turkish sultans and then fell into a prolonged phase of decline under the Circassians. The principal achievements of the Turkish Mamlüks lay in their expulsion of the remaining crusaders from the Levant and their rout of the Mongols in Palestine and Syria; they thereby earned the thanks of all Muslims for saving Arabic-Islāmic civilization from destruction. It is doubtful, however, that such a goal figured in their plans; rather, as rulers of Egypt they were seeking to reconstitute the Egyptian Empire, which for centuries,

Mamlük achievements

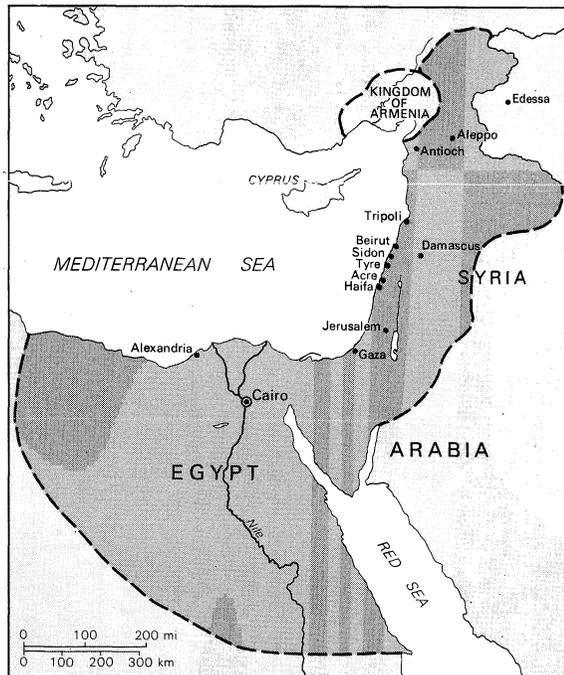

both in Islāmic and pre-Islāmic times, included the elimination of hostile forces from the eastern flank of Egypt and the maintenance of secure trade routes leading into Syria. Concomitant with their campaigns against crusaders and Mongols, and as a part of the same strategy, the Mamlūks also sought to extend their power into the Arabian Peninsula and into Anatolia and Little Armenia; to protect Egypt's rear, they strove to establish their presence in Nubia.

In order to consolidate their position in the Islāmic world and to clothe their regime in legitimacy, the Mamlūks revived the caliphate, which the Mongols had destroyed in 1258, and installed a caliph under their surveillance in Cairo. Their patronage of the rulers of the holy cities of Arabia, Mecca and Medina, served the same purpose. Spectacular success in war and diplomacy was underpinned economically by the Mamlūks' support of industries and crafts as well as by their efforts to restore Egypt's position as entrepôt in the spice trade between India and Europe. The Mamlūks' efforts were finally rewarded toward the end of the Bahṛī/Turkish period, when the inland routes of Asia were closed and Egypt once again became the principal transit route between the Orient and the Mediterranean.

Among the most outstanding Mamlūk sultans were Baybars I (1260–77) and al-Malik an-Nāṣir (1293–1341). The Mamlūks' failure to find an able successor after the latter's death weakened the strength and stability of their realm. But the historians of the era date the beginning of the dynasty's decline from the accession of the first Circassian sultan (Barqūq) in 1382, claiming that thereafter,

The decline of the dynasty

Mamlūk sultanate c. 1350.

advancement in the state and the army was dependent on race (*i.e.*, Circassian descent) rather than on proved skill in the art of war, which had served as the chief criterion for promotion during the Turkish period. Actually, the increased importance assigned to ethnic affiliation was but one cause of decline; equally or even more important were economic and other factors. In spite of the renewal of the flourishing spice commerce in Egypt and Syria by 1375, within the next 25 years the entire Mamlūk economy had begun to decay: agricultural revenues, tax and custom receipts, and industrial productivity had all fallen off sharply by the end of the 14th century, never to recover during the Mamlūk era. Part of the explanation undoubtedly lies in the inability of the Mamlūks, split into hostile factions, to provide necessary safeguards against the Bedouins for the peaceful conduct of trade and agri-

culture. But recent research indicates that the demographic losses caused by plagues that raged in Egypt and elsewhere in the East also contributed to economic decay. In such conditions the Mamlūks were unable to defend Syria against Timur Lenk in 1400. Under the rule of Sultan Barsbay (1422–38) internal stability was restored briefly and Mamlūk glory resuscitated by the conquest of Cyprus in 1426. Yet the increasingly higher taxes demanded to finance such ventures enlarged the Mamlūks' financial difficulties. The final economic blow fell with the Portuguese assault on trade in the Red Sea (*c.* 1500), which was accompanied by Ottoman expansion into Mamlūk territory in Syria. Having failed to adopt field artillery as a weapon in any but siege warfare, the Mamlūks were decisively defeated by the Ottomans both in Syria and in Egypt and from 1517 onward constituted only one of the several components that formed the political structure of Egypt.

**Government, society, and culture.** The extraordinary richness of historical sources for the Mamlūk dynasty (probably greater than that for any preceding period of Islāmic history) provides abundant details on the structure of Mamlūk government, society, and culture. Like all other Muslim governments, the Mamlūk state consisted of two classes—*ahl al-qalam* (people of the pen) and *ahl as-sayf* (people of the sword). The former consisted of scribes, judges, and legal scholars, and it staffed the vast bureaucracy that had existed in Egypt since ancient times and that was now responsible for administering the Islāmic law and the fiscal policy of the state. What distinguishes the Mamlūk from other Muslim governments is that *ahl as-sayf* consisted largely of Mamlūks who in addition to commanding and manning the army also filled the highest offices of state as a principle of policy: the sultan, the viceroy, the chief of chancery, and all the provincial governors were Mamlūks, as were numerous court officials who enjoyed considerable influence because of their intimacy with the sultan. Thus it is no exaggeration to say that Egypt and Syria were ruled for two and a half centuries by an elite whose members were of slave origin or descent. The reason the Mamlūks as a class were able to maintain political control is, very obviously, the fact that they held complete and absolute control of the army.

The Mamlūk army had three main divisions: The Royal Mamlūks were the personal property of the reigning sultan and were acquired either by purchase or inheritance; the Mamlūks of the Amirs were the property of officers (many, if not most, of whom were drawn from the Royal Mamlūks), who were ranked according to the number of Mamlūks that they owned; the *ḥalqah* was a nonslave cavalry unit that consisted of sons of Mamlūks and recruits from the free-born Muslim citizenry. These three units formed a hierarchy headed by the sultan; his ability to maintain himself on the throne depended mainly on the strength of his Royal Mamlūks who, in addition to forming the core of the army, filled all of the chief offices of state.

Military strength and the threat of force were not, of course, sufficient to give stability to the Mamlūk state. Stability was provided by a complex system of loyalties engendered by the common experience and common training required to become a Mamlūk. The aim of the system was to produce a class of skilled warriors who, being cut off from homeland, family, and religion, would be completely dependent on and loyal to the sultan or the officer who had purchased them, trained them, and then granted them freedom and enrolled them in his military service. Slave merchants, acting as agents of the Mamlūks, frequented the slave markets of western Asia and regularly delivered to Cairo consignments of adolescent boys—mainly from the Qipchak steppe and later from the Caucasus. In Egypt the boys were quartered in special barracks and enrolled in a Mamlūk school, where they were taught horsemanship and the military arts and given basic instruction in Islām. Upon graduation they were given both their freedom and their military equipment and were assigned to the ranks of their purchaser with fiefs to support them. During times of political stability

The Mamlūk army

The  
social  
hierarchy

and economic prosperity the system worked remarkably well in developing a strong sense of esprit de corps and loyalty toward their commanders among boys who had undergone the same experience at the same time. From the beginning, however, the system contained elements of rivalry and factionalism, which, in the absence of a strong ruler and adequate funds, could develop into anarchy.

Because the Mamluks controlled trade, the government, and the army and owned the major part of the land, they dominated the dynamics of Egyptian and Syrian society. Besides the military elite, society was composed of two classes: civilian notables, consisting mainly of religious scholars, scribes, and merchants; and the common people, consisting of artisans, workers, and peasants. The notables served Mamluk interests either in the governmental bureaucracy or in trade and commerce, which were directly and indirectly controlled by Mamluk needs. The notables were assimilated into Mamluk society; but the common people, in the absence of organized corporate life, were isolated both from the Mamluks and from the notables and always posed the danger of violent upheaval when their needs were ignored. It is a measure of the power and skill of the Mamluk government that violence was usually kept in check.

Culturally, the Mamluk period is known mainly for its achievements in historical writing and in architecture and for an abortive attempt at socio-religious reform. Mamluk historians were prolific chroniclers, biographers, and encyclopaedists; they were not strikingly original, with the exception of Ibn Khaldun (*q.v.*), whose formative and creative years were spent outside Mamluk territory in the Maghrib (North Africa). As builders of religious edifices—mosques, schools, monasteries and, above all, tombs—the Mamluks endowed Cairo with some of its most impressive monuments, many of which are still standing; the Mamluk tomb-mosques can be recognized by stone domes whose massiveness is offset by geometrical carvings. By far the most famous single religious figure of the period was Ibn Taymiyah; the stubborn attempts of this Syrian jurist to rid Mamluk Islam of superstition and foreign accretions made him a threat to public order, and the Mamluk authorities rewarded him with imprisonment.

#### THE MAMLUKS UNDER THE OTTOMANS (1517-1798)

With the Ottoman victories over the Mamluks in 1516-17, Egypt and Syria reverted to the status of provinces within an empire. Although the Mamluk sultanate was destroyed, this did not mean the destruction of the power of the Mamluks as a class. In fact the Ottoman sultan Selim I appointed Mamluks as his viceroys in both Egypt and Syria. Ottoman troops were garrisoned in both provinces as a check to the viceroys' ambitions, but administrative and fiscal practice remained for a time the same as it had been under the Mamluks, the main difference being that tax revenues were now sent to Istanbul. This arrangement lasted only until the mid-16th century; thereafter, Ottoman governors were sent from Istanbul. To assist the governors, the Ottoman government also sent military contingents and administrative personnel; from these groups an executive council (*diwan*) was formed in Cairo, which was responsible for the formulation and implementation of state policy. Although the Mamluks were relieved of their offices and their authority, they remained intact as a class in Egypt and continued to exercise considerable influence in the state. As had been the case during the Mamluk dynasty, the Mamluk elite continued to be replenished by purchases from slave markets. The slaves, after a period of apprenticeship, still formed the core of the army and were soon being appointed to offices in the Ottoman government. Thus, gradually the Mamluks infiltrated the Ottoman ruling class and eventually were able to dominate it.

One major innovation changed the character of the Mamluks. Earlier, during the era of the Mamluk sultanate, the sons of Mamluks had been excluded from serving in any but the nonslave regiments and from holding offices reserved for Mamluks in the state. But under Otto-

man rule the sons were no longer denied these privileges, so that the principles of Mamluk loyalty and solidarity were undermined by ties of kinship. Consequently, rather than grouping themselves into military factions that lasted no longer than the lifetime of their individual members, the Ottoman Mamluks formed "houses" that perpetuated themselves through their sons. The importance of these houses arose from the stubborn attempts of each house to dominate the others; thereby a new element of instability, perpetuated by heredity, was introduced into the Mamluk institution. To the degree that the Ottoman governors were able to exploit Mamluk divisiveness, they were able to retain some degree of influence in the government of Egypt. But near the end of the 17th century, when Ottoman power was in decline throughout the empire, the Mamluks once again held virtual control over the army, the revenues, and the government. Eventually, Istanbul was reduced to recognizing the autonomy of that faction of Mamluks that would guarantee annual payment of certain sums to the Ottomans. And thus it was that when Napoleon invaded Egypt in 1798 he was confronted by Mamluk armies and a Mamluk state. Their power there was finally destroyed by Egypt's new ruler, Muhammad 'Ali Pasha, in a massacre in 1811.

**BIBLIOGRAPHY.** S. LANE-POOLE, *A History of Egypt in the Middle Ages*, 4th ed. (1968), gives a reliable survey of Mamluk history in the general context of medieval Egyptian history. I.M. LAPIDUS, *Muslim Cities in the Later Middle Ages* (1967), focusses on the structure and dynamics of political and social classes in Mamluk Cairo, Damascus, and Aleppo. For the Mamluks under the Ottomans, P.M. HOLT, *Egypt and the Fertile Crescent, 1516-1922: A Political History* (1966), provides a more detailed survey than that given by Lane-Poole. Three monographs by D. AYALON analyze the structure and ethos of Mamluk institutions in meticulous detail: *L'Esclavage du mamelouk* (1951), an outline of the recruiting and training of Mamluks; *Gunpowder and Firearms in the Mamluk Kingdom* (1956), an examination of the result of Mamluk reluctance to adopt new equipment and technology; and the series of articles "Studies on the Structure of the Mamluk Army," *Bulletin of the School of Oriental and African Studies*, 15:203-228, 448-476 (1953), and 16:57-90 (1954), a description of the evolution of the Mamluk army. R. LOPEZ, H. MISKIMIN, and A. UDOVITICH, "England to Egypt, 1350-1500," in M.A. COOK (ed.), *Studies in the Economic History of the Middle East* (1970), sets forth the economic factors that contributed to the decline of the Mamluk state. The introductory chapter of S.J. SHAW, *The Financial and Administrative Organization and Development of Ottoman Egypt, 1517-1798* (1962), outlines the process by which the Mamluks infiltrated the Ottoman government of Egypt.

(D.P.L.)

## Mammalia

The class Mammalia is a group of back-boned animals, collectively known as mammals, in which the young are nourished with milk from special secreting glands (mam-mae) of the mother. Mammals are warm-blooded, four-limbed (except certain aquatic groups), and usually have hair. The word animal is often limited inappropriately to mammals (usually excluding man), but properly refers to any member of the kingdom Animalia, which includes virtually all multicellular organisms not considered plants.

#### GENERAL FEATURES

The evolution of the Mammalia has produced tremendous diversity in form and habits. Living kinds range in size from tiny shrews, weighing but a few grams, to the largest of all animals that has ever lived, the blue or sulphur-bottom whale, which reaches a length of more than 100 feet and a weight of 150 tons. Every major terrestrial and aquatic habitat has been invaded by mammals that swim, fly, run, burrow, glide, or climb.

There are approximately 4,000 species of living mammals, arranged in about 120 families and 20 orders. The rodents (order Rodentia) are the most numerous of existing mammals, both in number of species and number of individuals, and are one of the most diverse of living lineages. In contrast, the order Tubulidentata is represented by a single living species, the aardvark. The Pro-

boscidea (elephants) and Perissodactyla (horses, rhinoceroses, and allies) are excellent examples of orders in which far greater diversity occurred in mid- and late-Tertiary times (from about 3,000,000 to about 30,000,000 years ago) than today.

The tropical continental areas of the world around are the places of greatest present-day diversity of mammals, although members of the order occur on (or in seas adjacent to) all major land masses and on many oceanic islands (the latter principally, but by no means exclusively, reached by bats). Major regional faunas can be identified; these resulted in large part from evolution in comparative isolation of stocks of early mammals that reached these areas. South America (Neotropics), for example, was separated from North America (Nearctic) from Paleocene through much of Pliocene times (about 2,500,000 to 65,000,000 years ago) by inundation of the Panamanian Portal and adjacent areas in Middle America. Evolution of mammalian groups that had reached South America before the break between the continents, or some that "island-hopped" in after the break, proceeded quite independently from that of relatives that remained in North America. Some of the latter became extinct as the result of competition with more advanced groups, whereas those in South America flourished, some radiating to the extent that they have successfully competed with invaders since the rejoining of the two continents. Australia provides a parallel case of early isolation and adaptive radiation of mammals (monotremes, marsupials) thus isolated, but differs in that it was not later connected to any other land mass. The more advanced mammals of the infraclass Eutheria that reached Australia (rodents, bats) did so, evidently by "island-hopping," long after the adaptive radiation of the early isolates.

In contrast, North America and Eurasia (Palearctic) are separate land masses but have closely related faunas, the result of connections several times in the Pleistocene and earlier across the Bering Strait. Their faunas frequently are thought of as representing not two distinct units, but one, related to a degree that a single name, Holarctic, is applied to it.

#### IMPORTANCE TO MAN

Wild and domesticated mammals are so interlocked with man's political and social history that it is impractical to attempt to assess the relationship in precise economic terms. Throughout his cultural evolution, for example, man has been dependent on other mammals for a significant portion of his food and clothing. Domestication of mammals helped to provide a source of protein for ever-increasing human populations and provided means of transportation and heavy work as well. Today, domesticated strains of the house mouse, European rabbit, guinea pig, hamster, gerbil and other species provide much-needed laboratory subjects for the study of human-related physiology, psychology, and a variety of diseases from dental caries to cancer. Recent emphasis on the study of nonhuman primates (monkeys and apes) has opened broad, new areas of research relevant to man's welfare. The care of domestic and captive mammals is, of course, the basis for the practice of veterinary medicine.

Some primitive peoples still depend on wild mammals as a major source of food, and many different kinds (from fruit bats and armadillos to whales) regularly are captured and eaten. On the other hand, the hunting, primarily for sport, of various rodents, lagomorphs, carnivores, and ungulates supports a multibillion-dollar enterprise. In the United States alone, for example, it is estimated that more than 2,000,000 deer are harvested annually by licensed hunters.

Geopolitically, the quest for marine mammals was responsible for the charting of a number of areas in both Arctic and Antarctic regions. The presence of terrestrial fur bearers, particularly beaver and several species of mustelid carnivores (*e.g.*, marten and fisher), was one of the principal motivations for the opening of the American West, Alaska, and the Siberian taiga. Sale of wild-taken furs still is an important industry in both the Old and

New Worlds, but ranch-raised animals such as the mink, fox, and chinchilla now have become an important part of the fur industry, which directly and indirectly accounts for many millions of dollars in revenue each year in North America alone.

Aside from pelts and meat, special parts of some mammals regularly have been sought for their special attributes. The horns of rhinoceroses are used in concocting potions in the Orient; ivory from elephants and walrus is highly prized; and ambergris, a substance regurgitated by sperm whales, has been widely used as a base for perfumes (although now mostly replaced by synthetic substitutes).

Some mammals are directly detrimental to man and his activities. Murid rodents (house rats and mice of Old World origin) now occur in virtually all of the world's urban areas and each year cause substantial damage and economic loss. In some rural areas, herbivorous mammals eat or trample planted crops and compete with livestock for food, and native carnivores prey on domestic herds. These and other situations have led man to spend large sums annually to control populations of "undesirable" wild mammals, a practice long deplored by conservationists. Mammals are important reservoirs or agents of transmission of a variety of diseases that afflict man, such as plague, tularemia, yellow fever, rabies, leptospirosis, hemorrhagic fever, and Rocky Mountain spotted fever. The annual "economic debt" resulting from mammal-borne diseases of man and his domestic stock is incalculable.

Many large mammals that competed directly with man for food or space, or were specially sought by him for some reason, have been extirpated entirely or exist today only in parks and zoos; others are in danger of extinction, and their plight is receiving increased attention by a number of conservation agencies. Perhaps at least some can be saved. One of the most noteworthy cases of direct extirpation by man is the Steller's sea cow (*Hydrodamalis gigas*). These large (up to 12 metres, or 40 feet, long), inoffensive, marine mammals evidently lived in Recent times only along the coasts and shallow bays of the Commander Islands in the Bering Sea. Discovered in 1741, they were easily killed by Russian sealers and traders for food, their meat being highly prized, and the last known live individual was taken in 1768.

Of final note is the esthetic value of wild mammals and the relatively recent predilection of man to expend both considerable energy and resources to study and, if possible, conserve vanishing species, to set aside natural areas where native floral and faunal elements can exist in an otherwise highly agriculturalized or industrialized society, and to establish modern zoological parks and gardens. Such outdoor "laboratories" attract millions of visitors annually and will provide means by which present and future generations of humans can appreciate and study, in small measure at least, other kinds of mammals.

#### NATURAL HISTORY

The hallmarks of the mammalian level of organization are advanced reproduction and parental care, behavioral flexibility, and endothermy (the physiological maintenance of a relatively constant body temperature independent of that of the environment, allowing a high level of activity). Within the class, ecological diversity has resulted from adaptive specialization in food-getting, habitat preferences, and locomotion.

Throughout the past 70,000,000 years, the mammals have been the dominant animals in terrestrial ecosystems and important in nonterrestrial communities as well. The earliest mammals were small, active predacious, and terrestrial or semiarboreal. From this primitive stock the mammals have radiated into a wide spectrum of adaptive modes against the background of the diverse environment of the Cenozoic (the last 65,000,000 years). Branches of the ancestral terrestrial stock early exploited the protection and productivity of the trees, whereas other lineages added further dimensions to the mammalian spectrum by adapting to life beneath the ground, in the air, and in marine and freshwater habitats.

exploration

**Reproduction.** In reproductively mature female mammals an interaction of hormones from the pituitary gland and the ovaries produces a phenomenon known as the estrous cycle. Estrus, or "heat," typically coincides with ovulation, and during this time the female is receptive to the male. Estrus is preceded by proestrus, during which ovarian follicles mature under the influence of a follicle-stimulating hormone from the anterior pituitary. The follicular cells produce estrogen, a hormone that stimulates proliferation of the uterine lining, or endometrium. Following ovulation, in late estrus, the ruptured ovarian follicle forms a temporary endocrine gland known as the corpus luteum. Another hormone, progesterone, secreted by the corpus luteum, causes the endometrium to become quiescent and ready for implantation of the developing egg (blastocyst), should fertilization occur. In members of the infraclass Eutheria (known as placental mammals) the placenta, as well as transmitting nourishment to the embryo, has an endocrine function, producing hormones that maintain the endometrium throughout gestation.

If fertilization and implantation do not occur, a phase termed metestrus ensues, in which the reproductive tract assumes its normal condition. Metestrus may be followed by anestrus, a nonreproductive period characterized by quiescence or involution of the reproductive tract. On the other hand, anestrus may be followed by a brief quiescent period (diestrus) and another preparatory proestrus phase. Mammals that breed only once a year are termed monestrous, and exhibit a long anestrus; those that breed more than once a year are termed polyestrous. In many polyestrous species the estrous cycle ceases during gestation and lactation (milk production), but some rodents have a post-partum estrus, mating immediately after giving birth.

The menstrual cycle of higher primates is derived from the estrous cycle, but differs from it in that when progesterone secretion from the corpus luteum ceases, in the absence of fertilization, the uterine lining is sloughed. In anthropoids other than man a distinct period of "heat" occurs around the time of ovulation.

Egg-laying  
by  
mono-  
tremes

Monotremes lay shelled eggs, but the ovarian cycle is similar to that of other mammals. The eggs are predominantly yolk (telolecithal), like those of reptiles and birds. Cleavage of the egg cell in development is meroblastic (*i.e.*, the yolk does not divide) and the developing embryo lies on top of the yolk mass. The platypus lays one to three (usually two) eggs in a long nesting burrow, and the eggs are incubated for about ten days. The echidna generally produces a single egg, laid directly in a pouch developed by the female during the breeding season. It is incubated seven to ten days. Young monotremes are altricial (*i.e.*, in a relatively early stage of development and dependent upon the parent), reaching sexual maturity in about one year.

The reproduction of marsupials differs from that of placentals in that the uterine cycle of the female has no secretory phase and the uterine wall is not specialized for the implantation of the embryos. The period of intrauterine development varies from about eight days (*Dasyurus*) to 38 days (*Macropus*). After this period the young migrate from the vagina to attach to the teats for further development. Frequently the partially developed young outnumber the available teats and the excess individuals perish. In the American opossum, *Didelphis marsupialis*, litters of 25 young have been reported, but the pouch usually contains but 13 teats.

The pouch or marsupium is variously developed. Many species, such as kangaroos and opossums, have a single, well developed pouch; in some phalangerids the pouch is compartmented, with a single teat in each compartment. The South American caenolestids or rat opossums have no marsupium.

Born in an extremely altricial condition, the young of most marsupials are dependent on maternal care for considerable periods, 13 to 14 weeks in *Didelphis*. Young koalas are carried in the pouch for nearly eight months, kangaroos to ten months.

Bandicoots are unique among living marsupials in hav-

ing a chorioallantoic placenta, but unlike the placentae of eutherians it does not have villi (minute projections of the wall, or chorion). Embryonic gaseous exchange in the majority of marsupials is by means of the highly vascular yolk sac.

Reproductive patterns in placentals are diverse, but in all cases a secretory phase is present in the uterine cycle and the endometrium is maintained by secretions of progesterone from the corpus luteum. The blastocyst implants in the uterine wall. Villi are embedded in the lining of the uterus. The resulting complex of embryonic and maternal tissues is a true placenta. The uterine lining may be shed with the fetal membranes as "after birth" (a condition called deciduate) or may be resorbed by the female (nondeciduate). Placentae have been classified on the basis of the relationship between maternal and embryonic tissues. In the simplest nondeciduate placental arrangement the chorionic villi are in contact with uterine epithelium (the inner surface layer). In the "intimate deciduous" types, seen in primates, bats, insectivores, and rodents, the capillary endothelium (the layer containing minute blood vessels) of the uterine wall breaks down, and chorionic epithelium is in direct contact with maternal blood. In advanced stages of pregnancy in rabbits even the chorionic epithelium is eroded and the embryonic endothelium contacts the maternal blood supply. In no case, however, is there actual exchange of blood between mother and fetus; nutrients and gases must still pass through the walls of the fetal blood vessels.

The period of intrauterine development, or gestation, varies widely among eutherians, generally depending on the size of the animal, but influenced by the number of young per litter and the condition of young at birth. The gestation period of the domestic hamster (*Mesocricetus auratus*) is about two weeks, whereas that of the blue whale is 11 months and of the African elephant 21 to 22 months.

At birth the young may be well developed and able to move about at once (precocial) or they may be blind, hairless, and essentially helpless (altricial). In general, precocial young are born after a relatively long gestation period and in a small litter. Hares and many large grazing mammals bear precocial offspring. Rabbits, carnivores, and most rodents bear altricial young.

After birth young mammals are nourished by milk secreted by the mammary glands of the female. In therians (marsupials and placentals) the glands open through specialized nipples. The newborn young of marsupials are unable to suckle and milk is "pumped" to the young by the mother.

Milk consists of fat, protein (especially casein), and lactose (milk sugar), as well as vitamins and salts. The actual composition of milk of whales varies widely between species. The milk of whales and seals is some 12 times as rich in fats and four times as rich in protein as that of domestic cows, but contains almost no sugar. Milk has meant an efficient energy source for the rapid growth of young mammals; the weight at birth of some marine mammals doubles in five days.

**Behaviour.** *Social behaviour.* The dependence of the young mammal on its mother for nourishment has made possible a period of training. Such training permits the nongenetic transfer of information between generations. The ability of young mammals to learn from the experience of their elders has allowed a behavioral plasticity unknown in any other group of organisms and has been a primary reason for the success of the mammals. The possibility of training is one of the factors that has made an increase in neural complexity selectively adaptive. Increased associational potential and memory extends the possibility of learning from experience, and the individual can make adaptive behavioral responses to environmental change. Individual response to short-term change is far more efficient than genetic response.

Some kinds of mammals are solitary, except for brief periods when the female is in estrus. In other species, however, social groups are present. Such groups may be reproductive, defensive, or may serve both functions. In those cases that have been studied in detail a more-or-less

Composi-  
tion of  
milk

strict hierarchy of dominance prevails. Within the social group, maintenance of the hierarchy may depend on physical combat between individuals, but in many cases stereotyped patterns of behaviour evolve to displace actual combat, conserving energy, while maintaining the social structure.

Sexual dimorphism (a pronounced difference between sexes) frequently is extreme in social mammals. In large part this is because dominant males tend to be those that are largest or best armed. Dominant males also tend to have priority in mating, or may even have exclusive responsibility for mating within a "harem." Rapid evolution of secondary sexual characteristics can take place in a species with such a social structure even though the reproductive potential may be low.

A complex behaviour termed "play" frequently occurs between siblings, between members of an age class, or between parent and offspring. Play extends the period of maternal training and is especially important in social species, providing an opportunity to learn behaviour appropriate to the maintenance of dominance.

**Territoriality.** That area covered by an individual in his general activity is frequently termed the home range. A territory is a part of the home range defended against other members of the same species. As a generalization it may be said that territoriality is more important in the behaviour of birds than of mammals, but data for the latter are available primarily for diurnal species. The phenomenon of territoriality may be more widespread than is supposed. Frequently territories of mammals are "marked," either with urine or with secretions of specialized glands, as in lemurs, a form of territorial labelling less evident to humans than the singing or visual displays of birds. Many mammals that do not maintain territories per se nevertheless will not permit unlimited crowding and will fight to maintain individual distance. Such mechanisms result in more economical spacing of individuals over the available habitat.

**Ecology. Response to environmental cycles.** Mammals may react to environmental extremes by acclimatization, compensatory behaviour, or physiological specialization. Physiological responses to adverse conditions include torpidity, hibernation (in winter), and estivation (in summer). Torpidity may occur in the daily cycle or during unfavourable weather; short-term torpidity generally is economical only for small mammals that can cool and warm rapidly. The body temperature of most temperate-zone bats drops near that of the ambient air whenever the animal sleeps. The winter dormancy of bears at high latitudes is an analogous phenomenon and cannot be considered true hibernation.

Hibernation

True hibernation involves physiological regulation to minimize the expenditure of energy. The body temperature is lowered and breathing may be slowed to as low as 1 percent of the rate in an active individual. There is a corresponding slowing of circulation and typically a reduction in the peripheral blood supply. When the body temperature nears the freezing point, spontaneous arousal occurs, although other kinds of stimuli generally elicit only a very slow response. In mammals that exhibit winter dormancy (such as bears, skunks, and raccoons), arousal may be quite rapid. Hibernation has evidently originated independently in a number of mammalian lines and the comparative physiology of this complex phenomenon is only now beginning to be understood (see DORMANCY).

Inactivity in response to adverse summer conditions (heat, drought, lack of food) is termed estivation. Estivation in some species is simply prolonged rest, usually in a favourable microhabitat; other estivating mammals regulate the metabolism, although the effects are typically not so pronounced as in hibernation.

Behavioral response to adverse conditions may involve the selection or construction of a suitable microhabitat (such as the cool, moist burrows of desert rodents). Migration is a second kind of behavioral response. The most obvious kind of mammalian migration is latitudinal. Many temperate-zone bats, for example, undertake extensive migrations, although other bat species hibernate near the summer foraging grounds in caves or other equa-

Migrations

ble shelters during severe weather when insects are not available. Caribou (*Rangifer tarandus*) migrate from the tundra to the forest edge in search of suitable winter range and a number of cetaceans and pinnipeds undertake long migrations from polar waters to more temperate latitudes. Gray whales (*Eschrichtius robustus*), for example, migrate southward to calving grounds along the coasts of South Korea and Baja California from summer feeding grounds in the Okhotsk, Bering, and Chukchi seas. Of comparable extent is the dispersive feeding migration of the northern fur seal (*Callorhinus ursinus*).

Migrations of lesser extent include the altitudinal movements of some ungulates, the American elk or wapiti (*Cervus canadensis*) and bighorn sheep (*Ovis canadensis*), for example, and the local migrations of certain bats from summer roosts to hibernacula. Most migratory patterns of mammals are part of a recurrent annual cycle, but the irruptive emigrations of lemmings and snowshoe hares are largely acyclic responses to population pressure on food supplies.

**Populations.** A population consists of individuals of three "ecological ages"—prereproductive, reproductive, and postreproductive. The structure and dynamics of a population depend, among other things, on the relative lengths of these ages, the rate of recruitment of individuals (either by birth or by immigration), and the rate of emigration or death. The reproductive potential of some rodents (particularly muroids) is well known; some mice are reproductively mature at four weeks of age, have gestation periods of three weeks or less, and may experience post-partum estrus, with the result that pregnancy and lactation may overlap. Litter size, moreover, may average four or more, and breeding may occur throughout the year in favourable localities. The reproductive potential of a species is, of course, a theoretical maximum that is rarely met inasmuch as, among other reasons, a given female typically does not reproduce throughout the year. Growth of a population depends on the survival of individuals to reproductive age. The absolute age at sexual maturity ranges from less than four weeks in some rodents to some 15 years in the African elephant (*Loxodonta africana*).

Postreproductive individuals are rare in most mammalian populations. Survival through more than a single reproductive season is probably uncommon in many small kinds, such as mice and shrews. Larger species typically have longer life spans than smaller ones, but some bats are known, on the basis of banding records, to live nearly 20 years. Many species show greater longevity in captivity than in the wild. Captive spiny anteaters (*Tachyglossus*) are reported to have lived more than 50 years. Horses are known to live more than 60 years, and the oldest known elephant lived to be nearly 70. Man has greater potential longevity than any other known species.

Longevity

**Locomotion.** Specialization in habitat preference has been accompanied by locomotor adaptations. Convergent evolution within a given adaptive mode has contributed to the ecological similarity of regional mammalian faunas. Terrestrial mammals have a number of modes of progression. The primitive mammalian stock was doubtless ambulatory and plantigrade, walking with the digits, metacarpals, and metatarsals (bones of the midfoot), and parts of the ankle and wrist in contact with the ground. The limbs of ambulatory mammals are typically mobile, capable of considerable rotation.

Mammals modified for running are termed cursorial. The stance of cursorial species may be digitigrade (the complete digits contacting the ground, as in dogs) or unguligrade (only tips of digits contacting the ground, as in horses). In advanced groups limb movement consists of a single forward and backward direction.

Saltatory (leaping) locomotion, sometimes called "ricochetal," has arisen in several unrelated groups, and typically is found in mammals of open habitats. Jumping mammals (some marsupials, lagomorphs, and several independent lineages of rodents) typically have elongate, plantigrade hind feet, reduced forelimbs, and long tails.

Mammals of several orders have attained great size and have converged on specializations for "graviportal"

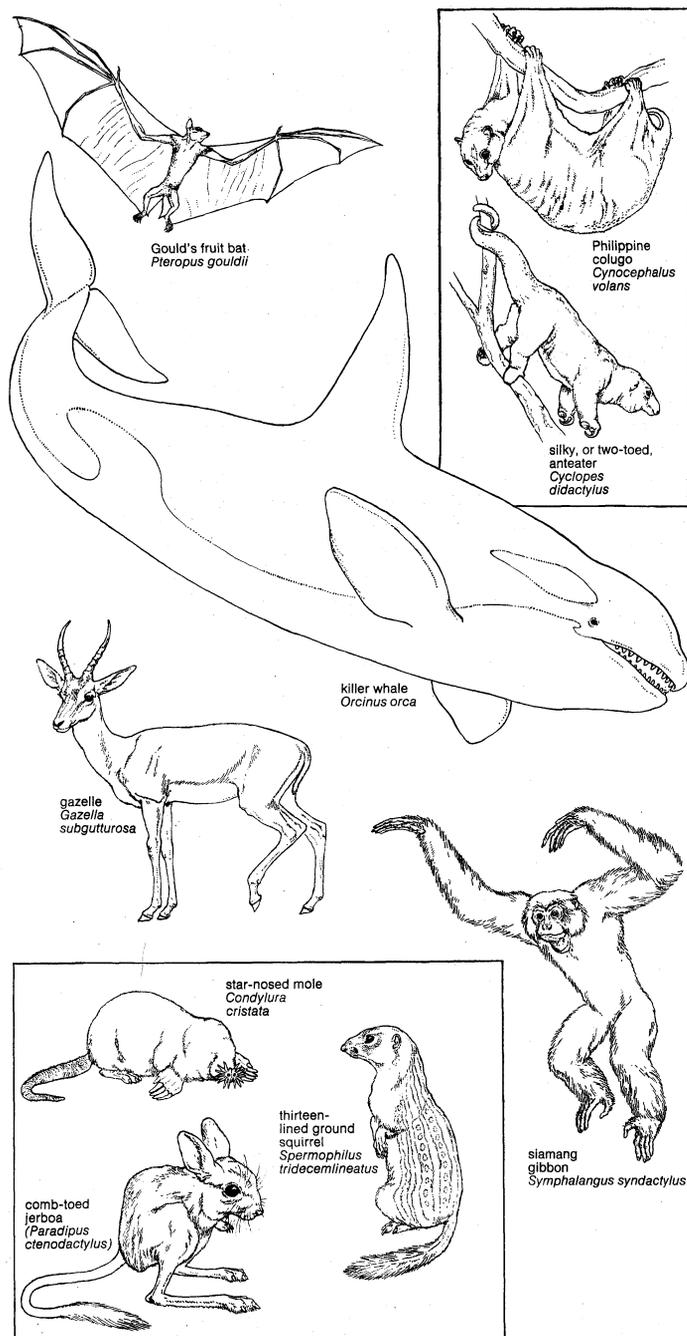

Figure 1: Range of body plans in mammals.

Drawing by R. Keane based on photographs courtesy of (Gould's fruit bat) J. Warham, (Philippine colugo) J.N. Hamlet, (silky, or two-toed anteater) New York Zoological Society, (comb-toed jerboa) Zeitschr. Säugetierk

(ponderous) locomotion. Such kinds have no digit reduction and deploy the digits in a circle around the axis of the limb for maximum support, like the pedestal of a column.

The bats are the only truly flying mammals. Only with active flight have the resources of the aerial habitat been successfully exploited. Mammals of several kinds (dermopterans, marsupials, rodents) are adapted for gliding. A gliding habit is frequently accompanied by scansorial (climbing) locomotion. Many nongliders, such as tree squirrels, are also scansorial.

Well-adapted arboreal mammals frequently are plantigrade, five-toed, and equipped with highly mobile limbs. Many New World monkeys have a prehensile tail, which is used as a "fifth hand." Gibbons have reduced the primitive, opposable anthropoid thumb as a specialization for brachiation, or "arm-walking," in which the animal hangs from branches and moves by a series of long

swings. The highly arboreal tarsiers have expanded pads on the digits to improve the grasp, and many other arboreal kinds have claws (sloths) or well-developed nails.

Several groups of mammals have independently assumed aquatic habits. In some cases semi-aquatic or aquatic mammals are relatively unmodified representatives of otherwise terrestrial groups (for example, otters, muskrats, water shrews). Other kinds have undergone profound modification for natorial locomotion and a pelagic habit. Pinniped carnivores (walruses and seals) give birth to their young on land, but cetaceans are completely helpless out of water, on which they depend for mechanical support and thermal insulation.

**Food habits.** The earliest mammals, like their reptilian forebears, were active predators. From such a basal stock there has been a complex radiation of trophic adaptations. Modern mammals occupy a wide spectrum of feeding niches. In most terrestrial and some aquatic communities, carnivorous mammals are at the top of the food pyramid. There are also mammalian primary consumers in most ecosystems. The voracious shrews, smallest of mammals, sometimes prey on vertebrates larger than themselves. They may eat twice their weight in food each day to maintain their active metabolism and compensate for heat loss caused by an unfavourable surface-to-volume ratio. The largest of vertebrates, the blue whale, feeds on krill, minute planktonic crustaceans.

Within a given lineage the adaptive radiation in food habits may be broad. Some of the Carnivora have become omnivorous (raccoons, bears) or largely herbivorous (giant panda). Marsupials exhibit a great variety of feeding types, and in Australia marsupials have radiated to fill ecological niches highly analogous to those of placental mammals elsewhere; there are marsupial "moles," "anteaters," "mice," "rats," "cats," and "wolves." Some bandicoots have ecological roles similar to those of rabbits, and wombats are semifossorial (*i.e.*, partially burrowing) herbivores analogous to marmots. In Australia the niche of large grazers and browsers is filled by a variety of kangaroos and wallabies.

Within the bats there has also been a remarkable adaptive radiation in food habits. Early in the history of the order there evidently was a divergence into insectivorous and frugivorous lines. The frugivorous line (Megachiroptera) has generally maintained its fruit eating habit, although some have become rather specialized nectar-feeders. The Microchiroptera have been less conservative and have undergone considerable divergence in feeding habits. A majority of living microchiropterans are insectivorous, but members of two different families have become fish eaters. Within the large neotropical family Phyllostomatidae there are groups specialized to feed on fruit, nectar, insects, and small vertebrates (including other bats). Aberrant members of the family are the vampire bats (desmodontines) with a specialized dentition to aid the blood-lapping habit.

Radiation of bats

#### FORM AND FUNCTION

**The skin and hair.** The skin of mammals is constructed of two layers, a superficial nonvascular epidermis and an inner layer, the dermis or corium. The two layers interdigitate in dermal papillae (fingerlike projections), ridges of sensitive vascular dermis projecting into the epidermis. The outermost layers of the epidermis are cornified (*i.e.*, impregnated with various tough proteins) and enucleate (lacking cell nuclei). The epidermis is composed of flattened (squamous) cells in layers and is the interface between the individual and the environment. Its primary function is defensive, and it is cornified to resist abrasion. The surface of the skin is coated with lipids and organic salts, the so-called "acid mantle," thought to have antifungal and antibacterial properties. Deep in the epidermis is an electronegative layer, a further deterrent to foreign organic or ionic agents.

The dermis lies beneath the epidermis and nourishes it. The cutaneous circulation of the dermis is variously developed in mammals but it is typically extensive, out of proportion to the nutritional needs of the tissue. The major role of the cutaneous circulations is to moderate

body temperature and blood pressure by forming a peripheral shunt, an alternate route for the blood. Also in the dermis are sensory nerve endings to alert the individual to pressure (touch), heat, cold, and pain. In general, skin bearing hairs has few or no specialized sensory endings, but hairless skin, such as the lips and fingertips of man, has specialized endings. The sensation of touch on hairy skin in man depends on stimulation of the nerve fibres of the hairs.

Hair is derived from an invagination (pocketing) of the epidermis termed a follicle. Collectively, the hair is called the pelage. The individual hair is a rod of keratinized cells that may be cylindrical or more-or-less flattened. Keratin is a protein also found in claws and nails. The inner medulla of the hair is hollow and contains air; in the outer cortex layer there are frequently pigment granules. Associated with the hair follicle are nerve endings and a muscle, the arrector pili. The latter allows the erection of individual hairs to alter the insulative qualities of the pelage. The follicle also gives rise to sebaceous glands that produce sebum, a substance that lubricates the hair.

Types of  
hair

Most mammals have three distinct kinds of hairs. Guard hairs protect the rest of the pelage from abrasion and frequently from moisture, and usually lend a characteristic colour pattern. The thicker underfur is primarily insulative and may differ in colour from the guard hairs. The third common hair-type is the vibrissa, or whisker, a stiff, typically elongate, hair that functions in tactile sensation. Hairs may be further modified to form rigid quills. The "horn" of the rhinoceros is composed of a fibrous keratin material derived from hair. Examples of keratinized derivatives of the integument other than hair are horns, hooves, nails, claws, and baleen.

Even though the primary function of the skin is defensive, it has been modified in mammals to serve such diverse functions as thermoregulation and nourishment of young. Secretions of sweat glands promote cooling due to evaporation at the surface of the body, and mammary glands are thought to be derived from sweat glands.

In certain groups (primates in particular) the skin of the face is under intricate muscular control and movements of the skin express and communicate "emotion." In many mammals the colour and pattern of the pelage is important in communicative behaviour. Patterns may be dymanic (startling, such as the mane of the male lion or hamadryas baboon), sematic (warning, such as the bold pattern of skunks), or cryptic (concealing), perhaps the most common adaptation of pelage colour.

Hair has been secondarily lost or considerably reduced in some kinds of mammals. In adult cetaceans insulation is provided by thick subcutaneous fat deposits, or blubber, with hair limited to a few stiff vibrissae about the mouth. The naked skin of whales is one of a number of features that contribute to the remarkably advanced hydrodynamics of locomotion in the group. Some fossorial mammals also tend toward reduction of the hair. This is shown most strikingly by the sand rats (*Heterocephalus*) of northeast Africa, but considerable loss of hair has also occurred in some species of pocket gophers (*Geomysidae*). Hair may also be lost on restricted areas of the skin, as from the face in many monkeys, or the buttocks of mandrills, and may be sparse on elephants and such highly modified kinds as pangolins and armadillos.

Indeterminate (continuous) growth, as seen in the hair of the head in man, is rare among mammals. Hairs with determinate growth are subject to wear and must be replaced periodically—a process termed molt. The first coat of a young mammal is referred to as the juvenal pelage, which typically is of fine texture like the underfur of adults and is replaced by a postjuvenal molt. Juvenal pelage is succeeded by the subadult pelage, which in some species is not markedly distinct from that of the adult, or directly by adult pelage. Once this pelage is acquired molting continues to recur at intervals, often annually or semi-annually, sometimes more frequently. The pattern of molt typically is orderly, but varies widely between species. Some mammals apparently molt continuously, with a few hairs replaced at a time throughout the year.

**Dentition.** Specialization in food habits has led to profound dental changes. The primitive mammalian tooth had high, sharp cusps and served to tear flesh or crush chitinous material (primarily the exoskeletons of terrestrial arthropods, such as insects). Herbivores tend to have specialized cheek teeth with complex occlusal (contact) patterns and various ways of expanding the crown and circumventing the problem of wear. Omnivorous mammals, such as bears, pigs, and man, tend to have molars with low, rounded cusps, termed "bunodont."

A prime example of convergence in conjunction with dietary specialization is seen in those mammals adapted to feeding on social insects (generally termed myrmecophagy, "anteating"). This habit has led to remarkably similar morphology in such diverse groups as the monotreme echidnas (*Tachyglossidae*), one dasyurid marsupial (*Myrmecobiinae*), some edentates (*Myrmecophagidae*) the aardvark, and pangolins (*Pholidota*). Trends frequently associated with myrmecophagy include: strong claws, an elongate, terete skull, a vermiform, extensible tongue, marked reduction in the mandible, and loss or extreme simplification of the dentition.

Anteating

Specialized herbivores evolved early in mammalian history. The earliest (and with the longest evolutionary history) were the multituberculates. Evolutionary convergence in teeth (*i.e.*, resemblances not due to common ancestry) has occurred widely in herbivorous groups; most have incisors modified for nipping or gnawing, have lost teeth with the resultant development of a gap (diastema) in the tooth row, and exhibit some molarization (expansion and flattening) of premolars to expand the grinding surface of the cheek teeth. Rootless incisors or cheek teeth have evolved frequently, an open pulp cavity allowing continual growth throughout life. Herbivorous specializations have evolved independently in multituberculates, rodents, lagomorphs, primates, and in the wide radiation of ungulate and subungulate orders.

**Skeleton.** The mammalian skeletal system shows a number of advances over that of lower vertebrates. The mode of ossification of the long bones is characteristic. In lower vertebrates each long bone has a single centre of ossification, the diaphysis, and replacement of cartilage by bone proceeds from the centre toward the ends, which may remain cartilaginous, even in adults. In mammals secondary centres of ossification, the epiphyses, develop at the ends of the bones. Growth of bones occurs in zones of cartilage between diaphysis and epiphyses. Mammalian skeletal growth is termed determinate, for once the actively growing zone of cartilage is obliterated, growth in length ceases. As in all bony vertebrates, of course, there is continual renewal of bone throughout life. The advantage of epiphyseal ossification lies in the fact that the bones have strong articular surfaces before the skeleton is mature. In general, the skeleton of the adult mammal has less structural cartilage than does that of a reptile.

The skeletal system of mammals and other vertebrates is broadly divisible functionally into axial and appendicular portions. The axial skeleton consists of the braincase (cranium) and the backbone and ribs, and serves primarily to protect the central nervous system. The limbs and their girdles constitute the appendicular skeleton. In addition, there are skeletal elements derived from the gill arches of primitive vertebrates, collectively termed the visceral skeleton. Visceral elements in the mammalian skeleton include the jaws, the hyoid apparatus supporting the tongue, and the auditory ossicles of the middle ear. The postcranial axial skeleton in mammals generally has remained rather conservative during the course of evolution. The vast majority of mammals have seven cervical (neck) vertebrae; exceptions are sloths, with six or nine cervicals, and the Sirenia with six. The anterior two cervical vertebrae are differentiated as atlas and axis. Specialized articulations of these two bones allow complex movements of the head on the trunk. Thoracic vertebrae bear ribs and are variable in number. The anterior ribs converge toward the ventral midline to articulate with the sternum, or breastbone, forming a semirigid thoracic "basket" for the protection of heart and lungs. Posterior to the thoracic region are the lumbar vertebrae, ranging

from two to 21 in number (most frequently four to seven). Mammals have no lumbar ribs. There are usually three to five sacral vertebrae, but some edentates have as many as 13. Sacral vertebrae fuse to form the sacrum, to which the pelvic girdle is attached. Caudal (tail) vertebrae range in number from five (fused elements of the coccyx of man) to 50.

The basic structure of the vertebral column is comparable throughout the Mammalia, although in many instances modifications have occurred in specialized locomotor modes to gain particular mechanical advantages. The vertebral column and associated muscles of many mammals is structurally analogous to a cantilever girder.

#### The skull

The skull is composite in origin and complex in function. Functionally the bones of the head are separable into the braincase and the jaws. In general, it is the head of the animal that meets the environment. The skull protects the brain and sense capsules, houses the teeth and tongue, and the entrance to the pharynx. Thus the head functions in sensory reception, food acquisition, defense, respiration, and (in higher groups) communication. To serve these functions, bony elements have been recruited from the visceral skeleton, the endochondral skeleton, and from the dermal skeleton of lower vertebrates.

The skull of mammals differs markedly from that of reptiles because of the great expansion of the brain. The sphenoid bones that form the reptilian braincase form only the floor of the braincase in mammals. The side is formed in part by the alisphenoid bone, derived from the epipterygoid, a part of the reptilian palate. Dermal elements, the frontals and parietals, have come to lie deep to (beneath) the muscles of the jaw to form the dorsum of the braincase. Reptilian dermal roofing bones, lying superficial to the muscles of the jaw, are represented in mammals only by the jugal bone of the zygomatic arch, which lies under the eye.

In mammals, a secondary palate is formed by processes of the maxillary bones and the palatines, with the pterygoid bones reduced in importance. The secondary palate separates the nasal passages from the oral cavity and allows continuous breathing while chewing or suckling.

Other specializations of the mammalian skull include paired occipital condyles (the articulating surfaces at the neck) and an expanded nasal chamber with complexly folded turbinal bones, providing a large area for detection of odours. Eutherians have evolved bony protection for the middle ear, the auditory bulla. The development of this structure varies, although an annular (ring-shaped) tympanic bone is always present.

#### Bones of the ear

The bones of the mammalian middle ear are a diagnostic feature of the class. The three auditory ossicles form a series of levers that serve mechanically to increase the amplitude of sound waves reaching the tympanic membrane, or eardrum, produced as disturbances of the air. The innermost bone is the stapes, or "stirrup bone." It

rests against the oval window of the inner ear. The stapes is homologous with the entire stapedial structure of reptiles, which, in turn, was derived from the hyomandibular arch of primitive vertebrates. The incus, or "anvil," articulates with the stapes. The incus was derived from the quadrate bone, which is involved in the jaw articulation in reptiles. The malleus, or "hammer," rests against the tympanic membrane and articulates with the incus. The malleus is the homologue of the reptilian articular bone. The mechanical efficiency of the middle ear has thus been increased by the incorporation of two bones of the reptilian jaw assemblage. In mammals the lower jaw is a single bone, the dentary, which articulates with the squamosal of the skull.

The limbs and girdles have been greatly modified with locomotor adaptations. The ancestral mammal had well-developed limbs and was five-toed. In each limb there were two distal (outer) elements (radius and ulna in the forelimb; tibia and fibula in the hindlimb) and a single proximal (inner or upper) element (humerus; femur). There were nine bones in the wrist, the carpals; and seven bones in the ankle, the tarsals. The phalangeal formula (the number of phalangeal bones in each digit, numbered from inside outward) is 2-3-3-3-3 in primitive mammals; in primitive reptiles it is 2-3-4-5-3. Modifications in mammalian limbs have involved reduction, loss, or fusion of bones. Loss of the clavicle from the shoulder girdle, reduction in the number of toes, and modifications of tarsal and carpal bones are typical correlates of cursorial locomotion. Scansorial and arboreal groups tend to maintain or emphasize the primitive divergence of the thumb and hallux (the inner toe on the hindfoot). Some details of limb modifications are included in the synopsis of the orders of mammals (see below *Annotated classification*).

Centres of ossification sometimes develop in nonbony connective tissue. Such bones are termed heterotopic or sesamoid elements. The kneecap (patella) is such a bone. Another important bone of this sort, found in many kinds of mammals, is the baculum or os penis, which occurs as a stiffening rod in the penis of such groups as carnivores, many bats, rodents, and some insectivores, and in many primates. The os clitoridis is a homologous structure found in females.

**Muscles.** The muscular system of mammals is generally comparable to that of reptiles. With changes in locomotion, the proportions and specific functions of muscular elements have been altered, but the relationships of these muscles remain essentially the same. Exceptions to this generalization are the muscles of the skin and of the jaw.

The panniculus carnosus is a sheath of dermal (skin) muscle, developed in many mammals, which allows the movement of the skin independent of the movement of deeper muscle masses. Such movement functions in such mundane activities as the twitching of the skin to foil insect pests and in some forms also is important in shivering, a characteristic heat-producing response to thermal stress. The dermal musculature of the facial region is particularly well developed in primates and carnivores, but occurs in other groups as well. Facial mobility allows expression that may be of importance in the behavioral maintenance of interspecific social structure.

The temporalis muscle is the major adductor (closer) of the reptilian jaw. In mammals the temporalis is divided into a deep temporalis proper and a more superficial masseter muscle. The temporalis attaches to the coronoid process of the mandible (lower jaw) and the temporal bone of the skull. The masseter passes from the angular process of the mandible to the zygomatic arch. The masseter allows an anteroposterior (forward-backward) movement of the jaw and is highly developed in mammals, such as rodents, in which grinding is the important function of the dentition.

#### Muscles of the jaw

**Viscera. Digestive system.** The alimentary canal is highly specialized in many kinds of mammals. In general, specializations of the gut accompany herbivorous habits. The intestines of herbivores are typically elongate and the stomach may also be specialized. Subdivision of the gut allows areas of differing physiological environments for the activities of different sorts of enzymes and symbiotic

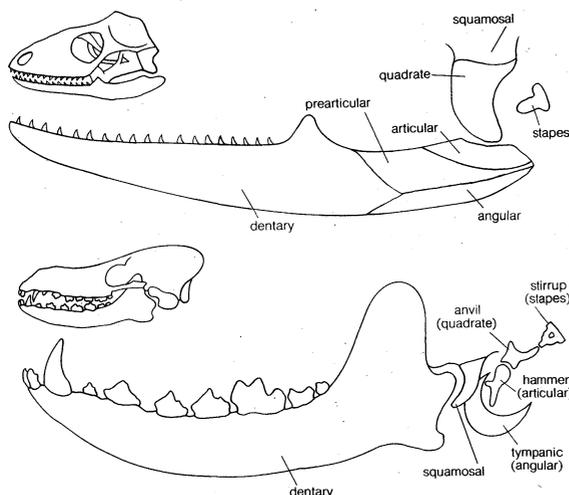

Figure 2: Comparison of lower jaw and ear region in the skull of (top) a reptile and (bottom) a mammal.

bacteria (which aid the animal by breaking down certain "indigestible" compounds). In ruminant artiodactyls the stomach has up to four chambers, each with a particular function in the processing of vegetable material. A cecum is common in many herbivores. The cecum is a blind sac at the distal end of the small intestine where complex compounds like cellulose are acted upon by symbiotic bacteria. The vermiform appendix is a diverticulum of the cecum. The appendix is rich in lymphoid tissue and in many mammals is concerned with defense against toxic bacterial products.

Hares and rabbits, the sewellel or "mountain beaver" (*Aplodontia rufa*), and some insectivores exhibit a phenomenon, known as reingestion, in which at intervals specialized fecal pellets are produced, which are taken in the mouth and passed through the alimentary canal a second time. Where known to be present, this pattern seems to be obligatory. Reingestion is poorly understood, but it is generally supposed that the process allows the animal to absorb in the upper gut vitamins produced by the microflora of the lower gut but not absorbable there.

**Excretory system.** The mammalian kidney is constructed of a large number of functional units called nephrons. Each nephron consists of a distal tubule, a medial section termed the loop of Henle, a proximal tubule, and a renal corpuscle. The renal corpuscle is a knot of capillaries, called a glomerulus, surrounded by a sheath, Bowman's capsule. The renal corpuscle is a pressure filter, relying on blood pressure to remove water, ions, and small organic molecules from the blood. Some of the material removed is waste, but some is of value to the organism. The filtrate is sorted by the tubules, and water and needed solutes are reabsorbed. Reabsorption is both passive (osmotic) and active (based on ion transport systems). The distal convoluted tubules drain into collecting tubules which, in turn, empty into the calyces, or branches, of the renal pelvis, the expanded end of the ureter. The pressure-pump nephron of mammals is so efficient that the renal portal system of lower vertebrates has been completely lost. Mammalian kidneys show considerable variety in structure, relative to the environmental demands on a given species. In particular, desert rodents have long loops of Henle and are able to reabsorb much water and to excrete a highly concentrated urine. Urea is the end product of protein metabolism in mammals, and excretion is therefore called ureotelic.

**Reproductive system.** The testes of mammals descend from the abdominal cavity to lie in a compartmented pouch termed the scrotum. In some species the testes are permanently scrotal and the scrotum is sealed off from the general abdominal cavity. In others the testes migrate to the scrotum only during the breeding season. It is thought that the temperature of the abdominal cavity is too high to allow spermatogenesis; the scrotum allows cooling of the testes.

The transport of spermatozoa is comparable to that in reptiles, relying on ducts derived from urinary ducts of earlier vertebrates. Mammalian specialities are the bulbourethral (or Cowper's) glands, the prostate gland, and the seminal vesicle or vesicular gland. Each of these glands adds secretions to the spermatozoa to form semen, which passes from the body via a canal (urethra) in the highly vascular, erectile penis. The tip of the penis, the glans, may have a complex morphology and has been used as a taxonomic character in some groups. The penis may be retracted into a sheath along the abdomen or may be pendulous, as in bats and many primates.

The structure of the female reproductive tract is variable. Four uterine types are generally recognized among placentals, based on the relationship of the uterine horns (branches). A duplex uterus characterizes rodents and rabbits; the uterine horns are completely separated and have separate cervixes opening into the vagina. Carnivores have a bipartite uterus, in which the horns are largely separate but enter the vagina by a single cervix. In the bicornate uterus, typical of many ungulates, the horns are distinct for less than half their length; the lower part of the uterus is a common chamber, the body. Higher primates have a simplex uterus in which all separation

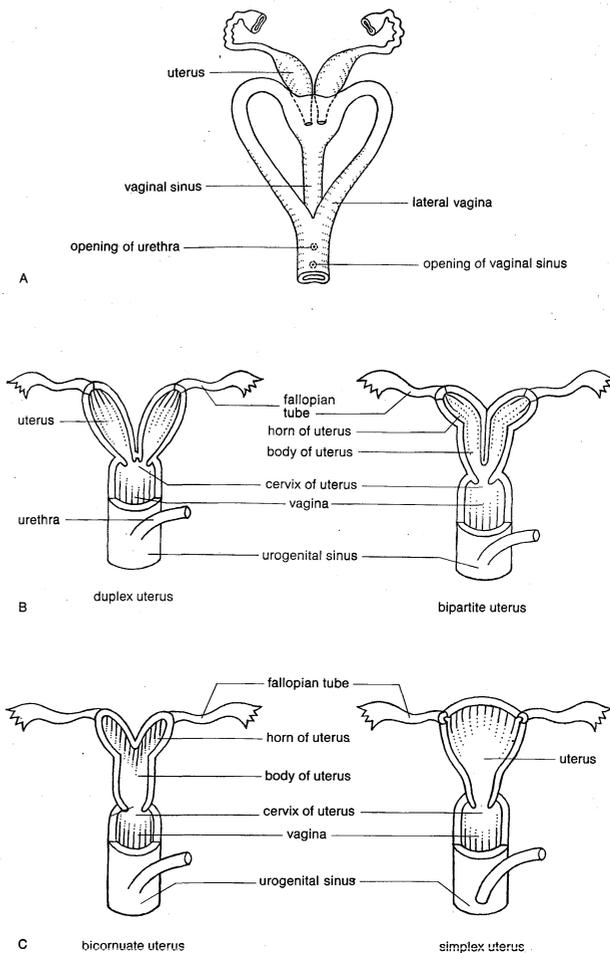

Figure 3: Female reproductive systems.

(A) Duplex uterus with median vaginal tube (kangaroo).

(B, C) Placental uteri.

From (A) A. S. Romer, *The Vertebrate Body*, 4th ed. (1970); W. B. Saunders Company, Philadelphia; (B, C) W. F. Walker, *Vertebrate Dissection*, 4th ed. (1970); W. B. Saunders Company, Philadelphia

between the horns is lacking, forming a single chamber.

The female reproductive tract of marsupials is termed didelphous; the vagina is paired, as are oviducts and uteri. In primitive marsupials there are paired vaginae lateral to the uteri. In more advanced groups, such as kangaroos, the lateral vaginae persist and conduct the migration of spermatozoa, but a medial "pseud-vagina" functions as the birth canal.

Monotremes have paired uteri and oviducts, which empty into a urogenital sinus (cavity) as do fluid wastes. The sinus passes into the cloaca, a common receptacle for reproductive and excretory products.

**Circulatory system.** In mammals as in birds, right and left ventricles of the heart are completely separated, so that pulmonary (lung) and systemic (body) circulations are completely independent. Oxygenated blood arrives in the left atrium from the lungs and passes to the left ventricle, whence it is forced through the aorta to the systemic circulation. Deoxygenated blood from the tissues returns to the right atrium via a large vein, the vena cava, and is pumped to the pulmonary capillary bed through the pulmonary artery.

Among vertebrates, contraction of the heart is myogenic; rhythm is inherent in all cardiac muscle, but in myogenic hearts the pacemaker is derived from cardiac tissue. The pacemaker in mammals (and also in birds) is an oblong mass of specialized cells called the sinoatrial node, located in the right atrium near the junction with the venae cavae. A wave of excitation spreads from this node to the atrioventricular node, which is located in the right atrium near the base of the interatrial septum. From this point excitation is conducted along the atrioventricular bundle (bundle of His) and enters the main mass of

Action of the kidney

Types of uterus

cardiac tissue along fine branches, the Purkinje fibres. Homeostatic control of the heart by neuroendocrine or other agents is mediated through the intrinsic control network of the heart.

Blood leaves the left ventricle through the aorta. The mammalian aorta is an unpaired structure derived from the left fourth aortic arch of the primitive vertebrate. Birds, on the other hand, retain the right fourth arch.

The circulatory system forms a complex communication and distribution network to all physiologically active tissues of the body. A constant, copious supply of oxygen is required to sustain the active, endothermous physiology of the higher vertebrates. The efficiency of the four-chambered heart is important to this function. Oxygen is transported by specialized red blood cells, or erythrocytes, as in all vertebrates. Packaging the oxygen-bearing pigment hemoglobin in erythrocytes keeps the viscosity of the blood minimal and thereby allows efficient circulation while limiting the mechanical load on the heart. The mammalian erythrocyte is a highly evolved structure; its discoid, biconcave shape allows maximal surface area per unit volume. When mature and functional, mammalian red blood cells are enucleate.

**Respiratory system.** Closely coupled with the circulatory system is the ventilatory (breathing) apparatus, the lungs and associated structures. Ventilation in mammals is unique. The lungs themselves are less efficient than those of birds, for air movement consists of an ebb and flow, rather than a one-way circuit, so a residuum of air remains that cannot be expired. Ventilation in mammals is by means of a negative pressure pump made possible by the development of a definitive thoracic cavity with the evolution of the diaphragm.

The diaphragm is a unique, composite structure consisting of (1) the transverse septum (a wall that primitively separates the heart from the general viscera); (2) pleuroperitoneal folds from the body wall; (3) mesenteric folds; and (4) axial muscles inserting on a central tendon, or diaphragmatic aponeurosis.

The lungs lie in separate, airtight compartments called pleural cavities, separated by the mediastinum. As the size of the pleural cavity is increased the lung is expanded and air flows in passively. Enlargement of the pleural cavity is produced by contraction of the diaphragm or by elevation of the ribs. The relaxed diaphragm domes upward, but when contracted it stretches flat. Expiration is an active movement brought about by contraction of abdominal muscles against the viscera.

Air typically enters the respiratory passages through the nostrils where it may be warmed and moistened. It passes above the bony palate and the soft palate and enters the pharynx. In the pharynx the passages for air and food cross. Air enters the trachea, which divides at the level of the lungs into primary bronchi. A characteristic feature of the trachea of many mammals is the larynx. Vocal cords stretch across the larynx and are vibrated by forced expiration to produce sound. The laryngeal apparatus may be greatly modified for the production of complex vocalizations. In some groups, for example, howler monkeys (*Alouatta*), the hyoid apparatus is incorporated into the sound-producing organ, as a resonating chamber.

**Nervous and endocrine systems.** The nervous system and the system of endocrine glands are closely related to one another in their function, for both serve to coordinate activity. The endocrine glands of mammals generally have more complex regulatory functions than do those of lower vertebrates. This is particularly true of the pituitary gland, which supplies hormones that regulate the reproductive cycle. Follicle stimulating hormone (FSH) initiates the maturation of the ovarian follicle. Luteinizing hormone (LH) mediates the formation of the corpus luteum from the follicle following ovulation. Prolactin, also a product of the anterior pituitary, stimulates the secretion of milk.

Control of the pituitary glands is partially by means of neurohumours from the hypothalamus, a part of the fore-brain in contact with the pituitary gland by nervous and circulatory pathways. The hypothalamus is of the utmost importance in mammals, for it integrates stimuli from

both internal and external environments, channelling signals to higher centres or into autonomic pathways.

The cerebellum of vertebrates is at the anterior end of the hindbrain. Its function is to coordinate motor activities and to maintain posture. In most mammals the cerebellum is highly developed and its surface may be convoluted to increase its area. The data with which the cerebellum works arrive from proprioceptors ("self-sensors") in the muscles and from the membranous labyrinth of the inner ear, the latter giving information on position and movements of the head.

In the vertebrate ancestors of the mammals the cerebral hemispheres were centres for the reception of olfactory stimuli. Vertebrate evolution has favoured an increasing importance of these lobes in the integration of stimuli. Their great development in mammals as centres of association is responsible for the "creative" behaviour of members of the class; *i.e.*, the ability to learn, to adapt as individuals to short-term environmental change through appropriate responses on the basis of previous experience. In vertebrate evolution the gray matter of the cerebrum has moved from a primitive internal position in the hemispheres to a superficial position. The superficial gray matter is termed the pallium. The paleopallium of amphibians has become the olfactory lobes of the higher vertebrates; the dorsolateral surface, or archipallium, the mammalian hippocampus. The great neural advance of the mammals lies in the elaboration of the neopallium, which makes up the bulk of the cerebrum. The neopallium is an association centre, the dominant centre of neural function, and is involved in so-called "intelligent" response. By contrast, the highest centre in the avian brain is the corpus striatum, an evolutionary product of the basal nuclei of the amphibian brain. The bulk of the complex behaviour of birds is instinctive. The surface of the neopallium tends in some mammals to be greatly expanded by convoluting, forming folds (gyri) between deep grooves (sulci).

#### THE EVOLUTION OF THE MAMMALIAN CONDITION

Mammals were derived in the Triassic Period from members of the reptilian order Therapsida. The therapsids, members of the subclass Synapsida (sometimes called the mammal-like reptiles), generally were unimpressive in relation to other reptiles of their time. Synapsids were present in the Carboniferous Period (about 280,000,000 to 345,000,000 years ago) and are one of the earliest known reptilian groups. They were the dominant reptiles of Permian times (about 225,000,000 to 280,000,000 years ago), and although they were primarily predacious in habit, the adaptive radiation included herbivorous species as well. In the Mesozoic (about 225,000,000 to 65,000,000 years ago), the importance of the synapsids was generally assumed by the archosaurs or "ruling reptiles," the therapsids, in general, being small, active carnivores. Therapsids tended to evolve a specialized heterodont dentition and to improve the mechanics of locomotion by bringing the plane of action of the limbs close to the trunk. A secondary palate was developed and the temporal musculature was expanded.

The several features that separate modern reptiles from modern mammals doubtless evolved at different rates.

Drawing by R. Keane based on A.S. Romer, *The Vertebrate Story*, copyright 1959; the University of Chicago Press

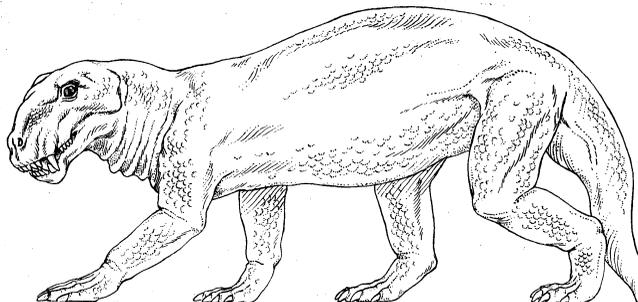

Figure 4: Reconstruction of *Lycaenops*, a late Permian mammal-like reptile.

Many attributes of mammals are correlated with their highly active habit; for example, efficient double circulation with a completely four-chambered heart, anucleate and biconcave erythrocytes, the diaphragm, and the secondary palate (which separates passages for food and air and allows breathing during mastication or suckling). Hair for insulation is a correlate of endothermy, the physiological maintenance of individual temperature independent of environmental temperature, and endothermy allows high levels of sustained activity. The unique characteristics of mammals thus would seem to have evolved as a complex interrelated system.

Because the characteristics that separate reptiles and mammals evolved at different rates and in response to a variety of interrelated conditions, at any point in the period of transition from reptiles to mammals there were forms that combined various characteristics of both groups. Such a pattern of evolution is termed "mosaic" and is a common phenomenon in those transitions marking the origin of major new adaptive types. To simplify definitions and to allow the strict delimitation of the Mammalia, some authors have suggested basing the boundary on a single character, the articulation of the jaw between the dentary and squamosal bones and the attendant movement of accessory jaw bones to the middle ear as auditory ossicles. The use of a single osteological character allows the placement in a logical classification of numerous fossil species, other mammalian characters of which, such as the degree of endothermy and nursing of young and the condition of the internal organs, probably never will be evaluated. It must be recognized, however, that were the advanced therapsids alive, taxonomists would be hard-put to decide which to place in the Reptilia and which in the Mammalia.

#### CLASSIFICATION

**Distinguishing taxonomic features.** The higher classification of the Mammalia is based on consideration of a broad array of characters. Traditionally, evidence from comparative anatomy was of predominant importance, but more recently information from such disciplines as physiology, serology, and genetics has proved useful in considering relationships. Comparative study of living organisms is supplemented by the findings of paleontology. Study of the fossil record adds a historical dimension to knowledge of mammalian relationships. In some cases, the horses for example, the fossil record has been adequate to allow lineages to be traced in great detail.

Relative to that of other major vertebrate groups, the fossil record of mammals is good. Fossilization depends upon a great many factors, most important among which are the structure of the organism, its habitat, and conditions at the time of death. The most common remains of mammals are teeth and the associated bones of the jaw and skull. Enamel covering the typical mammalian tooth is composed of prismatic rods of crystalline apatite and is the hardest tissue in the mammalian body. It is highly resistant to chemical and physical weathering. Because of the abundance of teeth in deposits of fossil mammals, dental characteristics have been stressed in the interpretation of mammalian phylogeny and relationships. Dental features are particularly well suited for this important role in classification because they reflect the broad radiation of mammalian feeding specializations from the primitive predaceous habit.

**Annotated classification.** The following classification has wide acceptance.

#### CLASS MAMMALIA

Vertebrate animals with the lower jaw formed by a single bone (dentary), articulating directly with the squamosal bone of the skull; dentition generally heterodont, thecodont, and diphodont; body covered with hair derived from epidermis; young nourished by milk from mammary glands. For additional characteristics of the class, see *Form and function*, above. Groups preceded by a dagger mark (†) below are extinct.

#### Subclass Prototheria

Mammals in which principal cusps of molars form an antero-posterior row and much of the side of the braincase is formed by the periotic bone rather than by the alisphenoid. Primitive

characters include uncoiled cochlea of the inner ear and absence of spine on the scapula (shoulder blade).

#### †*Infraclass Eotheria*

Fossil only; Upper Triassic to Lower Cretaceous of Eurasia and North America. Upper molars with internal and external cingula (shelves at base of crown), lower molars with internal cingulum only.

†*Order Triconodonta* (triconodonts). Fossil only; Northern Hemisphere; Upper Triassic to Lower Cretaceous. Probably carnivorous, the teeth well differentiated; molars typically with 3 prominent cusps; dentary bone lacking angular process.

†*Order Docodonta* (docodonts). Known only from fossil teeth and jaws from Upper Jurassic of Europe. Molars expanded, with transverse median furrow; angular process of mandible directed ventrally rather than posteriorly ("pseudangular").

#### *Infraclass Ornithodelphia*

*Order Monotremata* (monotremes). Pleistocene to Recent of Australia and New Guinea; possible record in Miocene of Australia family (Ectopodontidae). Reproduction by shelled eggs, incubated by female; no organized nipple, the milk flowing from mammary ducts onto the fur of the abdomen; cloaca present; adults toothless, rostrum covered with horny beak. Total length to 80 cm. Examples: duck-billed platypus, and echidnas or spiny anteaters (see MONOTREMATA).

#### †*Infraclass Allotheria*

†*Order Multituberculata* (multituberculates). Fossil only; Upper Jurassic to lower Eocene of North America and Eurasia. The earliest herbivorous mammals; specializations of teeth and jaws superficially rodent-like; molars elongate, with two or three longitudinal rows of cusps; lower premolars tending to become serrated shearing blades. Size larger than typical Mesozoic mammals, to about that of a woodchuck.

#### Subclass Theria

#### †*Infraclass Trituberculata*

†*Order Symmetrodonta* (symmetrodonts). Fossil only; Upper Jurassic to Lower Cretaceous of Eurasia and North America. Molars with 3 prominent cusps arranged in symmetrical triangles; lower molars without posterior talonid basin ("heel").

†*Order Pantotheria* (pantotheres). Fossil only; Middle Jurassic to Lower Cretaceous of North America and Europe. Molars with 3 prominent anterior cusps (trigonid), asymmetrical; posterior basin (talonid) of lower molars developed, as in higher mammals.

#### *Infraclass Metatheria*

*Order Marsupialia* (marsupials). Upper Cretaceous to Recent of North and South America, Europe, Australia. Placenta formed from yolk sac (simple chorio-allantoic placenta in bandicoots), the young born in a relatively undeveloped state after brief gestation, developing further attached to mammae in marsupium (pouch) or along marsupial fold; female reproductive tract bifid, uterus and vagina double, penis bifurcate, posterior to scrotum. Angular process of mandible inflected; auditory bullae (when present) formed from alisphenoid bone and thus not homologous with bullae of eutherians. Epipubis ("marsupial bone") present; length of head and body varying from about 10 cm (small opossums) to more than 160 cm (kangaroos). Examples: opossums, kangaroos, wallabies, bandicoots, wombats, phalangers, koala (see MARSUPIALIA).

#### *Infraclass Eutheria* (placental mammals)

*Order Insectivora* (insectivores). Upper Cretaceous to Recent, worldwide except Australia, polar regions, and many oceanic islands. A diverse group of mammals sharing certain primitive characteristics but highly specialized in several adaptive modes; dentition generally heterodont, rooted, variously modified; molars usually tuberculosectorial. Stance plantigrade to semiplantigrade; habit fossorial, terrestrial, arboreal, semiaquatic; insectivorous to omnivorous. Braincase low, rising but little above plane of rostrum; snout generally long, pointed, modified for olfaction and touch; zygomatic arch complete or incomplete. Length of head and body, 5 cm (smallest shrews) to 45 cm (largest hedgehogs). Shrews of the genera *Microsorex*, *Sorex*, and *Suncus* are the smallest of living mammals. Examples: shrews, moles, hedgehogs, tenrecs, solenodon (see INSECTIVORA).

*Order Macroscelidea* (elephant shrews). Lower Oligocene to Recent of Africa. Antermost incisors widely spaced (incisor series forming a straight, anteroposterior row); posterior incisors caniniform; upper canine premolariform, bicuspid; posterior premolars molariform, last premolar largest tooth in dental series; molars quadrate, reduced in size or absent posteriorly; auditory bullae well developed. Stance plantigrade, hind feet elongate, modified for hopping gait; tail elongate.

Length of head and body of living species, 12 to 20 cm; tail 12 to 18 cm (see INSECTIVORA).

*Order Dermoptera* (colugos or "flying lemurs"). Upper Paleocene to lower Eocene of North America (Plagiomenidae), Recent of Southeast Asia (Cynocephalidae). In living species, upper incisors reduced, lower incisors procumbent, spatulate, pectinate (comb-like), molars low-crowned, used for shearing the vegetable diet. The most specialized and efficient of mammalian gliders; the patagium (gliding membrane) extends from the neck to phalanges of hand, to phalanges of foot, to tip of tail; total length of head and body, 34–45 cm.

†*Order Tillodontia* (tillodonts). Fossil only; upper Paleocene to middle Eocene of Northern Hemisphere. Omnivorous or herbivorous; incisors rootless, enlarged, molars low-crowned; perhaps superficially bearlike in appearance; total length to approximately 120 cm.

†*Order Taeniodonta* (taeniodonts). Fossil only; lower Paleocene to upper Eocene of North America, middle Eocene of Asia. Large, browsing herbivores; outer incisors rodent-like, inner incisors lost; canines well developed; cheek teeth simple, rootless pegs; length of skull to about 35 cm.

*Order Chiroptera* (bats). Middle Eocene to Recent in tropical and temperate regions; volant, the wings consisting of a fold of skin (patagium) supported by elongated bones of the second through fifth digits; thumb clawed in suborder Microchiroptera, thumb and index finger clawed in Megachiroptera; hind limbs variously specialized but generally weak. Incisors generally reduced, canines prominent, cheek teeth rather primitive, with prominent ectoloph. Length of head and body from about 3 to 40 cm; wing span to about 120 cm (see CHIROPTERA).

*Order Primates* (primates). Late Cretaceous to Recent of Eurasia, Africa, North and South America. A diverse group of generalized, generally omnivorous mammals, modified for arboreality (some secondarily terrestrial). Dentition little specialized; a pair of incisors lost above and below, canines prominent, sexually dimorphic in some species; premolars usually bicuspid, sometimes caniniform; molars typically low-crowned, tuberculosectorial to bunodont. Limbs and girdles adapted for flexibility with little loss or fusion of elements; clavicle present; digits I (hallux and pollex) divergent, tending to become opposable; stance plantigrade. Olfaction de-emphasized in favour of vision, and snout reduced; eyes rotated forward allowing trend toward stereoscopic vision; in more advanced groups cerebrum expanded to cover cerebellum, braincase expanded. Length of head and body (including extended hind limbs), 15 cm (pygmy marmosets, tarsiers) to more than 200 cm (*Homo*). Examples: lemurs, lorises, Old World and New World monkeys, marmosets, great apes, man (see PRIMATES).

*Order Edentata* (edentates). Lower Eocene to Recent of North and South America. Anterior teeth lost and cheek teeth reduced to simple rootless pegs without enamel, or (in anteaters) lost altogether. Secondary articulations (xenarthrous processes) present between vertebrae in addition to zygapophyses (the usual articulating surfaces); cervical vertebrae 6 to 9, in some cases fused; acromion and coracoid processes of scapula enlarged, often joining to form bony ring; claws generally stout. Several groups walk on the sides of feet and structure may be modified accordingly. Brain small, skull low, zygomatic arch usually incomplete. Total length of fossil edentates to 300 cm; living species to 185 cm (giant anteaters). Examples: sloths, armadillos, anteaters (see EDENTATA).

*Order Pholidota* (pangolins). Oligocene to Recent of Eurasia and Africa; possible North America representatives (Paleanodontidae) upper Paleocene to lower Oligocene. Body covered with heavy, overlapping scales with hairs only at bases of scales; tail prehensile in some species. Myrmecophagous (anteating); skull elongate, braincase low; lower jaw reduced to thin shaft of bone; feet 5-toed but only 3 toes of forefeet strongly clawed. Total length 75 to 170 cm.

*Order Tubulidentata* (aardvark). Miocene to Recent of Africa, Pliocene of Eurasia; possible representatives in Eocene and Oligocene of Europe. Teeth reduced to 4 or 5 simple pegs in each jaw of adults, without enamel, the dentine intersected by numerous tubules (hence the ordinal name). Four toes on forefeet, 5 behind, each bearing a strong, stout, hooflike "nail." Skull elongate and tubular; tongue vermiform; mandible not so reduced as in other "anteaters." Legs powerful, skeleton generally primitive but tibia and fibula fused. One species; total length to 200 cm.

*Order Lagomorpha* (lagomorphs). Upper Paleocene to Recent of Eurasia, North America, Africa, northern South America. Dentition superficially rodent-like, but with 2 pairs of upper incisors (a small pair situated behind the larger func-

tional pair); canine and anterior premolars lost, forming prominent diastema (gap); cheek teeth high-crowned, rootless, 6 above and 5 below (more than in any rodent), and not occluding directly, so that mastication is a lateral movement; maxillary bone fenestrate (*i.e.*, with holes). Fibula articulating with calcaneum; infraorbital canal small. Scrotum anterior to penis. Total length, 15 cm (pikas) to 70 cm (hares). Examples: hares, rabbits, pikas (see LAGOMORPHA).

*Order Rodentia* (rodents). Lower Eocene to Recent, worldwide except Antarctica and some oceanic islands. Single pair of rootless incisors above and below; canines and anterior premolars lost forming prominent diastema; never more than 2 premolars above and 1 below; cheek teeth frequently rootless, hypsodont; cusp patterns variable, cheek teeth ranging from pegs to massive teeth with highly complex occlusal patterns. Powerful jaw musculature developed in connection with grinding dentition; angular process of mandible well developed for muscle attachment. Postorbital bar absent; infraorbital foramen variously modified, in advanced groups passing portions of masseter muscle; postcranial skeleton relatively unspecialized. Forelimbs flexible, digits clawed, little reduction in number on forefeet, some specialization of hindfeet and reduction of digits associated with saltation; stance plantigrade or semiplantigrade. Total length of living species, 10 cm (pygmy mice, some pocket mice) to 125 cm (capibara). Examples: mice and rats, squirrels, porcupines, beaver (see RODENTIA).

†*Order Creodonta* (creodonts). Fossil only; Middle Cretaceous to upper Oligocene of North America, Eurasia, Africa. Primitive carnivorous mammals; canines well developed; cheek teeth specialized for shearing, but carnassial pair farther back in tooth row than in Carnivora. Auditory bullae unossified. Distal phalanges channelled for insertion of claws; no fusion of scaphoid, lunar, and centrale bones of wrist. More than 50 genera, in about 5 families. Size to that of bear or larger.

*Order Carnivora* (carnivores). Middle Paleocene to Recent on all continents (probably accompanied early man to Australia). Teeth variously modified, sectorial to bunodont, but the carnassial (shearing) pair of teeth always consisting of the last upper premolar over the first lower molar; dentition simplified in advanced pinnipeds (seals), nearly homodont, with no carnassials. Auditory bullae ossified in advanced forms. Terminal phalanges not channelled for insertion of claws; scaphoid, lunar, centrale bones of wrist fused. Carnivorous, omnivorous, herbivorous. Total head and body length 15 to 370 cm. Examples: cats, dogs, bears, weasels, civets, hyenas, raccoons, seals, sea lions, walruses (see CARNIVORA).

†*Order Archaeoceti* (archaeocetes, Zeuglodonts). Fossil only; lower Eocene to middle Miocene of North Africa, Europe, North America. Primitive whale-like marine mammals, dentition not highly modified; anterior teeth simple, peglike; cheek teeth sectorial as in early carnivores; teeth not exceeding basic placental number (44); nostrils placed well back on elongate snout; skull not "telescoped" as in modern whales; hindlimbs vestigial by upper Eocene; body elongate, some serpentine; total length to more than 2,000 cm (65 ft) (see WHALE).

*Order Odontoceti* (toothed whales). Upper Eocene to Recent in all oceans and occasionally in freshwater. Dentition generally simple, undifferentiated (homodont), exceeding the primitive placental number (to 300 teeth in some porpoises) or secondarily reduced (to a single tooth in *Monodon*, the narwhal); nostrils located on top of head, above and between eyes, forming single "blow-hole"; skull asymmetrical, markedly "telescoped," with reduction of frontals and parietals and concomitant extensive posterior expansion of maxillaries and premaxillaries. Relative to Archaeoceti, body shorter, stouter, total length 150 cm (5 ft) (small porpoises) to about 1,800 cm (about 59 ft) (male sperm whales). Examples: dolphins, porpoises, narwhal, sperm whales (see WHALE).

*Order Mysticeti* (baleen or "whale-bone" whales). Upper Eocene to Recent in all oceans. Teeth absent; "whale-bone" (baleen) present, consisting of ridged "curtains" of keratin extending from roof of mouth, used to strain krill (zooplankton); mouth cavernous, esophagus constricted to maximum diameter of about 20 cm; mandibular symphysis lacking; skull symmetrical, markedly "telescoped," with anterior expansion of occipitals; nostrils moved posteriorly, "blow-hole" double, anterior to orbits (eyes). Total length from 600 cm (20 ft) (pygmy right whale) to more than 3,000 cm (100 ft) (blue or sulphur-bottom whale); the blue whale, weighing to 150 tons, is the largest of all known vertebrates, living or extinct. Examples: rorquals (including blue whale), gray whales, bow-heads, right whales (see WHALE).

†*Order Condylarthra* (condylarths). Fossil only; Upper Cretaceous to lower Oligocene of Eurasia, North and South

America. Probably the basal stock from which most later ungulate groups evolved; directly descended from primitive placentals, and characteristics diverse. Tendency toward rounded molar cusps of equal height (bunodonty), formation of diastema, reduction of canine teeth, assumption of digitigrade stance and "experimentation" with hooves (ungules). About 90 genera and seven families: some species at least as large as modern bears.

†*Order Pyrotheria* (pyrotheres). Fossil only; Eocene and Oligocene of South America. Incisors enlarged, tusklike; diastema prominent; cheek teeth low-crowned and with transverse crests; nostrils on top of heavy skull, suggesting development of fleshy proboscis. About 4 genera known; as in many other ungulate groups, trend to large size (to that of elephants); length of skull to 60 cm.

†*Order Xenungulata* (xenungulates). Known only from a few fragmentary fossils from upper Paleocene of South America. Generally poorly known, but molars with tendency toward converging transverse crests as in Dinocerata of Northern Hemisphere; postcranial remains scanty but build obviously massive. Size to that of a modern rhinoceros.

†*Order Pantodonta* (pantodonts). Fossil only; Paleocene to Oligocene of North America and Asia. A varied group of herbivores, prominent in the Paleocene. Cheek teeth low-crowned, with transverse crests variously arranged, canines small or greatly developed. About a dozen genera; total length approximately 100 to 450 cm.

†*Order Dinocerata* (uintatheres). Fossil only; Paleocene and Eocene of North America and Eocene of Asia. Skull low, later representatives with bony projections on nasal, maxillary, and frontal bones. Upper incisors absent, lower incisors reduced, saber-like upper canines (evidently only in males); upper molars unique, with 2 transverse crests forming a "V." Limbs graviportal (massive); about 8 genera; size to that of large rhinoceros.

*Order Proboscidea* (elephants and allies). Upper Eocene to Recent in Eurasia, Africa, North and South America. Earliest known representatives characterized by low-crown molars with two transverse lobes, diastema resulting from loss of outer lower incisor, canine and first premolar, and formation of upper and lower tusks by modification of incisors. Nasal opening toward top of skull, indicating that a fleshy proboscis ("trunk") was present, but perhaps of modest size; early proboscideans relatively long-bodied and short-limbed, superficially tapir-like. Middle and later Cenozoic times saw wide radiation from basal stock; about 2 dozen fossil genera known. Two living genera (*Elephas*, the Indian elephant; *Loxodonta*, the African elephant) with high and truncate skull; massive tusks; short mandible; peculiar cheek tooth arrangement in which a single, high-crowned, lophodont tooth is exposed in each half of the jaw at any one time, and replacement occurs continually from behind; long proboscis; graviportal limbs and girdles; length of head and body to 640 cm (about 20 ft) (see PROBOSCIDEA).

*Order Sirenia* ("sea cows," dugongs, and manatees). Middle Eocene to Recent of Africa, Asia, North and South America. In living species: hindlimbs lacking, pelvis vestigial; front limbs modified into flippers; tail flattened, expanded; body fusiform, neck indistinct, anterior teeth reduced, replaced by horny plates used in cropping estuarine vegetation; molars of living dugongs bunodont, premolars lóst; cheek teeth of manatees bilophodont, increased to 20 or more in each jaw, with 6 in each jaw at a given time and worn teeth replaced from behind as in modern proboscideans. Total length to 450 cm (15 ft) (see SIRENIA).

†*Order Desmostylia* (desmostylians). Known only as fossils from lower Miocene to lower Pliocene in shallow marine deposits of North Pacific Ocean. Skull massive, low, elongate; anterior teeth modified as tusks, 1 pair (canines) above, 2 pairs (canines and incisors) below; cheek teeth peculiar, cusps forming cylinders of enamel and replaced in a continual forward movement as in elephants and manatees; limbs and girdles massive; appearance perhaps superficially hippopotamus-like; total length to about 250 cm (about 8 ft).

†*Order Embrithopoda* (embrithopods). Known only from fossils from lower Oligocene of North Africa. Limbs 5-toed, progression graviportal; superficially rhinoceros-like, large paired horns on nasal bones and smaller horns on frontals (i.e., behind the larger pair). Incisors not enlarged as in other subungulates; cheek teeth high-crowned; total length to about 330 cm (11 ft).

*Order Hyracoidea* (hyracooids). Lower Miocene to Recent of Africa and southwestern Asia. Most generalized of subungulates, although postorbital bar present and permanent denti-

tion reduced; last upper incisors and canine lost, forming diastema; remaining incisors rootless; molars high-crowned. Superficially rabbit- or rodent-like; herbivorous, living on rock slopes or semiarboreal. Total length of fossil species to about 200 cm (6.5 ft); living members 30 to 65 cm. Living examples: rock hyrax, tree hyrax.

†*Order Notoungulata* (notoungulates). Known only as fossils; upper Paleocene to Pleistocene of South America and Paleocene and Eocene of North America and Asia. Varied assemblage, united by dental peculiarities; accessory cusps in central valley of upper molars; lower molars with crescentric ridges, the entoconid lying within the arc of the larger posterior crescent; usually no diastema or reduction in dentition; cheek teeth tending to become rootless, high-crowned, lophodont. Tendency for reduction of toes from 5 to 3; total length approximately 30 to 300 cm (1 to 10 ft).

†*Order Astrapotheria* (astrapotheres). Known only as fossils; upper Paleocene to upper Miocene of South America. Upper incisors lost, canine enlarged, rootless; lower incisors and canine enlarged; diastema prominent; premolars reduced; molars greatly enlarged. Forelimbs stout, feet digitigrade, hind limbs relatively weakly developed, semiplantigrade. Skull truncate; position and character of nasal opening suggests presence of fleshy proboscis; absence of upper incisors suggests that heavy lower incisors may have opposed a modified upper lip to allow cropping of vegetation. Total length to about 280 cm (9 ft).

†*Order Litopterna* (litopterns). Known only as fossils; upper Paleocene to Pleistocene of South America. Hoofed herbivores with tendency toward reduced toes; from 5 to 3 or even 1. Dentition usually complete (or with some loss of incisors); no diastema; cheek teeth low-crowned, selenodont; tendency for molarization of premolars. Size to that of small horse.

*Order Perissodactyla* (perissodactyls). Lower Eocene to Recent; North America, Eurasia, Africa. Incisors variously modified, canines lost or specialized, diastema nearly always present, with loss of first premolars above and then below; molars primitively bunodont, becoming progressively more lophodont, hypsodont; molarization of premolars common at later stages. Hornlike projections on skull not uncommon. Trends toward lengthening of limbs, with limitation of motion to forward and backward. Feet mesaxonic (i.e., with axis through toe III), reduction typically to 3 digits and later to a single digit; digits mostly hooved, but those of chalicotheres clawed. Range in body size from that of small dog (Eocene horses) to that of largest of known land mammals, *Baluchitherium*, an Oligocene rhinocerotid of Asia, nearly 600 cm (20 ft) in height at the shoulder. Examples: titanotheres, chalicotheres, tapirs, rhinoceroses, horses (see PERISSODACTYLA).

*Order Artiodactyla* (artiodactyls). Lower Eocene to Recent; worldwide except Australia. Dentition complete, bunodont (as in pigs) or variously reduced; incisors often reduced and upper incisors lost, vegetation cropped with lower incisors opposing gums of premaxilla; canine and first premolars frequently lost, forming prominent diastema; remaining premolars simple, not completely molariform; cheek teeth primitively low-crowned, bunodont, becoming hypsodont, selenodont (cusps expanding into crescents) in more advanced forms. Unguligrade, foot paraxonic (i.e., the axis between digits III and IV); digit I lost first; digits II and V frequently rudimentary (dew claws), but more prominent in pigs and hippopotamuses; in advanced types metapodials III and IV fused to form cannon bone, adding extra functional joint to limb; astragalus distinctive, the articular surface a double pulley allowing efficient flexion and extension of hindlimb but precluding lateral movement. Parietal bones of skull reduced, frontal bones expanded, frequently bearing antlers or horns. Height at shoulder, 25 cm (10 in) in small antelope to 370 cm (about 12 ft) giraffe. Examples: pigs, cattle, sheep, goats, antelope, pronghorn, giraffe (see ARTIODACTYLA).

**Critical appraisal.** Three subclasses of Mammalia generally have been recognized for many years: Prototheria, the monotremes; Allotheria, the extinct multituberculates; and Theria, including marsupials and placentals as well as the extinct symmetrodonts and pantotheres. However, a number of Mesozoic groups could not be placed satisfactorily in any of these subclasses as defined. Recent evidence on the formation of the braincase in nontherian mammals has suggested that the primitive taxa may in fact constitute a more coherent group than was once supposed. All nontherian mammals are thus placed in a single subclass, Prototheria; infraordinal status is proposed for monotremes, triconodonts and symmetrodonts, and multituberculates.

*Monotremes and multituberculates.* Monotremes and multituberculates represent highly modified offshoots of the earliest mammalian stock. The fossil record of undoubted monotremes is limited to the Pleistocene. Surely the group is an ancient one and, although living representatives are highly specialized, represents the grade of evolution of the reptilian-mammalian transition. Their primitive organization is underscored in the relatively unspecialized brain, retention of the oviparous habit and a cloaca, incomplete homeothermy, and reptile-like frontal and pterygoid bones.

The multituberculates also were derived from the earliest mammalian stock. They were adapted early to a herbivorous diet and developed gnawing incisors and elongate, grinding cheek teeth. The fossil record of the multituberculates, from Upper Jurassic to lower Eocene, is longer than that for any other mammalian order. The extinction of multituberculates in the Early Cenozoic may have been due to competition from placental herbivores, in particular the early rodents.

*Marsupials.* The split between marsupials and placentals has yet to be identified with any certainty. *Pappotherium* of the Lower Cretaceous of Texas was thought for a time to represent a common ancestor of the therian infraclasses, but more recently it has been discovered that recognizable didelphoid marsupials were contemporaneous with the pappotheriids.

The earliest records of marsupials are from North America but the great adaptive radiation of this group occurred in South America and Australia. Mostly free of competition from placentals on Cenozoic island continents, marsupials converged in many cases with the specializations of placentals elsewhere. Australia has been isolated from other major land masses throughout the Cenozoic and South America was an island from Paleocene to Pliocene. Invasions by placentals in later Cenozoic times reduced the once flourishing South America marsupial fauna to the remnant extant today. The South American and Australian radiations were independent, although both assemblages had a common source in generalized didelphoid (opossum-like) groups and evolved in parallel fashion in a number of instances. In general, higher categories in the classification of marsupials are not coordinate with those of the Eutheria. Some families of marsupials, for example, encompass a range of diversity comparable to that in eutherian orders.

Drawing by R. Keane

Figure 5: Reconstruction of *Melanodon*, a shrew-sized insectivorous pantothere from the Upper Jurassic of North America.

*Insectivores and colugos.* Modern insectivores are divisible into several subgroups. The lipotyphlans include modern shrews, moles, and hedgehogs. The molars of hedgehogs are quadritubercular; those of shrews and moles are complicated by the development of a W-shaped external ridge or ectoloph. Lipotyphlans maintain the primitive insectivorous habits of their Mesozoic forebears. Zalambdodonts are represented by the peculiar selenodonts of the Greater Antilles, the tenrecs of Madagascar and West Africa, and the chrysochlorids—Cape golden moles—of southern Africa. The zalambdodonts may or may not represent a natural group. Their early history is obscure. All have V-shaped upper molars.

Tree shrews (tupaids) of Southeast Asia are the sole survivors of a third insectivore group, sometimes called proteutherians, which includes a great variety of Late Cretaceous and Early Cenozoic mammals of uncertain relationships. Living tupaids have frequently been

classified as Primates, for they have remarkably advanced brains and versatile limbs. In such features as dentition, however, they remain quite primitive.

The macroselids, or elephant shrews, are here treated as a separate order. They have frequently been grouped with tupaids as a suborder of the Insectivora, or as a distinct Order Menotyphla. Colugos, the so-called flying lemurs, here maintained as a distinct order, Dermoptera, likewise have been considered by some authorities as insectivores.

*Tillodonts and taeniodonts.* The relationships of tillo-donts and taeniodonts are obscure. Although apparently quite independent, both groups were evidently derived from primitive placental stocks, and both evolved rootless, rodent-like incisors. Neither group was ancestral to later, more successful mammalian types.

*Bats.* Bats are an ancient group; except for extensive skeletal and sensory modifications associated with flight they share many primitive characteristics with their insectivore ancestors. Bats first appear in the fossil record in the Eocene as highly adapted fliers. Were well-preserved postcranial (body and limb) remains of the earliest Cenozoic insectivores better known, some might well be found to represent intermediate stages in the evolution of flight; to date no such intermediate stages have been found. Many have thought that the Dermoptera might represent a grade through which the lineage of the bats must have passed in evolving truly volant habits; surely dermopterans and bats are not closely related, save in their retention of primitive characters of early placentals. In recent years research has brought to light important differences between the two suborders of bats, the Megachiroptera and the Microchiroptera, and some workers have suggested that the two groups be treated as separate orders, maintaining that the similarities between them are due to parallelism and convergence in adapting to the stringent demands of flight.

*Primates.* The Primates form a relatively coherent group, although the distinction between them and their insectivore ancestors is a difficult one and some groups, such as the tree shrews, can be placed in either order with nearly equal justification. Disagreement on classification within the order centres on the validity of the suborder Prosimii as a natural unit that includes such divergent kinds as tarsiers, lemurs, lorises, and galagos, and on the relationship between the Old World and New World monkeys. The two monkey groups may have evolved independently from prosimian ancestors; considerable convergence and parallelism no doubt are involved in the similarities between the two as both have radiated widely in response to available arboreal habitats.

*Edentates and pangolins.* The edentates have undergone their greatest radiation in South America. They are a highly aberrant group, of unknown ancestry, and apparently were isolated early in South America, as were the archaic South American ungulates. Edentates have commonly been subdivided into Loricata (armadillos and extinct glyptodonts), Pilosa (tree sloths and extinct ground sloths) and Vermilingua (anteaters). Each of these subgroups has had a long and independent history, but they share the unique character of xenarthrous vertebrae. The palaeodonts of the Eocene and Oligocene of North America have been considered as nonxenarthrous edentates (a view presented in EDENTATA); they are here allocated to the order Pholidota. Little is known of the relationships of pholidotes (pangolins), once considered relatives of the Edentata; the groups are now rather generally conceded to be convergent.

*Aardvarks.* Aardvarks (Tubulidentata) also were thought at one time to be related to true edentates, but are now considered an independent lineage. Although they are known from Miocene deposits, no direct evidence exists of relationships with other groups. In some respects the skeleton resembles that of certain early condylarths, and it seems probable that tubulidentates descended from an early ungulate stock.

*Lagomorphs.* The Lagomorpha long were included (as a suborder Duplicidentata) in the Rodentia on the basis of dental similarities. Although ordinal rank for the

Lagomorpha has been firmly established, some recent classifications still include rodents and lagomorphs together in a cohort Glires, again based on dental similarities, which almost certainly represent convergence. Various other mammalian lineages of diverse affinities (multituberculates, taeniodonts, tillodonts, and certain primates, for example) have "experimented" with gnawing incisors. The earliest known fossil lagomorphs clearly represent the group and yield no clues as to origin. On the basis of serology and some dental characters, a relationship to ungulates through the condylarths has been suggested. More than likely, however, those characters held in common are primitive and lagomorphs arose directly from a primitive insectivore stock.

**Rodents.** In terms of numbers of individuals and numbers and diversity of species, the rodents are the most successful of living mammals and have evidently been so throughout much of the middle and later Cenozoic. The earliest known rodents (paramyids), of Paleocene age, were already highly specialized mammals. Fossil evidence indicating relationships with more primitive groups is lacking; rodents may have been derived directly from a basal eutherian stock.

The higher classification of rodents has been in a state of flux in recent years. Three suborders (Sciuromorpha, Myomorpha, and Hystricomorpha) were recognized based on the relationship of the zygomatic muscle to the infraorbital foramen. The sciuriforms, or Protrogomorpha, included the earliest known rodents and also modern squirrels, beavers, and sewellels or "mountain beavers." In these taxa the masseter muscle originates from the anterior portion of the zygomatic arch or from the side of the skull in front of the orbit. The infraorbital canal is small, carrying nerves and blood vessels as in primitive mammals. In the Myomorpha, the rats and mice and their allies, the deep portion of the masseter muscle passes through the enlarged infraorbital canal. The so-called hystricomorphs, including Old World porcupines and a great variety of South American rodents, have a greatly enlarged and round infraorbital foramen, rather than a slitlike one like that of myomorphs.

Recent authors have doubted the validity of this arrangement and the utility of the infraorbital canal and zygomatic structure as a diagnostic feature. Many would admit the general validity of the Sciuromorpha and Myomorpha although some groups traditionally included would be reallocated. The "Hystricomorpha," on the other hand, is almost unanimously considered to be polyphyletic, and is now commonly subdivided into Caviomorpha for the complex South American "hystricomorph" radiation, and Hystricomorpha for Old World porcupines and their allies. The tendency has generally been to de-emphasize the use of subordinal classification and instead to bring together related families into a number of superfamilies. Perfection of the higher classification of rodents is difficult because fossil evidence is meager for some groups, particularly those of small or modest size, and because the successful radiation of the Rodentia has obviously led to perplexing convergence in numerous lines.

**Creodonts.** Creodonts were derived from the basic insectivore radiation as early carnivorous mammals, largely in response to the ecological opportunity presented by the evolution of herbivorous types.

**Carnivores.** True carnivores evidently are not descendants of the creodonts, but direct derivatives of Paleocene insectivores. The diversification of fissioned (terrestrial) carnivores from the basal stock (family Miacidae) occurred in the upper Eocene and lower Miocene, early dividing into arctoid or canoid (canids, ursids, procyonids, mustelids) and aeluroid or feloid (felids, hyaenids, viverrids) lines. The Pinnipedia (seals, sea lions, walruses) are here considered a suborder of the Carnivora. Appearing in the fossil record in the Miocene, the modern pinniped families already were distinct. The previous history of the group is obscure, but pinnipeds apparently were derived from arctoid fissioned, although some have thought them to have been derived from creodonts. Some authorities have treated pinnipeds as a

distinct order, in which case they represent the most recently evolved mammalian order.

**Whales.** The whales and their allies have traditionally been treated as a single order, Cetacea, a reasonable arrangement on the basis of certain criteria. It is obvious, however, that cetaceans diverged early into archaeocetes, odontocetes, and mysticetes, if, indeed, the groups had a common ancestry. The earliest known fossils are perfectly good whales and clearly are assignable to one of the three groups; thus there is no concrete evidence linking the three nor is there evidence as to their ancestry. The morphological characters that whales share can be interpreted as due to parallelism resulting from stringent selection in similar habitats, or to the retention of primitive placental characteristics. Until evidence is available to establish the monophyly of cetaceans it seems preferable to treat them as representing three separate orders.

**Ungulates.** The term "ungulate" denotes a broad, loose association of orders including most large herbivorous mammals. The name of the group implies that its members are hoofed, but some of the ungulates (chalicotheres, for example) had clawed digits and others (such as sirenians) show considerable reduction of digits and limbs. The ungulates may be of common ancestry or may be a product of convergence from several sources among primitive placental stocks. Certain supposed early ungulates (condylarths) and early carnivorous mammals (creodonts) have many characters in common; their supposed descendants frequently have been united in a common cohort, Ferungulata.

From A.S. Romer, *Vertebrate Paleontology*, 3rd ed., copyright 1966; the University of Chicago Press

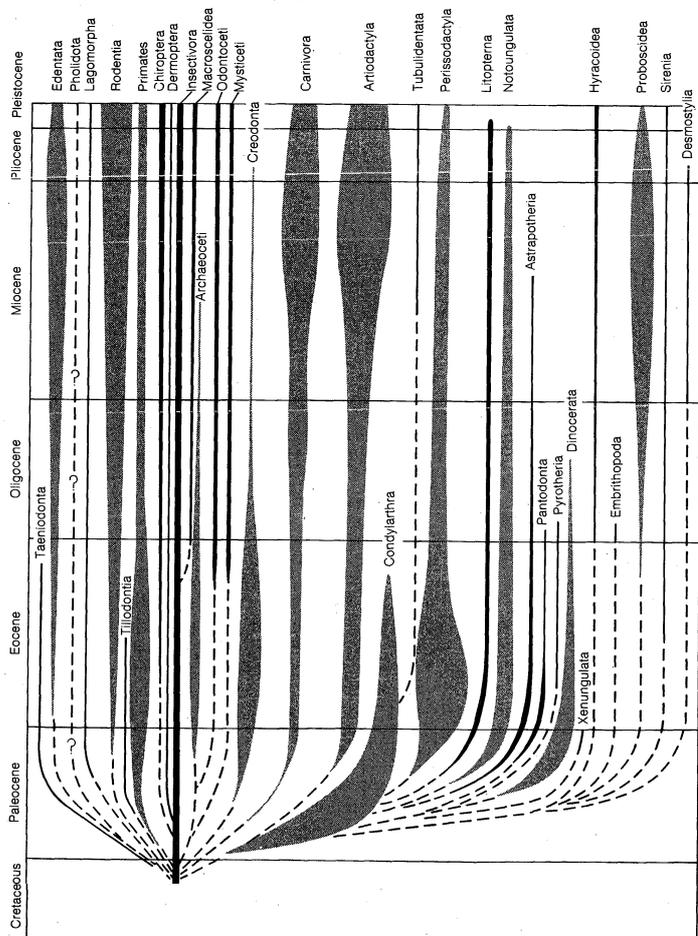

Figure 6: Dendrogram of the placental mammals.

The principal characteristics shared by ungulates are those of the dentition and limbs, related to modification of the primitive placental into an efficient herbivore. There has been a tendency toward elongation of individual molar cusps to form crescentic ridges (selenodonty)

or to form ridges between adjacent cusps (lophodonty). A concomitant trend has been an increase in the height of molars from low-crowned (brachyodont) to high-crowned (hypsodont), which has allowed the efficient utilization of abrasive forage such as grass. The extent of the grinding surface has been increased by increasing the length of the molars or by "molarization" of premolars.

The radiation of large herbivores was accompanied closely by a radiation of large carnivores. The adaptive response of ungulates to predation has been varied: modified dentition (tusks), skeletal elements (horns, antlers), and behaviour have been turned to defensive purposes. Extremely large size or swift, cursorial locomotion were at a premium. Defensive gregariousness is common in extant species.

The general trend in mammalian locomotion has been plantigrade to digitigrade to unguligrade, frequently with reduction of digits. One mode of digit reduction has been mesaxonic, the axis of the foot passing through digit III (as in horses); other groups have paraxonic limbs, with the axis lying between digits III and IV. Elongation of metapodials has occurred commonly, forming a third functional segment of the limb, allowing fast cursorial gaits.

Exceptions to these trends in limb modifications occur in lineages with early trends toward extremely large size. In such groups, columnar, graviportal limbs have developed with proximal segments (femur, humerus) emphasized and metapodials de-emphasized; all digits usually are retained.

The ungulate radiation has been complex. Various subdivisions have been proposed. The condylarths may or may not be basal to the entire radiation, but they evidently gave rise to the perissodactyls.

*Perissodactyls.* This is a compact order, consisting of five subdivisions: horses, chalicotheres, titanotheres, rhinoceroses, and tapiroids. The history of the perissodactyls is perhaps better known than that of any other mammalian group. *Hyracotherium* ("Eohippus"), usually considered the base of the horse lineage, was probably near the source of the entire order.

*Artiodactyls.* The Artiodactyla first appear in the early Eocene. Dental characters point to an origin for the group among hypsodontid condylarths but the earliest known artiodactyls already had the unique and specialized "double-pulley" astragalus. Knowledge of transitional stages between condylarthran and artiodactyl tarsi would be of considerable interest and importance.

*Archaic ungulates.* A number of kinds of archaic ungulates, which generally evolved in the Western Hemisphere, have been lumped in the past in a single order, Amblypoda. Each of these groups—pantodonts, uintatheres (Dinocerata), pyrotheres, xenungulates—is here accorded ordinal rank. The relationships of these groups—if any—are obscure and their origin is unknown.

*Litopterns.* The Litopterna of South America were early derivatives of the condylarths, and some workers would include both in a single order. One family (Protheriidae) closely paralleled the contemporaneous radiation of perissodactyls on the northern continents, but the macrauchenids converged toward the camels.

*Notoungulates.* The order Notoungulata was an early and varied assemblage, apparently restricted to South America in the Eocene, perhaps by competition with early members of more advanced ungulate groups. The greatest development of the order was in the Oligocene, after which there was a gradual decline, hastened by the entry into South America of placental carnivores and modern artiodactyls. The origin and affinities of the notoungulates are unknown, but the order may well have descended from the condylarths.

*Astrapotheres.* Astrapotheres were once considered to have been notoungulates. It is now generally conceded that their peculiarities recommend recognition as a separate order. This group may have had its origin among primitive notoungulates, or it may have arisen independently.

*Hyracoids.* The products of the early Cenozoic radiation of ungulates in Africa are commonly grouped as

"subungulates." The Hyracoidea is the most generalized of these orders but the true relationships of the hyracoids to other ungulates are unknown. In common with other subungulate orders, hyracoids were more diverse in the Middle Cenozoic than they are today.

*Embrithopods.* The extinct Order Embrithopoda contains a single known genus, *Arsinoitherium*. Relationship with hyracoids has been suggested but concrete evidence is lacking. Aside from logical association with other subungulate groups, little can be said of the position or affinities of the Embrithopoda.

*Elephants and allies.* The best known of the subungulates are the Proboscidea. The later record of the order is relatively good and indicates a remarkably successful and widespread radiation in the latter part of the Cenozoic—a radiation characterized by the recurrence of several trends in separate lines. Among these trends were an emphasis on the development of the upper tusk with loss of the lower tusk in most groups, increase in the size of the skull and shortening of the neck, increase in the length of the proboscis, increase in overall size, with perfection of graviportal limbs and girdles, lengthening of the lower jaw (secondarily shortened in some groups), and reduction and specialization of cheek teeth.

*Sirenians.* The origin of the Sirenia is obscure. The earliest known sirenians were completely aquatic although the pelvic girdle was not so much reduced as in later forms. Dental and cranial peculiarities suggest that proboscideans and sirenians may have arisen from a common swamp-dwelling or amphibious ancestor. Concrete evidence is generally lacking regarding this and other relationships among subungulates due to a paucity of fossiliferous continental sediments of early Cenozoic age in Africa.

*Desmostylians.* Because of dental peculiarities and their association with shallow-water marine sediments, fossil remains of the order Desmostylia were long thought to represent aberrant sirenians; recent discoveries of massive limb bones of these mammals indicate, however, that they had quite different adaptations. The nature of the cheek teeth and their mode of replacement suggests relationships with the largely African subungulates, although desmostylians are known only from fossil deposits along the shores of the North Pacific.

**BIBLIOGRAPHY.** The literature on the biology of mammals is vast. The following list includes only a sample of available sources, with emphasis on those in the English language. Standard general references on the mammals are: F.E. BEDDARD, *Mammalia* (1902); W.H. FLOWER and R. LYECKER, *An Introduction to the Study of Mammals, Living and Extinct* (1891); and J.Z. YOUNG, *The Life of Mammals* (1957).

Less technical accounts include: F. BOURLIERE, *Vie et moeurs des mammifères* (1951; Eng. trans., *The Natural History of Mammals*, 1954); and L.H. MATTHEWS, *The Life of Mammals* (1970). Widely used textbooks in mammalogy are: E.L. COCKRUM, *Introduction to Mammalogy* (1962); and D.E. DAVIS and F.B. GOLLEY, *Principles in Mammalogy* (1963). The only thorough up-to-date treatment in English of the families of living mammals is S. ANDERSON and J.K. JONES, JR., (eds.), *Recent Mammals of the World: A Synopsis of Families* (1967). E.P. WALKER *et al.*, *Mammals of the World*, 3 vol. (1964), is a semitechnical work including illustrations of representatives of most living genera; the third volume is a classified bibliography. Perhaps the most comprehensive reference on the biology of mammals is P.P. GRASSE (ed.), *Traité de zoologie*, vol. 16-17 (1967-68, 1955).

The morphology and classification of early mammals is reviewed by J.A. HOPSON and A.W. CROMPTON, "Origin of Mammals," *Evolutionary Biol.*, 3:15-72 (1969); and J.A. HOPSON, "The Classification of Nontherian Mammals," *J. Mammal.*, 51:1-9 (1970). A standard reference on the classification of mammals is G.G. SIMPSON, "The Principles of Classification and a Classification of the Mammals," *Bull. Am. Mus. Nat. Hist.*, 85:1-350 (1945); the evolution of major mammalian groups is treated by A.S. ROMER in *Vertebrate Paleontology*, 3rd ed. (1966), and *Notes and Comments on Vertebrate Paleontology* (1968).

Basic references on the status of endangered species of mammals are: F. HARPER, *Extinct and Vanishing Mammals of the Old World* (1945); and G.M. ALLEN, *Extinct and Vanishing Mammals of the Western Hemisphere with the Marine Species of All the Oceans* (1942).

Recent summaries of specialized topics in mammalogy include: H.T. ANDERSEN (ed.), *The Biology of Marine Mammals* (1969); S.A. ASDELL, *Patterns of Mammalian Reproduction*, 2nd ed. (1964); L.S. CRANDALL, *The Management of Wild Mammals in Captivity* (1964); R.F. EWER, *Ethology of Mammals* (1968); C.P. LYMAN and A.R. DAWE (eds.), *Mammalian Hibernation* (1960); W.V. MAYER and R.G. VAN GELDER (eds.), *Physiological Mammalogy*, 2 vol. (1963-64); A.G. SEARLE, *Comparative Genetics of Coat Colour in Mammals* (1968).

Some widely known journals that publish papers dealing exclusively with mammals are: *Journal of Mammalogy*, *Mammalia*, and *Säugetierkundliche Mitteilungen* (all issued quarterly), and *Zeitschrift für Säugetierkunde* (6/yr.). Additional technical literature is published by university and public museums and government agencies. Semitechnical and popular accounts of mammals appear in a wide variety of publications of state game departments, museums, and zoological gardens.

(J.K.J./D.M.A.)

## Mammary Glands, Human

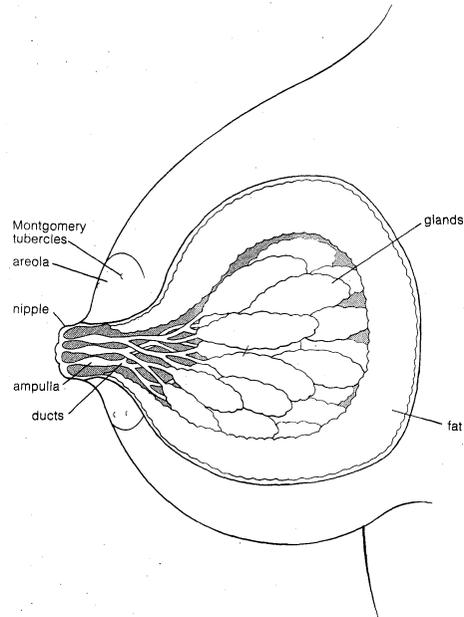

The mammary glands, a distinguishing feature of mammals, are milk-producing organs contained within the breasts. The human female breasts, important in human biology not only for their milk production, but also for their aesthetic and erotic role, are especially prone to pathological changes that are potentially lethal. In the male the mammary glands normally remain rudimentary and are less subject to pathological change.

**Anatomy and physiology.** *Development.* Mammary glands are derived from a modification of sweat glands. They first appear in the sixth week of fetal life as clumps of cells proliferating from a longitudinal ridge of ectoderm (the outermost of the three germ layers of the embryo) along the "milk line," from the buds, or beginnings, of the lower limbs to those of the upper limbs. The number of these clumps that ultimately become breasts, or mammae, varies with each mammalian species according to the size of its litter. In the human normally only one develops on each side of the chest. A lesser development of one or more breasts (polymastia) or nipples (polythelia) may, however, occur anywhere along the milk line. By the end of fetal life these cells are recognizable as the primitive ductal epithelium from which the future milk-bearing ducts and secretory sacs, or acini, will grow.

*Anatomy of the mature breast.* The mammary gland of a woman who has not borne children consists of a conical disk of glandular tissue 10-12 centimetres in diameter, 3-5 centimetres in thickness and weighing 150-200 grams. During lactation the gland weighs 400-500 grams. It is encased in variable quantities of fat that give it its characteristic shape. The glandular tissue itself is made up of 15-20 lobes composed of solid cords of ductal cells; each lobe is subdivided into many smaller lobules, separated by broad fibrous suspensory bands (Cooper's ligaments), which connect the skin with the fascia, or sheet of connective tissue, that covers the pectoral muscles which lie beneath the breast. Each lobe is drained by a separate excretory duct. These converge beneath the nipple, where they widen into milk reservoirs, before narrowing again to merge as pinpoint openings at the summit of the nipple. Circular and radiating muscles in the areola, a circular disk of roughened pigmented skin surrounding the nipple, cause the nipple to become firm and erect upon tactile stimulation; this facilitates suckling. The areola also contains sebaceous glands to provide lubrication for the nipple during nursing.

Blood is supplied to the breast through the axillary, intercostal, and internal thoracic vessels. The nerve supply is from branches of the fourth, fifth, and sixth intercostal nerves.

*Hormonal relationships.* Under the primary influence of estrogens from the maturing ovary at puberty, the ductal cells proliferate and form branches. After ovulation, progesterone from the corpus luteum, an organ that develops in the ovary each time an ovum has been shed and has the function of preparing the uterus for receiving the developing embryo, causes the terminal ductal cells to differentiate into the milk-producing cells, which form acini. Interspersed with these cells are smooth muscle

Lactating female breast.

From C. Smout, F. Jacoby, and E. Lillie, *Gynecological and Obstetrical Anatomy*; H.K. Lewis and Co., Ltd., London

cells, which can contract and assist in the ejection of milk. The acini are collapsed or filled with desquamated epithelium (epithelium that has been shed), until the stimulus of pregnancy causes proliferation of all the epithelial cells. The breast becomes enlarged, tense, and sensitive, and the areola widened and more deeply pigmented. The actual secretion of milk is induced by hormones—prolactin from the pituitary and somatomammotropin from the placenta. At the end of lactation the mammary glands and areolae return almost but not completely to their state before pregnancy (see also LACTATION, HUMAN). After the menopause the glands atrophy and are largely replaced by connective tissue and fat.

**Diseases of the breast.** The occurrence of supernumerary breasts and nipples has been mentioned. Absence of one or both breasts occurs, but rarely. Inequality in size is frequent, the left breast being larger more often than the right. Variations in size and shape are commonly of racial or genetic origin, but may be induced by a tight brassiere or by manipulation to cause elongation for the greater convenience of nursing an infant carried on the back.

Painful breasts may occur whenever estrogens are present in large amounts, as at puberty, during pregnancy, prior to menstruation, or after administration of the estrogens.

Fibrocystic disease, also called chronic cystic mastitis, may result in later reproductive life from the cumulative effect of the ebb and flow of endocrine stimulation with each menstrual cycle; this produces nodular fibrosis—or lumps of fibrous tissue—and cysts of various size. The condition can usually be distinguished from cancer because it is intermittently painful and tends to subside after menstrual periods. It may predispose to carcinoma, however. Early biopsy is indicated for any nodules that persist.

Precocious breast development may occur as a result of lesions in the pituitary-hypothalamic area that cause premature release of gonadotropins, or as a result of congenital anomalies of the ovaries with the autonomous production of estrogens.

Gynecomastia, or enlargement of the breast in the male, occurs whenever estrogens are present in excess. This may be physiological, during the height of male hormone production in adolescence; pathological from failure of estrogen removal by the liver, as in cirrhosis; or the result of medical treatment, as when estrogens are administered for the treatment of carcinoma of the prostate, or after the use of certain drugs such as digitalis and spironolactone. Gynecomastia occurring spontaneously in the adult male

Breast enlargement in male

suggests the existence of an estrogen-secreting tumour of the adrenal gland or testis, or of a gonadotropin-producing choriocarcinoma. Such tumours are highly malignant, and early removal is imperative. Gynecomastia may also be an indication of a sex chromatin abnormality in which an apparent male is genetically a female (Klinefelter's syndrome).

The only common infectious disease unique to the breast is acute mastitis, which occurs during lactation as the result of an invasion of pyogenic skin organisms through the nipple. The severe local inflammation, with high fever and prostration, responds promptly to antibiotics, usually without suppuration. Mastitis is ordinarily prevented by proper hygiene.

Benign  
tumours;  
carcinoma

Benign tumours include fibroadenoma, more common in women under 30, and intraductal papilloma, which may cause bleeding from the nipple. These tumours should be removed. Malignant tumours may arise from any of the cell types contained in the breast, but sarcomas make up only 3 percent of all breast tumours.

Carcinoma of the female breast is the commonest form of malignant tumour in the western civilized world, afflicting about 4 percent of all adult women, approximately half of whom will succumb to it. For reasons not yet clear it is less prevalent in Oriental countries. Rare under the age of 25, it increases in incidence up to the menopause, and then levels off. Hereditary factors play a role, but their exact importance has not been clearly established. The disease is more common in childless women with a late menopause, suggesting that it may be related to the total duration of ovarian activity. It is known that estrogens will stimulate the growth of mammary cancer, but there is no evidence that they will initiate it. These hormones should not be administered to women with fibrocystic disease or a family history of mammary cancer. Only 1 percent of the cases of carcinoma of the breast occur in males.

Cancer affecting the inner part of the breast is more difficult to deal with than cancer nearer the surface because of the course of the lymph channels. Lymph from the inner half of the breast drains directly through the chest wall to the internal mammary lymph nodes beneath the sternum, where metastases quickly become inaccessible. The outer half is drained by way of the pectoral, axillary, and supraclavicular nodes, where metastases can be fairly readily palpated and occasionally successfully removed.

Breast carcinoma arises more often in the ductal than the acinar cells, but may have several independent points of origin. Metastases are prone to occur early, sometimes when the original lesion is still microscopic in size, to the regional lymph nodes in the armpit or the area of the breastbone, depending upon the primary site. Further spread then occurs through the bloodstream to the skeleton, liver, lungs, brain, and generally throughout the body. Death results most commonly from destruction of the liver, less often from damage to the lungs or brain, or from hemorrhage.

An epidermoid type of carcinoma may occur in the nipple; this tumour, called Paget's disease of the nipple, may cause intermittent ulceration and bleeding.

Cancer is suspected when a painless lump in the breast is detected; the lump is firmer in consistency than the surrounding breast tissue and usually remains fixed when the overlying skin is retracted. Most lumps of this type are detected by the victims themselves as the result of self-examination, a practice that should be encouraged by gynecologists. Occasionally a bloody discharge from the nipple or retraction of the nipple will call attention to an underlying tumour.

Surgical removal of the breast before the tumour has extended beyond its primary site offers the only hope of a permanent cure. The chances of survival diminish rapidly in proportion to the distance from the origin at which lymph nodes have been invaded by tumour.

When distant metastases have become manifest, palliation may be achieved by local X-ray treatment, or by removal of the ovaries and the adrenal glands and by use of one of the chemicals that destroy cancer cells. Lesser

benefit may be obtained by the administration of hormones like cortisone or testosterone, and in some elderly patients a paradoxical effect may follow large doses of estrogens.

## Ma'mūn, Al-

Al-Ma'mūn, the seventh 'Abbāsīd caliph and the first to introduce elements of Greek and Hellenistic philosophy into Islām, is best remembered for his attempts to bring about a reconciliation between Shi'ites and Sunnites and to impose upon his subjects a more rationalist Muslim creed.

The son of the celebrated caliph Hārūn ar-Rashīd and an Iranian concubine, al-Ma'mūn was born in 786, six months before his half brother al-Amīn, the son of a legitimate wife of Arab blood. When it became necessary for ar-Rashīd to choose an heir, he is said to have hesitated before deciding finally in favour of al-Amīn. In 802, on the occasion of a pilgrimage to Mecca, the Caliph formally announced the respective rights of the two brothers: al-Ma'mūn recognized al-Amīn as successor to the caliphate in Baghdad, but al-Amīn acknowledged his brother's almost absolute sovereignty over the eastern provinces of the empire, with his seat Merv in the Khorāsān.

Hārūn ar-Rashīd's death in March 809 nevertheless created discord that soon developed into armed conflict between the two brothers. Al-Ma'mūn, in effect stripped by al-Amīn of his rights to the succession, was supported by an Iranian, al-Faql ibn Sahl, whom he was to make his vizier, as well as by an Iranian general, Ṭāhir. Ṭāhir's victory over al-Amīn's army on the outskirts of the present Tehrān, allowed al-Ma'mūn's troops to occupy western Iran. Al-Amīn appealed in vain to new troops recruited in part from among the Arabs of Syria. He was finally besieged in Baghdad in April 812. There was desperate resistance, and the city was taken only in September 813. The Caliph, who had in the meantime been declared deposed in Iraq and Arabia, wished to surrender but was killed, contrary, it seems, to Al-Ma'mūn's orders. Thus ended one of the most merciless civil wars known to the Islāmic East. The war had originated in Hārūn ar-Rashīd's ill-advised decision, but it also revealed internal divisions in the 'Abbāsīd empire. It was not merely a question of a personal rivalry between the two brothers—one of whom, al-Ma'mūn, was unquestionably of far superior intelligence—it was also a question of a clash between different politico-religious trends that had become apparent during the preceding reign, al-Amīn stressing traditionalism and Arab culture, while al-Ma'mūn, open to new movements of thought and outside influences, courted the support of Iranian figures and of the eastern provinces.

Al-Ma'mūn, having become caliph of the entire 'Abbāsīd empire, decided to continue to reside at Merv, assisted by his faithful Iranian vizier al-Faql. It was then that al-Ma'mūn, determined to put an end to the division of the Islāmic world between Sunnites and Shi'ites—between the adherents of the 'Abbāsīd caliphs, descendants of Muḥammad's uncle al-'Abbās, and the defenders of 'Alī, the prophet's cousin and son-in-law and his descendants—made a decision startling to his contemporaries and injurious to his own position. He designated as his heir not a member of his own family but 'Alī ar-Rīdā, a descendant of 'Alī. In an attempt visibly to reconcile the

Early  
years

Attempted  
reconciliation  
between  
Sunnites  
and  
Shi'ites

two rival families, al-Ma'mūn gave 'Alī ar-Riḍā his own daughter as a wife. As a further symbol of reconciliation, he adopted the green flag in place of the traditional black flag of the 'Abbāsīd family. But this spectacular measure did not achieve the anticipated result. It was not sufficient to pacify the Shī'ite extremists, while on the other hand it embittered the partisans of 'Abbāsīd legitimism and of Sunnism, particularly in Iraq. In Baghdad, declaring al-Ma'mūn deposed, they proclaimed as the new caliph the 'Abbāsīd prince Ibrāhīm, son of the third caliph, al-Mahdī. When news of this insurrection finally reached al-Ma'mūn, he abruptly decided to leave Merv for Baghdad. During the long journey, two dramatic events took place: the vizier al-Faḍl was assassinated in February 818, and 'Alī ar-Riḍā died in August of the same year after a brief illness that chroniclers ascribed to poisoning. Thus the man whose elevation to the position of heir presumptive had bedevilled the Caliph's rule as well as the vizier closely associated with that policy were eliminated. Notwithstanding his denials, historians have generally attributed the deaths to al-Ma'mūn.

During the following 15 years, al-Ma'mūn showed himself to be a judicious sovereign. He closely controlled his ministers and did not again appoint an all-powerful vizier. He also tried to maintain strict control over the provincial governors but was forced to allow a relative degree of autonomy to his former general, Ṭāhīr, who had been named governor of Khorāsān.

Although al-Ma'mūn, on his arrival in Baghdad, abandoned his policy of reconciliation with the descendants of 'Alī, which he symbolized by reinstating the traditional black flag, he did not give up hope of attaining the same goal by a more circuitous path. He had already, at Merv, shown his sympathy for the representatives of the Mu'tazilite movement, those supporters of Islām who adopted rationalist methods and borrowed from the works of ancient Greek or Hellenistic philosophers the modes of reasoning that seemed to them best suited for combatting the influence of such doctrines as Manichaeism (a dualistic religion founded in Iran). Al-Ma'mūn encouraged the translation of Greek philosophical and scientific works and founded an academy called the House of Wisdom (Bayt al-Ḥikmah) to which the translators, most often Christians, were attached. He also imported manuscripts of particularly important works that did not exist in the Islāmic countries from Byzantium. Developing an interest in the sciences as well, he established observatories at which Muslim scholars could verify the astronomic knowledge handed down from antiquity.

Not content with extending his patronage to the translators and scientific research, al-Ma'mūn imposed on all his subjects the Mu'tazilite doctrine, characterized by a purified concept of divinity, belief in free will, and full human responsibility. One of the most innovative aspects of this theodicy was the affirmation of the created and not eternal character of the Qur'ān, the word of God. Such a doctrine was likely to diminish the influence of the learned doctors, the interpreters of the sacred text, who found themselves defending 'Abbāsīd legitimism; in addition, the doctrine demanded exceptional moral and religious qualities of the caliph, for it went so far as to authorize rebellion against a wicked sovereign. This tenet of the Mu'tazilite doctrine diverged from the traditional concept upon which the 'Abbāsīd caliphs had based their authority, and many adherents of the doctrine manifested an avowed sympathy for Shī'ism. Al-Ma'mūn, attracted by the intellectual rigour of Mu'tazilism, also saw in it the means of encouraging public opinion to accept a new, more flexible conception of the caliphate. In fact, when he announced his adherence to the thesis of the "created Qur'ān" in 827, al-Ma'mūn also asserted the superiority of 'Alī over the other Companions of the Prophet. This position of al-Ma'mūn's manifested clear political implications.

At the beginning of 833 al-Ma'mūn decided to require adherence to Mu'tazilism from all his subjects. As the Caliph was then on an expedition against the Byzantines in the region of Tarsus, he entrusted this task to his rep-

resentative in Baghdad, the prefect of police Ishāq ibn Ibrāhīm. The latter first called together the *qādīs* (judges) to urge them to recognize the Mu'tazilite doctrine; then it was the turn of the specialists in Hadīth Muslim tradition; but among this group protestations were raised that the Caliph hoped to silence through the use of threats. Some resisted obstinately, refusing to pronounce the Qur'ān a "created" work. This was notably true of Aḥmad ibn Ḥanbal, the founder of the Ḥanbalite school of Islāmic law, who was to have been sent, under a heavy guard, before the Caliph, but was temporarily spared by the sudden death of al-Ma'mūn at Tarsus in August 833. This episode, called the trial (*mihnah*) by the traditionalists, showed that one portion of the public opinion resisted the beliefs that al-Ma'mūn had wished to impose. The strength of this opposition serves to explain why the caliphs, a few decades later, abandoning their attempt at reorienting religious beliefs, returned to traditional dogma.

Possessed of a distinguished and sagacious mind, al-Ma'mūn set forth in the political domain very personal ideas that, in effect, ended in failure. He was never able to put an end to the divisions that were tearing the community apart; and the violence that he did not hesitate to employ at the end of his reign—to impose a doctrine he considered salutary for the Islāmic community—tarnished the image of an otherwise exceptionally open-minded ruler.

**BIBLIOGRAPHY.** The only biography of the caliph al-Ma'mūn is found in the *Encyclopaedia of Islam*, 1st ed., vol. 3 (1936), although this article is now largely out of date. For the history of the dynasty, see the article "Abbasids," in the *Encyclopaedia of Islam*, 2nd ed., vol. 1 (1960); and also "The Abbasid Caliphate," in the *Cambridge History of Islam*, vol. 1 (1970). The problems of the relationship between al-Ma'mūn and Shī'ism are treated in F. GABRIELI, *Al-Ma'mun e gli Alidi* (1929), which is now completed by D. SOURDEL, "La Politique religieuse du calife 'abbaside al Ma'mun" in *Revue des études islamiques*, 30:27-48 (1962).

(D.So.)

## Man, Evolution of

From the point of view of the biologist, the problem of the evolutionary origin of man is only one of many problems of mammalian evolution, for, in his physical structure and physiological functions, man falls within the biologist's definition of a mammal and may be presumed to be the product of an evolutionary process similar to that which is now known from the fossil record to have occurred with other groups of mammals. At the time of the publication of Darwin's *Origin of Species* (1859), there was considerable opposition to the concept of evolution as a whole, mainly because so many people accepted the idea of the fixity and immutability of the species of animals and plants. In part, the opposition was due to the influence of the biblical story of the creation and to the fact that the hypothesis of adaptation through natural selection challenged the religious and philosophical "argument from design" for the existence of a divine intelligence. But opposition also arose because of the scientific evidence adduced by taxonomists that species are clear-cut and sharply defined and usually do not interbreed with other species. In the main, the cumulative evidence advanced by Darwin and Alfred Russel Wallace, in England, and by others eventually compelled acceptance of the main hypothesis of organic evolution (see EVOLUTION). Nevertheless, general acceptance was certainly delayed by the circumstance that the hypothesis inevitably involved consideration of man's relationship to the lower animals; and the implied conclusion that if man is the product of an evolutionary process then he is not a unique and special creation dominated the minds of many anti-evolutionists for a long time to come. It is possible that some of the more bitter controversies in the early days of evolutionary discussion might have been avoided if a clear distinction had been made between what may be termed anatomical and physiological man (*i.e.*, the biological species *Homo sapiens*) and the concept of man in its wider philosophical context, for it is certain that misconceptions have arisen in the past and still arise from

Attempt to impose a rationalist form of Islām

Support of Western philosophy and science

time to time from the use and misuse of the colloquial terms man and human in the discussion of evolutionary origins.

This article is divided into the following sections:

- I. Man's evolutionary relationships
  - The living primates
  - Fossil primates
  - The Hominidae
  - Homo sapiens* in the fossil record
- II. Evolutionary process in man
  - Genetics and man
  - Adaptation and genetic change
  - Man's continuing evolution

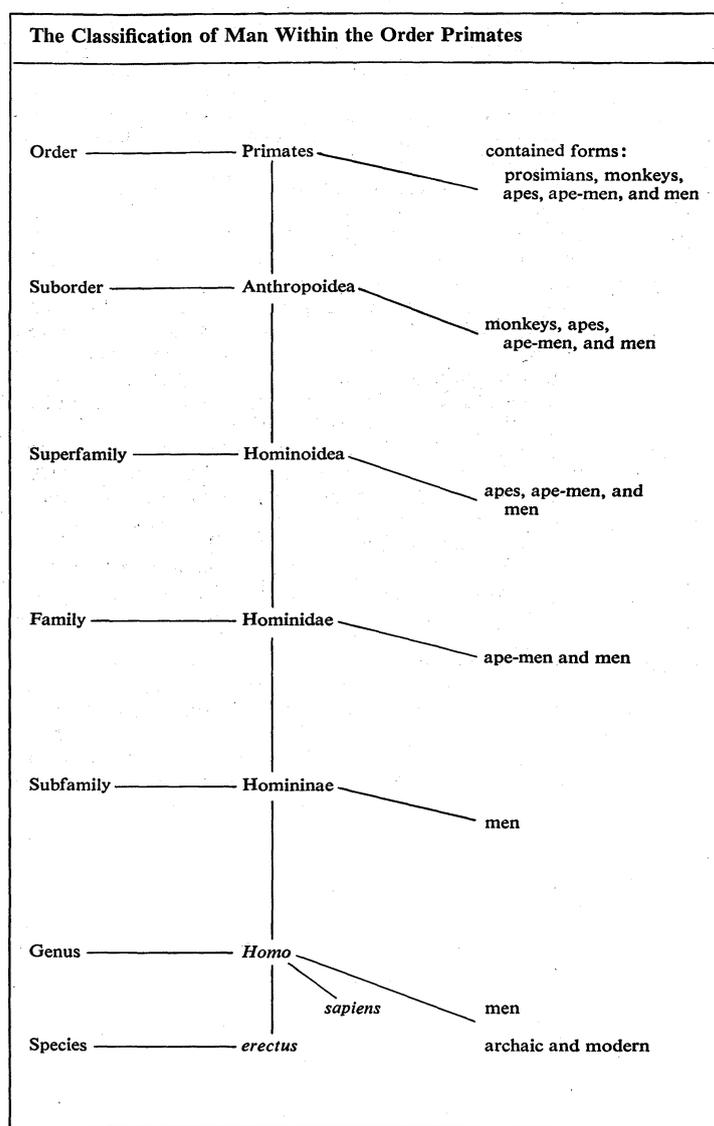

**I. Man's evolutionary relationships**

THE LIVING PRIMATES

Taxonomic classification includes man as a member of the order Primates, which is a part of the class Mammalia. Within the Primates are included such divergent creatures as the Southeast Asian tarsiers, the Madagascan lemurs, the South American monkeys, the African monkeys, the great apes (gibbons, orangutans, chimpanzees, gorillas), and finally, man himself (see the Table). The primates that exist today comprise a remarkable gradational series that links *Homo* anatomically with small mammals of very primitive types (see PRIMATES). The most lowly representatives of the living primates are the tree shrews, small squirrel-like creatures that have a wide distribution in Southeast Asia. So primitive are the tree shrews that some authorities refuse to include them among the primates. But even these authorities would agree that tree shrews must at least be very closely related to the ancestral stock from which the primates in general have derived. In a number of their anatomical characters, the tree shrews show such a close resemblance to undoubted primates (e.g., some of the lemurs) as to amount in certain details to an identity of structure. The lemurs in their more advanced anatomical structure show a mixture of characters that indicate an intermediate position between tree shrews and monkeys. The curious little tarsier (which inhabits Borneo, Sumatra, the Celebes, and the Philippines) is in some respects even more monkey-like. The various types of tailed monkeys represent a still higher grade of organization and through the gibbon, smallest of the apes, are linked with the larger tailless anthropoid apes, the chimpanzee, orangutan, and gorilla.

The manlike apes

As their name implies, the anthropoid apes are manlike in their anatomical structure. Their brains, although much smaller than a modern human brain, are relatively well developed as compared with lower primates and have the same patterns of convolutions as the human brain has (though in a simplified form); the similarities in many details of the intrinsic structure of the brain of the anthropoid ape are astonishingly precise. These anatomical resemblances in the brain have been found to be correlated with physiological similarities. Thus, the sensory and motor mechanisms fulfill functions so closely reproducing those of the human brain that for experimental studies anthropoid apes have been found to be far more reliable than any other nonhuman mammal in their application to problems of cerebral function in man. Many features of the skull and skeleton of the large apes approximate very closely to those of the Hominidae (the taxonomic family that includes living and fossil types of man), particularly if account is taken of certain extinct primitive hominids. Some of the structural similarities in the skeleton of the trunk and limbs are in part related to posture, for the chimpanzee and gorilla are capable, at times, of balancing themselves on their hindlimbs in a manner that suggests, albeit distantly, the erect posture characteristic of the Hominidae. In their dentition, particularly in the molar teeth, anthropoid apes also show a close resemblance to the Hominidae. Indeed, it is sometimes difficult to determine whether isolated fossil molar teeth belong to apes or hominids, for the distinctions that exist between the teeth of apes and those of man are in general far less obtrusive when fossil specimens are considered. Many of the muscles of the human body have the same disposition and attachments as those of the anthro-

pooid apes. In the sole of the human foot, for example, are found the same muscles that are used for the mobile functions of the ape foot, even though in man the mobility is not present. The disposition of the abdominal organs in apes corresponds quite closely with that of man, and even in their microscopic details some of the organs of the body show a remarkable resemblance. These examples of anatomical and physiological similarities between the large anthropoid apes and the Hominidae could well be multiplied. Their implications for a real phylogenetic relationship are further supported by reference to similarities in serum-protein patterns, immunological responses, some of the blood groups, parasitic infestation, and susceptibility to certain diseases (see IMMUNITY; BLOOD GROUPS AND FACTORS).

**Trends of primate evolutionary development.** As diversified as the primates are in terms of appearance, ecological adaptations, and behaviour, through their common ancestry they share a number of distinctive characteristics. Fundamentally they have avoided extreme anatomical specializations and have, for the most part, preserved a generalized morphology, which confers on them a considerable degree of functional plasticity. The order can be defined on the basis of the prevailing trends that have dominated its evolutionary development: a generalized structure of the limbs with the replacement of sharp claws by flattened nails resulting in a grasping hand; the elaboration of the visual sense and a corresponding reduction in the sense of smell; and the progressive development of a large and complicated brain. In the Hominidae,

Primate generalized morphology

these same tendencies have manifested themselves and have progressed further than among other groups of primates. The Hominiidae show also a unique specialization of the lower limb; the pelvis and leg have become adapted for support and bipedal propulsion of the body in the erect position, while the foot and toes have lost the prehensility characteristic of the primates in general.

In examining the development of the primates over a period of perhaps 70,000,000 years, the evolutionary trends that have emerged form a pattern of progressive adaptational changes largely related to arboreal life. Although a number of separate trends can be traced individually, they are largely grouped around several functional and behavioral centres. The very existence of evolutionary trends has been questioned, and some workers have suggested that they existed only in the mind of the paleontologist. But, if it is true that directed, straight-line, orthogenetic trends do not exist in nature, it is also true that within a single evolutionary lineage only certain types of variation can be accepted in a viable, reproductively successful population and that these variations, when observed in the context of geological time, will show up as evolutionary trends. While these trends in the primates are primarily related to increasing success in utilizing the arboreal environment, they have at the same time provided essential preadaptations for ground life in some primates and man.

Primate limb development

The first group of trends relates to the development of the limbs. Although some primates show a certain amount of specialization in their degree of adaptation to a specific niche, the primates have as a rule maintained a very generalized limb and hand structure. The basic pattern of pentadactylism (five digits on each hand and foot) of the early vertebrates has been retained, as have the fibula (one of two bones in the lower leg) and the radius (one of two bones in the lower arm), bones that are reduced to vestiges or are absent in some mammalian groups. The nonspecialized primate hands and feet are mobile and prehensile; the thumb and big toe remain flexible in most groups with true opposability of the thumb possible in some. Sharp claws have been replaced by flattened nails, which improve the use of the hand as a grasping instrument. The flexible, grasping hand of the primates allows use of the forelimb for nonlocomotor activities, including important primate activities such as grooming, one-handed feeding, and infant carriage. Freeing the hands from locomotion means that the body can be held upright, and this progressive development of an erect posture is another important trend in primate evolution.

A further major trend in primate evolution concerns the way in which primates perceive their environment. In most land mammals the sense of smell is the one most highly developed, as is demonstrated not only in the organization of the brain but in the more obvious development of the snout. In even the most primitive primates, however, the sense of smell has lost importance, and the visual sense has become paramount. Stereoscopic vision has been achieved by moving the eyes from the sides of the head to the front of the face, thereby allowing the visual fields to overlap and producing the ability to perceive in depth. Anatomically these changes are easy to trace in the fossil record. The importance of the eyes is demonstrated by the additional protection of a bony bar or a bony partition at the side of the head, resulting in a completely enclosed bony socket (the orbit) for the eye. This complete enclosure is absent in the closely related insectivores and in some of the most primitive living primates. The loss of importance of the olfactory sense and hence the diminution of the nose is demonstrated in the increasing orthognathism (straightness of the face) seen in the evolutionary line leading to man. The dentition has remained nonspecialized, and the occlusal (closing or biting) pattern of the molars is a simple arrangement of four or five small pointed projections (cusps). The primate dentition is composed of four distinct types of teeth: incisors (the front teeth), canines (the eyeteeth), premolars, and molars (the chewing teeth). While some groups may show specializations of

certain tooth groups (an incisor "comb" in the lemurs and enlarged canines in the baboons, for example), no group demonstrates pronounced specializations involving the entire dentition as is commonly seen in other groups of mammals.

**Evolutionary trends of primate behaviour.** Evolutionary trends involving behaviour are obviously difficult if not impossible to document, but observations on living primate groups suggest that certain behavioral responses are more appropriate than others to the primate way of life. From such observations workers have extrapolated that certain behavioral patterns have arisen during the course of primate evolution. Virtually all living primates demonstrate a social hierarchical structure that enables them to live together in social groups of variable composition. This social structure allows, indeed demands, prolongation of infant dependency and thereby intensifies the mother-offspring relationship. It is within the primate social structure that the roots of human behaviour are to be found.

Underlying and reinforcing all of these trends is the crucial development, both qualitatively and quantitatively, of the brain. The size of the brain has, during primate evolution, increased in absolute size and in size relative to body weight. That it has also increased in complexity is demonstrated by the deeper and more varied convolutions on its surface. Those areas of the brain concerned with vision, muscular coordination, memory, learning, and communication have especially shown development.

The primate brain

As varied as these trends may seem, none developed in isolation from the others. They form a tightly interlocking feedback system whereby advances in one area will be reinforced by and in turn necessitate changes in another area. For example, in the development of a successful adaptation to an arboreal environment, the ability to see well and to see in depth was obviously more crucial than the ability to smell acutely. The grasping hand with flat nails instead of claws is an important advantage when moving rapidly through the trees. A superior brain, stereoscopic vision, and a supremely flexible hand, along with a tendency for upright posture, were the important preadaptations (adaptations to one set of conditions that later proved to be useful or helpful under different conditions) that the ancestors of man carried with them when they left the trees for the savanna.

#### FOSSIL PRIMATES

Paleontology, or the study of fossils, provides the really crucial evidence concerning the evolution of the Hominiidae in the past. However extensive and compelling it may be, the evidence for evolution based on the study of creatures living today can be only indirect. Further evidence of evolutionary change can be seen in the persistence of certain anatomical structures such as the vermiform appendix, which remains only as a vestige and appears to have reduced functional significance. Direct evidence of evolution must depend on actual demonstration from the fossil record of a succession of stages representing the transformation of an ancestral into a descendant type. The comparative anatomy of living forms, together with the geographical distribution of local species and varieties that exist today, suggests that evolution might have occurred. Study of the process of natural selection, experimental genetics, population statistics, and so forth establishes quite clearly how evolution could have occurred. But that evolution did occur can be scientifically established only by fossilized representative samples of those intermediate types that have been postulated on the basis of indirect evidence. The field of paleontology that is related to the study of the origin of man is called paleoanthropology. It is concerned not only with fossilized early representatives of the Hominiidae and extinct primates from which this family may have been derived but also with relics of the cultural activities of ancient man and the nature of the environment in which he lived. In this article, however, attention will be confined almost entirely to the evidence of skeletal remains. Broadly speaking, the main features of the evolutionary succession of the primates are now known from the fossil rec-

Paleoanthropology

ord, and they conform in a remarkable way with inferences already reached by a consideration of living primates.

**Primate development in the Early Tertiary Period.** At the beginning of the geological phase now called the Tertiary Period—about 65,000,000 years ago—there were in existence the most primitive of the primates. So primitive are their anatomical characters as shown by fossils that it might be impossible to determine that they were primates but for the fact that they mark a gradation toward more highly organized creatures that definitely come within the category of primates.

The climate of the Early Tertiary Period was warm, with wide tropical and subtropical zones extending from the Equator up to the higher latitudes in both the Old and the New World. During the Paleocene Epoch, which lasted for about 11,000,000 years (c. 65,000,000–c. 54,000,000 BP [before present]), there were many primates in existence; 60 genera have been recognized and grouped into eight families. Three of these families had long chisel-shaped teeth that resembled those of the rodents with which they competed for a similar ecological niche, or habitat. It is likely that this confrontation was won by the rodents, for all of the early primate families with rodent-like teeth became extinct. It is possible that this early rodent competition was one of the factors that led the primates to occupy an arboreal habitat, but a number of groups of primates, such as the baboons, the great apes, and the hominids, later returned to the ground during the evolution of the primate order.

Early  
Tertiary  
primates

Early in the Tertiary Period, during the Paleocene and Eocene epochs (from about 65,000,000 to about 38,000,000 years ago), more advanced primates appeared that belong to the same zoological groups as the modern lemurs and tarsiers. The Lemuriformes are represented in the fossil record by a widespread family, the Adapidae, divided into two subfamilies, the Adapinae and the Notharctinae. The Tarsiiformes are known from two families, the Anaptomorphidae and the Omomyidae. It would appear that the characteristic tarsioid (tarsier-like) specialization of the skull and hindlimb were already well advanced in the fossil forms that are known, but some of the European genera have some structures that indicate relationships with the early monkeys. Generally speaking, however, little is known of the Eocene ancestors of the Old World monkeys and apes; thus the Eocene Epoch terminated after about 30,000,000 years of primate evolution with lemur-like forms and tarsier-like forms but little or no evidence of anything else.

Later, in the Oligocene Epoch (38,000,000–26,000,000 BP), which followed, there came into existence primitive monkeys and exceedingly primitive anthropoid apes. Excavations into the Fayum deposits of Egypt, of Oligocene age, have disclosed a deltaic shoreline bounded by tropical bush country that supported an extensive fauna including rodents, hyraxes, pigs, small elephants, and primates. One of the earliest fossil primates from the Fayum is *Parapithecus*, known from some lower jaws; *Apidium*, which is included in the same family, the Parapithecidae, is also found there. These may be the forerunners of African monkeys, and *Apidium* in particular may be ancestral to *Oreopithecus*, a gibbon-like form from the Pliocene Epoch (c. 7,000,000–2,500,000 BP). Also derived from the Egyptian Oligocene are several fossil apes of primitive type; these include *Aeolopithecus*, which may be an ancestral gibbon, and *Aegyptopithecus*, which may be ancestral to the modern great apes. One other fossil ape from the Fayum that deserves special mention is *Propliopithecus*, formerly believed to be an ancestral gibbon. It has recently been suggested, primarily on the basis of its generalized dentition, that *Propliopithecus* is possibly ancestral to the hominids. This, however, is a speculation that requires much more evidence before it can be generally accepted.

**Primate development in the Miocene Epoch.** The Miocene Epoch began about 26,000,000 years ago and lasted about 19,000,000 years. It was a remarkable phase in primate evolution in which there appears to have been an increase in the numbers of larger primates that were

widely spread throughout the Old World, including Europe, Asia, and Africa. The large number of specimens recovered from widely separated sites over a long period of time has led to taxonomic confusion, and over 50 species have been described and classified in 20 genera. Recently this number has been considerably reduced by an overdue taxonomic revision. The first large Miocene ape found was named *Dryopithecus fontani* (the "oak ape"); it was recovered in 1856 from French middle Miocene deposits. This early ape was characterized by a special arrangement of the cusp and fissure pattern of the molar teeth, the so-called dryopithecine Y-5 arrangement. *Dryopithecus* has also given rise to the name of the subfamily that includes other Miocene specimens, the subfamily Dryopithecinae. A large group of these Miocene fossil apes is known from East Africa, where they have been found in deposits that accumulated as a result of the volcanic activity associated with the formation of the East African Rift Valley.

The primitive characters of many of the Miocene apes are particularly relevant to the problem of the origin of the Hominidae. It has been seriously argued that hominids could hardly have an anthropoid-ape (pongid) ancestry because anthropoid apes are too specialized in limb structure and limb proportions—all living anthropoid apes have quite long arms and short legs. But there is a fallacy in the assumption that extinct anthropoid apes of earlier times must have shown the same degree of structural specialization as do the living apes, which are end products of the pongid sequence of evolution, today represented by the gorilla, chimpanzee, and orangutan. The structural specialization of the pongids was certainly not always present. Indeed, on the purely morphological evidence there is no improbability in the thesis that one of the known genera of the Miocene apes may represent the common ancestral stock that gave rise, by different and contrasting kinds of adaptive modifications, to the divergent evolutionary sequences of the Pongidae (the anthropoid apes) and Hominidae. It has been proposed, and by some even taken for granted, that pongid features such as sharp, overlapping canines and certain quite minor features of the molars and premolars constitute specializations that bar these early apes from consideration as ancestors of the Hominidae. But this is to make demonstrably untrue assumptions on the irreversibility of evolution. In genetic studies it has been shown that single mutations can be reversible in direction, and in phylogenetic studies there are many examples of what may be called negative reversals (i.e., the retrocession of characters previously well developed). There are strong morphological reasons for inferring that the hominid characters of the canines and premolars have been secondarily derived from those of the pongid type.

It may be noted that paleontologists frequently need to consider whether certain extinct types had already attained such a degree of structural specialization that they should be regarded as divergent or aberrant groups with no ancestral relationship to modern types. The answer must depend on the assessment of the total morphological pattern in terms of its probable genetic constitution and the probable complexity of the selective influences that have determined its initial evolutionary development; the degree to which morphological changes have committed the group to a mode of life that has restricted the opportunities for selection in other evolutionary directions must also be gauged.

#### THE HOMINIDAE

**Ramapithecus.** Exactly when the Hominidae, as a separate and independent line of evolution, became segregated from the anthropoid-ape family (Pongidae) is not certainly known; indeed, it is still the most serious gap in the fossil record of the Hominidae (q.v.). The reappraisal in 1961 of a fragment of upper jaw (*Ramapithecus*) from the Miocene–Pliocene deposits of the Siwalik Hills of India has led to the suggestion, however, that the rounded dental arcade and the short face of *Ramapithecus* could allow its inclusion in the family Hominidae, an idea originally put forward in 1934 but ignored at that time.

Ape–  
Hominidae  
relation-  
ships

The  
earliest  
hominid

Later a second upper jaw and several pieces of lower jaw were referred to the same genus, *Ramapithecus*, and the genus was formally transferred to the family Hominidae. About the same time from Fort Ternan, East Africa, a portion of maxilla was reported from Pliocene deposits. The fragment was described under the name *Kenyapithecus wickerii* and later accepted as a member of the Hominidae, probably closely related to *Ramapithecus*. Subsequently the dating of this specimen was revised to the upper Miocene (perhaps 10,000,000 years ago). Despite the fragmentary nature of both the Indian and East African specimens and the complete lack of limb bones, some authorities have accepted the hominid status of these fossils and have even suggested that the two forms are specifically identical despite the temporal and geographic separation of the two sites; an assertion that is not unsupported by morphological and ecological evidence. More recently, in 1967, new material was reported again from early Miocene deposits in East Africa; material that is said to differ markedly from both the East African specimens named *Proconsul* and the dryopithecines from Europe and Asia. The new material was grouped under the name of *Kenyapithecus africanus* and was claimed as the oldest member of the family Hominidae known. This claim has, so far, not met with wide acceptance, and much more material of a better diagnostic nature will be required for its substantiation.

Although the remains of several types of apes are known from Pliocene and Miocene deposits in Europe, Africa, and Asia, they consist almost entirely of teeth and fragments of jaws. Morphologically, most of these approximate quite closely those of the modern apes, but *Ramapithecus* does show certain hominid traits, and many authorities now regard it as a very early hominid and not, properly speaking, an anthropoid ape (pongid). If this is correct, it may then be reasonably presumed that the ramapithecine phase of hominid evolution was succeeded by a phase characterized by a larger brain, in which the limb structure and dentition would show some modification in the direction of evolution that has characterized the Hominidae. The answer to the question of whether there is any fossil evidence that such a type ever existed is to be found in remarkable discoveries made in South Africa and East Africa of the remains of creatures to which (as a group) the name Australopithecinae has been given. It is difficult to give them a less pedantic name without misleading implications because of the curious mixture of anatomical features that characterize these creatures, but they are sometimes referred to as ape-men, man-apes, or near-men.

**The Australopithecinae.** The first fossil evidence of the existence of these creatures was obtained at Taung, in South Africa, in 1924—the skull and a natural cast of the inside of the skull of an immature individual (see AUSTRALOPITHECUS). This specimen shows a number of features (particularly in the milk teeth) in which it approximates much more closely to the Hominidae than do any of the known anthropoid apes. But, because the distinguishing characters of the skulls of adult apes and of the Hominidae are not so conspicuous in immature individuals, considerable doubt was then expressed regarding the significance of the apparently hominid features of the Taung skull.

Later, from 1937 onward, considerably more remains of the same type were discovered in the stalagmitic deposits of ancient caves and fissures formed in dolomitic limestone at sites in the Transvaal, South Africa. As the result of excavations extending over a number of years, a great quantity of important fossil material was collected, consisting of a number of skulls of immature and adult individuals, many upper and lower jaws, numerous examples of the permanent and deciduous dentition, several specimens of the limb skeleton, several parts of the bony pelvis, and the lower part of a vertebral column. The fossil material seems to fall into two categories, gracile (slender) and robust; more information is available about the anatomy of the Australopithecinae than about that of almost any other extinct group of higher primates. The outstanding characters are (1) a small cranial

capacity, equivalent to that of the modern large apes (but in some examples probably exceeding it, at any rate in relation to body size); (2) massive projecting jaws; (3) large molar and premolar (or bicuspid) teeth but remarkably small incisors and canines; and (4) pelvis and limb bones constructed on the hominid plan (but showing significant differences from those of modern *H. sapiens*). The combination of a small braincase with large jaws gives the skull a most apelike appearance; and largely for this reason some authorities at first took the view that, taxonomically, the creatures were really apes. A critical analysis of the cranial and dental characters, however, and especially the evidence of the pelvis and limb skeleton make it clear that the total morphological pattern of the remains conforms to the pattern diagnostic of hominid evolution and certainly not to the evolutionary sequence of anthropoid apes.

The australopithecine skull (Figure 1) presents a number of features that, taken in combination, are never found in apes but are characteristic of hominids. These

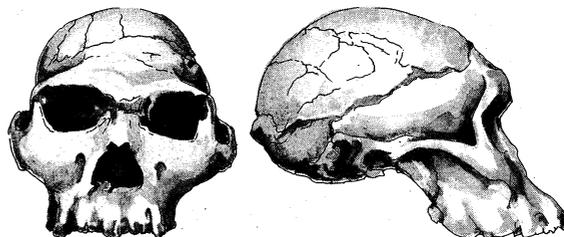

Figure 1: Skull of gracile australopithecine, "STS 5," Sterkfontein, Republic of South Africa.

include the cranial height, the low position of the occipital protuberance (the bulge at the back of the head), the detailed conformation of a number of features in the skull base, and the shape of the mandible (lower jaw). In the largest australopithecine skulls, the vertex is marked by a low median crest related to the growth of large temporal muscles that moved the massive jaws. The contour of the back of the australopithecine skull, combined with details of the cranial base, led to inferences that the Australopithecinae must have been adapted to an erect posture and gait approximating that of *Homo*. This inference received remarkable corroboration from the discovery of portions of thighbones and of the pelvic bones. The latter are of particular importance, for the total morphological pattern of the bony pelvis of the Hominidae is perhaps their most characteristic skeletal feature and, indeed, is what distinguishes them from all other primates (including the anthropoid apes). This pattern, moreover, in its major features represents an adaptation to the mechanical requirements of an upright, or erect, posture. Not one of these features is found in the ape pelvis. On the other hand, pelvic bones of the Australopithecinae all show every one of them consistently; the pelvis is constructed fundamentally on the hominid plan and was adapted for erect, bipedal posture and gait.

Until 1959 no indubitable australopithecine remains had been found outside South Africa. In that year an almost complete skull of the same group of primitive hominids was discovered in a stratum of deposits of early Pleistocene date (1,700,000 years BP) at Olduvai Gorge, Tanzania (Figure 2). It is very similar to some of the more massive skulls from the Transvaal, and the cranial vault (top of the skull) is surmounted by a sagittal crest (a bony ridge running from back to front) of the same type. This skull was at first named *Zinjanthropus*, but it does not seem to be distinct at the genus level from the South African fossils. The latter also have been multiplied by some authorities into a number of different genera (e.g., *Australopithecus*, *Plesianthropus*, *Paranthropus*). But, in spite of conflicting opinion, there seems to be no compelling reason at present for recognizing more than one genus (*Australopithecus*), and the differences that *Zinjanthropus* shows are so minor that they merit a distinction equivalent to no more than a geographical variety or, at the very most, to a species distinction.

The  
ape-man,  
or  
man-ape

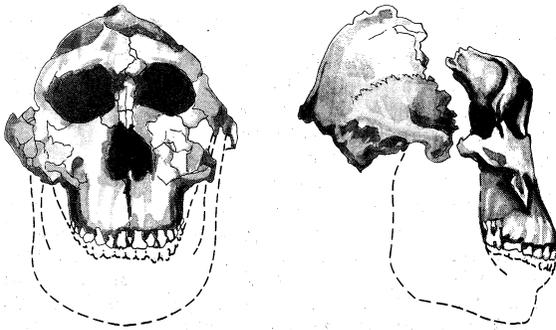

Figure 2: Skull of robust australopithecine from Bed I, Olduvai Gorge, Tanzania.

Recent discoveries from the Omo region of southern Ethiopia, from northern Kenya, and from the east of Lake Rudolf have confirmed the presence of robust australopithecines in deposits of a similar and possibly earlier date than those from Olduvai Gorge. Numerous portions of mandibles, a palate, an incomplete skull, and a complete skull are known, as well as a number of limb bones. Some of the newer fossils are remarkably robust, not to mention massive in their proportions.

At a level in the Olduvai deposits that is slightly below the remains of the robust australopithecine, a juvenile mandible was found in 1960 associated with a pair of parietal bones (from the sides of the skull), a clavicle, some hand bones, an almost complete foot, and numerous tools of the Oldowan culture. It has been claimed that the dental, cranial, and locomotor difference between these finds and the smaller or gracile australopithecines from the Transvaal were sufficient to allow them generic separation, and they were accordingly allocated to a new species of the genus *Homo*, *Homo habilis*. But the wisdom of this step has been seriously questioned, as has the validity of the nomenclature. Nonetheless, opinion has varied widely in designating this material as either simply a geographical variant of a gracile australopithecine or as a primitive specimen of *Homo erectus* (*q.v.*), the human species ancestral to *Homo sapiens*. Subsequent finds at Olduvai from Bed I and lower Bed II have proved that the smaller Olduvai form was not an isolated or aberrant individual, but so far they have done little to advance the claims of this group for membership of the genus *Homo*.

Below subfamily level the taxonomy of the Australopithecinae remains confused. According to one view, there were two species of the genus *Australopithecus*, *A. africanus* and *A. robustus*; the former was small, gracile, upright, and bipedal (stood on two legs) and probably omnivorous in diet, while the latter was robust, less efficiently bipedal, and more dentally specialized for a predominantly vegetarian diet. A second view maintains that there was only one species of australopithecine and that the observed differences between the known samples can be explained as being due to sexual dimorphism. A third view holds that the robust forms should be regarded as the only true members of the subfamily Australopithecinae and placed in a separate genus (*Paranthropus*) while all of the gracile material should be placed in the genus *Homo* as *Homo africanus*. Yet a fourth view would allocate all of the robust material and some of the gracile material to the genus *Australopithecus* (perhaps explaining their differences as being due to sexual dimorphism) while reallocating some of the formerly gracile material to the genus *Homo*. This view would allow representatives of the genus *Homo* to occupy the same territory as members of the genus *Australopithecus* at a relatively early date and would deny the known australopithecines any part in human ancestry. Evidence for this hypothesis is being derived from the area of Kenya to the east of Lake Rudolf, where in 1970 and 1971 mandibular and postcranial remains (body and limbs, including the jaw) were recovered from deposits alleged to be from between 1,000,000 and 2,600,000 years ago. Stone tools of the Oldowan culture have been recovered from the same area and have been attributed to the older deposits.

The clear implication of the last view is that the diver-

gence between the hominids and the australopithecines must have taken place in the Pliocene, but good evidence is entirely lacking. The earliest known hominid fragments from this time range include a small piece of jaw dated at 5,500,000 years BP from Lothagam, Kenya, and a fragment of humerus dated at 4,000,000 years BP from Kanapoi, Kenya. Both have been regarded as australopithecine, but the evidence for this is slender.

The taxonomic status of a previously unknown fossil—whether it is a primitive, small-brained hominid or a member of the anthropoid-ape family—must depend on a recognition of the fundamentally different trends that have characterized the evolution of these two families and that are diagnostic of each of them as a natural taxonomic group. The indirect evidence of comparative anatomy and the direct evidence of paleontology lead to the conclusion that the anthropoid-ape family and the Hominidae represent divergent lines of evolution deriving from a common ancestry. The anthropoid-ape sequence of evolution became adapted for a quite specialized arboreal life with accompanying changes in the limbs, skull, and dentition. The hominid sequence, by contrast, became adapted for life on the ground, with profound modifications of the pelvic and limb skeleton (and also the skull) for erect bipedal posture.

The question arises whether some members of the Australopithecinae could have been the ancestors of later hominids, including *H. erectus* and *H. sapiens*. There appears to be no sound morphological argument against such an inference; indeed, the australopithecines in many ways conform very closely to theoretical postulates for the phase of hominid evolution that is presumed to have preceded the *H. erectus* phase.

**Homo erectus.** A variety of names have in the past been applied to members of this group (*e.g.*, *Pithecanthropus* in Java, *Sinanthropus* in China, and *Atlantropus* in North Africa), but the essential similarity of these middle Pleistocene (perhaps 1,000,000 to 500,000 years old) men is now widely accepted, and they are referred to as *Homo erectus*. The small differences between widely spaced members of the group are probably no more than racial variations.

Representatives of *Homo erectus* populations are now known from China, Java, Africa, and Europe. Although the known material suggests the existence of an earlier, less advanced and a later, more developed group, they all show a similar morphological pattern: mean cranial capacity of about 1,000 cubic centimetres (60 cubic inches); flat, retreating forehead; large, projecting brow ridges; flattened skull vault; low maximum skull breadth; back of the skull sharply angulate, suggesting heavy neck muscles; and no chin. The teeth and jaws show considerable variability, although they are often larger than those found in *Homo sapiens*.

The first discovery of *Homo erectus*, made at Trinil, in central Java, consisted of a skullcap found in 1891 and a femur (thighbone) found a year later. These were discovered in alluvial deposits on the bank of the Solo River at a stratigraphic level of middle Pleistocene age that probably corresponds to the time of the second (or Mindel) glaciation in other parts of the world. Although the femur and skullcap reportedly came from the same geological layer, it has been suggested that they might represent rather different levels of evolutionary development. While the skullcap is very small, its cranial capacity considerably exceeds that of any of the great apes. The femur, which shows a remarkable pathological growth, is very well preserved and shows considerable, though not total, similarity to that of modern man. Attempts to show the contemporaneity of the two specimens through chemical dating techniques have so far been inconclusive, and the question of their association remains unanswered. A considerable amount of material attributable to *Homo erectus* is now known from Java: eight fragmentary skulls (the last, VIII, demonstrates the face), numerous upper and lower jaw fragments, many teeth, and five more femurs (thighbones). The available skeletal evidence entirely supports the view that *Homo erectus* had a fully erect posture and was capable of walking bipedally.

Java man

Taxonomic  
classifi-  
cation

*Homo erectus* material has also been found in the beds underlying the Trinil deposits; these beds, called the Djertis, may be as much as 1,900,000 years old. Material from this level includes an infant skull found at Modjokerto; this skull is of particular interest, for, although it belonged to an individual perhaps not more than two or three years old, it shows the incipient development of some of the characteristic features of the adult *Homo erectus* skull. Also from this level is a lower jaw fragment, with three teeth, of considerable size. Although first referred to as a new genus, *Meganthropus*, there is no convincing evidence that it is other than a large *Homo erectus*. No stone tools have been found in direct association with *H. erectus* in Java.

The Chinese representatives of *Homo erectus* are known from remains discovered at Lower Cave, Chou-k'ou-tien, near Peking. The first find, in 1927, consisted of a lower molar tooth. Two years later, a well-preserved cranium of very primitive type was found at the same site. *Homo erectus* from China is known from the very fragmentary remains of perhaps 40 individuals in all, which include portions of the facial skeleton, several mandibles, about 150 teeth, and a few limb bones. Occupation of the Lower Cave probably extended from the late second glacial period (c. 500,000–400,000 BP) into the second interglacial (400,000–200,000 BP); they are therefore not quite as ancient as the Javan populations and seem to represent a slight evolutionary advance. The cranial capacity has a mean value of more than 1,000 cubic centimetres, but this seems to have been remarkably variable, for in five individuals it shows a range from 915 to 1,225 cubic centimetres (55 to 75 cubic inches). The latter figure comes well within the range of variation for *Homo sapiens*. All of the skulls (see Figure 3) show a marked

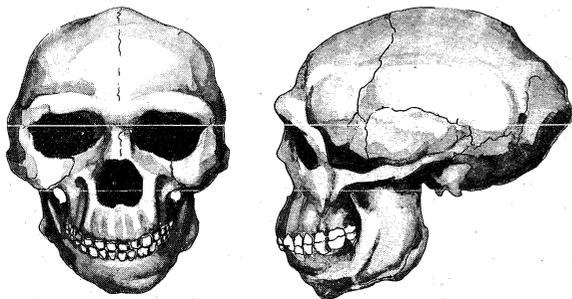

Figure 3: Skull of *Homo erectus*, Lower Cave, Chou-k'ou-tien, China.

flattening of the cranial vault (top of the skull), heavily constructed brow ridges, and thick bony walls of the braincase. The facial skeleton is strongly built, the jaws and teeth are large, and the mandible lacks a chin. The forehead region is better developed than in the Javan specimens and is probably associated with the slightly larger cranial capacity. The teeth conform in all essentials to the hominid pattern, and the canines, though in some individuals large and conical, do not project to any marked degree beyond the level of the adjacent teeth. The limb bones found at Lower Cave comprise portions of seven femora, two humeri (the bones of the upper arm), a clavicle, and one of the small bones of the wrist. Although none of the femurs is complete, the preserved portions suggest a characteristic pattern: they are remarkably flattened from front to back (a condition known as platymeria), and they show relatively straight shafts and thick shaft walls with consequently narrowed marrow cavities. These features all occur in modern human groups and are certainly not inconsistent with bipedal walking; however, it is unlikely that this same pattern of features would occur in modern man. In other words, the gene frequency patterns, in this case for femoral morphology, must have been different in *H. sapiens* and *H. erectus*.

Excavations were resumed at the Lower Cave in 1958, and several more *Homo erectus* specimens have been found since that time; all of the earlier material was

unfortunately lost in 1941 and can now be studied only through casts.

In the deposits that yielded the remains of *Homo erectus* at Chou-k'ou-tien, crude stone tools (cores from which flakes had been chipped) and trimmed flakes of quartz and other materials were also found, comprising a local Paleolithic stone-tool industry of an archaic but fairly uniform character. Some animal bones, which evidently had been broken for their marrow content, also were found; finally, the deposits contained the remains of hearths and quantities of charred bones, evidence that these ancient hominids were skillful hunters and had learned the use of fire for domestic purposes. It seems clear that man already had developed a very active communal life.

Possible evidence of *H. erectus* in Europe was found in a sandpit at Mauer, Germany, in 1907. It is a well-preserved, massive, chinless jaw (sometimes called the Heidelberg jaw) with teeth of a typically hominid pattern. This fossil was found in association with extinct mammals characteristic of the early part of the Pleistocene, but there were no tools. Because of the conditions of its discovery, however, its age cannot be accurately assessed; it may possibly date to the first interglacial period (approximately 700,000–500,000 BP). Three lower jaws, quite similar to the Heidelberg and Peking material, were found at Ternifine, in Algeria, in 1954, in association with stone tools of the type known as early Acheulean. A single skull bone is also known from the site; this also seems to resemble the Peking remains. A fragmentary mandible, also discovered in 1954, near Casablanca, Morocco, appears to be later than the Ternifine material, possibly third glacial (c. 200,000–100,000 BP), and it, too, was found with tools of Acheulean type.

The important East African early-man site at Olduvai Gorge, Tanzania, has also yielded evidence of *Homo erectus*. In 1960 a skull was found in Olduvai Bed II, and, although it is somewhat larger than previously known *H. erectus* skulls, it demonstrates the large, continuous brow ridges, low maximum skull breadth, and other features characteristic of this group. It was found associated with tools of the Developed Oldowan type. A fragmentary pelvis and femur, which are known as Olduvai Hominid 28, were found in 1970 in Bed IV, also at Olduvai. Other femurs are of course known from Java and China, but the pelvis is unique in the middle Pleistocene record of fossil man. The pelvis, which is strong and robustly built, is similar to the modern human pelvis in many respects. The femur, however, is remarkably similar to the Peking femurs; it demonstrates the same front to back flattening, relatively straight shaft, and thick walls that characterize the Peking remains. The pelvis and femur are associated with numerous tools of Acheulean type and are approximately 500,000 years old.

Controversial human remains, first called *Telanthropus*, found at the South African australopithecine site at Swartkrans, have been attributed to *Homo erectus* by some workers. These remains consist of two jaws and several skull and facial pieces. It has been suggested that the large brow ridges, small jaws and teeth, and certain morphological features of the face point to a more advanced hominid, which should be included in the genus *Homo*. Others have argued that these features, because they may reflect only size differences, should not be considered as taxonomically significant; these workers would include *Telanthropus* with the australopithecines. A further possibility is that this material represents a form transitional from *Australopithecus* to *H. erectus*, but it is not possible to indicate this under present classificatory practices.

A number of crude, quartzite tools found in the Swartkrans deposits bear a close resemblance not only to tools from another South African site, at Sterkfontein, but also to those from Bed II at Olduvai. Tools of this type from Olduvai have been named Oldowan. The association at Swartkrans of the tools and the hominid remains is not clear, and none of the South African sites has yet been satisfactorily dated.

Perhaps the most striking aspect of *Homo erectus* evolu-

Peking  
man

The  
Heidel-  
berg jaw

Oldowan  
stone-tool  
culture

tion during the middle Pleistocene is the combination of very primitive features of the skull and jaws with limb bones of nearly modern development. This phenomenon, called mosaic evolution, refers to differential rates of evolutionary progress in different parts of the body. The capability for efficient bipedal locomotion was apparently achieved at least by the earliest middle Pleistocene, yet the brain at this time was only slightly larger than that of the largest apes. Within the next few hundred thousand years, the size of the brain increased greatly. After man began to enter his own ecological niche, circumscribed only by the limits of his cultural achievements, his cranial evolution proceeded at an almost exponential rate.

The persuasive and consistent suggestion from the human fossil record is that the evolutionary pressures for a novel and almost unique method of locomotion, erect bipedalism, were at first more intense than the pressures for a large and complex brain. This is certainly not to say that these features were developing independently—quite the contrary—but the “need” for habitual bipedalism was apparently more insistent than the “need” for a larger brain in man’s early evolution. Moreover, it is likely that the complete release of the forelimbs from locomotion was one of the stimuli that led to the elaboration and enlargement of human mental capacity. The freed forelimbs were then at liberty to explore and utilize the environment in unique ways.

#### HOMO SAPIENS IN THE FOSSIL RECORD

**Geological dating methods.** Before the evolutionary history of man in terms of fossil remains is traced in further detail, it is desirable to note the geological changes that marked the Pleistocene Epoch. The date of the transition from the Pliocene to the Pleistocene is an arbitrary point in time, and geologists have not found it easy to agree on its definition. Broadly speaking, it was marked by the gradual onset of a cooler climate in many parts of the world about 2,500,000 years ago and by a general lowering of temperature that finally led to the great ice ages, during which, in modern temperate zones, ice caps and glaciers originating on high levels spread out for considerable distances over lowlands. This process of glaciation was recurrent and extended throughout most of the Pleistocene Epoch; it is now generally agreed that there were four main glacial periods, of varying duration and severity, separated by interglacial periods during which the climate became warmer and in some cases (even in Europe) almost subtropical. Evidence of the successive glaciations can be detected in the characteristic geological deposits left by melting ice and also in the fossil remains of Arctic or sub-Arctic animals and plants from the glaciated regions. By the determination of the rhythmic succession of glacial and interglacial phases during the Pleistocene, geologists have provided a time scale for inferring the relative antiquity of fossil hominids and the implements they left behind.

Even in those parts of the world where there was no actual glaciation, such as the equatorial regions, there was a succession of alternating rainy and dry periods, but there is no evidence that these pluvial and interpluvial phases were closely correlated with the glacial and interglacial periods in the Northern and Southern hemispheres. The recurrent glaciations were accompanied by considerable falls in sea level, which had a profound effect on the formation of river valleys and caused the opening of land bridges that permitted migration of hominid populations and, consequently, encouraged gene flow and mixture between such populations. Similarly, the rise in sea levels during the interglacials cut these routes and produced isolation of hominid populations. With a fall in sea level, the erosive power of the rivers increased, and they cut their valleys more deeply. With the rise in sea level during the interglacial periods, the rivers flowed more sluggishly and laid down such stratified deposits as gravel and sand over their alluvial plains. As a result, series of terraces were formed along the riverbanks, and it is in these terraces that some of the oldest remains of Paleolithic (Old Stone Age) man and his stone implements have been found. The time relationship of the

terraces to the glaciations has been worked out in some detail by geologists, and largely on this basis the relative antiquity of the fossils can be established.

In recent years new chemical and physical methods that have been developed have assisted greatly in establishing a chronology that enables paleontologists to set their materials in a proper phylogenetic context. Relative dating, or the assessment of contemporaneity of a fossil and its layer, has been aided by the fluorine and uranium methods, while absolute dating (or age in years) has often established the sequence of fossils in the deposits. The most valuable absolute dating methods are the radioactive-carbon technique, which operates between 60,000 years BP and the present; the potassium-argon technique, which most easily dates material older than 350,000 years BP; and the fission-track method, which is helping to bridge the gaps between the other methods (see *DATING, RELATIVE AND ABSOLUTE*).

**The antiquity of *Homo sapiens*.** It is a curious fact that, although evidence for the evolution of man is extensive, direct fossil evidence of the earliest members of the species *Homo sapiens* is relatively scarce. The species *Homo sapiens* (of which the modern human races comprise a number of different geographical varieties) may be defined in terms of the anatomical characters shared by its members. The definition for prehistoric representatives of the species must be limited to skeletal characters, the only remains to be found. The definition of *H. sapiens* in terms of skeletal characteristics includes such features as a mean cranial capacity of about 1,350 cubic centimetres (82 cubic inches), an approximately vertical forehead, a rounded occipital (back) part of the skull with a relatively small area for the attachment of the neck musculature, jaws and teeth of reduced size, small canine teeth of spatulate form, the presence of a pointed or projecting chin, limb bones adapted to a fully erect posture and gait, and so forth (see *HOMO SAPIENS*). Any skeletal remains that conform to this pattern to an extent that precludes classification in other groups of higher primates must be assumed to belong to *H. sapiens*. In the past there was a tendency to create entirely new species of *Homo* on the basis of fragments of prehistoric human skeletons, even though the remains showed no significant differences from modern man. This tendency was prompted by the supposed antiquity of the remains or by a failure to realize how variable some features are even in modern man. One of the best examples of this kind of fallacy is the so-called Galley Hill skeleton, discovered in 1888 in the Thames Valley, in England, and supposed to be of very great antiquity. Some anatomists thought they could recognize very primitive features in this specimen, particularly in the shape of the lower jaw. An apparently exhaustive study of the femur, involving an elaborate statistical comparison of a number of measurements and indices, even led to the conclusion that it was quite distinct from modern man. But in later years it was determined, largely as a result of the analysis of its fluorine content, that the skeleton was a burial of comparatively recent date—perhaps the remains of a Neolithic man (c. 8000–2000 BC) or possibly even a later interment. The explanation of the discrepancy is an important matter, for statistical tables are apt to give an impression that conclusions based on them are final and indisputable. But it has come to be realized that the validity of statistical methods in the study of fossils depends on the actual number of measurements taken, on whether the measurements compared are really strictly equivalent in the morphological sense, on whether they are taxonomically relevant, and so forth. It also has been demonstrated that, if the individual characters of a bone or a tooth are compared independently, one by one, instead of as components of a total pattern (which can be done by a statistical method known as multivariate analysis), entirely different and sometimes very misleading conclusions may be reached. In the case of the Galley Hill femur, the statistical study was made with only a very limited sample of modern femurs, which were assumed to be representative of *H. sapiens* as a whole. Obviously the comparison must be made with adequate samples of all the main varieties

The early *H. sapiens* fossils

Galley Hill skeleton

The ice ages

of *H. sapiens* before it can be legitimately concluded that there is a distinction. The weakness of "matching typology" is particularly apparent when closely related or transitional forms are being considered, a point made by Darwin when he stated that:

In a series of forms graduating insensibly from some ape-like creature to man as he now exists, it would be impossible to fix on any point where the term "man" ought to be used.

Characters may be identified that are commonly seen in less evolved examples, yet at the same time more advanced features may be present in the same specimen, a situation that results from the mosaic evolutionary process. It is now clear that *Homo sapiens*, evolving relatively rapidly during the late middle Pleistocene, was subject to this mosaic process.

The species of the genus *Homo* that immediately preceded early *Homo sapiens* was *Homo erectus*, and it is most likely that it was from advanced members of the latter species that sapient man (*H. sapiens*) evolved. The skull of *Homo erectus* (*q.v.*) has been described as of low cranial capacity with a large face, a low maximum breadth and a sharply angulate occipital region (back of the skull). By comparison, the skulls of modern *Homo sapiens* show an expanded cranial vault, a vertical forehead, and a high maximum breadth; at the same time, the face is shortened by regression of the jaws and teeth, leaving the chin and nose as prominent features of the sapient face—a continuation of trends that are traceable well back into primate evolution. The skeleton of the trunk and lower limbs of *Homo sapiens* is characterized by its virtually complete adaptation for a fully upright posture and a striding bipedal gait. The hands of *Homo sapiens* are capable of both power and precision grips; they also possess remarkable manipulative abilities, which, with a sapient brain, can skillfully fabricate stone tools and produce art and sculpture.

**Early *Homo sapiens* remains in Europe and Africa.** Fossil remains of early *Homo sapiens* are known from sites in both Europe and Africa, and later examples have come from a wide range of sites in the Old World and later still from the New World. In 1965 some fossil human remains were found at a site named Vértesszöllös, near Budapest. The remains were derived from the third of four geological layers that showed signs of human occupation, in a quarry cut into the fourth terrace of the Danube River system. The contemporaneity of the fossil finds and the layers in which they were found was established by means of the fluorine test; radiometric dating has given a date of 350,000 years BP. The site also yielded fossil mammal bones as well as stone tools and signs of the use of fire. The find consisted of some milk teeth and an occipital bone (from the back of the skull) that is broad, thick, and well preserved. The shape of this bone is distinctive and has several features that recall the *Homo erectus* occipital; on the other hand, the estimated cranial capacity of Vértesszöllös man is 1,400 cubic centimetres (85 cubic inches), well into the normal range for *Homo sapiens*. These remains have been attributed to a *sapiens-erectus* intermediate type on the grounds that the remains show a mélange of features typical of the mosaic evolutionary process. If this assessment is correct, Vértesszöllös man must lie at the root of the *H. sapiens* evolutionary line, 100,000 years ahead of his nearest rival.

A better known early example of *Homo sapiens* comes from the Thames Middle Gravels at Swanscombe, Kent; gravels attributed to the Great Interglacial Age, about 250,000 years BP. In 1935, 1936, and 1955, three parts of a skull were unearthed that fit together to form the back of a cranial vault (braincase). The deposits at Swanscombe are well-known for their rich quantities of stone tools and fossil mammal bones; the fauna as a whole indicates warm interglacial conditions, with the river high, sluggish, and bordered by marshes and lagoons. Recent excavations have shown that animals were butchered at the water's edge with stone tools made at the site from flint transported from another location. The Swanscombe skull is generally accepted as being representative of early *Homo sapiens*, although some authorities have

emphasized its Neanderthal features (see NEANDERTHAL MAN).

Another skull of about the same date is from Steinheim, near Stuttgart, West Germany. It was recovered in 1933 from interglacial sands and gravels; there were no tools recovered from the site. This skull is more complete than that from Swanscombe and includes the right side of the face and some small upper teeth. Once again, the features of the skull are mixed; while the back part is reminiscent of the Swanscombe skull, the frontal region and face seem to be rather Neanderthal. Further European early sapient remains are known from Fontéchevade, Charente, France; Quinzano d'Oglio and Saccopastore, Italy; and Ehringsdorf, Germany, but none is as old as the Vértesszöllös, Swanscombe, and Steinheim finds.

The record of early *Homo sapiens* has been augmented recently by new finds in southern Ethiopia, from the banks of the Omo River, which drains southward into Lake Rudolf. Here in deposits attributed to the East African late middle Pleistocene, a skull (Omo II) and a partial skeleton (Omo I) were found. The Omo II skull is the more primitive of the two, having flattened frontal (at the front of the skull) and occipital (at the back of the skull) regions, thick walls but a rounded vault, large mastoid processes (pointed bony processes at the base of the skull behind the ears), and high cranial capacity; once again mixed features. The Omo I skull is more modern, as are its postcranial bones. The relationship of these remains to each other, assuming that their geological contemporaneity is assured, is a matter of considerable interest, as is their relationship to the other samples of the genus *Homo* from earlier deposits in East Africa. It seems likely that the Omo assemblage goes some way to bridge the gap between advanced *Homo erectus* and early *Homo sapiens* in this area.

**"Neanderthaloid" remains from Asia and Africa.** In passing to the upper Pleistocene for evidence of human evolution, the amount and distribution of material greatly increase. From the Far East, a group of skulls are known from the Solo area of Java. They were found in association with some stone tools and many mammalian bones. All of the skulls are thick, with divided brow ridges, sloping foreheads, and strongly marked occipital ridges, features that recall the Omo II skull or even *Homo erectus*. From southern Africa, a skull from Broken Hill, Zambia, shows similar features but has exaggerated brow ridges. Another example of this group is derived from Saldanha, near Cape Town. All of these remains have been termed Neanderthaloid because of the supposed resemblance of their principal features to those of the classic Neanderthals of the Würm (Last) Glaciation; however, this designation is not universally accepted, for it seems to imply a close genetic association between forms that are very widely separated.

In the Near East, controversial remains are known from Mt. Carmel, Israel; two caves—Maghārat at-Tabūn and Maghārat as-Skhūl—have produced skeletal material. The Tabūn skeleton is that of a young woman with distinctly Neanderthal features, while the Skhūl material represents ten individuals of rather more modern features. This mixture of features was interpreted as being due to either a "hybridization" between a Neanderthal and a more modern sapient or to the material representing the extremes of a range of normal variation within the population at that time period. Subsequent work has shown, however, that the two sites are separated in time by as much as 10,000 years, so that the later Skhūl remains could relate to more modern forms of *Homo sapiens*, who were superseding the Neanderthals in the locality.

The taxonomic position of the whole group of early sapient remains is still somewhat problematical. For the present, therefore, it seems most appropriate to regard them all as intermediates shading off toward *Homo erectus* at the earlier end of the time range and toward Neanderthal man and modern man at the other end of the morphological spectrum.

**Neanderthal man.** This group consists of a widely known series of remains derived from sites arranged roughly in an arc across southern Europe and the Near

Swanscombe and Steinheim fossils

Vértesszöllös man

Fossils with Neanderthal-like features

East. The majority of the Neanderthal sites are from periods of glaciation and date from the Würm (Last) Glaciation. The first Neanderthaler was found in 1856 from the Neander Valley near Düsseldorf, in Germany. Subsequent finds are known from France, Italy, Belgium, Greece, Czechoslovakia, Russia, North Africa, and parts of the Middle East. They tend to show a group of quite distinctive skeletal characteristics that at one time led to their being regarded as distinct species of man. Modern taxonomists, however, tend to attribute the whole group to *Homo sapiens* and only allow subspecific differentiation (*Homo sapiens neanderthalensis*). The pattern of the Neanderthal morphology is one of a short, thickset, powerfully muscled group, well adapted to cold conditions.

The earliest assessment of their functional morphology suggested that the Neanderthalers were incompletely erect in posture and had a stooping bent-kneed gait. More recent opinion has revised this view in the light of the assessment of a wider range of Neanderthal skeletons and suggests that they were fully erect, active bipeds capable of hunting large game under almost Arctic conditions. The characteristic features of the Neanderthal morphology include large heads, large faces with receding jaws, stout and often curved long bones (arm and leg bones), and large joints (Figure 4). Neanderthalers were cave

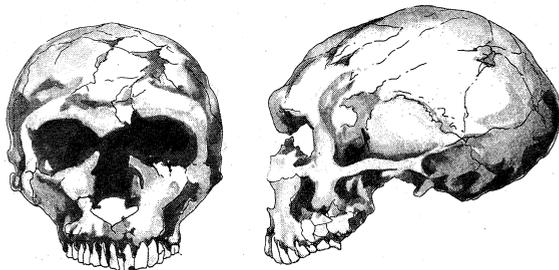

Figure 4: Male Neanderthal skull, La Ferrassie, France.

Neanderthal man and his culture

dwellers who had the use of fire and manufactured stone tools that would have permitted them to prepare skins for clothing and weapons for the hunt. The beginnings of magic or mysticism can be discerned from Neanderthal sites, for they deliberately buried their dead and on occasion provided the departed with grave goods or objects deliberately arranged around the body in the grave. The cave bear (*Ursus spelaeus*) seemed to play a part in their lives (perhaps religious), for skulls of this extinct animal are often found at Neanderthal sites.

Clearly the Neanderthalers were a successful group for many thousands of years, but their traces disappear from the fossil record, and they are superseded by other sapients with a more advanced culture and a different morphology. In Europe these are known as the Cro-Magnon peoples (see CRO-MAGNON MAN). The reasons for the relatively sudden disappearance of the Neanderthalers are still a matter of some debate. Varying suggestions have been put forward, including catastrophic extinction due to disease, lack of adaptation to the warmer climate following the glaciation, annihilation by the more advanced sapient invaders, or genetic absorption by the new group. It is not unlikely, however, that all of these factors played a part in their demise. If absorption did take place, then it cannot be said that the Neanderthalers are an extinct side branch of the human evolutionary line, and the occurrence of Neanderthal genes in modern human populations must be allowed. This view is finding most favour at present.

**Fossil examples of modern *Homo sapiens*.** The modern distribution of *Homo sapiens* is worldwide, with indigenous populations in all the major continents except Antarctica. Within the continent of Africa, numerous discoveries of fossil sapients have been made. These include those from Kenya (Gambles Cave, Elmenteita, Naivasha), South Africa (Homa, Boskop, Florisbad), and North Africa (Tangier, Taforalt, Mechta). Although they differ in anatomical details, the range of variability that they exhibit is in no way greater than that known for

the extant races of modern man. Similarly, in Asia the fossil record of upper Pleistocene man can be traced from Upper Cave remains described from Chou-k'ou-tien. This group was thought at first to show the racial characters of the Eskimo, the Melanesians, and the Ainu, but this seems unlikely to be the case. Other Asian fossils include Wadjak man, an upper Pleistocene or Holocene (Recent) discovery from Java; and a skull from Niah Cave in Borneo. Both of these finds have been described as having Australoid features and may represent the ancestors of the modern aboriginal Australians.

The fossil history of man in Australia has received several new finds to add to the sparse record of the past. The older specimens include the Talgai and Cohuna skulls, but more recently new acquisitions have been made from Green Gully and Lake Nitche. The most recent dating evidence indicates a probable antiquity of man in Australia in excess of 25,000 years BP. The presence of fossil man in North America has traditionally been denied, but recent dating evidence from hearths and other archaeological sites has shown a possible antiquity of as much as 30,000 years. Skeletal evidence from both North and South America is scanty and undiagnostic, but nothing other than *Homo sapiens* remains have been identified.

Finally, in Europe the upper Pleistocene representatives of *Homo sapiens* that are most widely known are the Cro-Magnon group (see CRO-MAGNON MAN). Skeletal remains, having the same general features as those from the type site, are known from France (Abri-Pataud, Bruniquel, Chancelade, Combe-Capelle, La Madelaine), Italy (Grimaldi), Great Britain (Paviland), and many other sites. In general the skulls of these men are long with upright foreheads and jaws with well-marked chins; the postcranial skeleton indicates a tall upright people of modern skeletal form.

To attempt to identify an evolutionary centre for *Homo sapiens* would seem to be a difficult task, save for the belief that it must be within the Eurasian-African landmass. The evidence suggests that North America and Australia were peopled at about the same time (probably less than 30,000 years BP), while South America was entered later (10,000 BP?). North America was most likely colonized by groups migrating across the Bering Strait at a time of low sea level, and Australia was entered from the Southeast Asian peninsula at a similar period. Direct evidence for these migrations is lacking, but it seems the most plausible interpretation that can be advanced. The differentiation of the modern human races from an ancestral sapient stock arising within the Eurasian-African landmass is still uncertain, but several theories are available. The antiquity of human races has been the subject of considerable dispute and is a controversy that remains unabated at present.

One view is that racial differences observed in modern man originated in *Homo erectus*, remained stable through the species change, and continue today with relatively unchanged characteristics. This view sees five races arising from geographically separated groups of *H. erectus*. Support for this point of view has not been forthcoming, although some workers have commented on postulated resemblances between certain fossil specimens of *H. sapiens* and some modern racial groups (e.g., between the Grimaldi fossils and the Negroids, and the Chancelade remains and an Eskimoid type). While it is possible, and even likely, that fossil populations could demonstrate some similarities to modern groups in certain adaptive features, the total gene frequency patterns would certainly differ between groups so far separated in time. Finally, although human variations must have formed in response to a variety of factors, both environmental and behavioral, these factors cannot have had the same characteristics in terms of magnitude and direction for very long periods of time; hence the racial variation of prehistoric times must have been differently distributed than at present.

An alternative view of racial origins, which incorporates those ideas, is that human races have no great antiquity and may be seen as merely transitional episodes in the history of man. This view recognizes that what appear

An evolutionary centre for *H. sapiens*

Modern  
human  
races

today as racial traits are adaptational features that reflect a wide range of environmental, social, and cultural pressures. These pressures must change through time not only because the environment changes but because the gene pool itself changes. Although there is no clear consensus on the number of modern races, most workers accept the existence of several major races corresponding to large geographic areas. This view recognizes the effectiveness of geographic barriers first in reducing free gene flow and second in changing the environment sufficiently to elicit different adaptive responses from the gene pool (see RACES OF MANKIND). The number of races recognized depends in part on the criteria used and in part on the reason for the classification. Six to nine major geographic races may be defined: the European Caucasoids, the African Negroids, the Asian Mongoloids, the Australoids, and the American Indians, as well as the peoples of the Pacific islands, usually divided into at least three distinct groups—the Polynesians, the Melanesians, and the Micronesians.

## II. Evolutionary process in man

Evolution may be defined as change in the genetic composition of a population through time (see also GENETICS, HUMAN). It may be thought of as progressing on two levels: the production of variation and the selection of those gene combinations most "fit" in a particular environment. It would be wrong to consider that evolution is "caused" by any one factor. Indeed, the error of many earlier theories of evolution was neither intrinsic nor factual but lay in the consideration of evolutionary change solely in the light of a single process. While the modern theory of evolution relies heavily on the Darwinian concept of natural selection, many other factors unknown in Darwin's day have enlarged and enhanced man's knowledge of evolutionary process. The modern synthesis of evolutionary theory is a composite approach that views evolutionary process in the light of different scientific disciplines such as paleontology, biology, biochemistry, ecology, and many others, all of which have made significant contributions. The synthesis of fact and theory from these various fields has been the major contribution of evolutionary biology to 20th-century science.

### GENETICS AND MAN

**Mutation.** The ultimate source of all new genetic variation is change in the genetic material itself. Genetic information is passed from parent to offspring through the complicated protein molecule known as deoxyribonucleic acid (DNA). The DNA is carried on long strands called chromosomes. Each species has a characteristic number of these strands—in man the number is 46. These 46 chromosomes comprise 23 pairs. The DNA molecules in similar positions along paired strands will code for the same feature, and, in the chemical relationships between these positions (or genes), one gene of each pair will generally be dominant, and the other will be recessive. It is usual for the activity of a gene on one strand to be masked or inhibited by its counterpart on the other strand. An important exception to this is in the determination of coloration patterns, in which the genes may appear to blend, producing colour patterns different from those of the parents.

Alteration of the genetic material is called mutation and can be of two types: point mutations, in which the molecular composition of a discrete location on the chromosome strand can be changed by a chemical process or the physical interaction of a particle (perhaps resulting from radioactivity) with the DNA molecules that make up the chromosome at that point, and mechanical mutations, in which the gross structure of the chromosome is altered, often in the process of cell reproduction. Point mutation is well documented in human populations; for example, normal hemoglobin is formed of a long chain of amino acids; if the genetic code for one of these amino acids, glutamic acid, is changed, the amino acid is replaced by another amino acid, valine, and the abnormal hemoglobin responsible for sickle-cell anemia results. This disease is of considerable importance in some human populations

Types of  
mutation

and will be discussed in more detail below. Mechanical mutations do not involve chemical changes in the DNA but are physical alterations involving the body of the chromosome itself; these abnormalities usually occur during cell reproduction. One such process involves the exchange (called crossover) of material between two adjacent paired chromosomes. Other types of chromosomal mutations can be due to the inversion or translocation of chromosomal material, its loss or deletion, or the nondisjunction of chromosome pairs.

While the ultimate source of all intrinsic genetic change must occur through mutation, the vast majority of these alterations result in the death of the individual or so reduce his "fitness" that he suffers "genetic death" (*i.e.*, fails to reproduce) even though he may live to great age. The greatest source of variability is simply a change in the frequency of existing genes under various environmental and, in some cases, social stimuli. The genes themselves contain a vast reservoir of variability, only part of which can be realized in any single population. Here an important distinction must be made between the genotype—the chemical composition of the genes—and the phenotype—the external appearance—of the individual. Similar genotypes can in certain situations give quite different phenotypes, presumably because only part of the genes' activity occurs at any one time. This phenotypic flexibility may be of considerable importance in the origin of certain racial variations in living groups, but its long-term significance in evolutionary process is not yet understood.

Most variability arises, then, as existing genetic material is recombined or "reshuffled" into new patterns via sexual reproduction. Alterations in gene frequencies will occur mainly under pressure of selection. Besides the reservoir or variability that any sexually reproducing local population contains, another important source of genetic potential can be derived from interbreeding with nonlocal groups. This is sometimes called gene flow, and, although there may be a temporary disruption of the genetic equilibrium, once a balance is again obtained the hybrid population may be more "fit" than the parent generation. Heterosis, or hybrid vigour (the phenomenon whereby an organism that is the result of crossbreeding between parents of different genetic populations shows increased "fitness" and general vitality), is well documented for some human groups, most notably the people of Pitcairn Island, who are ultimately derived from crosses between Tahitian women and the British sailors from the "Bounty," groups whose ancestors were genetically separated by distance for thousands of years.

Hybrid  
vigour

Observations on the occurrence of genetically derived traits in fossil man can be used to suggest earlier patterns of gene flow. Such observations have been made with regard to *Homo erectus*, and the suggestion has been made that genetic exchange was occurring between widely spaced members of this group during the middle Pleistocene. It has been pointed out by a number of workers that the approximately contemporaneous Ternifine mandibles (jawbones) of Algeria and the Peking mandibles of China show extreme similarities; the great similarities between the Peking femurs (thighbones) and the Olduvai Hominid 28 femur have also been noted. A reasonable explanation of this similarity is that migratory hunting patterns had brought many groups of *Homo erectus* into contact and that exogamous (marrying outside the tribal group) breeding patterns had resulted in the widespread occurrence of certain traits. These similarities are very likely too great and consistent to have resulted from separate evolution along parallel lines in isolation; and, indeed, the degree of similarity seen in the available material makes it extremely unlikely that long-term isolation was a factor in human evolution after the early middle Pleistocene.

**Natural selection.** Genetic variation derives from several sources and provides only the raw materials of evolution; random variation can only have a disrupting effect on genetic equilibrium unless deleterious combinations of genes are eliminated and advantageous ones are preserved. The process by which this occurs is called natural

Evolutionary  
fitness

selection. Although Darwin is credited with the first full statement of the theory of evolution through natural selection, the origins of the concept are deeply rooted in European thought and may be traced to the early 17th century. Indeed, the practices of artificial selection of domesticated plants and animals, which so influenced Darwin, can be traced at least as far as the Romans and perhaps even to Neolithic times. The theory of natural selection can be stated as follows: All living things vary and reproduce themselves many times, yet the number of a given group tends to remain constant. Therefore there is a competition for survival, and only those most fitted to external conditions survive. In essence, the idea of natural selection is statistical; those members of a population who are most evolutionarily "fit" are those who will leave the greatest number of offspring. These will not be the only members of the population to leave offspring, but it is probable, in a statistical sense, that they will leave more living descendants in the long run than the less well adapted members of the population. "Fitness" therefore refers to a population's ability to cope successfully with a particular environment at a particular time; it is tied to time and place in an absolute way. The factors that help determine the course and direction of evolution are many: predation and disease; migration and conflict; behaviour and temperament; competition for breeding space and mates; competition for living space and food. Purely physical factors in the environment are no less important: stability or instability of the climate; solar radiation; natural disaster; pollution of the soil, water, and air—all will have their effect and take their toll on living groups. Evolution is not, therefore, something that has occurred and been completed. Any population is constantly evolving, assimilating changes and variations in its gene pool in response to stimuli from a large number of sources—some that are recognized and some that are not.

#### ADAPTATION AND GENETIC CHANGE

There are a number of ways in which a population can adapt to the changing world in which it lives; under the heading of natural selection, it is possible to define several mechanisms that help maintain a viable relationship between that population and the environment of which it is a part. In a seeming paradox, natural selection can work to maintain the status quo in a changing environment while at the same time drawing on new or existing material in the gene pool to meet the demands of the environment in a new way. Natural selection is then both conservative and dynamic, with both mechanisms working to achieve the same end result, that of adaptation to the environment. Conservative, or stabilizing, natural selection basically works to eliminate detrimental genetic effects or genes harmful in a particular situation; it tends to reduce variation in the gene pool. It would appear that this aspect of natural selection has become less effective in man with the development of modern medical research and practice. Chronic and often lethal diseases caused by genetic conditions, such as diabetes mellitus, hemophilia, and phenylketonuria, are certainly more common now than several decades ago because of modern medical care, for persons with these diseases live and produce children with the disease, although they would have died or failed to reproduce under less advanced medical techniques. These individuals, however, are not less fit in a Darwinian sense than the "normal" members of the population as long as their environment includes this medical care; it is only in the absence of this care that they are less fit.

**Homeostatic change.** A nongenetic correlate of conservative natural selection is homeostasis. This term refers to adaptive physiological cultural flexibility that is genetically based, and it means the retention and preservation in a population of its internal equilibrium in the face of disruptive external environmental conditions. By drawing on this source of variation, a population may adapt its physiology or behaviour in response to new environmental demands without actual changes in the gene pool; because it is an immediate response, it may enhance a group's survival potential. One type of homeo-

static response has been called acclimatization; the efficiency and scope of this process are genetically based, yet the full range of responses is seldom, if ever, activated. Because man occupies a wider range of habitats and is therefore exposed to more extreme conditions than any other species, the necessity for broad responsive ability to changes in environmental conditions such as climate is obvious. Homeostatic responses merge undetectably with both dynamic and conservative natural selection and cannot, indeed perhaps need not, be separated from them for most purposes. The extent of homeostatic response is unique in man, not only in the diversity of the physiological responses that deal with the extremes of the environment but also because of the added dimension of culture as an adaptive mechanism. It is this aspect, culture, that allows man not only to fully inhabit and utilize a wide range of environments but also to alter these environments to his own ends. The diversity of the ways in which man deals with environmental extremes can be seen in the various mechanisms (skeletal, physiological, and cultural) used by man in cold climates.

**Blood types, abnormal hemoglobin, and disease.** Diversifying, or dynamic, natural selection is one of the important and basic processes by which evolutionary changes occur. Under conditions of changing environmental pressure, advantageous genotypes will be assimilated into the gene pool, and those individuals within the population who have superior fitness will leave more numerous offspring than those without. One such adaptation is the maintenance of a potentially lethal gene for an abnormal hemoglobin in populations that are exposed to malaria. Sickle-cell anemia and several related anemias are genetically based blood disorders that can kill an individual who inherits a gene for the condition from both parents (homozygous condition); those with only a single abnormal gene (heterozygous condition) will demonstrate the disease under certain conditions but are less affected and usually do not die of it. In certain areas of tropical Africa, however, as well as around the Mediterranean and in regions of the Far East, to be without one gene for the abnormal hemoglobin can mean death or serious illness from malaria prior to breeding. The presence of the abnormal hemoglobin therefore confers protection in certain environments, while outside these areas the abnormal gene has no adaptive significance and will be selected against. The abnormal hemoglobin is virtually absent in nonmalarial areas except in the descendants of people formerly living in such areas.

Other examples of diversifying selection are to be found in the distribution patterns of the ABO blood group system (see BLOOD GROUPS AND FACTORS). Although the data is incomplete, it would appear that individuals with certain blood types are more susceptible to certain diseases and that, therefore, in areas where these diseases are common, these blood groups will be selected against. Suggestions have been made that blood group O individuals are less susceptible to syphilis, group A to plague, and group B to streptococcal infections; fieldwork seems to support statistical correlations between certain types of disorders of the gastrointestinal tract and some ABO blood groups. For example, a higher frequency of duodenal and gastric ulcers in group O and a higher incidence of cancer of the stomach of group A have been demonstrated.

**Random genetic drift.** Genetic drift is another mechanism by which evolutionary changes may occur. Drift can be defined as the apparently random variation of certain gene frequencies under special conditions of small population size or of isolation or both. Also called the Sewall Wright effect and non-Darwinian evolution, it has been the subject of considerable controversy in the recent literature. From these discussions it emerges that many of the features previously thought caused by drift are now known to have been the result of previously unrecognized natural selection. Central to the definition of genetic drift is the assumption that genes can be neutral and without effect in terms of evolutionary adaptation, and it is this assumption that has led to the greatest controversy. Some workers have argued that 5 to 10 percent of all mutations

Acclima-  
tization

Lethal  
genetic  
disorders

are selectively neutral and may be maintained in the gene pool without effect. Others have asserted that, because genetic systems have complex chemical interrelationships, with each gene contributing something to the finished product, it is unlikely that a single gene or group of genes could be totally without effect. This latter position recognizes that, while certain observable features may have little apparent effect on fitness, the genes responsible may be inextricably associated with other genetic features that do have important fitness correlations.

The near absence of blood group B in the American Indian has been attributed to genetic drift. However, B-type blood reaches its highest frequency in some Mongoloid groups thought to be ancestral to the early inhabitants of the New World. This and the probability that many incursions from Asia must have occurred in the late Pleistocene Epoch (35,000–10,000 BP) make drift a somewhat untenable explanation of the lack. A more likely explanation is that holders of B blood were faced with some as yet undefined environmental hazard in the New World that made blood type B a genetic liability and it was subsequently lost through selection.

#### MAN'S CONTINUING EVOLUTION

The question of man's continuing evolution may be posed on two levels, because it is possible to define two distinct yet interrelated levels of evolutionary change: the first can be called phyletic evolution; and the second, phenetic evolution.

**Phyletic evolution.** This term refers to cumulative and important changes in the population gene pool that lead eventually to speciation (separation into new species) and the higher levels of taxonomic differentiation. It is phyletic evolution that is usually identified in the fossil record. Phenetic evolution is more subtle, and, while it is identifiable in living populations, it is less easy to see in fossil groups. It involves changes of a lower magnitude than phyletic evolution and may be called ecotypic evolution. As with all evolutionary changes, phenetic changes occur in response to environmental stimuli, but it is the consistency of these stimuli through time that determines whether the changes will become permanently impressed on a group's phyletic record or if they will be lost within a relatively short period due to changing pressures on the gene pool. Phenetic evolution is the mechanism underlying the formation of subspecies, races, or varieties.

It is difficult to identify any unequivocal evidence of phyletic evolution in man for perhaps the last 250,000 years, and the reasons for this difficulty are not hard to find. Man's adaptations to his environment have been as broad and generalized as the ecological niche that he occupies. As a species man inhabits and uses possibly more of the Earth's surface than does any other species, and the breadth of this niche demands considerable flexibility in the human gene pool. An additional factor in man's at least temporarily arrested phyletic evolution is the intervention of culture between man and his environment. With culture, first in the form of crude tools and perhaps skin clothing and now with a variety of sophisticated technologies interposed between man and the natural environment, the environment cannot exert pressures on the human species in the same way that it has in the past. A third factor must certainly be the size of the gene pool itself and the relatively extended length of a human generation. Evolutionary changes can occur with considerable rapidity in small populations and in populations that mature and reproduce quickly; but the flow of favourable genotypes, however advantageous, must be extremely slow in man's particular circumstances. In terms of man's total morphological pattern and its component parts, then, no important changes are preserved in the fossil record since late middle Pleistocene times. The last known evidence of human phyletic evolution concerns the *H. erectus*–*H. sapiens* transition; this period of transition occupied a considerable period of time, and, because of the incompleteness of the fossil record, scholars can only guess at many of its details. Certainly, *H. sapiens* did not spring fully formed from his *H. erectus* ancestors but, through the process of mosaic evolution,

crossed the sapient threshold at varying times in the development of different functional complexes. The resultant combination of *H. erectus* and *H. sapiens* features is well demonstrated in a number of specimens, notably Omo II, Steinheim, and Vértesszőllős.

**Phenetic evolution.** The apparent arrest of man's phyletic evolution should not suggest that the environment will never affect human development again; the observed fact of his continuing phenetic evolution clearly demonstrates the possibility of further phyletic evolution. Some of the clearest evidence that man is still responding to environmental stimuli comes from studies on the distributions of ABO blood groups; this and the importance of sickle-cell anemia in this context have already been described. Further evidence for phenetic evolution is to be found in the analysis of certain general morphological patterns, such as Bergmann's rule, which states that, within a polytypic warm-blooded species, the body size of a subspecies usually increases with decreasing temperature of its habitat, and Allen's rule, which states that in warm-blooded species there tends to be an increase in the relative size of protruding organs such as the ears and tail with increasing temperature of the habitat.

Disease is an especially acute natural selective agent, and it is well recognized that many diseases recur in cyclical patterns when their virulence is increased. This may be associated with conditions in the environment favourable to the disease-producing organism (pathogen) or by changes in the organism that suffers the disease (host); plague, tuberculosis, and scarlet fever may demonstrate this sort of pattern. In addition, populations that do not have natural immunity may be decimated by a disease that is relatively mild in nonsusceptible groups. Many Polynesian peoples, for example, have been virtually annihilated by measles. It is possible, therefore, that highly lethal worldwide epidemics could act as potent selective forces; such selection could be caused by some new or previously unrecognized disease or by a new episode of high lethality in an existing one. The effects of disease are one example of how further evolution in man may occur. Although clear conclusions with regard to human populations are not yet available, experiments with laboratory animals indicate further possibilities. A number of pathologies, both social and physical, have been induced in laboratory animals under conditions of crowding: infertility, cannibalism, mental aberration, and early death have all been observed. Environmental pollution is also known to seriously damage laboratory animals, but again the application of these results to human populations is not yet defined. Clearly, in order to obtain an understanding of the course of human evolution in a modern context, it is necessary for information to be combined from a wider range of disciplines than was formerly the case. The facts of organic evolution as the overall mechanism by which man has evolved are no longer in serious dispute; undisputed too is his continuing need for reactive and progressive changes, whether evolutionary or cultural, in response to a changing world.

**BIBLIOGRAPHY.** CHARLES DARWIN, *The Descent of Man and Selection in Relation to Sex*, 2nd ed. (1874), historically the foundation reference; G.G. SIMPSON, *Tempo and Mode in Evolution* (1944, reprinted 1965); THEODOSIUS DOBZHANSKY, *Mankind Evolving* (1962); and ERNST MAYR, *Animal Species and Evolution* (1963), all consider theoretical aspects of evolution as a process; while RENE DUBOS, *Man Adapting* (1965), relates man to his environment. E. GENET-VARICIN, *Les Singes actuels et fossiles* (1963); and J.R. and P.H. NAPIER, *A Handbook of Living Primates* (1967), gives good accounts of both modern and fossil primates; W.E. LE GROS CLARK, *The Antecedents of Man* (1959) and *The Fossil Evidence for Human Evolution* (1955); K.P. OAKLEY, *Frameworks for Dating Fossil Man* (1964); and M.H. DAY, *Guide to Fossil Man* (1965), provide information on the fossil history of man. JOHN BUETTNER-JANUSCH, *Origins of Man* (1966), is a modern general text; and DAVID PILBEAM, *The Evolution of Man* (1970), provides a concise account of the subject in readable form. L.S.B. LEAKEY, *Olduvai Gorge, 1951–61*, vol. 1 (1965); P.V. TOBIAS, *Olduvai Gorge*, vol. 2 (1967); and M.D. LEAKEY, *Olduvai Gorge*, vol. 3 (1971), are definitive monographs on the Olduvai Gorge site, including paleontology, anatomy of *A. boisei*, and

Disease as a selection factor

Levels of evolutionary change

archaeology. SHERWOOD L. WASHBURN (ed.), *Classification and Human Evolution* (1963), is an important collection of papers dealing with taxonomy. E. Biol.*, 15:109-118 (1950); E.L. SIMONS, "Some Fallacies in the Study of Hominid Phylogeny," *Science*, 141:879-889 (1963); G.A. BARTHOLOMEW and J.B. BIRDSSELL, "Ecology and the Prothominids," *Am. Anthropol.*, 55:481-498 (1953); and F. CLARK HOWELL, "European and Northwest African Middle Pleistocene Hominids," *Curr. Anthropol.*, 1:195-232 (1960), are key papers dealing with modern views on specific areas of particular importance at the present time.

(M.H.D.)

## Manchester

The Manchester of the 1970s remains one of the great regional cities of Britain, dominating much of northwest England, but it has lost that extraordinary vitality and unique influence that made it such a phenomenon of the Industrial Revolution. For Manchester was an urban prototype: in many respects it could claim to be the first of the new generation of huge industrial cities created in the Western world during the last 200 years. In 1717 it was merely a market town of 10,000 people, but by 1851 its textile (chiefly cotton) industries had so prospered that it had become a manufacturing and commercial city of over 300,000 inhabitants, already spilling out its suburbs and absorbing its industrial satellites. By the opening of the 20th century, salients of urban growth were linking Manchester to the ring of cotton manufacturing towns—Bolton, Rochdale, and Oldham, for example—that almost surround the city, and a new form of urban development, a conurbation, or metropolitan area, was evolving. By 1911 this already had a population of 2,350,000. In the following half-century, the pace of growth slowed dramatically, for by 1971 the population total was only 2,460,000. If the 19th century—when it was indisputably Britain's second city—was Manchester's golden age, the 20th century has seen it beset by increasing industrial problems associated with the decline of the textile trades (the result of foreign competition and technological obsolescence), and the city has lost much of its economic impetus.

Nineteenth-century achievement

The Manchester of the 19th century was a city of enormous vitality, not only in its economic growth but also in its political, cultural, and intellectual life. Its prosperous and influential middle class pioneered the development of the amenities and institutions of a great modern city. *The Manchester Guardian* became Britain's leading provincial newspaper, achieving an international influence, while the Hallé Orchestra was its equal in the world of music. Owens College (now known as Victoria University of Manchester) became the nucleus of the first and largest of the great English civic universities, while the academic success of the Manchester Grammar School made it something of a model in the development of selective secondary education in England. Politically, Victorian Manchester often led the nation: in the agitation for parliamentary reform and for free trade its influence was crucial. Among its intellectual achievements were John Dalton's development of the atomic theory as the foundation of modern chemistry, and the work of the "Manchester school" in the application of economic principles to the problems of commerce, industry, and government. At the end of the 19th century, Manchester made itself unique among British inland cities by becoming a port. This was accomplished by the building of the 37-mile-long (60-kilometre) ship canal leading to the Mersey estuary at Eastham and hence to the Irish Sea and the world markets beyond.

Twentieth-century problems

There was a price to be paid for this precocious growth; in its urban fabric, inner Manchester has remained essentially a 19th-century city, and by the second half of the 20th century it faced massive redevelopment problems. An industrial collar of obsolescent factory zones encircles the city centre, and huge areas of old slum housing survived with little renewal into the 1960s. In 1955 Manchester and its near neighbour Salford had a total of

80,000 houses classified as unfit. Clearance and redevelopment are nevertheless accelerating; the Hulme renewal scheme, underway in the early 1970s, is the largest project of its kind in Europe. Over 30,000 people lived in poor housing on its 350 acres, and the replacement housing will provide homes for 15,000. Manchester, then, is a city in transition: its face is being transformed by redevelopment, and its dependence on the insecure base of the textile industries is declining with the growth of a broader economic structure. The rate of population increase, on the other hand, has diminished; by the 1970s the population of the city itself was actually declining, while that of the conurbation had been virtually static in population for 50 years. This demographic trend has inevitably sapped the vitality of the city, impressive physical transformations notwithstanding.

**History.** Early in the Roman conquest of Britain a fort was established (AD 78-86) on a low sandstone plateau at the confluence of the Rivers Medlock and Irwell, almost a mile from the site of the medieval town. Of earth and timber, the fort was occupied intermittently, was partly rebuilt in stone by the emperor Hadrian (reigned AD 117-138), and was abandoned in the 4th century. Few traces survive: in fact, the Romans did no more than give Manchester its name, derived from Mamucium (Place of the Breastlike Hill). For the following five and a half centuries, there was no known occupation of the site, but in 919 the West Saxon king Edward the Elder sent a force to repair the ruined Roman fort and make it a defense against the Norsemen. By 1086 a manor of Manchester existed, but by then the settlement was relocated at the junction of the Rivers Irk and Irwell near the present cathedral. The Norman barony of Manchester was one of the largest landholdings in Lancashire, and its lords, the Grelley family, built a fortified hall close to the church. During the 13th century Manchester began its transition from village to town; corn and fulling mills (the latter for cloth) were established, and both a weekly market and an annual fair were held. Sometime before 1301 a charter was granted; there were then about 150 burgesses (adult male citizens) in the town. The parish served by the church was a huge one, and already the infant Manchester was acquiring a regional importance. Yet it was subordinate to its near neighbour Salford (facing Manchester across the River Irwell), which was the capital manor of the hundred (district) and had an earlier borough charter. The full development of the medieval borough followed the establishment in 1421 of a college of priests to take charge of the church. Part of the college survives as Chetham's Hospital, while a free church school set up in 1506 became the Manchester Grammar School in 1515, founded by Hugh Oldham, bishop of Exeter.

Early growth

By the 16th century Manchester was a flourishing market borough already important in the wool trade, exporting cloth to Europe via London in the reign of Elizabeth I. Merchant families like the Mosleys acquired great wealth. The antiquary John Leland, who visited the town in 1538, thought it one of the "best builded" in the country. By 1620 a new industrial era had begun, with the weaving of fustians, a cloth with a linen warp (the thread extended lengthwise in the loom) but a cotton weft (the weaker cross thread). This was the origin of the cotton industry that was to transform south Lancashire after 1770. As the trade grew, the town expanded, and new "improvements" were added, including the fine square and church of St. Ann (1712).

From the 1760s onward, growth quickened with the onset of the Industrial Revolution. The first canal (the Bridgewater), bringing cheap coal from Worsley, reached the town in 1762; later extended, it linked Manchester with the Mersey and Liverpool by 1776, and so served the import-export needs of the infant cotton industry. Manchester's first cotton mill was built in the early 1780s. By 1800 Manchester was said to be "steam mill mad," and by 1830 there were 99 cotton-spinning mills. The world's first modern railway, the Liverpool and Manchester, was opened in 1830, and by the 1850s the greater part of the present railway system of the city was com-

Manchester skyline viewed from the mathematics building of Manchester University Institute of Science and Technology.

*The Guardian*, Manchester and London

### The industrial era

plete. Despite its growth to a population of over 70,000 by 1801, the town had no system of government and was still managed, like a village, by a manorial court leet (a court held semiannually by the lord of the manor or his steward to conduct local government). A police force was established in 1792, but not until 1838 did a charter of incorporation set up an elected council and a system of local government.

The economic history of Manchester during the second half of the 19th century is one both of growth and diversification. The city became less important as a cotton-manufacturing centre than as the commercial and financial nucleus of the trade; on the floor of the Royal Exchange the yarn and cloth of the entire industry was bought and sold. From an early textile-machinery industry many specialized types of engineering developed. Products included steam engines and locomotives, armaments, machine tools, and, later, those of electrical engineering. The opening of the Manchester Ship Canal (1894) gave a stimulus to this industrial diversity. By 1910 Manchester had become the fourth port of the country, and alongside the docks, at Trafford Park, the first (and still the largest) industrial estate in Britain was being developed. New industries also took sites here, with a prominent role being played by such American companies as Westinghouse and Ford, the latter moving to Essex in 1929. Ultimately, more than 50,000 workers were to be accommodated within factories of the estate.

**Site and urban structure.** Manchester occupies a featureless plain made up of river gravels and the glacial-transported debris known as drift. It lies at a height of 100–350 feet (30–107 metres) above sea level, enclosed by the slopes of the Pennine range on the east and the upland spur of Rossendale on the north. Much of the plain is underlain by coal measures; mining was once widespread, but only a single large newly sunk pit remains, at Agecroft. Within this physical unit, known as the Manchester embayment, the conurbation of southeast Lancashire and northeast Cheshire (often labelled by the acronym SELNEC) has evolved. Manchester, the central city, has an elongated north–south extent, the result of late 19th- and early 20th-century territorial expansion. In 1930 the city extended its boundaries far to the south beyond the Mersey, to annex nine square miles of north Cheshire, the site of what became the great Wythenshawe complex of housing estates (population more than 103,000). Two large and independent towns adjoin Manchester on the west and southwest, the county borough of Salford (population 131,000) and the borough of Stretford (population 54,000). Together, these three administrative units form the core of the conurbation, the chief

concentration of industrial and commercial employment. From them, suburbs have spread far to the west and south, chiefly within the county of Cheshire. To the north and east of Manchester smaller industrial towns and villages, mixed with suburban development, extend as a continuous urban area to the foot of the encircling upland. Close to the upland margin lies a ring of large autonomous county boroughs, traditionally the major centres of the cotton-spinning industry—Bolton, Bury, and Rochdale on the north and Oldham, Ashton (a municipal borough), and Stockport on the east.

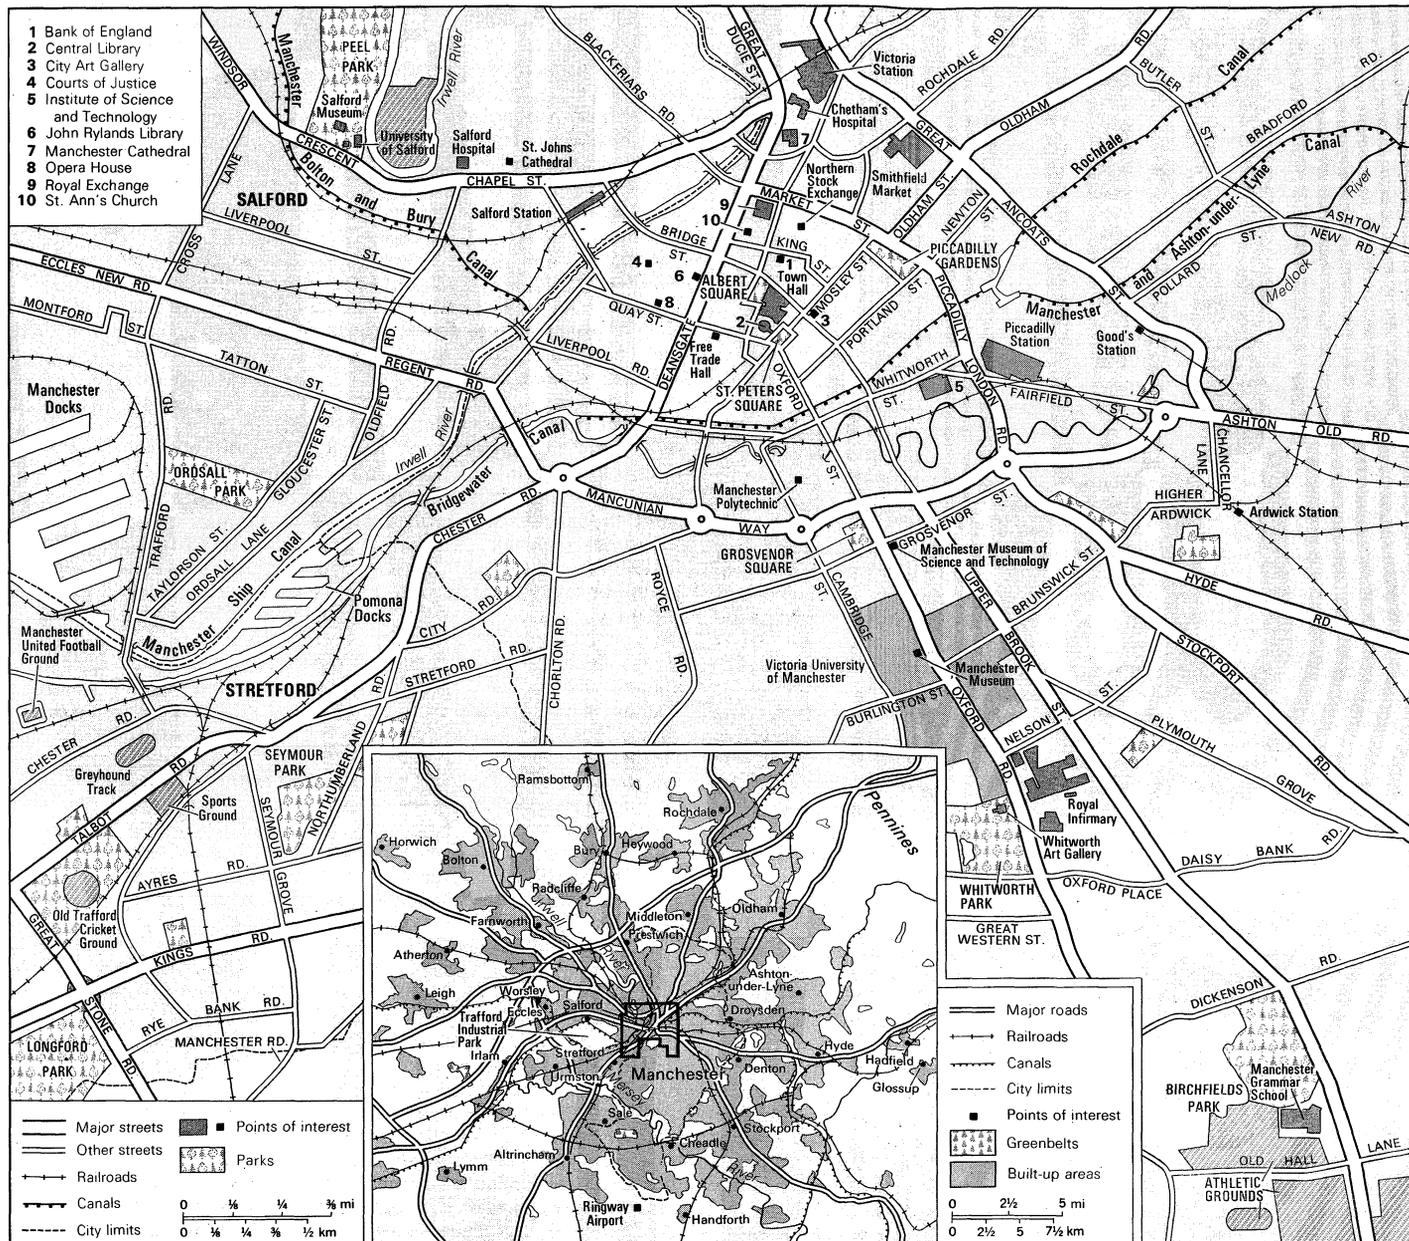

The urban structure of metropolitan Manchester is largely determined by its industrial zones. By far the most important of these is the one bisecting it from east to west. This contains most of the heavier industry—steel and petrochemicals on the Ship Canal near Irlam; electrical engineering in Trafford Park and Salford; and machine tools and metal fabrication in east Manchester. Industry in the south is confined to a few new, compact, largely planned factory estates, notably at Altrincham and Wythenshawe. North and east of Manchester ribbons of long-established industry follow every railway, river valley, and abandoned canal. The electrochemical industries of the Irwell valley, the dyestuffs of the Irk, and, everywhere, the old textile mills, are the dominant features.

**Demography.** The SELNEC (see above) conurbation is one of the world's most crowded metropolitan areas: its 2,460,000 people occupy 357 square miles at an average density of 6,891 per square mile. In the centre, densities are much higher: in Manchester they reach 15,000, and in Salford 18,400, per square mile. This overcrowding explains the chief demographic trend of the conurbation: population loss by migration. Manchester itself lost 8.3 percent of its population between 1961 and 1966 by net out-migration, and Salford 8.6 percent. These are among the highest rates of migrational loss for all British cities. Natural increase is below national average, for the migration is of young and fertile families, leaving an older population in the core cities. Thus, overall population decline is serious. Manchester has shrunk from 766,000 inhabitants in 1931 to 541,000 in 1971, a loss of almost 29 percent. This trend is also widespread in the old industrial towns of the conurbation; Bolton's population fell by 4.2 percent, and Oldham's by 8.4 percent, between 1961 and 1971.

Much of this migration is short-range, to suburban areas, and, as a result, the "dormitory" districts of the southern fringe are still growing strongly. The population trend of the metropolitan area as a whole is thus more favourable than that of its major cities. The conurbation

### The structure of the conurbation

### Migratory loss

Central Manchester and (inset) its metropolitan area.

Commonwealth immigration

declined by 0.9 percent during the period 1961-71; its low rate of natural increase (0.4 percent in 1970) was wholly offset by a net out-migration which reduced population by 2 percent annually during 1961-71. Increasingly, the migration from the crowded central cities is planned, as slum families are rehoused. Manchester has exported population to "overspill" estates at Middleton and Hyde, and Salford to Worsley. All of these are large schemes, involving population transfers of at least 10,000, and all lie within the conurbation. Longer range and larger scale movement to two New Town projects, at Warrington and Preston (18 miles west and 30 miles northwest, respectively, of Manchester), will commence in the 1970s. This out-migration has been partly balanced by an in-migration of migrants from Commonwealth countries, particularly those of the West Indies and the Indian subcontinent. By the early 1970s, Manchester itself had a multiracial immigrant community of at least 15,000 (probably in excess of 25,000 when children of British birth are included), chiefly concentrated in the Moss Side area. Some of the textile towns, too, have attracted Commonwealth migrants, chiefly Indian and Pakistani textile workers; Bolton has a community of at least 3,000 and Oldham 2,000. The metropolitan area as a whole has been one of the main magnets to Common-

wealth immigrants in Britain; they total 33,000, and the non-European communities (including children born in Britain) probably have a population approaching 50,000. **Economic life.** In terms of the urban economy, an initial distinction must be drawn between two areas: Greater Manchester (the city itself, together with Salford, Stretford, and the southern suburbs) and the textile towns of the north and east of the conurbation. The former area has greater economic breadth, together with most of the new growth industries; the latter has a narrow economic base, and the bulk of the declining textile sector. These contrasts are shown in the accompanying Table (1966 data). In Greater Manchester, the engineering and electrical group is clearly the leading industry, with an output ranging from heavy generating equipment to computers and microcircuits, and from machine tools to constructional engineering. This is the only major industry still growing strongly in the area. Clothing factories (many of workshop size) are the most important employers of female labour, especially in the rainwear trade. As in the case of textiles—now a relic industry here—the clothing industry is in serious decline. The importance of paper and printing partly reflects Manchester's importance as the country's second centre of newspaper publishing, as well as its

## Employment in Manufacturing Industries

	Greater Manchester		the textile towns	
	employees	percentage	employees	percentage
Engineering and electrical	118,000	33	50,000	22
Textiles	28,000	8	83,000	37
Clothing	41,000	11	10,000	4
Paper and printing	31,000	9	15,000	7
Food and drink	33,000	9	9,000	4
Chemicals	31,000	9	5,000	2
Vehicles	12,000	3	19,000	8
Other manufactures	63,000	18	35,000	15
Total factory employment	357,000		226,000	

paper products trade. Within the chemical group, Greater Manchester houses not only Imperial Chemical Industries' dyestuffs division but also (on a rural site to the south at Alderley) this giant company's fine chemicals research laboratories. The fate of the vehicle industry in Manchester epitomizes the area's problems of economic rebuilding; employment in this industry has dropped from about 130,000 in 1958 to 12,000 in 1966, largely through the closure of several railway engineering plants.

In the textile towns of the conurbation, mills still provide over a third of all employment and more than half the employment for women. Fortunately, the long decline of the cotton industry is almost at an end: it has been transformed into a general textile manufacture with an increasing emphasis on man-made fibres. Now that it is virtually an extension of the chemical industry, its future is more secure. Engineering in the textile towns is also changing. It was once concerned mainly with textile equipment, but now its products have broadened. In the recent diversification of employment in these towns, the conversion of former cotton mills to new uses has been vital. Food and tobacco products, plastics, surgical dressings, and electrical and aerospace components are among the new products of the old mills.

The city of Manchester itself depends less on manufactures than on services for employment. In 1967 there were 134,000 factory jobs, but 218,400 in the service trades; and though the former had declined by 26 percent since 1958, the latter had been broadly stable. Some services—transport and distribution, for example—are declining, but others, notably finance and the professional and scientific group, are growing quickly. The latter is now, after distribution, the largest single employer among all industrial and service sectors, and its growth rate (43 percent between 1958 and 1967) has been much the fastest.

**Political and governmental institutions.** Though the conurbation of metropolitan Manchester is a single cohesive socio-economic unit, its local government is totally fragmented. The dominant unit is the county borough of Manchester, which assumes the financial burden of supplying central facilities (major museums and libraries, the airport) for the area as a whole. There are six other county boroughs, each independent and able to develop its own social, educational, and planning policies. The 15 municipal boroughs have, in practice, a high degree of autonomy; but the 30 urban districts have more limited powers, and look to the county authorities for many services. Thus three counties (Lancashire, Cheshire, and Derbyshire) share the administration of this much-divided conurbation. Division of responsibility has led to serious problems; Manchester, for example, spent 20 unsuccessful years seeking a New Town site in Cheshire (Lymm, Mobberley, and Congleton were all investigated) to absorb its surplus population. The need for a metropolitan system of government has long been recognized. In 1969 the Royal Commission on Local Government proposed a metropolitan unit of 1,043 square miles, with a population of 3,232,000, to administer the SELNEC area. Much larger than the conurbation (as a result of the enclosing of satellites and dormitories beyond the edge of continuous urbanization), this new unit was to be divided into nine metropolitan "boroughs" ranging in size from 176,000 to 979,000, each with full autonomy over community services, while the metropolitan authority would

administer general planning and environmental services. A modified form of these proposals seems likely to be adopted during the course of the 1970s. Manchester is not only the central city of a large metropolitan area but also the de facto regional capital of northwest England. It has long housed the regional offices of many national ministries and when, in 1965, it became the home of the Northwest Economic Planning Council and Board (the former a nominated body and the latter a technical panel) its regional role was strengthened.

**Services.** Apart from its massive volume of retail and wholesale trade, Manchester has a number of distinctions as a regional service centre. It houses a branch of the Bank of England and the Northern Stock Exchange; it has the headquarters of the Co-operative Wholesale Society and one of the few provincial Crown courts. Its airport (at Ringway, ten miles south of the city) is the leading British terminal outside of London in the volume of international traffic handled and in the diversity of both its European and transatlantic services. Owned by the city, Ringway handled nearly 1,900,000 passengers in 1970 (1,000,000 on international services) and is the country's second airfreight terminal, handling 42,000 tons in 1970. In its role as a seaport, the city possesses two groups of docks at the head of the Ship Canal. The larger system (in Salford) handles ocean shipping, while the smaller Pomona docks in Manchester are for coastal traffic. Seaborne traffic averaged over 16,000,000 tons annually during the 1960s. This figure is perhaps misleading: the Ship Canal is, in fact, a linear port along its course from the Mersey, and much of its traffic never reaches Manchester. The largest import is petroleum for the Stanlow refineries, most of it handled at the seaward end of the system. Among the other leading imports, iron ore is destined for the Irlam steel works, and wood pulp for a paper plant at Ellesmere Port. Manchester itself handles imports of timber, foodstuffs, cotton, and general cargo, and is the chief outlet for manufactured exports. Container facilities have been developed, particularly in connection with liner services via the St. Lawrence Seaway to the Great Lakes ports. Passenger transport within the metropolitan city is now controlled by a single Passenger Transport Authority. Formed in 1969, this took over the bus fleets of 11 municipal undertakings. Its function is to develop public transport by road and by commuter rail services as a single system.

**Cultural life.** In some respects modern Manchester's cultural life is less rich than formerly. For example, its great newspaper, *The Guardian*, has (in the Mancunian view) fled to London and dropped the city's name from its title. Music, on the other hand, maintains its strength. The Hallé concerts reached their centenary in 1958, and, under Sir John Barbirolli's leadership, the orchestra continued its international reputation.

Of all Manchester's pioneer cultural achievements, none has prospered more than its university. After its foundation in 1851 at a site in Quay Street, the college received a charter in 1872 and began growth on its present site in 1873. By 1880 it had combined with member colleges in both Leeds and Liverpool to form a federal institution. Since becoming a separate body again in 1903, the university has grown to become one of the largest in Britain, with an enrollment of over 10,000 students. The faculty of technology has become autonomous as an Institute of Science and Technology; and with the foundation of the University of Salford in the early 1960s there are now three universities in and near the city.

A university precinct has been planned as a major feature in Manchester's redevelopment. This is to contain all the main higher educational institutions and will have a future student population of at least 25,000. The most ambitious project of its kind in Britain, it was quickly taking shape on the ground during the early 1970s. The precinct runs from the city centre southward for over a mile; at its broadest it is almost a half-mile wide. At the northern end lies the Institute of Science and Technology complex and a new Central Technical College; farther south are the sites of the Regional College of Art, the School of Music, and the Manchester Business School.

The role of textiles

The role of the canal

Political fragmentation

The main mass of the university occupies the southern half of the precinct, with the medical school and teaching hospitals at the southern border. Farther south still, on a 24-acre site at Fallowfield, lies the student village. The whole project reflects the growing importance of technology and research in the city's economic life.

## Manchuria, History of

The geographical division of Manchuria into regions of forested hills and mountains, fertile plains, and semi-arid grasslands made possible the development of distinctive cultural patterns among its inhabitants. Because of its accessibility from Siberia, the Mongolian Plateau, the Korean peninsula, and China proper, many peoples have mingled and fought within its boundaries. Prior to the 17th century, the history of Manchuria was shaped by the needs and ambitions of three converging ethnic groups: the Chinese, the Tungus, and the Mongols and Proto-Mongols.

The Tungus were forest and plain dwellers. They had a mixed economy of primitive agriculture, fishing, hunting, and livestock breeding. They were known in various historical periods by such names as Su-shen, I-lou, Fu-yu, Mo-ho, Juchen, and Manchu. The Mongols and Proto-Mongols were nomadic pastoralists who occupied the grasslands of the eastern rim of the Mongolian Plateau and the eastern slope of the Great Khingan Mountains. They were known by such names as Tung-hu, Hsien-pei, Wu-huan, Shih-wei, Khitan, and Mongol. The agricultural Chinese migrated from the north of China to cultivate the soil of the rich Liao Plain in south Manchuria. The successive hegemonies and kingdoms in Manchuria resulted from violent clashes among these ethnic groups. Beginning in the late 19th century, the imperialistic expansion of Russia and Japan brought about rapid economic and political changes in the country while subjecting it to intense international rivalry.

### MANCHURIA TO C. 1900

**Early history.** Prehistoric Manchuria was the eastern terminus of a natural highway for nomadic peoples who moved across the great Eurasian plain from the Volga to the Korean peninsula. Paleolithic and Neolithic sites in Manchuria often showed evidences of cultural diffusion from North China, the Gobi region, the Eurasian steppes, and Siberia. Of great interest is the discovery of painted ceramic wares in south Manchuria akin to the Yang-shao ware of North China and the stone-cist graves that spread from the Shantung peninsula in North China to south Manchuria and Korea.

As early as 1000 BC, certain Manchurian tribes are mentioned in Chinese sources. A pastoral tribe, the Tung-hu, made their appearance in Chinese history during the period of Warring States (481-221 BC), when they were confronted by the expanding Chinese feudal kingdom of Yen. Their defeat opened the way for the expansion of Yen territory into the Liao Plain and the settlement of Chinese colonies in south Manchuria.

Chinese immigration into south Manchuria accelerated during the period of political chaos that preceded the unification of China by the Ch'in dynasty (221-206 BC). In the succeeding Han dynasty (206 BC-AD 220), a rebel Han general, Wei Man, fled from Liao-tung into Korea, where he founded the Chosŏn kingdom with the help of Chinese colonists. After the death of Wei Man in 108 BC,

the Chosŏn kingdom and the adjacent Manchurian and Korean lands were overrun by the Han, who organized the conquered territories into military commanderies.

During the chaotic period following the collapse of the Han empire, China was able to maintain only a loose hegemony over Manchuria. Throughout the Inner Asian frontiers of China, the contest between the agricultural Chinese and the nomadic and semi-nomadic tribes of the steppes and forests often led to bloody warfare, interspersed with long periods of peaceful coexistence. The frontiers were not rigidly defined, and there was constant intermingling of populations. The Chinese learned from the nomads the art of cavalry warfare, and the nomads, in turn, learned from the Chinese the art of political organization. Both benefitted from trade.

The Tung-hu tribes that had been driven north by the Yen kingdom during the 3rd century BC regained their strength during the Han dynasty. Toward the end of that dynasty, the Tung-hu were divided into two major groups: the Wu-huan in the south and Hsien-pei in the north. The Wu-huan raided the Han frontier while China was in the throes of civil war, but they were decisively defeated in 207. Thereafter, the Hsien-pei gained ascendancy among the Tung-hu tribes. In 281 the Mu-jung branch of the Hsien-pei tribes plundered the area near modern Peking. In 285, soon after their great chief Mu-jung Hui came to power, they ravaged the Tungus Fu-yu tribes to the north, initiating a prolonged struggle between the two peoples. When China was in political disarray after 300, Mu-jung Hui moved his capital to Ch'ch'eng near the Chinese-settled Liao-tung. In 352 the Mu-jung king assumed the title of emperor and called his domain the Yen kingdom (known to historians as the Former Yen kingdom to distinguish it from other kingdoms of the same name). Further conquests enabled the Yen to control a large part of North China and to move their capital there in 359. Thereafter, the Mu-jung power began to decline, and the kingdom was overthrown in 370.

Under the Sui (581-618) and T'ang (618-907) dynasties China was able to reassert a limited control over south Manchuria. The T'ang also claimed the allegiance of many Manchurian tribes that lived beyond its frontier. As T'ang power waned, these tribes claimed independence. Ta-tso-jung, leader of the Mo-ho tribes, proclaimed the founding of the Chen kingdom in 698, which became the P'o-hai kingdom in 712. Centred in the modern province of Kirin, P'o-hai, at its height, covered nearly the whole of Manchuria and North Korea. Its population numbered over 100,000 households and included a sizeable number of Chinese and Koreans. It was through P'o-hai that Buddhism was introduced among the Tungus in Manchuria.

**The Khitan and Juchen empires.** With the collapse of the T'ang dynasty in 907, the Khitan, who belonged to the Yu-wen branch of the Hsien-pei tribes, gradually gained ascendancy in Manchuria. Under the leadership of their chief, A-pao-chi (872-926), the Khitan united their Hsien-pei neighbours and began expanding south against China and west against the Turkic nations. By 907 A-pao-chi was ready to have himself crowned emperor. When P'o-hai invaded a Khitan city in 924, the Khitan retaliated in 926 by overthrowing P'o-hai.

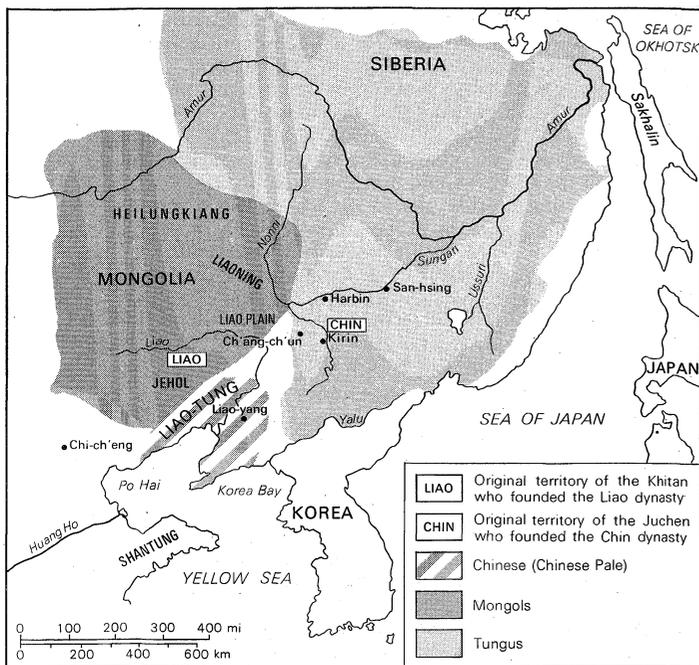

Under A-pao-chi's successor, Te-kuang, the Khitan acquired 16 strategic prefectures in northern China. In 947 Te-kuang adopted a Chinese name, Liao, for his dynasty, signifying his ambition to rule over the whole of China. Although that ambition was never realized, the Khitan did humiliate successive Chinese dynasties by requiring them to pay tribute to the Liao court. At the height of its power, the Khitan empire occupied practically the whole of Manchuria, part of North Korea, part of North China, and the greater part of the Mongolian Plateau.

The Khitan nobility preferred to reside in China, where they could enjoy a more sophisticated and luxurious life. There ensued a marked decline in administrative efficiency and military prowess toward the end of the dynasty. The non-Khitan subjects staged frequent rebellions against their overlord. Of particular importance among

these rebels were the Juchen tribes, who lived beyond the Liao frontier but were under tributary relationship to the Liao court.

As tributary subjects, the Juchen chiefs were obliged to appear before the reigning Liao emperor, who came to fish once each year in the Sungari River. The emperor, according to custom, invited the Juchen chiefs to celebrate the occasion with a sumptuous feast and often asked them to perform their native dance for him, a gesture symbolic of the political relationships between the two peoples. In 1112 the Liao emperor, T'ien-tsu, while intoxicated, ordered A-ku-ta, the paramount chief of the Juchen, to dance before him. The proud warrior twice refused the Emperor's request. It was a dramatic signal indicating the waning of the Khitan power. In 1115 A-ku-ta proclaimed the establishment of the Chin kingdom. An alliance between the Juchen Chin kingdom and the Chinese Sung dynasty succeeded in destroying the Liao empire in 1125.

After the destruction of their common enemy, the Chin turned against the Sung. In 1127 the Juchen sacked the Sung capital and the Sung court retreated to the south, where it existed as the Southern Sung dynasty. After experimenting with puppet Chinese rulers governing the occupied Sung territory, the Juchen decided to incorporate it into their own domain. In 1214 their capital was moved from Manchuria to Yen-ching (modern Peking). By then, however, the formidable Chin military machine had become moribund and was an easy prey to the Mongols, who rose to power in the Mongolian Plateau in the 12th century (see MONGOLS).

In 1210 the Mongols invaded Chin under the leadership of the great Genghis Khan, and by 1234 Chin had succumbed to the combined pressure of the Mongols and the Sung Chinese. Occupying the whole of Manchuria, the Mongols made it one province, the Liaoyang.

In 1280 the Mongols completed the conquest of China, where they established the Yuan dynasty. The Mongols, like their Juchen predecessors, located their capital in Peking, away from their steppe homeland. Although they had conquered the whole of China, the Mongols were less affected by Chinese culture than the Khitan and Juchen had been. Their harsh rule precipitated a series of rebellions among the Chinese, who overthrew the dynasty in 1368. The victorious Chinese established a native dynasty (the Ming), pursued the Mongols into the steppes, and reinstated Chinese rule over Liao-tung.

The Ming Chinese, however, did not attempt to govern the tribal peoples directly. The Juchen in Manchuria, who had reverted to their ancestral way of living, were divided into three major groups: the Chien-chou, Hai-hsi, and Yeh-jen. Each group comprised a number of tribes and clans, each of which was led by a chief. The authority of the tribal chief had to be confirmed by the Ming government. The Chinese tried to keep the tribes divided into as many subdivisions as possible, in order to prevent them from uniting into a single frontier power. A similar tactic was also used in regard to the Mongol tribes near the Ming frontier. During the 15th and 16th centuries, the Mongols had regained their strength and were pressing upon the Chinese frontier. As a result, the Ming position in Manchuria gradually deteriorated, and by the 17th century the Juchen were strong enough to challenge the Ming rule.

It was the Chien-chou tribes, under the leadership of Nurhachi (1559-1626), who succeeded in forging a new and greater Juchen empire. Beginning in 1583, Nurhachi led a series of campaigns that ultimately brought all the Juchen tribes under his control. In 1616 he was proclaimed *han* (emperor) by his subjects and allies. Nurhachi named his dynasty Chin in an attempt to rekindle the desire for Imperial greatness among the Juchen people. In 1621 he captured the Ming cities of Shen-yang (Mukden) and Liao-yang in south Manchuria. After Nurhachi's death, his son and successor, Abahai, continued the task of territorial expansion. When Abahai died in 1643, Manchu arms had been carried east into Korea, north into the Amur and Ussuri valleys, west to Inner Mongolia, and south to the Great Wall. Abahai adopted the name Manchu for his people and changed the dynastic designation from Chin to Ch'ing. In 1644 the Manchus, with the help of dissident Chinese, established themselves as the new rulers of the Chinese empire.

**Sinicization of Manchuria.** Although the Chinese had colonized the Liao Plain more than a thousand years before and had made it a centre of Chinese cultural influence, they had never been able to secure a foothold in central and north Manchuria, which remained predominantly a preserve of tribal groups. Paradoxically, it was during the period of Manchu ascendancy that the Chinese succeeded in penetrating the Sungari and Amur valleys.

The Manchu population had been organized by Nurhachi and Abahai into military and administrative units called banners. During and after the conquest of China, the majority of the Manchu bannermen followed the Manchu court into China. The Chinese population in Liao-tung was decimated by years of warfare, and, consequently, the whole of Manchuria was underpopulated. Until 1688 the Ch'ing government encouraged Chinese immigration to Liao-tung in order to revive its economy. After 1688 Chinese immigration was restricted. Two lines of barriers, known as the Willow Palisades, were constructed in Manchuria, separating the traditional area of Chinese settlement in Liao-tung from the tribal frontier in the west, north, and east. Chinese were prohibited from crossing the palisades without authorization.

Almost from the very beginning, the Manchus had to modify their exclusion policy. The rise of Manchu power in the 17th century coincided with the eastward march of the Russian power. The might and interests of both empires clashed in the Amur Valley, and the thinly spread Manchu garrison had to be strengthened with Chinese recruits for the emergency. These recruits, chosen from the ranks of political exiles, captured rebel soldiers, and criminal convicts formed the earliest nuclei of Chinese settlements in the frontier garrison towns, such as Ninguta, Kirin, Tsitsihar, and Aigun.

Natural resources, such as ginseng (a medicinal herb), fur, gold, and fertile soil, attracted an unending stream of voluntary immigrants to Manchuria, despite the official ban. Land-hungry peasants slipped past the Willow Palisades in large numbers, and a series of great famines in the 18th century made it impossible to stem the flow of peasant refugees. The flow of immigration became a flood tide in the 19th and 20th centuries as China was torn by a series of great rebellions, and Manchuria be-

came the target of expansionist Russia and Japan. Instead of maintaining the ineffective ban against Chinese immigration, the Ch'ing government actively sponsored planned colonization of virgin lands in Kirin and Heilung-kiang. The immigrant communities were served by merchants operating from commercial centres, such as Kirin, Mukden, Ying-kou, Tsitsihar, and San-hsing. Their economy developed from primitive self-sufficiency to an important centre of international trade.

The  
bandit  
society

In this unstable frontier society Manchurian bandits preyed upon the population in the mountains and plains alike. Mounted to cover the great distances between Manchurian settlements, these outlaws moved easily from banditry to soldiering, and many military careers were built by men who rose from the outlaw ranks.

The great Manchuria frontier was thus inexorably Sinitized by Chinese colonists: the non-Manchu Tungus tribesmen of the Ussuri and Amur valleys declined in number year after year; the Manchu bannermen soon merged imperceptibly into the Chinese population; the Mongol nomads, faced with displacement from their traditional pastoral grounds, often forsook their ancestral occupation for the life of a peasant.

#### MANCHURIA SINCE C. 1900

**Russian and Japanese aggression in Manchuria.** The Russian advance into the Amur region was halted in the 17th century by Manchu arms and the 1689 Treaty of Nerchinsk, but it was resumed in the latter 19th century, when the Ch'ing empire was staggered by the great Taiping Rebellion and by humiliating defeats from the armed forces of Western nations. It meekly accepted Tsarist Russia's imposition of the Treaty of Aigun in 1858, which ceded territories to Russia on the left bank of the Amur. The Treaty of Peking in 1860 gave up the lands east of the Ussuri. Russia now looked upon Manchuria as its legitimate sphere of interest.

Russian  
railway  
rights

When China ceded the Liao-tung Peninsula to Japan at the conclusion of the Sino-Japanese War of 1894-95, Russia, supported by Germany and France, compelled Japan to return it to China for an increased indemnity. Deeply disturbed by the rising Japanese power, China concluded a secret alliance with Russia in 1896, granting the Russians the right to build the Chinese Eastern Railway across north Manchuria from Siberia to Vladivostok. Ostensibly directed against Japan, it merely opened the way for Russia to penetrate further into Manchuria.

Russia's ulterior motive became apparent in 1898 when it intimidated China into granting a 25-year lease of the Liao-tung Peninsula and the right to build a connecting railway from the ports of Dairen and Port Arthur to the Chinese Eastern Railway. The Russian government thereby succeeded in establishing throughout the railway zone a system of municipal, judicial, police, and military administration that, in effect, constituted a Russian-occupied conclave within Manchuria. In 1900, under the pretext of restoring order after the Boxer Rebellion against foreigners, Russia occupied the whole of Manchuria. The withdrawal of the Russian troops, as provided by the Boxer Protocol, was deliberately delayed by the Russians in an attempt to win more political and economic privileges from the Chinese.

The clash of Russian and Japanese interests in Manchuria and Korea led to the outbreak of the Russo-Japanese War of 1904-05. After its defeat, Russia ceded to Japan all its interests in south Manchuria. Henceforth, rivalry between Russia and Japan in Manchuria was tempered by the desire of both nations to prevent Western powers, particularly the United States, from intruding into their spheres of influence. By secret agreements concluded by them in 1907, 1910, 1912, and 1916, they promised to maintain the status quo and cooperate in protecting their interests against outsiders.

**The Chinese response.** China responded to the new situation in Manchuria by adopting a more positive approach toward the political integration of the region with China proper. Chinese immigration was officially encouraged through the selling of public lands to individuals and to land companies at an attractive price. Mongol lands

were taken out of tribal control for sale to peasant cultivators. The hitherto predominant position of the bannermen in the political and military establishments was eroded by the introduction into Manchuria of Chinese troops and administrative personnel. The tributary relationships with the tribal peoples were dissolved in favour of direct administration of tribal areas and the eventual assimilation of tribal peoples. Toward the end of the Ch'ing dynasty, the whole of Manchuria had become a truly Chinese territory.

**Further Japanese expansion.** The Chinese Revolution of 1911 came to Manchuria when its armed forces were divided into two antagonistic factions: the new modernized army, whose officers were sympathetic to the republican cause, and the old provincial army, whose officers remained loyal to the old order. When confronted by a plot to detach the Manchurian provinces from Imperial control, Governor General Chao Erh-sun successfully checkmated the revolutionaries by calling for help from Chang Tso-lin, the leader of the old provincial army. After the dynasty was overthrown, Chang Tso-lin allied himself with the influential Chinese warlord Yüan Shih-k'ai and was able to extend his power over the whole of Manchuria.

Chang  
Tso-lin

Internal political instability in the young Chinese Republic and the outbreak of World War I in Europe provided the Japanese with a golden opportunity to advance their interest in Manchuria. Japan presented China with the notorious 21 Demands in 1915. After strenuous negotiations, the Chinese were forced to make major concessions regarding Manchuria: the extension of the Kwantung lease and the South Manchurian Railway concessions to 99 years; and the granting to Japanese subjects permission to reside, travel, engage in business, lease and own lands anywhere in Manchuria and east Inner Mongolia.

With its interests safeguarded by treaties and the might of the Kwantung Army, Japan was ready to expand its investments in Manchuria. In 1919 the Kwantung Army became a separate command. Not subject to close scrutiny by the Tokyo government, it was determined to promote the rapid development of Manchuria for the benefit of the Japanese empire, by force if necessary. The fall of the tsarist government in 1917 and agreement by the Soviet Union on joint Sino-Soviet management of the Chinese Eastern Railway and reversion of the line to China without compensation in 1936 provided future opportunity for expansion into northern Manchuria.

The  
Kwan-  
tung  
Army

Rapid economic development in Manchuria encouraged Chang Tso-lin to play a decisive role in warlord politics. His ambition ran afoul not only of his fellow warlords but also of those Japanese leaders who preferred to see him as the autonomous leader in Manchuria amenable to the Japanese. When Chang Tso-lin, who had dominated the Peking government since 1926, faced defeat at the hands of the Kuomintang Army in 1928, the Japanese government advised him to withdraw his army into Manchuria to prevent hostilities from spreading north of the Great Wall. In return, Japan promised to support Chang's position in Manchuria. The radical elements in the Kwantung Army, however, wanted to disarm Chang's army and take over Manchuria. On June 4, 1928, Chang was assassinated under the direction of the senior staff officer of the Kwantung Army and with the approval of the commander in chief. The plot did not succeed in creating panic among the Chinese leaders in Manchuria nor was it approved by the Tokyo government. Consequently, the Kwantung Army had to wait for another chance to seize Manchuria.

Chang Tso-lin's son and successor, Chang Hsüeh-liang, ignoring Japanese warnings, decided to cast his lot with the Kuomintang government in Nanking. Chinese nationalism, inflamed by Japanese attempts to obstruct the unification of China, won popular support in Manchuria. Many young Japanese businessmen, fearing Japanese interests and privileges might be ousted, organized the Manchuria Youth League, which had as its objective the formation of an independent Manchuria. The Kwantung Army, on the other hand, favoured the establishment of a

Japanese puppet state and the removal of Soviet presence in north Manchuria. It also considered Manchuria as a potential base for Japanese military expansion in Asia. The stage was set for an overt clash between Chinese nationalism and Japanese imperialism.

Japanese invasion

On the morning of September 18, 1931, two explosions occurred outside Mukden. Immediately afterward, the Kwantung Army and the Japanese railway guards began attacking the Chinese barracks and the city wall. By dawn the next day, Mukden had been occupied. Honjō Shigeru, the commander in chief of the Kwantung Army, issued a proclamation saying that Chinese soldiers had dynamited the South Manchurian Railway and had attacked Japanese railway guards. The Kwantung Army, he stated, had no choice but to punish the Chinese Army by occupying the city. So began the Mukden Incident, which ultimately led to the Sino-Japanese War.

Although the invasion of Manchuria had been under discussion by the Japanese high command in Tokyo, the bombing plot was conceived and carried out by young Kwantung officers. Once firing had begun, the Kwantung Army moved forward according to predrawn plans for the occupation of Manchuria, despite restraining orders issued from Tokyo. The Nanking government directed the Manchurian leaders not to resist the Japanese. Relying upon the League of Nations to halt the Japanese aggression, it also refused to negotiate directly with Japan. This negative and passive stance enabled the Japanese to occupy all of Manchuria within five months. On March 9, 1932, the Japanese created the puppet state of Manchukuo. The last Manchu emperor, P'u-yi, was brought to Manchuria from Tientsin and made chief executive.

The League of Nations sent an International Commission of Inquiry, headed by Lord Lytton, to investigate the incident. The commission found Japan guilty of aggression and branded Manchukuo a puppet state; but it did not recommend sanction against the aggressor. The United States was unwilling to intervene, except to announce that it would not recognize the legal status of Manchukuo. The Kwantung Army then extended its conquest to Jehol. On March 27, 1933, following the issuance of the Lytton Report, Japan withdrew from the League. Realizing that there would be no foreign assistance, China agreed to sign the T'ang-ku Truce on May 31, 1933, which ended the Japanese advance toward North China and created a demilitarized zone between the Great Wall and Peking. The Japanese then enthroned P'u-yi as emperor of Manchukuo on March 1, 1934.

**Manchuria under the Japanese.** The creation of Manchukuo greatly enhanced the power of the Kwantung Army, whose commander in chief also served as governor of the Kwantung Leased Territory and ambassador to Manchukuo, thus concentrating all military and political powers into a single source of authority. The key official in the Manchukuo government was the director general of the General Affairs Board of the State Council, who was always a Japanese. Japanese officials were placed in key positions throughout all ministries and offices. Having succeeded in ruling Manchuria through the facade of a puppet state, the Japanese pressured the Soviet Union to sell to Manchukuo the Chinese Eastern Railway.

Economic exploitation

The Kwantung Army then proceeded to transform Manchuria into an industrial and war base for Japan's expansion in Asia. It took over direction of the South Manchurian Railway Company, which became the chief agent of Japanese economic exploitation in Manchuria. The Manchurian Heavy Industry Company, a giant holding company, was organized in 1937 to finance and direct most of the important Manchurian industries. As a result, metallurgy, mining, electric power, chemicals, transportation, and communication all made impressive gains. At the end of the war, Manchuria was the most industrialized region in China.

The agrarian policy of the Kwantung Army was also designed to implement its military objectives. First, the Kwantung Army intended to settle large numbers of Japanese and Korean farmers in Manchuria and to limit the

number of Chinese immigrants. It aimed specifically at the formation of solid blocs of Japanese farmers, preferably army reservists, at strategic frontier locations as a defense measure against the Soviet Union. Second, the Kwantung Army encouraged the diversification of crops in order to achieve agricultural self-sufficiency for war purposes. Manchuria's most pressing agrarian problem, farm tenancy, remained unsolved, since the Japanese needed the cooperation of the landlord-usurer class.

Despite the Manchukuo facade, Manchuria was a land under Japanese colonial rule. The Kwantung Army was never able to completely suppress all armed resistance by the Chinese and Korean population. After the fall of Manchuria, many Manchurian soldiers, aided by armed civilians, including bandits, cooperated with the Chinese and Korean Communist underground in organizing a vast anti-Japanese guerrilla movement. In 1934 alone the Japanese reported to have suffered about 50,000 casualties in fighting the guerrillas.

Resistance to the Japanese

**The triumph of Communism.** At the Yalta Conference of February 1945, Soviet premier Joseph Stalin demanded the restoration of all former Russian rights and privileges in Manchuria as a price for Soviet entry into the Pacific war. Pres. Franklin D. Roosevelt of the United States and British prime minister Winston Churchill accepted Stalin's demand without consulting China. After Germany's surrender in May 1945, Soviet troops began to move from Europe to Asia. Thereupon, China sent T.V. Soong to the Soviet Union to negotiate an agreement before Soviet troops could enter Manchuria. Stalin offered China a 33-year treaty of friendship and alliance against future Japanese aggression. On August 9 the Soviet Union declared war on Japan and invaded Manchuria. The Sino-Soviet Treaty was signed on August 14, 1945. By August 15 the war was over. The next day, the Manchukuo emperor P'u-yi was captured by the Russians. Having struck a good bargain for joining the war, the Soviets now plundered Manchuria as a conquered territory, systematically confiscating food, gold bullion, industrial machinery, and other stockpiles. The actual extent of Soviet looting in Manchuria is not known, but it probably ran into billions of dollars.

Soviet spoliation of the country

To the Nanking government, the political damage of the Soviet occupation was even greater than the economic ravage. Under the protection of the Soviet Army, underground Chinese Communist guerrillas united with Communist troops from North China to form the United Democratic Army. Equipped with Japanese arms turned over to them by the Russians, the Communist force blocked all land routes from China proper to Manchuria and occupied several important ports where Kuomintang troops might have landed. The Soviet Army refused to let them enter Dairen. Delayed by the Soviets and harassed by the Communists, Kuomintang progress in taking over the major Manchurian cities was exceedingly slow. It was June 1946 when the Kuomintang occupied Ch'ang-ch'un. By then the Soviets had withdrawn completely, and the countryside was in the hands of the Communists. Nearly 500,000 of the elite Kuomintang troops found themselves surrounded by Communists in Ch'ang-ch'un, Mukden, Chin-chou and Ying-kou. By the end of 1948 the Kuomintang had suffered military defeat in Manchuria.

On August 27, 1949, the Northeast People's Government was formally established. The top political figure was Kao Kang, who headed both the party and government in Manchuria. Kao led a delegation to the Soviet Union to conclude a trade agreement in August 1949. Later, in December, Mao Tse-tung visited the Soviet Union and negotiated with Stalin a 30-year treaty of friendship, alliance, and mutual assistance. In return for a Soviet pledge of military and economic assistance, China conceded the privileges granted to the Soviets in Manchuria by the Nanking government. These privileges were to be in force until a peace treaty with Japan could be concluded or, at the latest, until the end of 1952.

The Communist rehabilitation of the Manchurian economy began with the land reform in 1946, and by the end of 1949 all the lands had been redistributed among the peasants. The power of the landlords was eliminated.

Because of the existence of extensive tracts of public lands in Manchuria, a large number of state farms were set up, which were equipped with machinery and engaged in experimental farming. Otherwise, the course of agrarian reform in Manchuria, from the formation of mutual-aid teams to cooperatives and communes, did not differ from elsewhere in China proper.

Industrially, the initial task of the Communists was to reconstruct the existing industrial plants so that Manchuria could serve as a major base for the further industrialization of China. During the First Five-Year Plan of 1953–57, Manchuria received the bulk of Chinese industrial investment. Today, Manchuria is still the industrial heartland of China.

Party  
purges

The importance of Manchuria to the economic development of China, its proximity to the Soviet Union, its long history of political separatism, and the ambitions of Kao Kang might have been responsible for the first important purge of party leadership after the establishment of the People's Republic. Kao Kang had exercised virtually autonomous power in Manchuria and enjoyed frequent contacts with the Soviets. It was possible that he had tried to use Soviet support to gain for himself even greater power within the party and government. In 1953 Peking abolished the Northeast People's Government and replaced it with the Northeast Administrative Commission. In 1954 the commission was dissolved, and Manchuria was divided into three provinces: Liaoning, Kirin, and Heilungkiang. A Yen-pien Korean Autonomous District was created in eastern Kirin where the Korean minority congregated. The Mongol-inhabited western Manchuria became part of the Inner Mongolia Autonomous Region. Kao Kang was transferred from Manchuria to Peking, and in 1955 he was purged from the party. Since then Manchuria has been fully integrated into the political structure of China. Like the rest of China, Manchuria was buffeted by the violence and disorder of the Great Proletariat Cultural Revolution that started in 1966. By 1969 the Maoists had won, and in 1970 the reconstruction of the party structure in Liaoning was completed. It was during the turmoil of the Cultural Revolution that tensions between China and the Soviet Union, whose relations had deteriorated since 1956, reached the point of open hostility in May 1969, when a dispute over the ownership of an uninhabited island in the Ussuri led to armed clashes. The incident reminds the world that Manchuria is still the historic zone of conflict where peoples and nations have fought for its possession since the dawn of history.

## Manet, Édouard

In the span of French painting, rich and unbroken since the 17th century, a single artist—Édouard Manet—accomplished by himself the 19th-century transition from the Realism of Gustave Courbet to Impressionism. Lacking great imagination for the invention of themes, Manet was almost always inspired by a painting, drawing, or print either by a master or an unknown. His qualities are purely pictorial. They rise from the luminosity of his brushwork, the fine quality of his palette, and the breadth of his design. With no posterity to carry on his work, this revolutionary in spite of himself carried the light to Impressionism. His art has on its viewers the power to cleanse the dust from the eyes and wash the vision.

Giraudon

'The Studio in the Batignolles.' Manet is seated at the easel in his Batignolles studio; Pierre-Auguste Renoir and Emile Zola are standing second and third from the left, respectively. Oil painting by Henri Fantin-Latour, 1870. In the Louvre, Paris. 1.74 × 2.08 m.

**Early life and works.** Manet was born on January 23, 1832, at 5 rue des Petits-Augustins (today rue Bonaparte) in Paris. He was the son of Auguste Manet, stern chief of personnel at the Ministry of Justice, and of Eugénie-Désirée Fournier. The child was baptized on February 2 at the church of Saint-Germain-des Prés.

From 1839, Manet was a day pupil at Canon Poilou's school in Vaugirard, where he began the study of French and the classics. He was later (1844-48) a boarder at the Collège Rollin, then located near the Panthéon. A poor student, he was interested only in the special drawing course offered by the school. At the Collège Rollin, he met his future biographer, A. Proust.

Although his father wanted him to enroll in law school, he could not be persuaded to do so. When his father refused to let him become a painter, he applied for the naval college but failed the entrance examination. He therefore embarked, on December 9, 1848, as an apprentice pilot on the transport vessel "Le Havre et Guadeloupe" and sailed for Rio de Janeiro, at a salary of 15 francs a month. During the crossing he wrote his parents amusing letters embellished with sketches in which his art was already apparent.

Upon his return to France in June 1849, he failed the naval examination a second time, and his parents now finally yielded to their son's stubborn determination to become a painter. In 1850 Manet entered the studio of Thomas Couture, a classical painter who had been a pupil of Antoine-Jean Gros and had painted "The Romans of the Decadence" (Louvre, Paris). Whatever may be said of him, Couture had some qualities of a great painter, and, despite faults that included both boorishness and banality, he was not a bad teacher. "I may not claim to train geniuses," he said to his pupils, "but at least I train painters to know their craft." Little as his teacher may have understood him, Manet was to owe to Couture a good grasp of drawing and pictorial technique.

The Manet family had moved to 6 rue du Mont-Thabor, where a young Dutchwoman, Suzanne Leenhoff, came to give piano lessons to Édouard. There seems to have been a love affair between the young painter and his music teacher. Indeed she later gave birth to a son whose paternity, though never acknowledged, has been attributed to Manet. The child, who was named Léon-Édouard Koëlla-Leenhoff, was represented as being Suzanne's younger brother, with Manet as the godfather.

In 1856, after six years with Couture, Manet set up a studio—which he shared with Albert de Balleroy, a painter of military subjects—in the rue Lavoisier in the Saint-Augustin quarter. There he painted "The Boy with Cherries" (c. 1858; Gulbenkian Collection, Paris), the model for which one day hanged himself from a nail in the studio. Obsessed by the child's tragic death, the artist left the rue Lavoisier and moved to 58 rue de Villiers, where he painted "The Absinthe Drinker." In 1856 he made short trips to Holland, Germany, and Italy. Meanwhile, at the Louvre he copied Titian's "Virgin with Rabbit," as well as Velázquez's "Portrait de l'Infante Marie-Marguerite," of which he left a watercolour and a recently discovered oil. At the Louvre, in 1857, Manet made the acquaintance of Henri Fantin-Latour, who was later to paint Manet's portrait.

Leaving his studio in the rue de Villiers, he moved to 58 rue de la Victoire and then to the rue de Douai, where he remained for 18 months. He met the poet Charles Baudelaire, at whose suggestion he painted "La Musique aux Tuileries" ("Concert in the Tuileries Gardens"), a picture painted outdoors, in which, it seems, the whole of Paris of the Second Empire is assembled—a smart, frivolous society composed chiefly of habitués of the Café Tortoni and of the Café Guerbois, the latter the rendezvous of the Batignolles artists. Passersby looked with curiosity at this elegantly dressed painter who set up his canvas and painted in the open air.

The following year (1861) Manet exhibited at the Salon "Spanish Singer," dubbed "Guitarero" by the French man of letters Théophile Gautier, who praised it enthusiastically in the periodical *Le Moniteur universel*. In 1862 there was "Lola de Valence" (Louvre, Paris), a dazzling portrait of a dancer who had appeared with a Spanish troupe at the Paris Hippodrome.

**Mature life and works.** Upon the death of his father, September 25, 1862, Manet moved to the rue Guyot. From that year until 1865 he took part in exhibitions organized by the Galerie Martinet. In 1863 the jury of the

Salon of the French Académie Royale rejected his "Déjeuner sur l'herbe" ("Luncheon on the Grass"), a work whose technique was entirely revolutionary, and Manet exhibited it at the Salon des Refusés (established to exhibit the many works rejected by the official Salon). Although inspired by works of the old masters—Giorgione's "Concert champêtre" and Raphael's "Judgment of Paris"—this large canvas, measuring 84¼ by 106¼ inches (214 by 270 centimetres), aroused loud disapproval and began for Manet that "carnival notoriety" from which he was long to suffer. His bourgeois critics were offended by the presence of a naked woman among the clothed young men.

Manet married Suzanne Leenhoff in Zalt-Bommel in The Netherlands on October 28, 1863, much to the surprise of Baudelaire and other friends, from whom he had partially concealed his intentions. In November 1864 the artist moved to a private apartment at 34 boulevard des Batignolles, where he was to remain until 1867. He began to frequent the racetrack, where he skillfully took up the theme of his friend Edgar Degas, who, in his studies of the turf, had preceded him by two years. Of the several pictures he painted on this subject, "The Races at Longchamp, Paris" is the major work.

At the Salon of 1865, "Olympia," painted two years earlier, created a scandal. This symphony in white—which the French statesman Georges Clemenceau was to install in the Louvre in 1907—was called indecent. As one 19th-century critic wrote:

Canes and umbrellas were brandished against this awakening beauty. A mob was formed which the army did nothing to disperse. The terrified administration felt obliged to have her guarded by two uniformed attendants. And that wasn't enough! Rearranging in their usual way, they hung her nudity at an enormous height where no one would see it, and from which she simultaneously defied the stares and uproar.

In his vexation, Manet left in August 1865 for Spain, but, disliking the food and frustrated by his total lack of knowledge of the language, he did not stay long. In Madrid he met Théodore Duret, who was later to be one of the first connoisseurs and champions of his work. The following year, "The Fifer," having been rejected by the Salon jury under the pretext that its modelling was flat, was displayed along with others in Manet's studio in the rue Guyot.

When a large number of his works were rejected for the Universal Exposition of 1867, Manet, in imitation of Gustave Courbet, who had had the same idea, had a stall erected at the corner of the Place de l'Alma and the Avenue Montaigne, and there in May he exhibited a group of works, including his paintings of toreadors and bullfights. "What a lot of Spaniards!" exclaimed Courbet on entering Manet's stall. And he added: "His figures are like the jack of diamonds on a playing card." When a friend reported Courbet's remark to Manet, the latter responded: "That doesn't surprise me. Courbet's ideal is a billiard ball!" In his own exhibition he showed about 50 paintings, but these were hardly received any more favourably than before. During the late 1860s his work was varied in character, but in general it seems to represent a greater concern with close relations of tone, with complexities of illumination and atmosphere, and sometimes exhibits a freedom of handling comparable with that in "La Musique aux Tuileries" (1862; National Gallery, London). "The Execution of the Emperor Maximilian of Mexico" of 1867, and "The Departure of the Folkestone Boat" (1869; Philadelphia Museum of Art) are representative of the work Manet was producing at this time.

Manet was not, however, entirely absent from the official Salon of 1867, since Fantin-Latour's portrait of him was displayed there. Wearing a top hat, his legs solidly planted, his walking stick clutched in his hands, the painter of "Olympia" is presented full face, his eyes thoughtful, his chin determined under his well-trimmed beard, and with an ambiguous smile on his lips that seems to mock the company.

Much taken by the naturalism of Manet's work, the

Entry into the studio of Thomas Couture

First Salon exhibition

Exhibition of 1867

young novelist Émile Zola undertook to defend and praise it in a long and courageous article published in the *Revue du XIX<sup>e</sup> Siècle* of January 1, 1867. In the face of the hostility of the public, Zola saw Manet as representative of all artists of importance who begin by offending public opinion. "In studying in Édouard Manet the reception given to original personalities," he wrote, "I protest against this reception. I make of an individual question a question that is of interest to all true artists." "You have given me a fine New Year's present," the painter wrote in thanking the writer. Manet's gratitude was to be expressed in his portrait of Zola, shown at the Salon of 1868, where it was badly hung. "At times," Zola wrote in describing his sittings with Manet, "I looked at the artist standing before his canvas, his face tense, his eyes clear, intent on his work. He had forgotten me, he no longer knew I was there."

Along with his portrait of Zola, Manet exhibited "The Balcony," in which there appeared for the first time—in the figure of the Spanish girl seated with her elbow on the railing—a portrait of Berthe Morisot, whom he had met at the Louvre, where she was copying a work by Peter Paul Rubens. From then on, Berthe, who was to become one of the leading female French Impressionists, was a frequent visitor to Manet's studio. He painted a series of portraits of her, until her marriage to his brother Eugène Manet.

After the praise published by Zola, Duret, and the art critic Louis-Édmond Duranty (with this last the painter had fought a comic-opera duel), Manet received, at the Salon of 1870, Fantin-Latour's homage in paint—"The Studio in the Batignolles" (Louvre, Paris), a kind of manifesto on his behalf. This large canvas shows him painting, surrounded by those who were his defenders at the time: Pierre-Auguste Renoir, Zola, the painter Frédéric Bazille, Claude Monet, Zacharie Astruc. The painting was caricatured in the *Journal amusant* under the title "Jesus Painting Among His Disciples."

On July 19, 1870, the Franco-Prussian War was declared. With the advance of the Prussian troops, Manet's wife left with her mother-in-law and her son for Oloron-Sainte-Marie in the Pyrenees, where friends had offered them hospitality. Manet enlisted as a staff lieutenant in the National Guard, and his superior officer was Jean-Louis-Ernest Meissonier, the painter of musketeers. Beginning on September 26, he corresponded with his wife, the letters being carried by balloon. Provisions were short. "I wish you could see me with my artilleryman's greatcoat," he wrote to his wife on November 19. "At the same time my knapsack is equipped with everything that I need for painting." On December 1 he was present at the battle that took place between Le Bourget and Champigny: "What pandemonium!" he wrote. "Anyway I'm still alive. The shells pass over your head on all sides." But hope was sinking, and the lack of provisions became intolerable. On January 30, 1871, he wrote these despairing words to Suzanne: "It's finished. . . . We cannot hold on any longer. We are dying of hunger. . . . We are all as thin as nails."

In February 1871, Manet rejoined his family at Oloron, returning to Paris shortly before the Commune. His studio in the rue Guyot was half-destroyed, but he had taken care to store his canvases in a safe place, and these he found intact. Paul Durand-Ruel bought almost everything that Manet's studio contained, paying 50,000 francs in the currency of the time. Manet rented lodgings on the ground floor at 51 rue de Saint-Pétersbourg, the same quarter where Léon Koëlla-Leenhoff had a room, and from then on he and his friends met at the Café de la Nouvelle-Athènes, which had replaced the Guerbois. In July of the following year, the artist set up his new studio at 4 rue de Saint-Pétersbourg (today known as rue de Leningrad).

In 1872 he also visited Holland, where he became much influenced by the works of Frans Hals. As a result he painted "Le Bon Bock" (1873; Philadelphia Museum of Art), which achieved considerable success at the Salon exhibition of 1873.

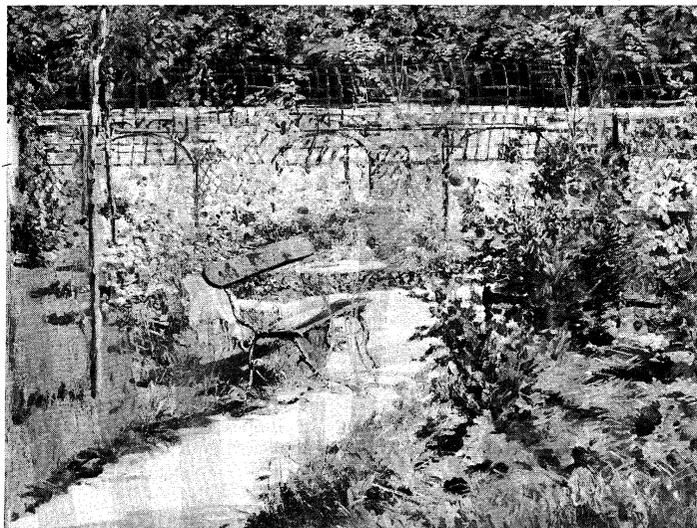

**Later life and works.** In the Batignolles studio-salon of

Nina de Callias, a charming hostess who entertained all of the outstanding artists, writers, and personalities of the bohemian world, Manet made the acquaintance of Charles Cros, a poet and a pioneer of the phonograph and of colour photography. He illustrated Cros's *Le Fleuve* with a series of eight etchings (1874). At Nina de Callias's, he also met the poet Stéphane Mallarmé, whose work he was later to illustrate.

But the year 1874 was chiefly notable for the development of Manet's friendship (the beginning, when they had first met in 1866, had been rather cool) with the young Impressionist painter Claude Monet, with whom he painted on the banks of the Seine. Under the title "Boating," Manet painted his most luminous plein-air picture. He took as a setting Le Petit Gennevilliers, with two figures seated in the sun in a boat. It was also at Argenteuil that Manet painted "Monet Working on His Boat in Argenteuil." Monet is shown painting his wife in an old boat that he had bought secondhand (he was penniless at the time, and Manet was generous in helping him). Yet, although he was friendly with Monet and the other Impressionists, Manet would not participate in their independent exhibitions and continued to submit his paintings to the official Salon.

In 1875 Richard Lesclide published Baudelaire's translation of Edgar Allan Poe's poem "The Raven," with four illustrations by Manet—wash drawings reproduced by lithography. The following year Alphonse Derenne published Mallarmé's poem "L'Après-midi d'un faune" ("Afternoon of a Faun") with five woodcuts after drawings by Manet, who had also painted the poet's portrait. At this time Manet exhibited "The Artist" (1875) and "The Laundress," two works rejected by the Salon, along with other paintings in his studio in the rue de Saint-Pétersbourg. This exhibition at home caused such an uproar with the comings and goings of spectators that the painter's landlord refused to renew his lease. Thus, Manet took possession in April 1879 of his final studio at 77 rue d'Amsterdam.

Private collection; photograph, The Metropolitan Museum of Art, New York

"The Artist's Garden in Versailles," oil painting by Édouard Manet, 1881. In a private collection.

Earlier, in "Nana," he had given the visual version of the harlot theme touched on by Zola in his novel *L'Assommoir*; and he had painted "The Plum," one of his major works, in which a solitary woman rests her elbow on the marble top of a café table. These were followed by "La Blonde aux seins nus," in which the pearl-white flesh tones gleam with light; the "Rue Mosnier, Paris, Decorated with Flags"; and "The Conservatory," the large fresh canvas of which the 19th-century writer Théodore de Banville remarked, "One expects to see them converse, the lady in a gray dress seated on a green bench and the gentleman with the fawn-colored beard." Then came "Chez le Père Lathuille," one of Ma-

Prussian  
War

Late  
pastels

net's chief works, the setting of which is a restaurant near the Café Guerbois in Clichy. It shows a coquette somewhat past her prime having lunch with her young lover.

From then on, Manet did a large number of pastels. In broad, determined strokes he captured the features of George Moore (1879; Metropolitan Museum of Art, New York), an Irish poet who was called "the Englishman of Montmartre" and who often came to join Manet and Degas at the Café de la Nouvelle-Athènes. Manet liked him, according to one critic, "for his bohemian and exotic ways, and the pallid languor of his head with its red hair."

In 1880, Manet had a one-man exhibition at the offices of *La Vie moderne*, a periodical published by Georges Charpentier, who also published Zola and other Naturalist writers. His legs already affected by the malady that was to prove fatal, he went to Bellevue for hydrotherapy. There he met the opera singer Émilie Ambre, who had had great success in the role of Carmen and who had taken with her, on her tour of the United States, Manet's "Execution of the Emperor Maximilian of Mexico," which she showed in New York and Boston.

In 1881 Manet rented a villa at Versailles, and on his return to Paris he painted "Jeanne," or "Spring" (1882; Harry Payne Bingham Collection, New York), the delightful profile posed by the actress Jeanne de Marsy. But the artist's illness was making alarming progress. The following year he went to stay in a villa at Rueil. He took part in an important exhibition of French art that was held in London at Burlington House, and at the Salon showed "A Bar at the Folies-Bergère," his last great composition. As he worked on his painting, Manet was forced to pause and sit down on a divan. "It was then that I saw," said Jeannot, "how much his illness had affected him—he supported himself on a cane and seemed to tremble."

On April 6, 1883, after painting some roses and lilacs brought to him by his former model Méry Laurent, Manet had to take to his bed. Gangrene broke out in his left leg, which was subsequently amputated. He died on April 30 and was buried in the cemetery of Passy.

In January 1884 a posthumous exhibition was held in the Salle de Melpomène of the École des Beaux-Arts. True to his admiration for the artist, Émile Zola wrote the preface to the catalog. It was after this memorial exhibition that his paintings began to gain prominence. In the same year, the price of Manet's pictures began to rise, and his stature in the art world was assured.

#### MAJOR WORKS

"The Absinthe Drinker" (1859; Ny Carlsberg Glyptothek, Copenhagen); "Spanish Singer" (1860; Metropolitan Museum of Art, New York); "La Musique aux Tuileries" (1862; National Gallery, London); "The Street Singer" (1862; Museum of Fine Arts, Boston); "Ballet Espagnol" (1862; Phillips Collection, Washington, D.C.); "Mademoiselle Victorine in the Costume of an Espada" (1862; Metropolitan Museum of Art, New York); "Olympia" (1863; Louvre, Paris); "Le Déjeuner sur l'herbe" (1863; Louvre); "The Races at Longchamp, Paris" (1864; Art Institute of Chicago); "Bullfight" (1866; Art Institute of Chicago); "The Fifer" (1866; Louvre); "The Execution of the Emperor Maximilian of Mexico" (1867; Städtische Kunsthalle, Mannheim); "Mme Édouard Manet au piano" (c. 1867-68; Louvre); "Portrait d'Émile Zola" (1868; Louvre); "The Luncheon" (1868; Neue Staatsgalerie, Munich); "The Balcony" (1869; Louvre); "La Brioche" (1870; David Rockefeller Collection, New York); "Gare Saint-Lazare" (1873; National Gallery of Art, Washington, D.C.); "Boating" (1874; Metropolitan Museum of Art, New York); "Monet Working on His Boat in Argenteuil" (1874; Neue Staatsgalerie, Munich); "The Laundress" (1875; Barnes Foundation, Merion, Pennsylvania); "Nana" (1877; Hamburger Kunsthalle); "The Plum" (1877; Arthur Sachs Collection, New York); "Skating" (1877; Fogg Art Museum, Cambridge, Massachusetts); "La Blonde aux seins nus" ("The Blonde with Bare Breasts"; 1878; Louvre); "Rue Mosnier, Paris, Decorated with Flags" (1878; Paul Mellon Collection, Upperville, Virginia); "The Conservatory" (1879; Nationalgalerie, Berlin); "Chez le Père Lathuille" (1879; Musée des Beaux-Arts, Tournai); "The Waitress" ("La Servante de bocks"; 1879; National Gallery, London); "The Artist's Garden in Versailles" (1881; John Barry Ryan Collection, New York); "A Bar at the Folies-Bergère" (1882; Courtauld Institute Galleries, London).

**BIBLIOGRAPHY.** EMILE ZOLA, "Une Nouvelle Manière de peintre, M. Édouard Manet," *Revue du XIX<sup>e</sup> siècle* (January 1867, reprinted in *Mes Haines*, 1880), an important text, the first to defend and praise Manet's work; EDMOND BAZIRE, *Manet* (1884), a fine analysis (in French) of the painter's work; JACQUES DE BIEZ, *Édouard Manet* (1884), the painter as seen by an informed contemporary (in French); THEODORE DURET, *Histoire d'Édouard Manet et de son oeuvre* (1902), the first attempt to catalog Manet's work; JULIUS MEIER-GRAEFE, *Édouard Manet* (1912), an important view of Manet and his work by the great German critic; ETIENNE MOREAU-NELATON, *Manet raconté par lui-même*, 2 vol. (1926), the first concerted work on Manet, well documented and with much source material; PAUL JAMOT and GEORGES WILDENSTEIN, *Catalogue critique de l'oeuvre de Manet*, 2 vol. (1932),—several works by Manet have been discovered since the publication of this catalog; ALAIN DE LEIRIS, *The Drawings of Édouard Manet* (1969), a scholarly compilation cataloging Manet's watercolours and drawings (good illustrations); ADOLPHE TABARANT, *Manet et ses oeuvres* (1947), the principal source for the study of Manet's life and works; PIERRE COURTHION and PIERRE CAILLER, *Manet raconté par lui-même et par ses amis*, 2 vol. (1953; Eng. trans., *Portrait of Manet by Himself and His Contemporaries*, 1960), a collection of important texts that have appeared on Manet; and PIERRE COURTHION, *Édouard Manet* (Eng. trans. 1962), a study of Manet's work, with unpublished documents on his graphic oeuvre and iconography.

(P.Co.)

## Manichaeism

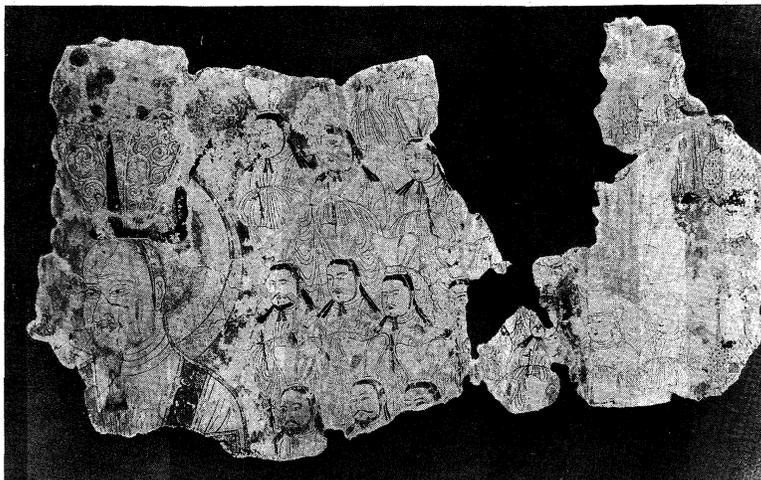

Manichaeism was a dualistic religious movement that arose in the 3rd century AD in Persia. Though for a long time Manichaeism was considered and treated as a Christian heresy, it was a religion in its own right. Because of the coherence of its doctrines and its rigid structure and institutions, it preserved throughout its history a unity and unique character. Moreover, in terms of its growth, but particularly in terms of its purpose and early ambition, Manichaeism should be counted among the universal religions. Indeed, it was a church, and its members referred to themselves as "the Holy Church" as well as "the Holy Religion."

#### HISTORY

**The origin of Manichaeism.** The term Manichaeism comes from the name of its founder, Mani (Manes), who was born April 14, 216, in southern Babylonia (then part of the Iranian Empire, now in Iraq). His family was perhaps related to the Arsacids, at that time the Parthian rulers of the empire. (The Arsacids were overthrown nine years after Mani's birth by Ardashir I, and were superseded by the Sāsānids.) When Mani was four years old, his father, Pātik, who was concerned with religious ideas, sent for him to Mesene (southern Babylonia). Sometime later a mysterious voice in the temple at Ctesiphon ordered Pātik to abstain from wine, meat, and sexual intercourse, and after this experience he joined a sect called the Baptistai ("Baptists") by the Greeks, *al-mugh-tasilah* ("those who cleanse themselves") by Arabic-speaking writers, and *menaqqedē* ("those who are purified") and *hallē hewārē* ("white gowns") by Syriac writers. This sect was identical with the Elkhasaites, a Judaizing Christian sect that followed the teachings of the visionary prophet Elkhasai (Alkhasaios), who flourished about AD 100 "in the land of the Parthians." It was in a community of such Jewish-Christian influences that Mani grew, formed his doctrines, and nourished his vocation during 21 years (from AD 219/220 to 240). Apparently through this experience, Christianity—or at least a sectarian picture of Christ and the gospel teaching—had a decisive influence on him and on the elaboration of his future message. Moreover, Mani incorporated many ideas borrowed from Elkhasai.

Although for a long while he demonstrated to the members of this Judaizing-Christian sect an apparent docility and fidelity, he came to disagree with them and to criticize two of their principal practices: the use of daily and frequently repeated ablutions and the prohibition against bread, fruits, and vegetables that were grown elsewhere and were of profane origin. Relations between him and the group deteriorated. The break, according to tradition,

The life  
of Mani

Fragment of wall painting depicting (left) presumably Mani, followed by members of the elect, accompanied by hearers (far right), from K'o-cha, China, 8th-9th century. In the Museum für Indische Kunst, West Berlin.

By courtesy of the Staatliche Museen zu Berlin

began to develop and then was intensified by two events. At the age of 12 (on April 7, AD 228), Mani had received an order from the angel at-Tawm ("the Twin," or "the Partner"—*i.e.*, his heavenly alter ego) to abandon the community but to delay his departure until he was older. When he was 24 years old (on April 19, AD 240), he was told to manifest himself publicly from then on and to proclaim his doctrine to all. The second of these two "annunciations" marked the solemn beginning of the new religion: Mani, in whom the Holy Spirit and all knowledge were thought to have been made incarnate at that time, was confirmed in his character and vocation as the "Apostle of Light" and supreme "Illuminator" (occasionally as the "Paraclete") sent by God. His attempt to begin his work with the conversion of those nearest to him, however, was not successful. He withdrew from the religious sect, accompanied by his father and only two other believers. In his eyes, the religion of the Baptistai would henceforth be a false religion instigated by the "Spirit of Error."

Mani went first to Ctesiphon and then to the northwestern part of the Indian peninsula (present-day Baluchistan). Two years later (probably in the spring of 242), Mani returned to Persia, where an interview was arranged with the new Sāsānid king, Shāpūr I. The results of the meeting were favourable; Mani was given permission to preach his new religion freely in the empire and would have the protection of local authorities. Moreover, it seems that the King was more or less attracted to the doctrine of Mani or at least was favourably disposed toward it. During the King's reign, Mani intensified his efforts at propaganda. He preached everywhere in the empire and, at the same time, organized numerous missions to foreign lands.

After the death of Shāpūr and the short reign of his son and successor Hormizd I, the situation changed completely. Vahrām I, the younger son of Shāpūr, succeeded to the throne and yielded to the increasing influence of the representatives (the Magi) of the official orthodox Sāsānid religion—a form of Zoroastrianism—who were intolerant of heresies and foreign cults. A final journey of Mani was shortened; an unexpected obstacle—without doubt an order of the police—forced Mani to return to the city of Gondēshāpūr (Bēlapat), where he arrived on a Sunday and almost immediately appeared before Vahrām himself. Mani was condemned and thrown into prison. Beginning on a Wednesday, there were 26 days of dramatic trials making up the "Passion of the Illuminator" or—to use the term used by the Manichaeans to describe this period—Mani's "crucifixion." Cruelly chained and gradually weakening, Mani did have the strength to address a final message to his church, which he committed to several disciples who were attending to him; he then died on a Monday.

It is difficult to determine exactly the dates of these last

events. There are some data available, but their interpretation is a difficult task; thus the "crucifixion" has been variously placed by scholars as between February 14 and March 2, 274; between January 19 and February 14, 276; or between January 31 and February 26, 277.

**The development of Manichaeism.** Mani viewed himself as the final successor of a long line of heavenly messengers or prophets sent to mankind, one after the other, and of whom, starting with Adam, the principal ones were Zoroaster, Buddha, and Jesus. The essential message of all earlier revelations—which had been restricted because they were local and which had been distorted by their disciples—was to be found in him and he could provide the key to their meaning. But beyond this, Mani felt that his message had universal meaning and value and was destined to supplant all others before the end of time. The Manichaean Church was thus dedicated from the beginning to a missionary ideal and work. Its permanent duty was to preach and convert the universe. Although it did not fulfill the grandiose plans laid out for the church, the religion of Mani did make its conquests and from the 3rd to the 15th centuries maintained or created its echoes over a large portion of the globe, from the European shores of the Atlantic to the Asian shores of the Pacific.

The beginning of this vast missionary movement goes back to the very origins of Manichaeism. From 240 on, Mani travelled extensively and established his religion at many places in the Sāsānian Empire and even converted a local ruler on his trip to India. The existence of missions organized by him during his lifetime is attested to in various reliable documents: the mission of Addā and Pāteg to Egypt, between 244 and 261, the mission of the same Addā and of 'Abzākhyā in the province of Kirkūk (northeastern Iraq), in 261/262, and, finally, the mission of Mār 'Ammo to Abharshahr and Marv in Khorāsān.

**Expansion to the West.** The principal effort of the young church in its endeavour to extend beyond the frontiers of the Iranian Empire seems to have been directed at first toward the West, toward the Roman Empire, where it could expect to find easier access in a Christian milieu. Manichaeism rapidly infiltrated the Roman part of Mesopotamia, then made headway in Syria, northern Arabia, and Egypt. In the middle of the 3rd century, missionaries established a centre at Hypsele (near modern Asyūt, Egypt); they made conversions all the way to Alexandria. Their success in the Nile Valley was so great that it soon provoked strong reaction from ecclesiastical authorities, from the philosophers, and even from the Roman emperor Diocletian.

From Egypt the Manichaean religion spread across North Africa where, possibly, it had already been introduced by one of Mani's disciples. The acceptance of Manichaeism by St. Augustine and his later polemic with it

Africa

(from 373 to 382) point to the importance Manichaeism had at the end of the 4th century in this area, especially at Carthage. Even though it was to retreat just about everywhere else in the West, Manichaeism remained strong in North Africa for many centuries, perhaps in a modified and more Christianized form. The religion reached Rome during the time of Pope Miltiades (311–314), and an inscription at Salonae (near modern Split, Yugoslavia) dedicated to a “Manichaean virgin” shows that, from the beginning of the 4th century, Dalmatia had also been the object of missionary efforts. It was certainly by way of Italy that Manichaeism reached the southern part of Gaul. From there, or by way of North Africa, it passed into the Spanish peninsula.

It is rather difficult to follow the stages of the propagation of Manichaeism in the West through the vast literature of the controversialists, the multiple imperial edicts of proscription, the rare concrete details furnished by the chronicles, the biographies, and the letters of this or that bishop. Nevertheless, it is certain that the 4th century marked the apogee of Manichaeism’s expansion in the Roman Empire; the fact that it was everywhere attacked and harassed indicates that it was present everywhere in a formidable manner. The decline, however, was to come quickly. Persecuted by the church and by the state, the object of repressive laws continually reinvoked and intensified, the Manichaean “heresy” seems to have disappeared almost entirely from western Europe toward the end of the 5th century and, in the course of the following century, from the eastern portion of the empire.

*Development in Iran and the East.* During the lifetime of Mani, the Manichaean religion had spread to the eastern provinces of the Iranian Empire. It seems, however, that prior to the fall of the Sāsānian Empire in 651, the missions had not crossed to the north of the Oxus River (Amu Darya) nor gone beyond the Pamir Mountains. Khorāsān provided a solid outpost; and it was there that, probably toward the end of the 5th century, the rigorous party of the *dēnāvārs* was formed. Their puritanism for a long time provoked a schism with the mother church in Babylonia, but the work of converting Central Asia and China was reserved to them.

Inside Iran itself, Manichaeism managed to maintain itself, if not to develop, during the reign of the Sāsānids, despite persecutions of which it was the object. The Arab conquest in the 7th century was not a fatal blow but, in fact, stimulated a temporary renewal of Manichaeism in Babylonia and encouraged the return of several groups that had fled to Iraq and the neighbouring regions. This period saw much literary activity and even dissensions that agitated and divided the mother church. This ferment indicates that the 8th century was a flourishing period for the Manichaeans of Mesopotamia, probably the result of the generally tolerant regime of the caliphate of the Umayyads. The arrival of the ‘Abbāsids in 775 brought a sudden change of attitude, and bloody persecutions were begun again. In the 10th century the Manichaeans were forced to seek refuge in Khorāsān, and the seat of the Manichaean leader was transferred from Babylon to Samarkand Province (now in Uzbek S.S.R.).

In the final third of the 7th century, however, a new outlet for the expansion of the Manichaean Church had opened up in the Far East. According to a fragment of a text from Central Asia, Manichaeism made its appearance in China in 675. The conquest of eastern Turkistan by the Chinese and the re-establishment of the great caravan routes corresponded with the arrival for the first time of a Manichaean missionary in China in 694. In 731 a *fou-to-tan* (Chinese: a Manichaean “bishop”), following the orders of the Emperor, composed a catechism of the religion. It was a kind of compendium intended to inform the authorities about the doctrines, scriptures, and the discipline of the sect; it also was intended to encourage official acceptance through a skillful mixture of Taoism, Buddhism, and authentic Manichaeism. In the following year (732), an edict accorded freedom of worship to the religion, and it enjoyed extraordinary success from that point. Beginning in 745, the Uighur, a Turkic people of western China, established an immense kingdom that was

centred in northern Mongolia and extended from the Ili River in the west to the Huang Ho in the east. One of their khans, or kings, was converted in 762 and Manichaeism became the official religion of the Uighur state. According to one recent hypothesis, the religion even pushed at an undetermined date into Siberia.

But the triumph in the East was also to be rather brief. The destruction of the Uighur kingdom by the Kirghiz Turks in 840 drastically changed the situation. Weakened and dispersed, the Manichaeans survived in some of the Uighur principalities formed toward the middle of the 9th century. It is likely that Manichaeism survived in East Turkistan until the beginning of the 13th century, when the Mongol invasion led by Genghis Khan delivered the fatal blow. In China, following the downfall of Uighur power, it was forbidden in 843 and was persecuted, but some vitality remained until the 14th century, and perhaps later (especially at Fukien and Formosa).

*Medieval offshoots of Manichaeism.* Manichaeism survived by means of sects that developed more or less directly from the original tradition; many historians have called these sects “neo-Manichaean.” Nevertheless, though the relationship of some of these sects to one another seems certain, the link of each particular sect, or its ancestor, to the authentic religion of Mani either has been or may still be cast in doubt. The fact that in their own times they were considered as “Manichaean” does not constitute a valid proof that they were, for the word was frequently applied to every movement suspected of being heterodox in both the Byzantine world and the medieval West, and even in the Islāmic world.

It is likely that three sects that appeared successively—the Paulicians, the Bogomils, and the Cathari—comprised links in the same chain. The Paulicians seem to have had their origin in Armenia in the 7th century, and they spread throughout the eastern section of the Byzantine Empire where they proved for a long time to be a formidable challenge to the religious orthodoxy in the empire and also a menace in the military and political spheres. In the eyes of Christians and contemporary witnesses, Paulicianism appeared as a resurgence of Manichaeism, but its assimilation to Manichaeism was not justified by the facts.

Paulician missionaries to Bulgaria seem to have contributed to the rise—in the first third of the 10th century—of the Bogomil movement. Bogomilism, an ascetic and revolutionary movement in revolt against the Byzantine orthodoxy, spread in the Balkan Peninsula, particularly in western Macedonia, Bosnia, and Slavonia. It reached Constantinople (modern Istanbul), was found on the coasts of Asia Minor, and then penetrated Russia, where it inspired mystical beliefs and strange rites.

Although the problem of the origin of the Cathari is far from having a definitive solution, it is no longer possible to doubt the role played by Bogomilism in the development of Catharism in the European West. According to the *Tractatus de hereticis* (“Treatise on Heretics”), written between 1260 and 1270, some French crusaders made contact in Constantinople, in 1147, with a local sect started by some of the Greek merchants of that city who had travelled to Bulgaria and had been won over to the Bogomil heresy. The French converts to the doctrine developed a separate community and, in 1149, brought the doctrine to their own land. The Cathari were commonly referred to as Albigensians after the city of Albi, one of their strongholds in Languedoc Province of southern France. A crusade undertaken against the heresy in 1209 crushed it almost definitively in 1244. Catharism lasted in Languedoc until the first half of the 14th century and continued with somewhat more vigour in Italy to the 15th century.

#### BELIEFS, PRACTICES, AND INSTITUTIONS

**Doctrines and mythology.** Mani intended to found a truly “ecumenical” religion, embracing all men, that could be substituted for its antecedents by integrating into it the partial truths contained in their teachings, particularly those to be found in the messages of Zoroaster, Buddha, and Jesus. This would appear to reduce the Manichaean doctrine to a simple combination of pieces

Relation-  
ship to  
Gnosticism

joined together in a more or less coherent fashion. Although there is no doubt that in composing his writings and elaborating his doctrine he drew from a variety of sources, to make the totality of his teaching into a kind of mosaic would risk missing the originality of the system and the initial insight that gave it birth. What Mani conceived and intended to promote was, in effect, a truth that was capable of being equally translated into diverse formulas according to the different circumstances where it was to be spread. The Indian, Iranian, or Christian elements, which, with varying degrees, are revealed in Manichaean documents, appear for the most part to be less the original components of the system and more the final or outer cover that resulted from a conscious and willful effort at adaptation. In reality, Manichaeism was a particularly interesting variety of Gnosticism, a dualistic religion that postulated salvation through a special knowledge of spiritual truth.

It is not difficult to establish that Manichaeism had certain historical contacts with Gnosticism. The "Baptist" sect in which Mani lived during his formative years could not help but imbue the thought of the adolescent with Gnostic influences. It is certain that Mani was influenced by the doctrines of Marcion and Bardesanes—Christian heretics of the 2nd century who taught forms of Gnosticism. More generally, the church of Mani borrowed a good part of the apocryphal literature of Gnostic sects. When the contents of the vast number of Gnostic writings discovered about 1945 in Upper Egypt (the Naj 'Hamādī codices) are better known, the relationship between Manichaeism and Gnosticism undoubtedly will appear still stronger and clearer.

Like every form of Gnosticism, Manichaeism arose out of the anguish inherent in the human condition. The situation into which man is thrown proves to him to be alien, unbearable, and radically evil. He feels enslaved to his body, to time, and to the world; he feels entangled in evil, constantly threatened and defiled by it; and he desires to be delivered from it. But if he is capable of experiencing this need for deliverance, it is because he is essentially superior to his present condition and a foreigner to the experience of his body, of time, and of the world. His present condition seems to be some kind of fall. Moreover, as he gets to know himself as essentially a stranger in the world, he learns that God himself can also only be a stranger in it. God who is nothing other than goodness and truth can not have willed this suffering and deceit. Thus, it is necessary to attribute this responsibility to a principle that is evil and opposed to God.

As in every form of Gnosticism, this knowledge of oneself and of God also contains the certitude of salvation. To know oneself is, in effect, to know oneself again, to recover one's true self, which was previously clouded by ignorance and lack of self-consciousness because of its mingling with the body and with Matter. In Manichaeism this recognition means that one sees himself as a particle of the Light, as coming from the transcendent world, and as one who, despite his abject present condition, does not cease to remain united to that superior world by eternal and immanent bonds with it. This is an essential point. Souls share in the very nature of God; souls are nothing other than a part of God that has fallen here below. Man is thus assured that God will not lose interest in the salvation of his own members; he is assured that God will recover those members and reintegrate them into himself. Through man, God saves himself: he is both the Saviour and the one who has been saved; he is the "saved-saviour." Men, too, are "saved-saviours." The element to be saved is man's soul; the saving element is the spirit or intelligence (in Greek, the *nous*).

The interior illumination, or gnosis, that communicates to man his newly found *nous* and the manifestation that the prophets make known to him are expressed in the form of a science capable not only of explaining to man his present condition but also of linking him to an original situation prior to the fall of his soul and to a future situation that will consist in the abolition of evil and the restoration of man's primordial condition. In other words, this gnosis will make man know where he is and

what he is, where he comes from, why he has fallen, and where he is going. But inasmuch as man shares the divine nature because of his spiritual side and is one with the world because of his body, this knowledge of his nature and of his destiny implies necessarily an encyclopaedic knowledge of the nature and destinies of God and of the universe.

This gnosis is expressed in a mythical form. It is presented in the form of a complicated construction that Mani himself filled with various episodes, numerous characters, and minute details and arranged according to symmetric patterns joining all the elements in relationships that are more or less artificial. But throughout the Manichaean mythology, there is only one hero and one situation that is constantly repeated: the soul fallen into Matter and then liberated by its *nous*. The unfolding of the myth is divided into three phases: a past period or moment in which there was a separation and thus a perfect duality of the two radically separate substances—Spirit and Matter, Good and Evil, Light and Darkness; a middle moment corresponding to the present during which a mixture of the two substances begins and continues; a later moment in the future, in which the primordial division will be re-established. To accept Manichaeism is nothing more than to profess this double doctrine of "the two principles" and "the three moments."

In the beginning, then, there were two antagonistic substances, the one absolutely good, the other radically evil—Light and Darkness. Both were uncreated, eternal, and equal, each one living in a separate region: the kingdom of God in the north, the east, and the west; the kingdom of Evil in the south. The kingdom of God had at its head the Father of Greatness; the kingdom of Evil, the Prince of Darkness. The former consisted of five "dwellings" or members of God (understanding, reason, thought, reflection, will) and was inhabited by innumerable "aeons." The latter consisted of five "pits," one on top of the other (the world of smoke, consuming fire, destructive wind, slime, and darkness), over which presided five chiefs, or "Archons," in monstrous demonic forms and where five different types of infernal creatures swarmed about. Here, all was disorder, stupidity, abomination, and stench, whereas the kingdom of God was characterized by peace, understanding, purity, and sweetness.

The middle moment opened with catastrophe. Darkness attempted to invade the kingdom of Light. God decided to combat the danger by means of his own soul personified in his own son whom he "evoked" from himself through the mediation of the Mother of Life; the son was the Primal Man. With his five sons (the five Light elements: air, wind, light, water, and fire) as his armour, the Primal Man went down to the infernal abyss, and his sons were devoured and swallowed up by the demons. Thus, one portion of the substance of Light was mixed with and enslaved to the substance of Matter. From that point on, God would devote himself to separating and freeing the divine substance.

It was first necessary to effect the salvation of the Primal Man himself. To accomplish this, the Father of Greatness proceeded to the second creation, which involved the successive evocations of the Friend of Lights, the Great Architect, and the Living Spirit. Accompanied by his five sons (the Ornament of Splendour, the King of Honour, Adamas of Light, the King of Glory, Atlas), the Living Spirit made his way to the frontier of the region of Darkness and made a piercing cry, which found an echo in the ardent, confident response of fallen Man. The call and the response became two divine hypostases, or persons. The Living Spirit descended again, this time to the very interior of the Darkness. He held out his right hand to the Primal Man, who grabbed it (this handclasp was to become a ritual and symbolic gesture in the Manichaean Church) and then the Living Spirit lifted the captive out of the Darkness. The Primal Man regained the paradise of Light, his heavenly country; the first to have fallen, he was thus the first to have been saved, the model of man's abasement but also of his salvation.

He did, however, leave behind his soul in the Darkness. To save it, God organized the visible world. The principal

Mani-  
chaeian  
mythology

The  
salvation  
of the  
divine  
substance

worker in this enterprise was again the Living Spirit. With the assistance of his five sons, he punished the demonic Archons, making the heavens from their excoriated skin, the mountains from their bones, the earth from their flesh and their excrement, and constructed a universe made of ten firmaments and eight earths. He divided the substance of Light mixed with Matter into three portions: the part that had undergone no contact formed the sun and the moon; the part affected only slightly by the combination gave birth to the stars; the rest comprised a third mass whose liberation required more skill and time.

This was the work particularly of entities derived from a third creation, principally the Third Messenger. The Third Messenger saved the world to the extent that he was able to organize a machine to draw up, refine, and sublimate the Light buried in the Darkness. The cosmic machine consisted of the "wheels" of wind, water, fire, especially the sun and the moon. During the first 15 days of the month, the liberated substance—all those particles of Light that are souls—rose in a "Column of Glory" up to the moon, which, inflated by this force, became the full moon. During the final half of the month, the force was transferred from the moon to the sun, from which it was taken to the New Paradise. But the Third Messenger also set into motion less mechanical means of liberation. He appeared nude in the sun—in feminine form to the male Archons, in masculine form to the female demons. In this way he was able to provoke the lust of the former and make them ejaculate, and with their semen there fell to the earth the Light they had swallowed up. The seed that fell into water became a sea monster that Adamas of Light ran through with a sword; the seed that fell on land became five trees from which all vegetation sprouted. The female devils miscarried and their aborted children fell to the earth, and devoured the buds of the trees, thereby assimilating the semen and the discharged Light, and then propagated more demons. The part of the substance of Light that was not yet saved was thus gathered together on the earth but scattered and imprisoned in the plants and the bodies of demons.

To defeat the process of redemption, Matter prompted the two demons Ashaqlin and Namraël to devour all the offspring of the abortions. Having thus increased the Light in their own bodies, the pair had intercourse and gave birth to Adam and Eve. Adam was delivered from the consciousness of the animal state to which he had at first been destined by a saviour, Jesus the Splendour, who awakened him to consciousness, opened his eyes, and made him aware of the divine origin of his soul. This episode, parallel to that of the salvation of the Primal Man, was conceived of as a typical example of the salvation obtained by gnosis. Unfortunately, the lineage of Adam has continued a pattern of copulation and procreation in accordance with the scheme of Matter. With the exception of those who practice an absolute continence, the shameful and painful successive imprisonment in bodily darkness that has been forced upon the luminous souls will cease only at the end of time, at the eve of the third movement of the myth. Then, after a period of apocalyptic calamities and a final judgment, the terrestrial globe will burn for 1,468 years; the last particles of Light that can still be saved will rise to the sky; the visible world will be annihilated, and Matter, with its demons, will be imprisoned in an immense pit. The absolute separation of Light and Darkness will be definitively re-established.

The result of this cosmogony is that man shares in the divine nature in virtue of his *nous*, his living self-consciousness. Salvation consists in his regaining consciousness of himself and of his relationship with God. This is accomplished by gnosis and in a particular manner by the revelation of Mani and his church. At death, man will return to the original paradise of Light. But if he persists in keeping his soul in the impurity of the flesh and in slavery to material lusting, he will condemn himself to rebirth in a succession of bodies: thus, no fornication, no procreation, no possessions, no cultivating or harvesting, no killing, no eating of meat or drinking of wine, for

these are contaminations of self, defilements of the imprisoned Light.

**The Manichaean community.** Realizing that such strict prescriptions could not be observed to the same degree by all, Manichaeism insisted on their fulfillment only by the best of the faithful. The community was divided into the elect, who felt able to embrace a rigorous rule, and the hearers, who supported the elect by works and alms. The elect could expect to attain paradise at death; the hearers (with rare exceptions) could hope for salvation only after a period of reincarnation.

Although all members were thought to be an integral part of the same brotherhood, the community had a hierarchical structure. At the head of the community was its leader, Mani's successor. Under him there were five grades: 12 teachers, 72 bishops, 360 priests, the general body of the elect, and the hearers. The elect were "sealed" with the three seals of mouth and hands and breast. They were bound to chastity, poverty, and abstinence from meat and wine. All ownership, all wealth, and every occupation were condemned. They were allowed one meal of vegetables a day and one piece of new clothing a year. Because they could not harm the Light particles by plowing or reaping, kneading or baking, their meals were prepared by hearers. They had the obligation to continue living in the world but to preach the good doctrine and to carry on in strength in the battle against Evil. The chief religious duty of the hearers was to care for the elect. They were enjoined to conform to a code of ten commandments and they also took full part in the religious observances. But they lived in the world and were allowed to own, build, plant and harvest, marry or live with a mistress, have children, drink wine, and eat meat.

Critics have been inclined to accuse Manichaeans of a hostility toward the exterior forms of worship and to minimize the importance that the community attached to its ritual practices. It is true that criticisms of such forms of piety and worship can be found in Manichaean literature, but such views are rare. The Manichaean Church was essentially and organically endowed with a liturgy and must have attempted to integrate and retain members through regular communal practices. When and where the political circumstances were favourable, the Manichaeans never failed to acquire and use sanctuaries and also monasteries. Furthermore—although this statement goes contrary to the traditional opinion—the Manichaeans did not repudiate images but rather attached a sacred character to them and even had a cult of the pictures representing their Master.

Music, too, was held in high esteem and played an important role in both the liturgical services and in the religious life of the faithful; they frequently sang hymns. Music was thought to have come from the kingdom of Light and was regarded as having a purgative and liberating character by which it could cooperate in the detachment of the soul from the dimness of the body and of Matter and could contribute to its elevation.

The Manichaeans had many religious practices, but it is difficult to determine their number, their nature, and their importance. The difficulty arises because the documents are limited in number and are incomplete and unclear in their coverage. It can be said—despite the contrary opinion of some specialists—that the Manichaeans did not practice a Baptism administered with water, as in Christian practice. Their liturgy did make use of ablutions, but this use was never equated with a baptismal rite. There is greater evidence for the existence of a "baptism of oil," that is, a Baptism using oil, or chrism, in the form of an anointing. Furthermore, although the elect did celebrate a meal that involved ritual functions, strictly speaking, it was not a Eucharist in the Christian sense.

The most fundamental Manichaean rites were prayer, almsgiving, and fasting. For each of the faithful, prayer was an obligatory act that was strictly and expressly regulated. The elect were required to pray seven times daily; the hearers had four periods of prayer (at noon, in the afternoon, at sunset, and three hours after nightfall). Prayers, with prostrations, were uttered facing the sun or moon insofar as these were viewed as stages along the

The elect and the hearers

The birth of Adam and Eve

Fasting  
and  
confession

soul's journey toward God. Almsgiving involved principally the hearers, and the term was applied particularly to the gift of food that was brought to the elect and whose delivery, reception, and eating was regulated by a ritual.

Fasting was enjoined on the hearers each Sunday, on the elect each Sunday and Monday. There was a second category of fasts that lasted longer and took place only during parts of certain months—the times being calculated from solar, lunar, and zodiacal data. The first three of these fasts were each of two days' duration; the fourth fast lasted 30 days but was broken each evening at sunset. The fourth fast preceded the feast of *bēma*, the most important feast of the Manichaean year, which occurred sometime in March. The fast and feast commemorated the "Passion" of Mani and his "Ascension" to paradise. Five sets of two-day fasts called *yimki* were mentioned in fragments of Manichaean calendars written in Sogdian, an Iranian language. They seem to correspond to the four great fasts just mentioned, with the final two fasts occurring at the beginning and within the period of the 30 days in which the "Passion" was commemorated. For the hearer, the Sunday fast involved abstinence from sexual relations with one's wife, from any food comprising meat or fish, and from all material work, whether at home, in the fields, or in one's trade. For the elect, for whom strict abstinence was always the rule, the Monday fast must have meant a reinforcement of the usual observances and was an integral part of the ritual for that day.

Fasting was closely connected with another of the Manichaean rites: confession of sins. One of the purposes of the weekly fast was to prepare for the ordinary confession that hearers and elect were required to make each Monday. The hearers confessed to the elect, and the elect to one another. Likewise, once a year, the great fast of 30 days was intended to prepare members of both groups for the general communal confession that constituted one of the essential acts of the celebration of *bēma*. This confession was addressed to Mani himself. Because this event took place near the end of the year, it served to wash away the filth of the year that had passed in order that the church, purified and renewed, could begin the new year with the confidence of rediscovered innocence. The Manichaean confession poses difficult questions. There is no doubt that once they acknowledged their faults the penitents asked pardon, or absolution, for them, but it is difficult to specify in what form this pardon was granted and how the Manichaeans viewed the efficacy of the rite.

The Manichaean Church also included an elaborate initiation rite involving a group of five ritual actions—called "signs" or "mysteries"—that was used to authenticate the integration of a neophyte into the community, or the admission of a hearer into the order of the elect or any promotion to a higher grade. The imposition of hands was the most important of these actions.

**The Manichaean scriptures.** Mani believed that the decadence of earlier religions was caused by the fact that their founders had not written down their revelations; they had communicated these revelations only orally. Their teaching was codified only after their death; moreover, that task was undertaken by followers who had retained only a part of the revelations or who had understood it imperfectly. Thus, the scriptures that were passed on gave rise to diverse interpretations, quarrels, competition, and heresies; in brief, they caused divisions in the religion and weakened it. In an attempt to prevent such an occurrence in his church and to assure the doctrinal unity of the message it was charged to spread, Mani took it upon himself to write down his revelation with his own hand and in his own lifetime to give canonical status to the writings in which that revelation was expressed. Scribes were to copy the scriptures without alteration, and apologists were to hand them on in their literal form, for—it was thought—they contained clearly and completely the body of knowledge revealed by Mani.

On the basis of comparative data provided particularly by Coptic documents found at al-Fayyūm in Middle Egypt and by documents found in Turfan (Chinese Turkistan)—including a version of the catechism prepared for the Chinese Emperor in 731, found in the caves of Tun-

huang—it has been determined that the Manichaean canon included seven works attributed to Mani, and written originally in Syriac, one of the eastern Aramaic languages: the "Living (or Great) Gospel"; the "Treasure of Life"; the "Book of Secrets"; the "Pragmateia," or "Treatise"; the "Book of Giants"; the "Epistles"; and the "Book of Psalms and Prayers."

The Chinese catechism added a book called *Ta-men-ho-yi* (The Drawing of the Two Great Principles); possibly it corresponds to Mani's work that elsewhere was called *Ardhang* ("Image"), an album of paintings and images that was intended to illustrate the key points of the doctrine for the benefit of those who could not read. Manichaeans also included among their sacred writings the *Shābuhragān*, written by Mani in Middle Persian and dedicated to Shāpūr I. The largest of the works dug up at al-Fayyūm, the *Kephalaia* ("The Principal Points of the Teaching of the Master"), was sometimes included in canons and appeared to record meetings of Mani with his disciples. It was, however, the work of a follower and is not wholly a faithful recording of the actual teaching of Mani.

In the Middle Ages, Manichaeism became extinct and the scriptures disappeared. The 20th century led to a partial recovery of them, mainly in Chinese Turkistan and Egypt. They include some sheets from the *Shābuhragān* in the original Middle Persian in addition to a large portion of secondary religious literature. A Latin text was discovered in a cave near Tébessa, Algeria, that concerns the elect and hearers. The various finds show that the doctrinal unity of Manichaeism was preserved despite its wide areal extent.

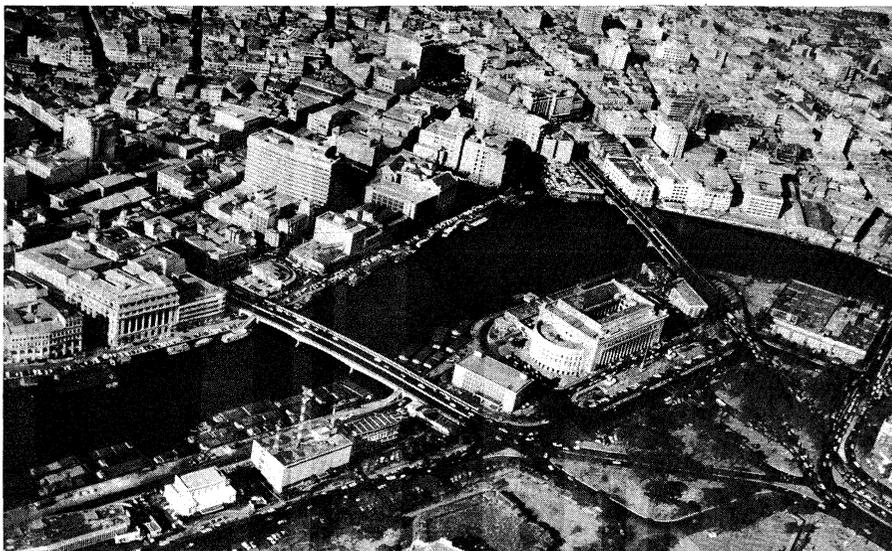

**BIBLIOGRAPHY.** A bibliography, still incomplete, is in L.J.R. ORT, *Mani: A Religio-Historical Description of His Personality*, pp. 261–277 (1967). The work of P. ALFARIC, *Les Écritures manichéennes* (1918), though old, remains a most valuable bibliography, but it needs to be revised and augmented. An excellent selection of Manichaean texts or texts relating to Manichaeism is in A. ADAM (ed. and trans.), *Texte zum Manichäismus* (1954). An index of the fragments of Manichaean writings discovered in Central Asia, is in E.M. BOYCE, *A Catalogue of the Iranian Manuscripts in Manichaean Script in the German Turfan Collection* (1960). Manichaean Coptic works published or in the course of publication are: *Homilien* (1934), *Kephalaia* (since 1935), and *A Manichaean Psalm-Book*, part 2 (1939). Documentation on Manichaean iconography is collected in A. VON LE COQ, *Die manichäischen Miniaturen* (1923). General studies or comprehensive expositions of Manichaeism include: F.C. BAUR, *Das manichäische Religionssystem nach den Quellen neu untersucht und entwickelt* (1831, reprinted 1928), based above all on the testimony of St. Augustine, a classic that preserves its high value; F.C. BURKITT, *The Religion of the Manichees* (1925); H.H. SCHAEFER, *Urform und Fortbildungen des manichäischen Systems* (1927), an outstanding and epoch-making essay, with an integral and coherent interpretation of Manichaeism in all the totality and diversity of its expressions; H.J. POLOTSKY, *Abriss des manichäischen Systems* (1934), a comprehensive work; H.C. PUECH, "Der Begriff der Erlösung im Manichäismus," in *Eranos-Jahrbuch 1936*, pp. 183–286 (1937); trans. as "The Concept of Redemption in Manichaeism," in *The Mystic Vision*, "Bollingen Series," 1969; *Le Manichéisme: son fondateur, sa doctrine* (1949), copious notes and numerous references; "Le Manichéisme," in *Histoire des Religions*, vol. 2, pp. 523–645 (1972); G. WIDENGREN, *Mani und der Manichäismus* (1961; Eng. trans., *Mani and Manichaeism*, 1965); and O. KLIMA, *Manis Zeit und Leben* (1962).

himself

## Manila

Manila, the major city of the Republic of the Philippines, is the country's economic and cultural centre as well as its de facto national capital. Located on Luzon Island, it spreads along the eastern shore of Manila Bay at the mouth of the Pasig River and is the country's most important port. Its name is derived from the flowering *nilad* plant, a flowering shrub adapted to marshy conditions, which once grew profusely along the banks of the river. Originally called *Maynilad*, the name was shortened first to *Maynila* and then to *Manila*. The city proper covers an area of approximately 15 square miles

Downtown Manila bisected by the Pasig River. The city's post office is in the foreground.  
Georg Gerster—Rapho Guillumette

(39 square kilometres) and houses a population of about 1,331,000. The greater metropolitan region—including the surrounding suburbs—has an area of 146 square miles (378 square kilometres) and a population of about 3,000,000.

Manila has been the country's principal city for four centuries and is the contemporary focus of its industrial development, as well as the international port of entry. Situated on one of the finest sheltered harbours of the Far East, it is only 600 miles east of Hong Kong. It has experienced rapid economic development since its destruction in World War II and its subsequent rebuilding; today it is plagued with such urban problems as pollution, traffic congestion, and overpopulation. Attempts are being made to ameliorate these problems, however, and Manila possesses some of the finest health facilities in the Orient.

**History.** In the early 16th century, Manila was a walled Muslim settlement whose ruler levied customs duties on all commerce that passed up the Pasig River. Spanish conquistadores under the leadership of Miguel López de Legaspi—first Spanish governor general of the Philippines—entered the mouth of the river in 1571. They destroyed the settlement and founded the fortress city of Intramuros (“Walled City”) in its place. Outside the city walls stood some scattered villages, each of which was ruled by a local chieftain; each of these villages was centred on a marketplace. As Spanish colonial rule became established, churches were built near the marketplaces, where the concentration of population was greatest. Manila spread beyond its walls, expanding north, east, and south, linking together the market-church complexes as it did so. These early villages now form the present districts of the city.

The propagation of Catholicism began with the Augustinian friar Andrés de Urdaneta, who accompanied the expedition of 1571. He was followed by Franciscan, Dominican, Jesuit, and other Augustinian priests, who founded churches, convents, and schools. In 1574 Manila was baptized under the authorization of Spain and the Vatican as the “Distinguished and Ever Loyal City” and became the centre of Catholicism as well as the centre of the Philippines. At various periods Manila was seriously threatened, and sometimes occupied, by foreign powers. It was invaded by the Chinese in 1574, raided by the Dutch in the mid-17th century. In the 18th century the city was captured and held by the British from 1762 to 1764 during the Seven Years' War. The Treaty of Paris (1763) resulted in the restoration of the city to Spain. It was opened to foreign trade in 1832. Commerce was further stimulated by the opening of the Suez Canal of 1869.

During the Spanish-American War in 1898, the Spanish

fleet was defeated at Manila Bay, after which the city surrendered to United States forces. It subsequently became the headquarters for the United States administration of the Philippines. Upon the outbreak of World War II, Manila was declared an open city and was occupied by the Japanese in January 1942. The city suffered little damage during the Japanese invasion but was levelled to the ground when it was recaptured by American forces in 1945. Rebuilt with aid from the United States, Manila was the capital of the Philippines from 1946 until 1948, when Quezon City, a suburban town northeast of Manila, was chosen as the site of the new national capital. The city remained the location of most of the government offices, however, and continues to be the Philippines' principal metropolitan area.

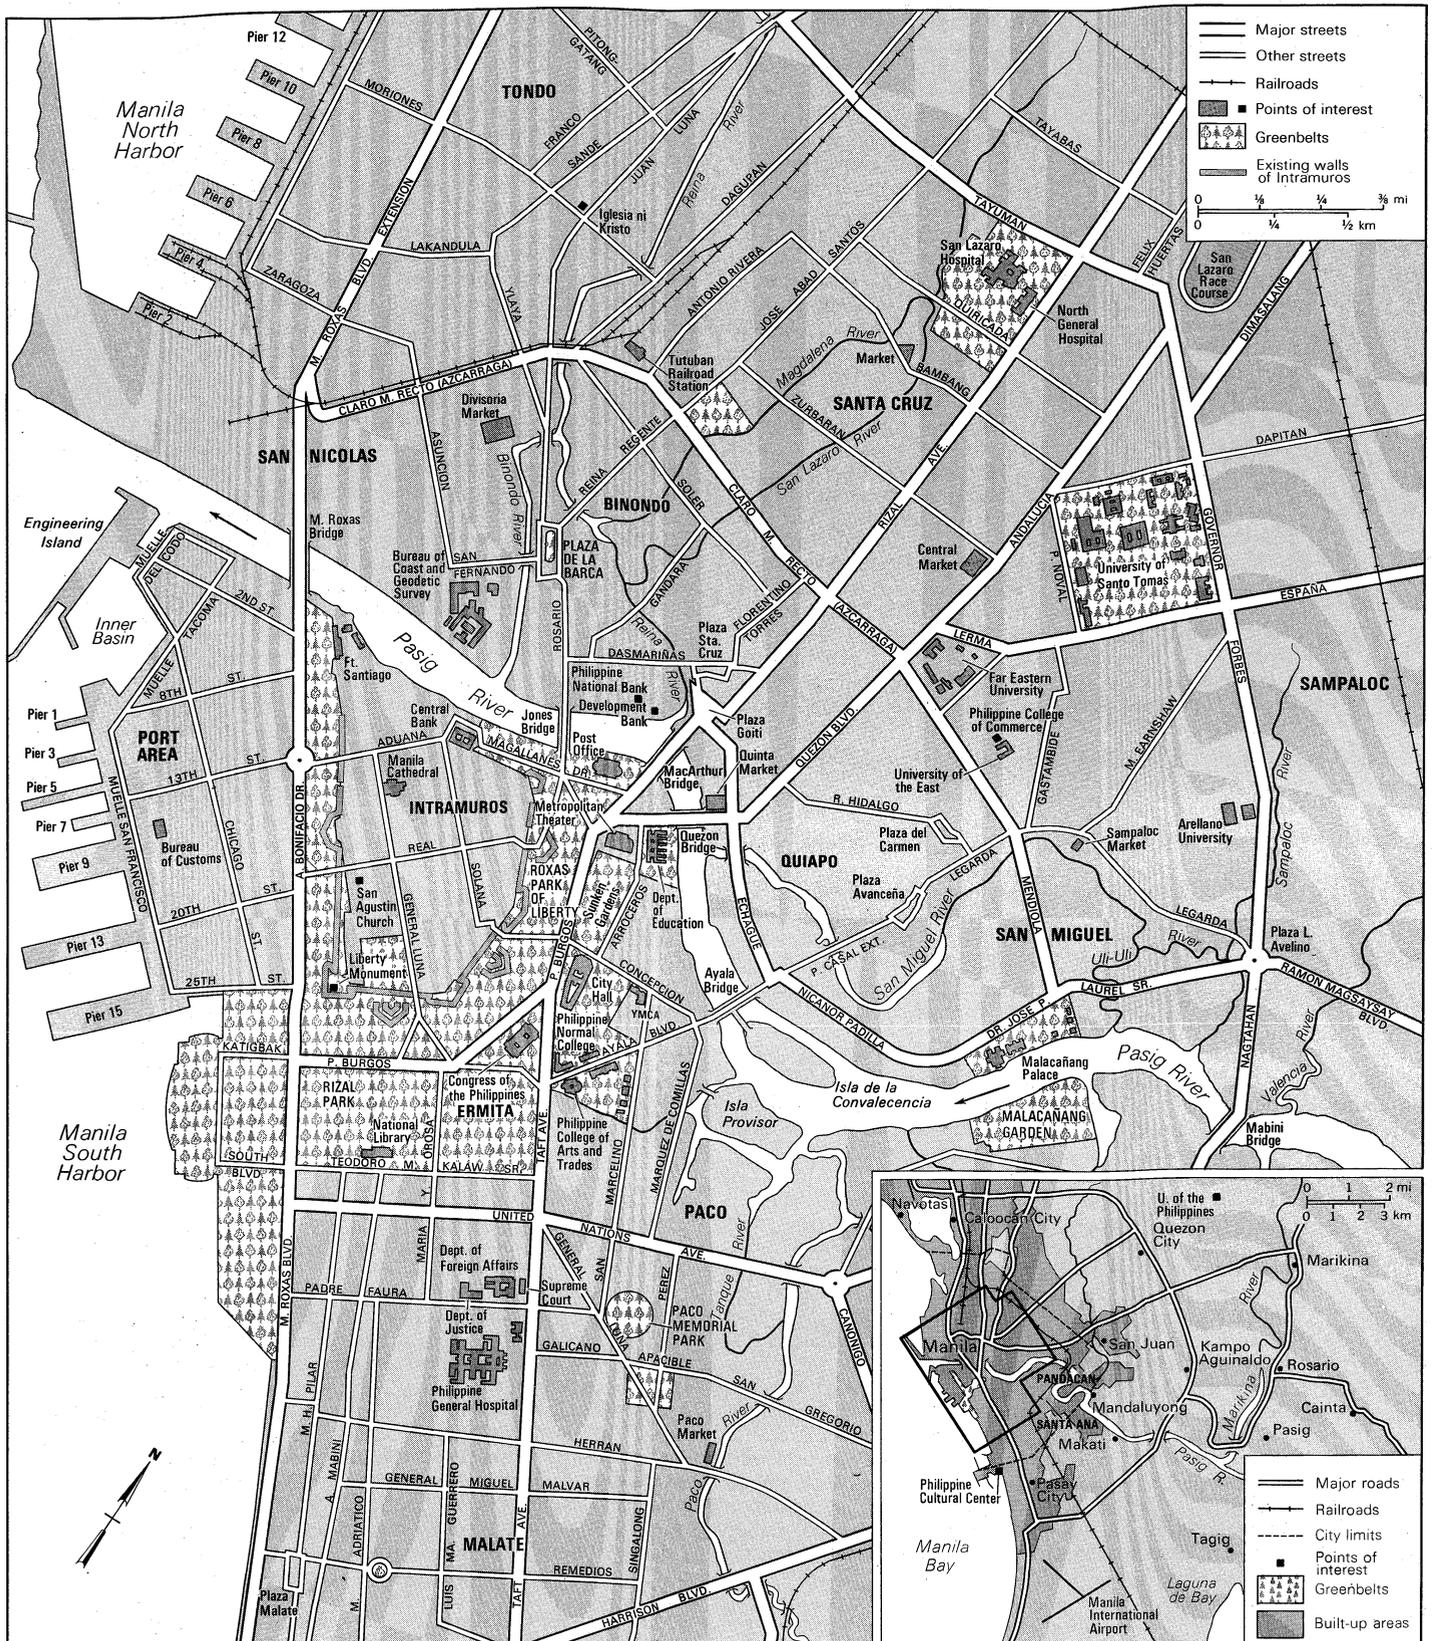

**The contemporary city.** *The physical setting.* Manila stands on the eastern shore of Manila Bay, 770 square miles (1,994 square kilometres), a large inlet with access to the sea through a channel 15 miles wide to the southwest. It occupies the low, narrow deltaic plain of the Pasig River, which flows northwestward to Manila Bay out of a large lake, Laguna de Bay, southeast of the city, which has an area of 343 square miles (888 square kilometres). Manila Bay lies to the west, the swampy delta of the southward-flowing Pampanga River to the north, the mountains of the Bataan Peninsula to the west, and Laguna de Bay to the southeast. Although the city's area is constricted, it is an excellent port site because of its sheltered harbour, its access to the inland agricultural areas by the river, and its relative proximity to the Asian mainland. The municipality itself occupies approximately 15 square miles; together with its surrounding suburbs, metropolitan Manila, as mentioned, spreads over 146 square miles.

*Climate.* The city is protected from extreme weather conditions by the hills of the Eastern Cordillera to the east and by the mountains of Bataan Peninsula, which lies to the west of Manila Bay. The tropical climate is characterized by a wet season that lasts from June to November and by a dry season lasting from December to May. High humidity and thunderstorms are common in July, when more rain is received than in other months. The average annual rainfall totals about 82 inches. There is little variation from the mean annual temperature of 81° F (27° C). The warmest months are from April to June, and the coolest are from November to February.

*Vegetation and animal life.* The city is dotted with tropical trees; including the palm, banyan, and acacia; bamboo is common in the public parks. Water buffalo, horses, dogs, pigs, and goats are common. The wealth of birdlife includes shrikes, doves, and pigeons, and Manila Bay abounds with sardines, anchovies, mackerel, tuna, snappers, and barracuda. The city's natural beauty

The Spanish period

The city site

Central Manila and (inset) its metropolitan area.

is being marred, however, by air and water pollution, which is caused by the expansion of industry and the growing number of vehicles.

**The city plan.** The city is bisected by the Pasig River. It is divided into 14 administrative districts—seven to the north and seven to the south of the river—that have developed from the original Intramuros and the 13 vil-

lages located outside its walls. The districts of Tondo, San Nicolas, Binondo, Santa Cruz, Quiapo, San Miguel, and Sampaloc lie to the north, and Port Area, Intramuros, Ermita, Malate, Paco, Pandacan, and Santa Ana are south of the river. The two sections of the city are connected by six bridges—Jones, Quezon, Ayala, MacArthur, Roxas, and Mabini.

The city's commercial districts

Although business areas are widespread, the districts of San Nicolas, Binondo, Santa Cruz, and Quiapo constitute the chief centres of trade and commerce. San Miguel is the site of Malacañang Palace, the presidential residence; several universities are located in Sampaloc. The northern shore is occupied by the heavily populated Tondo district, the site of the northern (local) port, while the southern shore is the location of the international port. Intramuros is renowned for its 16th-century San Agustin Church as well as for the ruins of its old walls and of Ft. Santiago. Ermita and Malate are choice residential districts and the sites of hotels and embassies; Paco, Pandacan, and Santa Ana are middle-income residential areas.

The metropolitan area includes the suburbs of Navotas and Caloocan City to the north, Quezon City to the northeast, San Juan and Mandaluyong to the east, and Makati and Pasay City (which stands on the shore of Manila Bay) to the south. They are mainly residential areas, but some larger industries have moved to them from the crowded city area where land values are high.

**The ports.** The main port area—an international port—is known as South Harbor. It is enclosed by a low breakwater and has six piers, four of which are used commercially. The Custom House and several warehouses and sheds are enclosed. The port is often congested, and ships are usually obliged to lie outside the breakwater to wait for entry. There are no rail facilities within the port area, and cargo is transported from the piers by trucks or barges. Several heavy industries that depend upon imported raw materials are located within the port area.

The local port occupies the North Harbor shore of Tondo district. Its seven piers are congested with heavy traffic from all ports in the Philippines. It is directly served by the railway and has several large warehouses.

**Transportation.** Within the Greater Manila area, transportation is provided principally by buses, jeepneys (small buses with the chassis of jeeps), and taxis. Bus services run to northern and southern Luzon; railroad services, operated by the Philippine National Railways, also connect the city with northern and southeastern Luzon. Interisland and international air transportation is provided by domestic and foreign airlines, and by shipping.

Traffic congestion is serious, with traffic tending to pile up at the six bridges during the morning and evening rush hours. The adjacent towns serve as dormitory suburbs, and a large number of people commute to their work in the city, thereby adding to the traffic problem.

**The people.** *Ethnic and religious groups.* Almost all Manilans are Filipinos. The largest foreign community is made up of Chinese, who comprise just over 6 percent of the population; there are also small groups of Americans and Europeans. About 93 percent of the population is Roman Catholic, 2 percent Protestant, and 2 percent Buddhist. The two national Christian churches—the Iglesia ni Kristo and the Aglipayan—claim the adherence of less than 3 percent of the city's inhabitants.

**Demography.** There are about 1,331,000 persons living within Manila's municipal area, resulting in an average population density of 89,000 people per square mile. Although Sampaloc is the largest district by area, Tondo has the largest population—434,000. The port area is occupied by fewer than 100 people, and the district of Intramuros has about 2,600 residents. The population of the metropolitan area reached about 3,000,000 in the early 1970s.

The population is young because of a high birth rate of 45 per 1,000 population and a low death rate of 11 per 1,000 population. The rate of natural increase is about three percent annually.

**Housing.** The city is plagued by an acute housing shortage, and tenement housing projects have been constructed by the government to help house the poor. In the early 1970s, about 40 percent of the families owned their homes, whereas the rest of the population was housed on a rental basis. There are five types of residential buildings—the single-family dwelling; the duplex for two independent households; the multistory *accessoria* whose dwell-

ing units have individual entrances from the outside; the apartment building; and the *barong-barong*, a shack of light materials that is common in the poor areas of Tondo and San Nicolas.

Architectural styles reflect American, Spanish, Chinese, and Malayan influences. Modern buildings—including multistoried commercial houses, government buildings, hotels, theatres, schools, and apartments—are made of reinforced concrete and hollow cement blocks. Houses of modern design—especially low, sprawling ranch houses with spacious lawns—are common in the districts of Ermita and Malate. Houses of Spanish design, with tile roofs, barred windows, and thick walls, were common before World War II and are still popular. The churches are American, Spanish, or European in character. Lumber, hollow cement blocks, and galvanized iron roofing are commonly used for middle-income dwellings.

**The economy.** *Manufacturing.* The diverse manufacturing activities include textile production, publishing and printing, food processing, and the production of paints, drugs, aluminum articles, rope and cordage, shoes, cigars and cigarettes, coconut oil, soap, and lumber. Factories generally operate on a small scale and are mostly located in the congested districts of San Nicolas (the railroad and truck terminus), Binondo, Tondo, and Santa Cruz. Heavy industry is located in the districts of Paco, Pandacan, and Santa Ana.

**Commerce and finance.** Manila is the centre of trade and finance in the Philippines. Trade flourishes within the Greater Manila area, as well as between the city and the provinces and with countries abroad. Most of the Philippines' imports and exports pass through the port of Manila. Banking and insurance have grown in importance in recent years. Financial institutions include such establishments as the Development Bank of the Philippines, the Philippine National Bank, the Philippine Veterans Bank, the government insurance system, the social security system, and private commercial and development banks. Private insurance companies and the Manila Stock Exchange also contribute to the mobilization of savings for investment.

**Public utilities.** Potable water is supplied by the National Waterworks and Sewerage Authority. Satisfactory sanitation conditions are maintained by constant surveillance of market facilities, restaurants, movie houses, recreation halls, and slaughter houses. Insecticides are sprayed regularly on open sewers, uncollected garbage, and standing water; garbage is collected by a fleet of trucks that operate night and day.

The Manila Electric Company provides electric power and lighting throughout the city and adjacent towns. Telephone and telegraph services are provided by the Bureau of Telecommunications and by several privately owned companies.

**Administration and social conditions.** *Government.* The city is governed by charter, with a mayor as its chief executive. He is elected by the city's voters for a four-year term. Voters must be literate citizens of the Philippines who are at least 21 years of age and who have resided in Manila for six months before the election. Legislative power and control of city appropriations are vested in a municipal board, presided over by the elected vice mayor, and composed of 20 elected councillors, five from each representative district. The secretary to the mayor is the custodian of all records and documents. For purposes of national representation, the city is divided into four districts, each of which is represented by one congressman in the House of Representatives. The city's fiscal and municipal court is under the supervision of the national Department of Justice. Although Manila is no longer the national capital, it houses such federal offices as the Malacañang Palace, the Congress of the Philippines, the Supreme Court, and various government departments, agencies, and bureaus.

**Health and safety.** The health facilities in Manila are among the best in the Far East. The city government maintains about 60 health centres, as well as the Lacson Memorial Hospital, at all of which patients are treated free of charge. It also subsidizes more than half a dozen

Banking facilities

Traffic problems

Types of residential buildings

The mayor and municipal board

government hospitals, and there are many missionary and private hospitals in the city.

Police and fire services are well organized, improved equipment and techniques are used, and personnel are comparatively well paid. With the growing population, however, additional trained men, equipment, and facilities, as well as an improved communication system, are needed. To intensify the campaign against crime, more police precincts were created in the early 1970s, and the Police Community Relation District was organized.

**Education.** More than 96 percent of the population is literate. More than 100 free public schools are maintained, in addition to the night vocational and secondary schools and the city-supported university. Educational opportunities are also provided for handicapped children, orphans of school age, and adults. As the education centre of the country, Greater Manila houses many of the major universities, including the University of the Philippines (with its main campus in Quezon City), the Philippine Normal College, the Philippine College of Commerce, and the Philippine College of Arts and Trades. There are several religious universities, including the University of Santo Tomas (founded in 1611), as well as nonsectarian institutions such as the University of the East and the Far Eastern University.

**Cultural life.** The centre of the performing arts in the country is the Philippine Cultural Center, and there is an open-air theatre in Rizal Park. The many libraries and museums include the National Library and the National Museum, known for its anthropological and archaeological exhibits; the National Institute of Science and Technology, with its scientific reference library and large collections of plants and animals; the geological museum of the Bureau of Mines; the Manila Aquarium; Ft. Santiago, which houses original works by the Philippine patriot José Rizal; and the Kamaynilaan (Manila City) Library and Museum, which contains valuable carvings, paintings, and archives.

**The media.** There are several English-language daily newspapers, including the *Manila Daily Bulletin*, *The Manila Times*, *The Philippines Herald*, and *The Manila Chronicle*. *Taliba* is printed in Pilipino, the national language. Weekly magazines include the *Philippines Free Press*, *The Sunday Times Magazine*, *The Weekly Nation*, and *The Graphic*. There are many large and well-equipped publishing houses located in the metropolitan area.

In the early 1970s there were 13 radio broadcasting stations and seven television stations operating within Greater Manila. Most residents have radios, and many also have television sets.

**Recreation.** The foremost recreation area is Rizal Park. Its grounds contain a Japanese garden, a Chinese garden, an open-air theatre, a playground, a grandstand, and a long promenade adjacent to Manila Bay. Other areas include the Manila Botanical and Zoological Garden, the Mehan Garden, the Paco Memorial Park, and the Philippine-Mexican Park. Athletic facilities include the Rizal Memorial Stadium and the Pius XII Catholic Center in Manila and the Araneta Coliseum in Quezon City. Annual festivals and carnivals are held in Sunken Gardens.

**Prospects for the future.** Manila is destined to retain its commercial, industrial, political, and cultural importance. The city is undergoing development to improve its physical environment and standard of living. All trends point to the city's future as a modern Oriental metropolis with all the conveniences of the 20th century.

**BIBLIOGRAPHY.** The literature about Manila is extensive. Much valuable information may be obtained from books, magazines, newspapers, government reports, atlases, and encyclopaedias. The following references represent only some of the most recent works.

General discussions on the history, government, economy, and living conditions in Manila include: T.A. AGONCILLO and O.M. ALFONSO, *History of the Filipino People* (1967); ALFONSO J. ALUIT, *The Galleon Guide to Manila and the Philippines* (1968); ROBERT E. HUKÉ, *Shadows on the Land: An Economic Geography of the Philippines* (1963); RIZAL CULTURAL COMMITTEE, OFFICE OF THE PROVINCIAL GOVERNOR,

*Rizal Province: A Political History* (1967); D.C. SALITA, T.W. LUNA, and E.N. SALUMBIDES, *Living in Our World* (1966).

Specific treatment of population, housing, charter provisions, needs, and resources of the capital city may be found in the BUREAU OF CENSUS AND STATISTICS, *Manila 1970 Census of Population and Housing* (1971); BUREAU OF PRINTING, *Revised Charter of the City of Manila* (1950); and ANTONIO J. VILLEGAS, *Manila: Its Needs and Resources* (1962). For maps and statistical information about the city, see R.S. HENDRY, L.R. DORAN, and A. MALAY, *Atlas of the Philippines* (1959); and BUREAU OF CENSUS AND STATISTICS, *Census Atlas of the Philippines, 1939* (1941).

(D.C.S.)

## Manipur

Manipur is a state of India, established in 1972 and located in the northeastern part of the country. It was previously a union territory. It is bordered by the Indian states of Nāgāland on the north and Assam to the west, by the union territory of Mizoram on the southwest, and by Burma to the south and east. It covers an area of 8,628 square miles (22,346 square kilometres) and is larger than Wales but smaller than British Honduras. Its population of almost 1,070,000 is approximately equal to that of Trinidad and Tobago. The capital, Imphāl, is the state's major trade centre.

Manipur is largely isolated from the rest of India, and the region has periodically been subject to invasions from the east. Its economy centres on agriculture and forestry, and there is lively activity in trade and cottage industries.

**History.** Although ancient hoes of ground stone have reportedly been found in the area, little is known of the history of the Manipur region before 1762. In that year the local prince, or raja, requested British aid to repel an invasion from Burma. Further communication was minimal until 1824, when the British were again requested to expel the Burmese. Disputed successions were a continual source of political turmoil until Chura Chand, a five-year-old member of the ruling family, was nominated raja in 1891. For the next eight years the administration was conducted under British supervision; slavery and forced labour were abolished and roads were constructed.

In 1907 the government was assumed by the raja and the durbar, or council, whose vice president was a member of the Indian civil service. Subsequently, the administration was transferred to the raja, and the vice president of the durbar became its president. After an uprising of the Kuki hill tribes in 1917, a new system of government was adopted; the region was divided into three subdivisions, each headed by an officer from the neighbouring government of Assam.

With the accession of Manipur to India in 1947, the political agency exercised by Assam was abolished. Two years later the administration was taken over by the Indian government, and the region was ruled as a union territory by a chief commissioner and an elected territorial council. The council was abolished in 1969, and Manipur was placed under presidential rule. It became a state of India in 1972.

**The landscape and environment.** The state is comprised of two major physical features, the Manipur River Valley and a large surrounding tract of mountainous country. The valley extends from north to south; it covers an area of about 650 square miles and lies at an altitude of 2,600 feet above sea level. The main physical feature of the valley is the reedy Lake Loktak, which covers an area of about 25 square miles. The lake is the source of the Manipur River, which flows southward through the valley into Burma, where it joins the Myittha River, a tributary of the Irrawaddy.

The hill ranges have a general north-south trend; connecting spurs and ridges run from west to east between them. The ranges include the Nāga Hills to the north, the Manipur Hills along the eastern Burmese border, and the Lushai and Chin hills to the south. The average elevation lies between 5,000 and 6,000 feet above sea level. The hills are highest in the north, where they attain 8,427 feet (2,569 metres) in Siruhi Kashong (Siruhi Peak). In the west the mountains are broken by the valley of the Surma River. Known as the Barak River in Manipur, it rises at

British  
interventionUpland  
areasUniversity  
educationThe city's  
parks

Mount Jāpvo and flows south and west to join the Meghna River of Bangladesh.

The climate is temperate in the valley and cold in the hills. Rainfall is abundant, with about 65 inches (1,700 millimetres) of precipitation occurring annually.

The hills are densely covered with tree jungle and forests containing stands of bamboo and teak. Other trees include oak, magnolia, and chinquapin. The Luzon pine grows in the Nāga Hills. Plants include rhododendrons, primroses, and blue poppies. Animal life includes the Asiatic elephant, tiger, and leopard. The rhinoceros is hunted for its horn, which, when ground, is valued as an aphrodisiac. The brow-antlered deer is in danger of extinction; in the 1960s only 100 specimens were known to exist. Gaurs are the largest wild oxen in the world; the smaller gayals have been domesticated. There is also a fair number of wild buffalo.

*The population.* The population numbered about 941,000 in 1966 and 1,070,000 in 1971. In 1971 the average population density was 124 persons per square mile. About two-thirds of the people are the Meithei, who occupy the Manipur Valley and are largely Hindus. Meithei women conduct most of the trade in the valley and enjoy high social status.

The rest of the population is composed of indigenous hill tribes that are divided into numerous clans and sections. The Nāgas are found mainly in the north and the Kukis in the south. The tribesmen speak languages of the Tibeto-Burman family and practice traditional animist religions, although some of the Nāgas have been converted to Christianity. About 60 percent of the population speak Manipuri, which, together with English, is the official language of the state.

*Administration and social conditions.* The five states and two union territories of northeastern India—Assam, Nāgāland, Tripura, Manipur, and Meghalaya states and Arunachal Pradesh and Mizoram—share a common governor and common high court. Within Manipur the government is headed by a lieutenant governor; the state is divided into five administrative districts. In 1972 a proposal was made to create a Northeastern Council composed of representatives of each of the states and territories. The council would discuss common problems and coordinate development programs. The national Parliament has direct legislative jurisdiction over the northeast.

In 1970 educational facilities included more than 2,000 primary, 300 middle, and 120 high schools, as well as 13 colleges. There were about 230,000 enrolled students. In 1971 only one-third of the population were literate. Classes are taught in the Manipuri language, and English and Hindi are taught as well.

Major health problems include tuberculosis, leprosy, venereal disease, and filariasis. Health facilities need to be improved; in 1970 there were 12 hospitals, almost 60 dispensaries, 12 health centres, and 65 specialist clinics.

*The economy and transport.* Agriculture and forestry are the main sources of income. Rice is the major crop, and the rich soil also supports sugarcane, mustard, tobacco, fruit orchards, and pulses such as peas and beans. Terracing is common in the hills, where the tribes plow the ground with hand hoes. Among some of the hill tribes, domestic animals are kept only for meat and are not milked or used for hauling. The Nāgas are known to use intoxicants to catch fish. Teak and bamboo are major forestry products.

Manufacturing is limited to several well-established cottage industries. The designed cloth produced on handlooms is in demand throughout India. Other industries include soapmaking, carpentry, and tanning.

Manipur remains somewhat isolated from the rest of India, and communications within the state are poor. A road runs north from Imphāl to the North-Eastern Railway line at Dimāpur, and another road leads southeast from the capital to Tamu on the Burmese border. There are air links from Imphāl to Silchar, Assam, and Calcutta, West Bengal.

*Cultural life.* Polo and hockey are popular sports. Manipur has given birth to an indigenous form of classical dance known as Manipuri dance. It is dissimilar to

other Indian dance forms; hand movements are used decoratively rather than as pantomime, bells are not accented, and both men and women perform communally. The dance dramas, interpreted by a narrator, are a part of religious life. Themes are generally taken from the life of Kṛṣṇa (Krishna), the pastoral god of Hinduism. Long an isolated art form, Manipuri dance was introduced to the rest of India by the poet Rabindranath Tagore in 1917.

(B.A.A.)

## Manitoba

Lying midway between the Atlantic and Pacific oceans, Manitoba became the fifth province of Canada when it was admitted to the confederation in 1870. Though it is known as one of the nation's Prairie Provinces, along with Saskatchewan and Alberta, more than 50 percent of its land area is forested. Its 251,000 square miles (650,000 square kilometres) contain 39,225 square miles of water, and of its more than 38,500 lakes, Lake Winnipeg is the 13th largest in the world. The province is bounded on the north by the Keewatin District of the Northwest Territories, on the northeast by Hudson Bay, on the east by Ontario, on the south by the United States (the states of Minnesota and North Dakota), and on the west by Saskatchewan.

About two-thirds of the 988,247 Manitobans counted in the 1971 census are now urban dwellers, but the province maintains the traditional conservatism of its rural days. It continues to draw the greatest proportion of its wealth from exploitation and processing of the products of its primary industries—farming, lumbering, mining, and fishing—though Winnipeg, its capital, is the focus of rapidly expanding manufacturing industries. The fourth-largest city of Canada, Winnipeg contains in its metropolitan area over one-half of the province's people and, in spite, or because of its relative isolation, is a major artistic and cultural centre. (For information on related topics, see the articles CANADA; CANADA, HISTORY OF; NORTH AMERICA; GREAT PLAINS; and HUDSON BAY.)

*The history of Manitoba.* *Early exploration and commerce.* When the first white man set foot in Manitoba, the province was inhabited by Cree, Assiniboin, and Ojibwa Indians and, along the shore of Hudson Bay, by Eskimos. Sir Thomas Button, an English explorer, came through the bay in 1612 and explored around the mouth of the Nelson River. In 1619 a Danish expedition wintered at the mouth of the Churchill River. The actual opening of Manitoba was the work of the Hudson's Bay Company, which was established in London in 1670. The company built northern trading posts at strategic fur-collecting points, the chief of which was York Factory at the mouth of the Nelson. From there in 1691, Henry Kelsey explored southward to the region of The Pas and to the prairies.

As the English moved down from the north, however, the French moved in from the east, and many clashes resulted. Pierre Gaultier, sieur de La Vérendrye, arrived at the Red River in 1731 on his way to the Pacific Coast. En route he built forts from Lake Superior to the Red River valley, including Ft. Rouge on the present site of Winnipeg—at the junction of the Red and Assiniboine rivers. In 1783, with Canada under the British flag, the Montreal-based North West Company began to compete for furs with the Hudson's Bay Company, and a fur war ensued that ended only in 1821 when the two companies merged.

*Settlement and provincial status.* The first settlement of Manitoba came in 1812 when Thomas Douglas, 5th earl of Selkirk, received a grant of land on the Red River from the Hudson's Bay Company and brought Scots and Irishmen to farm it. Frost, flood, and grasshoppers plagued them. They also were opposed by the Métis, French-Indian half-breeds, who were in the employ of the North West Company and feared that settlement would mean the end of buffalo hunting. In the Seven Oaks massacre, near Winnipeg, the governor of the Red River colony and a score of men were killed in 1816, but the

colony slowly prospered. The Dominion of Canada acquired all of the Hudson's Bay Company territory, known as Rupert's Land, in 1869. Under Louis Riel, the Métis resisted and refused to let government officials enter the territory until the government made concessions in the Manitoba Act of 1870, which made Manitoba a province.

In 1867 steamboats had linked the Red River colony with the United States. In 1878 the railway reached Winnipeg from St. Paul, Minnesota, and in 1882 from eastern Canada. With these came a flood of settlers that died down only at the outbreak of World War I. Provincial boundaries were extended westward in 1881, eastward in 1884, and northward in 1912 to give Manitoba its present dimensions. Western expansion saw the prairies broken for grain growing, while northward extension brought about exploitation of the great mineral resources; created such towns as Thompson, Flin Flon, The Pas, and Lynn Lake; and harnessed the rivers to produce cheap electrical power. The 1930s brought drought and depression, but World War II revived rural electrification and industry, beginning an expansion that has since continued.

**The natural and human landscape.** *Physical regions.* Extreme southern Manitoba is part of the Saskatchewan plain, a land of rich, level prairies and rolling pastures. The Manitoba Lowland to the north is the basin that once held glacial Lake Agassiz, remnants of which include Lake Winnipeg (9,230 square miles), Lake Winnipegosis (2,068), and Lake Manitoba (1,817). Upland plateaus, wooded river valleys, limestone outcrops, forests, and swamps mark the area that is drained by the Red and Assiniboine rivers into Lake Winnipeg.

To the north and east of the lowland is the geologically ancient Canadian, or Precambrian, Shield, an area of rocks, forests, and rivers. It covers three-fifths of the province and is drained by the Nelson and Churchill rivers into Hudson Bay. On the shore of the bay, the Hudson Bay Lowland extends 100 miles inland as a flat, almost treeless plain of tundra and boglike muskeg. Manitoba's highlands are on the Saskatchewan border. The Riding, Duck, and Porcupine mountains form the Manitoba Escarpment, whose high point is Baldy Mountain, at 2,727 feet (831 metres).

*Climate.* Manitoba has moderately dry climate with sharp seasonal temperature changes. Temperatures of  $-40^{\circ}\text{F}$  ( $-40^{\circ}\text{C}$ ) are not uncommon in any part of the province;  $100^{\circ}\text{F}$  ( $38^{\circ}\text{C}$ ) is not an uncommon summer reading in the south. Average daily high temperatures at Winnipeg range from  $8.8^{\circ}\text{F}$  ( $-12.9^{\circ}\text{C}$ ) in January to  $79.7^{\circ}\text{F}$  ( $26.5^{\circ}\text{C}$ ) in July; average lows vary from  $-8.6^{\circ}\text{F}$  ( $-22.6^{\circ}\text{C}$ ) in January to  $56.8^{\circ}\text{F}$  ( $13.8^{\circ}\text{C}$ ) in July. Annual precipitation varies from 13 inches to 22 inches in the southeast, (counting ten inches of snow as one inch of rain) with about 70 percent of it falling between May and October. Snow covers the ground from November to April in the south and for longer in the north.

*Vegetation and animal life.* Manitoba's more than 120,000 square miles of forest include open parklands of aspen, maple, elm, and oak in the south, becoming a mixed broadleaf and coniferous forest and then the true northern coniferous forest in the higher latitudes. The chief trees are spruce, aspen, jack pine, poplar, balsam, white birch, and tamarack. The southern prairies are relatively treeless except for bluffs of aspen, oak, willow, and poplar.

Caribou, moose, elk, deer, bear, beaver, fox, lynx, marten, and mink live in the northern forests; deer, coyote, rabbit, and muskrat inhabit the more southerly areas. Polar bears are found along Hudson Bay. Grouse, prairie chicken, and other game birds live in the uplands, and millions of geese and ducks breed in Manitoba's sloughs and ponds. Fish include bass, pickerel, sauger, trout, and whitefish. The Winnipeg goldeye, a whitefish that is smoked, is world-famous. Beluga whales are taken in Hudson Bay.

To conserve wildlife and waterfowl, government and private organizations cooperate in wildlife surveys and nature-management programs. Manitoba has Canada's

second-largest inland fishery, but commercial fishing in some lakes was halted in 1970 because of the mercury content in fish caught. The provincial government has taken legal action against companies alleged to be responsible for water pollution.

*Patterns of settlement.* Manitoba's countryside has an older, more settled look than that of other Prairie Provinces, but it is marked by deserted farmhouses, dying small towns, and abandoned railway lines. Farms have become larger and more mechanized, averaging about 500 acres (200 hectares) in size, leading to a population drain to the cities and towns. Most urban dwellers are in the south, more than 80 percent of them in the six cities and six municipalities that in January 1972 were consolidated into Winnipeg. The province's other urban dwellers live in small trading centres primarily serving the farm population or in northern Manitoba at mines and transportation junctions. The main urban centres (in addition to Winnipeg) are Brandon, an industrial city serving the southwest; Thompson, a nickel-mining and -processing centre in the northern forest; Flin Flon, a northern mining centre; The Pas, a trading and communications centre on the Saskatchewan River; Portage la Prairie, the chief trading centre between Winnipeg and Brandon; Selkirk, the centre of commercial fishing and water transportation on Lake Winnipeg; and Dauphin, serving west central Manitoba.

*The people of Manitoba.* Scottish and Irish settlers in 1812 were the backbone of early agricultural settlement in the Red River colony, joining the Métis in the area. Between 1870 and 1900, rail and river transportation caused Manitoba's population to grow tenfold, to more than 255,000. Many of the newcomers were from Europe and from eastern Canada. After that, natural increase provided the major growth until the population drain of the depression in the 1930s and of World War II, after which the population continued its growth.

The impact of Manitoba's many ethnic groups is still evident. Store signs in Ukrainian are common in north Winnipeg. Many of the districts originally settled by specific groups remain the centres of population for those groups. Manitobans of British descent are evenly distributed. French-speaking people live mainly along the Red River, from the U.S. border to Greater Winnipeg. St. Boniface is the largest French-speaking community in Canada outside the province of Quebec. Germans settled in the south centre, Scandinavians in the original Icelandic settlements around Gimli. Some 29,000 Indians and Eskimos remain, the latter living around Churchill on Hudson Bay; the former comprise some 50 bands speaking four Indian languages. The largest religious groups are United Church of Canada, Roman Catholic, and Anglican Church of Canada, but Lutherans, Mennonites, Presbyterians, Jews, Greek Orthodox, Ukrainian Catholics, Hutterian Brethren, and other smaller groups are found across the province.

In 1971 Manitoba's preponderance of births over deaths produced a rate of natural increase of 10.5 per 1,000 inhabitants. Relatively few foreign immigrants settle in the province, which tends to lose people to Ontario, Quebec, and British Columbia when the prairie economy slows down.

The province has few racial problems. The chief one is posed by the large-scale migration of Indians from reservations into the cities, particularly Winnipeg. There they have difficulty finding jobs, are often on welfare, and are forced to live in slum squalor. Provincial, federal, and city governments are tackling the problem, but as yet they have had little real success.

*The provincial economy. Resources, products, and management.* The rich southern farmlands are a main resource of Manitoba. The Canadian Shield area accounts for more than 80 percent of mineral production. Nearly one-half of the forests are commercially productive; and the thousands of square miles of water provide sport and commercial fishing and inexpensive electrical power. Per capita income in 1969 was \$2,900, compared to a national average of \$2,950.

Wheat is the main crop; others include oats, barley, rye,

Topo-  
graphical  
diversity

Impact of  
ethnic  
groups

Wildlife  
and its  
conser-  
vation

flax, rapeseed, sunflower seed, and vegetables. The major minerals are nickel, copper, gold, lead, silver, and zinc. Pulpwood for paper manufacture accounts for 60 percent of the timber cut. Main manufactures are foods and beverages, clothing, fabricated-metal goods, chemicals, space rockets, farm machinery, and cement. Among Manitoba's industrial installations are: a nuclear-research plant in Pinawa, an integrated forest-products complex in The Pas, a nickel complex in Thompson, a pulp mill in Pine Falls, and a fertilizer plant in Brandon. Large generating stations are being built on the Nelson River.

Most industry is privately owned, but the provincial government is moving into some areas. In 1971 it implemented a compulsory government-operated automobile-insurance program. Through the Manitoba Development Corporation, a government loan fund, it has acquired an interest in several businesses including the forest complex in The Pas. In 1970 about one-seventh of the labour force was covered by collective-bargaining agreements. The main labour organization is the Manitoba Federation of Labour, affiliated with the Canadian Labour Congress. Employers work through chambers of commerce and the Canadian Manufacturers' Association.

**Transportation.** Because of its strategic location between the east and west, Manitoba is a leading transportation centre. Main railway lines run east and west through Winnipeg, as does the Trans-Canada Highway. Changing economic conditions are lessening rail transportation's importance, and branch lines are being abandoned. Winnipeg, with nearly 50 trucking terminals, is served by 14 transcontinental carriers and is headquarters for eight of them. Four major airlines fly to all parts of Canada and to Europe and the United States. Thirty nonscheduled commercial air firms—bush fliers, freight haulers, and air taxis—are based in the province.

Churchill, on Hudson Bay, provides a short, direct sea route to Europe that is open for ten weeks in late summer. There is waterborne freight traffic on Lake Winnipeg in summer. In winter, northern mining and logging camps are supplied by sled trains hauled by tractors.

**Administration and social conditions.** *Structure of governments.* Manitoba derives its authority from two British statutes, the British North America Acts of 1867 and 1871, and one Canadian statute, the Manitoba Act of 1870. Power is divided between the federal government in Ottawa and the provincial government in Winnipeg. The lieutenant governor of Manitoba, appointed by the governor general in council (the federal government in Ottawa), represents the Crown; his duties are largely honorary. The functioning head of the government is the premier. The unicameral legislative assembly has 57 members and sits for five years or until dissolved by executive action. The highest court in Manitoba is the Court of Appeal, presided over by a chief justice and four associate judges. The Court of Queen's Bench hears important civil and criminal cases while lesser cases are heard in the courts of the six judicial districts.

Municipalities are creatures of the province, and local administration is under provincial control. Each of the some 200 incorporated entities is governed by a council headed by a mayor or reeve. Twenty districts are governed by provincial administrators, but there are no counties. After consolidation of Greater Winnipeg into a single administrative unit in 1972, the city was governed by a mayor and a 50-member council, all elected.

**Education.** Elementary, secondary, technical and vocational schools and universities are a provincial responsibility. Schools are administered by local or larger unit boards under supervision of the department of education and are financed by government grants and local taxes. The University of Winnipeg and the University of Manitoba are in Greater Winnipeg, Brandon University in Brandon. Winnipeg, Brandon, and The Pas have vocational-training schools.

**Living standards and services.** Manitoba is a low-wage area. Wages are well below those in eastern Canada and British Columbia, though higher than in the Atlantic provinces. Living costs are somewhat higher than the national average. The province supervises medical and

hospital insurance programs, and Manitobans participate in such federal welfare and security programs as children's allowances, old-age pensions, and the Canada Pension Plan. These are augmented by a wide provincial welfare program. Relief for indigents is administered by local councils and agencies. Most municipalities have their own police force, though provincial policing is done by the Royal Canadian Mounted Police.

**Cultural life and institutions.** Manitoba's mixed population gives it a rich and varied cultural life. Ethnic groups—European, Asian, Indian, and Eskimo—retain a vigorous measure of their traditional culture in customs, dance, art, music and song, language, and crafts.

Partly because of their past isolation from the rest of Canada, Manitobans have always been enthusiastic sponsors and supporters of the arts. Winnipeg is the home of the internationally famous Royal Winnipeg Ballet, the Winnipeg Symphony Orchestra, and the Manitoba Theatre Centre. One of Canada's leading theatrical companies, the Centre includes an experimental and a children's theatre and is lodged in a new downtown theatre. The Winnipeg Art Gallery, publicly supported, moved into a new building in 1971. A dozen commercial and private art galleries in Winnipeg and a large number of musical and theatrical groups operate throughout the metropolitan area. The centre of much activity is Winnipeg's downtown centennial complex, completed in 1967, which includes a concert hall, planetarium, and the Manitoba Museum of Man and Nature.

Regional activities include stampedes and roundups at Morris and Swan River, the Trappers' Festival at The Pas, the Trout Festival at Flin Flon, annual Icelandic celebrations at Gimli, and the International Music Camp at the International Peace Garden on the Manitoba-North Dakota boundary.

Manitoba has seven daily and more than 70 weekly newspapers, 17 radio stations, and nine television stations. The two largest provincial dailies, *The Winnipeg Free Press* and *The Winnipeg Tribune*, have a combined daily circulation of around 220,000. Winnipeg is also a centre of the ethnic press, with about 20 foreign-language papers published in the city.

**Prospects.** As befits a province lying halfway across Canada, Manitoba's population, wages, living costs, living standards, and rate of development are neither the highest nor the lowest in the country. A mixed economy balanced between primary and secondary industries but trending toward the latter, as well as the generally conservative outlook of its people, make the province sharply affected by, but less susceptible than most to, economic booms or slumps. Growth has been gradual but steady. The province's politics reflected this attitude until the election of 1969, which for the first time brought a socialist government to office. Though this may herald political changes, it is more likely that the conservative outlook of Manitobans will colour and moderate the government's policies.

**BIBLIOGRAPHY.** W.L. MORTON, *Manitoba: A History*, 2nd ed. (1967), is the standard and an excellent historical text on the province. His *Manitoba: The Birth of a Province* (1965), is a compendium of documents relating to the province's entry into confederation. The *Economic Atlas of Manitoba*, ed. by T.R. WEIR (1960), is a comprehensive record of economic aspects of the province; the *Atlas of Canada* (1958), includes geographical detail. A succinct but complete description of the provincial economy is *The Economy of the Province of Manitoba 1970* (1971); supplementary figures are contained in *Manitoba Facts and Figures* (1970). *The Government of Manitoba* by MURRAY S. DONNELLY (1963), is a scholarly and clear exposition of the provincial administration.

(P.McL.)

## Mann, Horace

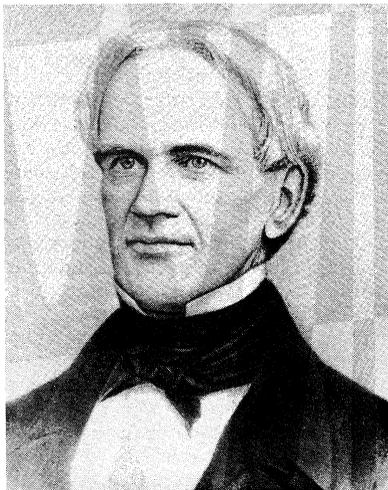

Among the educational leaders promoting the new national ideals of democracy, equality, and freedom in the years between the American Revolution and the Civil War, Horace Mann was the most influential spokesman. He is rightly called "the father of American public education," because the reforms he advocated and fought for

Ballet,  
music, and  
theatre

constitute the basis of public schooling as it is known in that country today.

Born in Franklin, Massachusetts, on May 4, 1796, Horace Mann grew up in an environment ruled by pov-

Horace Mann.

erty, hardship, and self-denial. He was taught briefly and erratically by comparatively poor teachers, but he managed to educate himself in the Franklin town library, and, with the help of some tutoring by an itinerant schoolmaster, he gained admission at the age of 20 to the sophomore class at Brown University. He did brilliant work at Brown, manifesting great interest in problems of politics, education, and social reform; his valedictory address, on the gradual advancement of the human race in dignity and happiness, was a model of humanitarian optimism, offering a way in which education, philanthropy, and republicanism could combine to allay the wants and shortcomings that beset mankind.

Upon graduation in 1819 Mann chose law as a career. He read law briefly with a Wrentham, Massachusetts, lawyer, taught for a year at Brown, and then studied at Litchfield (Connecticut) Law School, which led to his admission to the bar in 1823. He settled in Dedham, and there his legal acumen and oratorical skill soon won him a seat in the state House of Representatives, serving from 1827 to 1833. There he led the movement that established a state hospital for the insane at Worcester, the first of its kind in the United States. In 1833 he moved to Boston, and from 1835 to 1837 he served in the Massachusetts Senate, in 1836 as president of it.

Of the many causes Mann espoused, none was dearer to him than popular education. Nineteenth-century Massachusetts could boast a public school system going back to 1647. Yet during Mann's own lifetime, the quality of education had steadily deteriorated as school control had gradually slipped into the hands of economy-minded local districts. A vigorous reform movement arose, committed to halting this decline by reasserting the state's influence over the schools. The result was the establishment in 1837 of a state board of education, charged with collecting and publicizing school information throughout the state. Much against the advice of friends, who thought he was tossing aside a promising political career, Mann accepted the first secretaryship of this board.

Endowed with little direct power, the new office demanded moral leadership of the highest order and this Mann supplied for 11 years. He started a biweekly *Common School Journal* for teachers and lectured widely to interested groups of citizens. His annual reports to the board ranged far and wide through the field of pedagogy, stating the case for the public school and discussing its problems. Essentially his message centred in six fundamental propositions: (1) that a republic cannot long remain ignorant and free, hence the necessity of universal popular education; (2) that such education must be paid for, controlled, and sustained by an interested public; (3)

that such education is best provided in schools embracing children of all religious, social, and ethnic backgrounds; (4) that such education, while profoundly moral in character, must be free of sectarian religious influence; (5) that such education must be permeated throughout by the spirit, methods, and discipline of a free society, which preclude harsh pedagogy in the classroom; and (6) that such education can be provided only by well-trained, professional teachers. Mann encountered strong resistance to these ideas—from clergymen who deplored nonsectarian schools, from educators who condemned his pedagogy as subversive of classroom authority, and from politicians who opposed the board as an improper infringement of local educational authority—but his views prevailed.

Mann resigned the secretaryship in 1848 to take the seat of former Pres. John Quincy Adams in the United States Congress. There he proved himself to be a fierce enemy of slavery. In 1853, having run unsuccessfully for the Massachusetts governorship a year before, he accepted the presidency of Antioch College in Yellow Springs, Ohio, a new institution committed to coeducation, nonsectarianism, and equal opportunity for Negroes. There, amidst the usual crises attendant upon an infant college, Mann finished out his years. He died at Yellow Springs on August 2, 1859. Two months before, he had given his own valedictory to the graduating class: "I beseech you to treasure up in your hearts these my parting words: Be ashamed to die until you have won some victory for humanity."

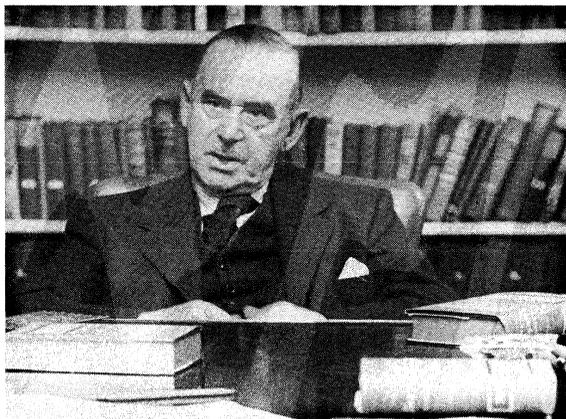

**BIBLIOGRAPHY.** The most comprehensive bibliography is CLYDE S. KING, *Horace Mann, 1796-1859: A Bibliography* (1966). The definitive biography is JONATHAN MESSERLI, *Horace Mann* (1972). A recent popular biography is LOUISE HALL THARP, *Until Victory: Horace Mann and Mary Peabody* (1953). JONATHAN C. MESSERLI throws new light on Mann's early years in "Horace Mann at Brown," *Harvard Educational Review*, 33:285-311 (1963). ROBERT L. STRAKER deals authoritatively with the Antioch period in *The Unseen Harvest: Horace Mann and Antioch College* (1955). The standard work is MARY TYLER (PEABODY) MANN (ed.), *Life and Works of Horace Mann*, rev. ed., 5 vol. (1891). Excerpts from the annual reports to the Massachusetts Board of Education are in L.A. CREMIN (ed.), *Republic and the School: Horace Mann on the Education of Free Men* (1957).

(L.A.Cr.)

## Mann, Thomas

The greatest German novelist of the 20th century, Thomas Mann was awarded the Nobel Prize for Literature in 1929, and by the end of his life his works had acquired the status of classics both within and without Germany. His subtly structured novels and shorter stories constitute a persistent and imaginative enquiry into the nature of Western bourgeois culture, in which a haunting awareness of its precariousness and threatened disintegration is balanced by an appreciation of and tender concern for its spiritual achievements. Round this central theme cluster a group of related problems that recur in different forms—the relation of thought to reality and of the artist to society, the complexity of reality and of time, the seductions of spirituality, eros, and death. Mann's imaginative and practical involvement in the social and political catastrophes of his time provided him with fresh insights that make his work rich and varied. His finely wrought essays, notably those on Tolstoy, Goethe, Freud, and Nietzsche, record the intellectual struggles through which he reached the ethical commitment that shapes the major imaginative works.

**Early literary endeavours.** Mann was born in Lübeck on June 6, 1875. His father, a prosperous grain merchant, died in 1891, and Mann moved to Munich, then a centre of art and literature, where he lived until 1933. After perfunctory work in an insurance office and on the editorial staff of *Simplicissimus*, a satirical weekly, he devoted himself to writing, as his elder brother Heinrich had already done. His early short tales, first collected as *Der kleine Herr Friedemann* (1898), reflect the aestheticism of the 1890s but are given depth by the influence of the philosophers Schopenhauer and Nietzsche and the composer Richard Wagner,

Thomas Mann.  
Elliot Erwitte—Magnum

The theme of the dilemma of the creative artist

to all of whom Mann was always to acknowledge a deep, if ambiguous, debt. Most of Mann's first stories centre in the problem of the creative artist, who in his devotion to form contests the meaninglessness of existence, an antithesis that Mann enlarged into that between "spirit" (*Geist*) and "life" (*Leben*). But while he showed sympathy for the artistic misfits he described, Mann was also aware that the world of imagination is a world of make-believe, and the closeness of the artist to the charlatan was already becoming a theme. At the same time, a certain nostalgia for ordinary, unproblematical life appeared in his work.

This ambivalence found full expression in his first novel, *Buddenbrooks* (1900), which Mann had at first intended to be a novella in which the experience of the transcendental realities of Wagner's music would extinguish the will to live in the son of a bourgeois family. On this beginning, the novel builds the story of the family and its business house over three generations, showing how an artistic streak not only unfits the family's later members for the practicalities of business life but undermines their vitality as well. But, almost against his will, in *Buddenbrooks* Mann wrote a tender elegy for the old bourgeois virtues. In the partially autobiographical *Tonio Kröger* (1903), he more explicitly paid tribute to the simplicities of German bourgeois life, though as a creative artist cut off from them; and in *Tristan* (1903) the artist who repudiates the ordinary world is almost cruelly satirized as a heartless fake.

In 1905 Mann married Katja Pringsheim, daughter of a Munich professor. There were six children of the marriage, which was a remarkably happy one. It was this happiness, perhaps, that led Mann, in *Royal Highness*, to provide a fairy-tale reconciliation of "form" and "life," of degenerate feudal authority and the vigour of modern American capitalism. In 1912, however, he returned to the tragic dilemma of the artist with *Death in Venice*, a sombre masterpiece. In this story, the main character, a distinguished writer whose nervous and "decadent" sensibility is controlled by the discipline of style and composition, seeks relaxation from overstrain in Venice, where, as disease creeps over the city, he succumbs to a homosexual passion and the wish for death. Symbols of eros and death weave a subtle pattern in the sensuous opulence of this tale, which closes an epoch in Mann's work.

**World War I years.** The outbreak of World War I evoked Mann's ardent patriotism and awoke, too, an awareness of the artist's social commitment that was to remain central in his later work. His brother Heinrich was one of the few German writers to question German war aims, and his criticism of German authoritarianism stung Thomas to a bitter attack on cosmopolitan litterateurs. In 1918 he published a large political treatise, *Reflections of an Unpolitical Man*, in which all his ingenuity of mind was summoned to justify the authoritarian state as against democracy, creative irrationalism as against "flat" rationalism, inward culture as against moralistic civilization. This work belongs to

Mann's German patriotism

the tradition of "revolutionary conservatism" that leads from the 19th-century German nationalistic and anti-democratic thinkers Paul Anton de Lagarde and H.S. Chamberlain, the apostle of the superiority of the "Germanic" race, toward National Socialism; and Mann later was to repudiate these ideas.

With the establishment of the German (Weimar) Republic in 1919, Mann slowly revised his outlook; the essays "Goethe and Tolstoi" and "Von deutscher Republik" ("The German Republic") show his somewhat hesitant espousal of democratic principles. His new position was clarified in the long novel *The Magic Mountain*. Its theme grows out of an earlier motif: a young engineer, Hans Castorp, visiting a cousin in a sanatorium in Davos, abandons practical life to submit to the rich seductions of disease, inwardness, and death. But the sanatorium comes to be the spiritual reflection of the possibilities and dangers of the actual world. A great variety of figures, brilliantly characterized, are woven into a subtle pattern, and the issues are focussed in the long arguments between an old-fashioned democratic humanist and a totalitarian irrationalist. In the end, somewhat skeptically but humanely, Castorp decides for life and service to his people: a decision Mann calls "a leave-taking from many a perilous sympathy, enchantment, and temptation, to which the European soul had been inclined." In this great work Mann formulates with remarkable insight the fateful choices facing Europe.

**Political crisis and World War II.** From this time onward Mann's imaginative effort was directed primarily to the novel, scarcely interrupted by the charming personal novella *Early Sorrow*, or by *Mario and the Magician*, a novella that, in the person of a seedy illusionist, symbolizes the character of Fascism. His literary and cultural essays began to play an ever-growing part in elucidating and communicating his awareness of the fragility of humaneness, tolerance, and reason in the face of political crisis. His essays on Freud (1929) and Wagner (1933) are concerned with this, as are those on Goethe (1932), who more and more became for Mann an exemplary figure in his wisdom and balance. The various essays on Nietzsche document with particular poignancy Mann's struggle against attitudes once dear to him. In 1930 he gave a courageous address in Berlin, "Ein Appell an die Vernunft" ("An Appeal to Reason"), appealing for the formation of a common front of the cultured bourgeoisie and the Socialist working class against the inhuman fanaticism of the National Socialists. In essays and on lecture tours in Germany, to Paris, Vienna, Warsaw, Amsterdam, and elsewhere during the 1930s, Mann, while steadfastly attacking Nazi policy, often expressed sympathy with Socialist and Communist principles in the very general sense that they were the guarantee of humanism and freedom.

Attacks on Nazi policy

When Hitler became chancellor early in 1933, Mann and his wife, on holiday in Switzerland, were warned by their son and daughter in Munich not to return. For some years his home was in Switzerland, near Zürich, but he travelled widely, visiting the U.S. on lecture tours and finally, in 1938, settling there, first at Princeton, and from 1941 to 1952 in southern California. In 1936 he was deprived of his German citizenship; in the same year the University of Bonn took away the honorary doctorate it had bestowed in 1919 (it was restored in 1949). In 1944 he became a United States citizen. During World War II he broadcast many times to Germany, speaking forcefully of the crimes of Hitlerism and appealing to the "other Germany" to assert its dignity.

Mann visited both East and West Germany several times after the war and received many public honours, but he refused to return to Germany to live. In 1952 he settled again near Zürich, where he died on August 12, 1955. His last major essays—on Goethe (1949), Chekhov (1954), and Schiller (1955)—are impressive evocations of the moral and social responsibilities of writers.

**Later novels.** The novels on which Mann was working throughout this period reflect variously the cultural crisis of his times. In 1933 he published *The Tales of Jacob* (U.S. title, *Joseph and His Brothers*), the first part of his

The  
Joseph  
series

four-part novel on the biblical Joseph, continued the following year in *The Young Joseph* and two years later with *Joseph in Egypt*, and completed with *Joseph the Provider* in 1943. In the complete work, published as *Joseph and His Brothers*, Mann reinterpreted the biblical story as the emergence of mobile, responsible individuality out of the tribal collective; of history out of myth; of a human God out of the awesome unknowable. In the first volume a timeless myth seems to be re-enacted in the lives of the Hebrews. Joseph, however, though sustained by the belief that his life too is the re-enactment of a myth, is thrown out of the "timeless collective" into Egypt, the world of change and history, and there learns the management of events, ideas, and himself. Though based on wide and scholarly study of history, the work is not a historical novel, and the "history" is full of irony and humour, of conscious modernization. Mann's fundamental concern is to provide a myth for his own times, capable of sustaining and directing his generation and of restoring a belief in the power of humane reason. The novel is inexhaustibly rich in its material, in the interwoven pattern of its motifs.

Mann took time off from this work to write, in the same spirit, his *Lotte in Weimar* (U.S. title, *The Beloved Returns*). Lotte (Charlotte) Kestner, the heroine of Goethe's *The Sorrows of Young Werther*, his semi-autobiographical story of unrequited love and Romantic despair, visits Weimar in old age to see once again her old lover, now famous, and win some acknowledgment from him. But Goethe remains distant and refuses to re-enter the past; she learns from him that true reverence for man means also acceptance of and reverence for change, intelligent activity directed to the "demand of the day." In this, as in the Joseph novels, in settings so distant from his own time, Mann was seeking to define the essential principles of humane civilization; their spacious and often humorous serenity of tone implicitly challenges the inhuman irrationalism of the Nazi ideology and regime.

In *Doctor Faustus* (1947), begun in 1943 at the darkest period of the war, Mann wrote the most directly political of his novels. It is the life story of a German composer, Adrian Leverkühn, born in 1885, who dies in 1940 after ten years of mental alienation. A solitary, estranged figure, he "speaks" the experience of his times in his music, and the story of Leverkühn's compositions is that of German culture in the two decades before 1930—more specifically of the collapse of traditional humanism and the victory of the mixture of sophisticated nihilism and barbaric primitivism that undermined it. With remarkable imaginative insight Mann interpreted the new musical forms and themes of Leverkühn's compositions up to the final work, a setting of the lament of Doctor Faustus in the 16th-century version of the Faust legend, who once, in hope, had made a pact with the Devil, but in the end is reduced to anguish and hopelessness. The one gleam of hope in this sombre work, however, in which the personal tragedy of Leverkühn is subtly related to Germany's destruction in the war through the comments of the fictitious narrator, Zeitblom, lies in its very grief. No other literary work expresses the tragedy of Germany as this does. Yet it illustrates a weakness in Mann's work. For while the interpretation of intellectual and artistic trends is rich and masterly, most of the characters are oversymbolical and tend toward a certain rigidity, even to caricature. Even in Leverkühn there is a strange automatism: he lacks the warmth and fluidity of life.

The composition of the novel was fully documented by Mann in 1949 in *The Genesis of a Novel. Doctor Faustus* exhausted him as no other work of his had done, and *The Holy Sinner* and *The Black Swan*, published in 1951 and 1953, respectively, show a relaxation of intensity in spite of their accomplished, even virtuoso style. Mann rounded off his imaginative work in 1954 with *The Confessions of Felix Krull, Confidence Man*, the gay, often uproariously funny story of a confidence man who wins the favour and love of others by enacting the roles they desire of him.

Mann's  
style

Mann's style is finely wrought and full of resources, enriched by humour, irony, and parody; his composition is subtle and many-layered, brilliantly realistic on one level and yet reaching to deeper levels of symbolism. His

works lack simplicity, and his tendency to set his characters at a distance by his own ironical view of them has sometimes laid him open to the charge of lack of heart. He was, however, aware that simplicity and sentiment lend themselves to manipulation by ideological and political powers, and the sometimes elaborate sophistication of his works cannot hide from the discerning reader his underlying impassioned and tender solicitude for mankind.

#### MAJOR WORKS

NOVELS: *Buddenbrooks* (published 1900, dated 1901; Eng. trans. 1924); *Königliche Hoheit* (1909; *Royal Highness*, first Eng. trans. 1916); *Der Zauberberg* (1924; *The Magic Mountain*, first Eng. trans. 1927); *Die Geschichten Jaakobs* (1933; *The Tales of Jacob*, 1934; U.S. title, *Joseph and His Brothers*), first part of four-part novel entitled *Joseph und seine Brüder* (*Joseph and His Brothers*, 1 vol. 1948), and continued in *Der junge Joseph* (1934; *The Young Joseph*, 1935), *Joseph in Ägypten* (1936; *Joseph in Egypt*, 1938), and *Joseph der Ernährer* (1943; *Joseph the Provider*, 1944); *Lotte in Weimar* (1939; Eng. trans. 1940; U.S. title, *The Beloved Returns*); *Doktor Faustus* (1947; Eng. trans. 1948); *Die Bekennnisse des Hochstaplers Felix Krull* (1954; *The Confessions of Felix Krull, Confidence Man*, 1955).

SHORT STORIES AND NOVELLAS: *Der kleine Herr Friedemann* (1898, collected early short stories; Eng. trans. in *Stories of Three Decades*, 1936; and *Stories of a Lifetime*, 1961, which contain translations of all Mann's more important short stories). NOVELLAS: *Tonio Kröger* (1903; first Eng. trans. in *Three Tales*, 1929); *Tristan* (1903; first Eng. trans. in *Three Tales*); *Der Tod in Venedig* (1912; *Death in Venice*, first Eng. trans. in *Three Tales*); *Unordnung und frühes Leid* (1926; trans. as *Early Sorrow*, 1929 and later); *Mario und der Zauberer* (1930; *Mario and the Magician*, 1930 and later); *Der Erwählte* (1951; *The Holy Sinner*, 1951); *Die Betrogene* (1953; *The Black Swan*, 1954).

PHILOSOPHICAL, POLITICAL, LITERARY PROSE WRITINGS, AND SPEECHES: *Betrachtungen eines Unpolitischen* (1918; *Reflections of an Unpolitical Man*, extracts trans. in *The Thomas Mann Reader*, 1950), political and philosophical treatise; *Goethe und Tolstoi* (1921; "Goethe and Tolstoi," first trans. in *Three Essays*, 1929), long philosophical, political, and literary essay; *Die Forderung des Tages* (1930), collected essays, mainly political; *Leiden und Grösse der Meister* (1935), collected essays, mainly philosophical and literary (including those on Freud, 1929, and Wagner, 1933), (both collections trans. in *Past Masters and Other Papers*, 1933, and *Essays of Three Decades*, 1947); *Neue Studien* (1948, collected essays; trans., with others, in *Last Essays*, 1959); *Deutsche Ansprache* (1930) and *Achtung, Europa!* (1938), collected speeches, lectures, and essays, mainly political; *Das Problem der Freiheit* (1939), long political and philosophical essay (all these, with others, trans. in *Order of the Day: Political Essays and Speeches of Two Decades*, 1942); *Deutsche Hörer* (1945), selections from broadcast talks (some trans. in *Listen, Germany! Twenty-Five Radio Messages to the German People Over BBC, 1940-42*, 1943); *Ansprache im Goethejahr* (1949), essays and lectures on Goethe (trans., with other important essays on Goethe, Chekhov, and Schiller in *Last Essays*, 1959); *Die Entstehung des Doktor Faustus* (1949; *The Genesis of a Novel*, 1961), fully documented account of the composition of *Doktor Faustus*.

#### BIBLIOGRAPHY

*Editions and correspondence*: The most complete edition is Mann's *Gesammelte Werke in zwölf Bänden*, ed. by HANS BUERGIN (1960); vol. 1-7 contain the novels, vol. 8 the *Novellen*, vol. 9-12 the essays, addresses, and speeches. There are several other collected editions and many editions of separate works. A full bibliography is included in HANS BUERGIN *et al.*, *Das Werk Thomas Manns* (1959). Films have been made of *Buddenbrooks* (1959) and *Death in Venice* (1970). Recordings of Thomas Mann reading from his works have been made: from *Felix Krull* (1954) and 2 records (1959); *Das Eisenbahnunglück* and *Schwere Stunde* (1955); and the essay on Schiller (1955). There are many volumes of Mann's correspondence, the most complete being the three volumes selected and edited by his daughter ERIKA MANN, *Briefe: 1889-1936* (1961), *1937-1947* (1963), and *1948-1955* (1965). A good selection, translated, is given by RICHARD and CLARA WINSTON, *Letters of Thomas Mann, 1889-1955*, 2 vol. (1970). Other collections are *Briefe an Paul Amann, 1915-1952*, ed. by HERBERT WEGENER (1959; Eng. trans., 1960); *Thomas Mann an Ernst Bertram: Briefe aus den Jahren 1910-1955*, ed. by INGE JENS (1960); *Thomas Mann-Karl Kerényi: Gespräch in Briefen*, ed. KARL KERÉNYI

(1960); *Briefwechsel: Thomas Mann—Robert Faesi*, ed. by ROBERT FAESI (1962); *Briefwechsel: Hermann Hesse—Thomas Mann*, ed. by ANNI CARLSSON (1968); *Thomas Mann und Hans Friedrich Blunck: Briefwechsel und Aufzeichnungen*, ed. by WALTER BLUNCK (1969); *Thomas Mann—Heinrich Mann: Briefwechsel 1900—1949*, ed. by HANS WYSLING (1968).

*Biography and criticism:* There is no definitive biography of Thomas Mann. HANS BUERGIN and HANS-OTTO MAYER give a detailed chronicle of his life in *Thomas Mann: Eine Chronik seines Lebens* (1965; Eng. trans., *Thomas Mann: A Chronicle of His Life*, 1969). The childhood home is described by his younger brother VIKTOR MANN in *Wir waren fünf* (1949). *Thomas Mann: Autobiographisches*, ed. by ERIKA MANN (1968), contains Mann's autobiographical essays and his daughter's account (1956) of the last year of his life (trans. by RICHARD GRAVES as *The Last Year of Thomas Mann*, 1958). KLAUS W. JONAS gives a full account of critical studies on Mann in *Fifty Years of Thomas Mann Studies: A Bibliography of Criticism* (1955). HERMANN J. WEIGAND, *Thomas Mann's Novel "Der Zauberberg"* (1933), is an excellent study of a single work; while KAETE HAMBURGER skillfully uses humour as a key to the interpretation of the Joseph novels in *Der Humor bei Thomas Mann: Zum Joseph-Roman* (1965). RICHARD H. THOMAS, *Thomas Mann: The Mediation of Art* (1956), is concerned with the relation of art and reality, the artist and the moralist in Mann. ERICH HELLER, *The Ironic German* (1958), finds the clue to the many ambiguities in Mann in his irony; while KURT SONTHEIMER, *Thomas Mann und die Deutschen* (1961), is a more straightforward examination of the complex relationship of Mann to his fellow Germans. JONAS LESSER, *Thomas Mann in der Epoche seiner Vollenendung* (1952), is a devoted study of the later Mann; while GEORG LUKACS' Marxist essays *Thomas Mann* (1949; rev. ed., 1957; trans. by STANLEY MITCHELL as *Essays on Thomas Mann*, 1964), are shrewdly critical as well as admiring. Various essays in CHARLES NEIDER (ed.), *The Stature of Thomas Mann* (1947); and in ERICH KAHLER, *The Orbit of Thomas Mann* (1969), may be recommended; while his position in the history of the German novel is indicated in ROY PASCAL, *The German Novel* (1956).

## Mansa Mūsā of Mali

Mansa Mūsā, ruler of the West African empire of Mali in the early 14th century, left a realm notable for its extent and riches, as well as its political organization. But he is best remembered for his pilgrimage to Mecca, which took place surrounded by unprecedented splendour. For almost two centuries his portrait adorned maps of Africa, and for a time he came to symbolize the continent to the European mind.

Mansa Mūsā's date of birth is not known. Either the grandson or the grandnephew of Sundiata, the founder of his dynasty, he came to the throne in 1307. In the 17th year of his reign (1324), he set out on his famous pilgrimage to Mecca. It was this pilgrimage that awakened the world to the stupendous wealth of Mali. Cairo and Mecca received this royal personage, whose glittering procession, in the superlatives employed by Arab chroniclers, almost put Africa's sun to shame. Travelling from his capital of Niani on the Upper Niger River to Walata (Oualāta, Mauritania) and on to Tuat (now in Algeria) before making his way to Cairo, Mansa Mūsā was accompanied by an impressive caravan consisting of 60,000 men including a personal retinue of 12,000 slaves, all clad in brocade and Persian silk. The Emperor himself rode on horseback and was directly preceded by 500 slaves, each carrying a gold-adorned staff weighing about six pounds. In addition, Mansa Mūsā had a baggage train of 80 camels, each carrying 300 pounds of gold.

Mansa Mūsā's prodigious generosity and piety, as well as the fine clothes and exemplary behaviour of his followers, did not fail to create a most favourable impression. The Cairo that Mansa Mūsā visited was ruled over by one of the greatest of the Mamlūk sultans, al-Malik an-Nāṣir. The black emperor's great civility not withstanding, the meeting between the two rulers might have ended in a serious diplomatic incident, for so absorbed was Mansa Mūsā in his religious observances that he was only with difficulty persuaded to pay a formal visit to the Sultan. The historian al-'Umarī, who visited Cairo 12 years after the Emperor's visit, found the inhabitants

of this city, with a population estimated at 1,000,000, still singing the praises of Mansa Mūsā. So lavish was the Emperor in his spending that he flooded the Cairo market with gold, thereby causing such a decline in its value that, some 12 years later, the market had still not fully recovered.

Rulers of West African states had made pilgrimages to Mecca before Mansa Mūsā, but the effect of his flamboyant journey was to advertise both Mali and Mansa Mūsā well beyond the African continent and to stimulate a desire among the Muslim kingdoms of North Africa, and among many of European nations as well, to reach the source of this incredible wealth.

Mansa Mūsā, whose empire was one of the largest in the world at that time, is reported to have observed that it would take a year to travel from one end of his empire to the other. While this was probably an exaggeration, it is known that during his pilgrimage to Mecca, one of his generals, Sagamandia (Sagaman-dir), extended the empire by capturing the Songhai capital of Gao. The Songhai kingdom measured several hundreds of miles across, so that the conquest meant the acquisition of a vast territory. The 14th-century traveller Ibn Baṭṭūṭa noted that it took about four months to travel from the northern borders of the Mali empire to Niani in the south.

The Emperor was so overjoyed by the new acquisition that he decided to delay his return to Niani and to visit Gao instead, there to receive the personal submission of the Songhai king and take the King's two sons as hostages. At both Gao and Timbuktu, a Songhai city almost rivalling Gao in importance, Mansa Mūsā commissioned Abū Ishāq as-Sāhili, a Granada poet and architect who had travelled with him from Mecca, to build mosques. The Gao mosque, built of burnt bricks, which had not, until then, been used as a material for building in West Africa, was still being admired as late as the 17th century.

Under Mansa Mūsā, Timbuktu grew to be a very important commercial city having caravan connections with Egypt and with all other important trade centres in North Africa. Side by side with the encouragement of trade and commerce, learning and the arts received royal patronage. Scholars who were mainly interested in history, Qur'anic theology, and law were to make the mosque of Sankore in Timbuktu a teaching centre and to lay the foundations of the University of Sankore. Mansa Mūsā probably died in 1332.

The organization and smooth administration of a purely African empire, the founding of the University of Sankore, the expansion of trade in Timbuktu, the architectural innovations in Gao, Timbuktu, Niani, and, indeed, throughout the whole of Mali and in the subsequent Songhai Empire are all testimony to Mansa Mūsā's superior administrative gifts. In addition, the moral and religious principles he had taught his subjects endured after his death.

**BIBLIOGRAPHY.** ABDERRAHMAN ES-SA'DI, *Tarikhe es-Soudan*, trans. into French by OCTAVE HOUDAS, 2 vol. (1898–1900, reprinted 1964), written by a 17th-century Sudanese, gives a useful account of the origin of the Ghana Empire and subsequent Sudanese history based on data now lost; IBN BATUTA, *Travels in Asia and Africa, 1325–1354*, trans. and selected by H.A.R. GIBB (1929); E.W. BOVILL, *Caravans of the Old Sahara* (1933) and *The Golden Trade of the Moors*, 2nd ed. rev. (1968), the latter contains a chapter on Mansa Mūsā; J.D. DE GRAFT-JOHNSON, *African Glory: The Story of Vanished Negro Civilizations* (1954), gives a vivid account of the great empires flourishing in the Western Sudan, including the Mali and Songhai empires; MAHMOUD KATI, *Tarikh el-Fettach*, trans. into French by OCTAVE HOUDAS and M. DELAFOSSE (1913), one of the two old histories of the Sudan published in Timbuktu; IBN KHALDOUN, *Histoire des Berbères et des dynasties musulmanes de l'Afrique septentrionale*, new ed., trans. into French by the baron DE SLANE, 4 vol. (1968–69), one of the main original sources of Sudanese history; AL-OMARI, *Masālik el-Absār* (1927), French translation of a work by a contemporary Arab scholar containing most of what is known about Mansa Mūsā's memorable pilgrimage to Mecca.

## Mansart, François

François Mansart is generally considered foremost among those who established classicism in Baroque architecture in mid-17th-century France. His works are characterized by subtlety, elegance, and harmony—the parts crisply delineated yet subordinated to the whole.

Mansart was born in Paris in January 1598, the grandson of a master mason and the son of a master carpenter. One of his uncles was a sculptor, another an architect. When his father died in 1610, Mansart's training was taken over by his brother-in-law, an architect and sculptor. Later, Mansart was apprenticed to and heavily influenced by Salomon de Brosse, a distinguished and successful architect during the reign of Henry IV and the regency of Marie de Médicis, mother of Louis XIII.

The 1600s, which saw the end of de Brosse's career and the beginning of Mansart's, could not have been more favourable for a young architect. Henry IV's entrance into Paris in 1594 as king of France signalled the beginning of a period of burgeoning political and social aspiration. Architecture reflected this aspiration, for the kings wanted their capital and their palaces to reflect the power of the crown; and the bourgeoisie commissioned châteaux (country houses) and *hôtels* (town houses) large enough for their coaches, stables of horses, and retinue of servants and splendid enough to receive the king and his entourage.

Most of Mansart's patrons were members of the middle class who had become rich in the service of the crown. They would have to have been very rich indeed to be Mansart's patrons. Not only did he draw up plans without regard to expense but refined and improved the plans—tearing down what had been built and rebuilding—as he went along. According to a contemporary, Mansart had cost one of his early patrons “more money than the Great Turk himself possesses.”

Mansart's career can be traced from 1623, when he designed the facade of the chapel of the Church of the Feuillants in the rue Saint-Honoré in Paris (no longer standing). Of his early works, the only one that survives is the château of Balleroy (begun c. 1626), near Bayeux, in the *département* of Calvados. Built for Jean de Choisy, chancellor to Gaston, duc d'Orléans, the brother of Louis XIII, the château consists of three blocks—a massive, free-standing main building to which two small pavilions are subordinated. One of the facades of the main building overlooks a court, the other a garden. The materials and treatment of the walls are characteristic of much of the work built during the reign of Henry IV. The walls are mainly of rough, brownish-yellow brick with little architectural ornament but emphasized by white stone quoins (corners) and white stone frames around the windows.

In 1635 Gaston commissioned Mansart to reconstruct his château at Blois, which had been built in the 15th and 16th centuries and used as a royal residence by three kings. Mansart proposed rebuilding it entirely, but only the north wing facing the gardens was reconstructed. The main building, flanked by pavilions, is subtly articulated by superimposed classical orders (Doric on the ground floor, Ionic on the first, and Corinthian on the second). The court entrance to the main building is approached on both sides by a curving colonnade. Mansart used the high-pitched, two-sloped roof that bears his name, mansard. (In fact, the roof had been used by earlier French architects.) The details are precise and restrained, the proportions of the masses harmonious.

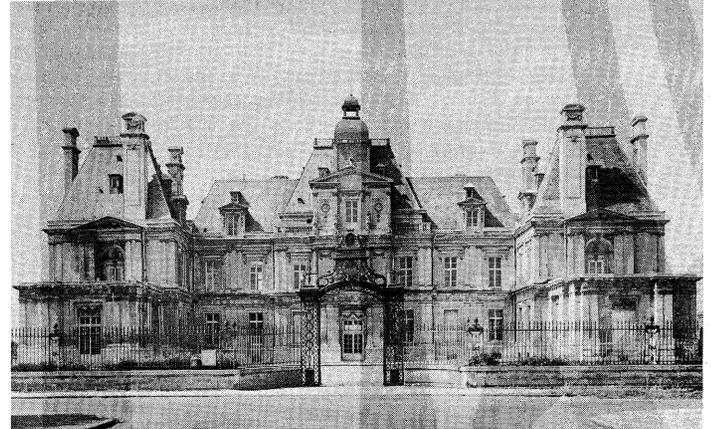

In the same period, Phélypeaux de La Vrillière, an officer of the crown, commissioned Mansart to build a town house in Paris (rebuilt after Mansart's death). The building, known from engraving, was a fine example of Mansart's ability to arrive at subtle, ingenious, and dignified solutions to the problems of building on awkwardly shaped sites.

In 1642 René de Longueuil, an immensely wealthy financier and officer of the royal treasury, commissioned Mansart to build a château on his estate. The château of Maisons (now called Maisons-Laffitte, in the chief town of the *département* of Yvelines) is unique in that it is the

only building by Mansart in which the interior decoration (graced particularly by a magnificent stairway) survives. The symmetrical design of the building (as well as the mansard roof) is similar to that of Mansart's earlier châteaux, but here there is a greater emphasis on relief. The central building is a free-standing

Château  
of Maisons

Wayne Andrews

The château Maisons-Laffitte (seen from the courtyard), *département* of Yvelines, France, designed by François Mansart, 1642.

block with a prominent rectangular frontispiece that projects from the main wall in a series of shallow steps. Two short wings, flanking the main building, stand out from it in clean, unbroken rectangular sections. Extending from each of the wings is a low, one-story block. The restrained play of subtly differentiated rectangular motifs makes the building a graceful and harmonious structure.

Because it is now surrounded by roads and houses, one can only imagine how noble the château looked, in the setting of terraced gardens designed for it by Mansart, when it opened with a reception for Anne of Austria and her son, the boy king Louis XIV. At times during the construction of the château, de Longueuil must have been sorely tried by Mansart's stubborn, independent, generally difficult personality, but on this day he was surely pleased with the architect he had chosen.

Perhaps Mansart's personality was responsible for the setbacks he began to encounter, the first of which was a royal commission he received in 1645 and lost in 1646. Anne of Austria asked Mansart to draw up plans for the convent and church of the Val-de-Grâce in Paris, which the sovereign had vowed to build if she bore a son. When the costs of laying the foundation exceeded the funds provided, Mansart was replaced by Jacques Lemercier, who more or less followed the original plans.

Along with a large fortune, Mansart had accumulated many enemies who accused him of capriciousness in the building and rebuilding of his projects, of wild extravagance, and of dishonesty. In 1651 a pamphlet entitled “La Mansarade” (possibly written by political enemies of the prime minister, Cardinal Mazarin, for whom Mansart had worked) accused him of having made deals with contractors and charged him with profligacy. The attack did not prevent him from continuing to work for prominent people.

With the accession of Louis XIV to the throne in 1661, private patrons became fewer and fewer. Architects, painters, sculptors, and craftsmen were called upon to build, decorate, and furnish structures commissioned by the King. When, in 1664, Louis decided to complete the palace of the Louvre, his chief minister and *surintendant des bâtiments* (roughly, “superintendent of buildings”), Jean-Baptiste Colbert, asked Mansart to draw up plans for the east wing (the colonnaded wing). Possibly because he could not produce and keep to any final plan, Mansart lost the commission.

In 1665 Colbert again asked Mansart to produce designs—this time for a chapel for the tombs of the royal family of the Bourbons to be built at the end of the Saint-Denis basilica. Mansart planned his design (which was never

Early  
works

executed) around a central, domed space, which later inspired his grandnephew Jules Hardouin-Mansart in his design for the dome of the church of Les Invalides.

When Mansart died in September 1666, the world was quite different from the one in which his career had begun. France had become the centre of Europe and Louis the centre of France—not only politically but also in matters of culture and taste. French architects, artists, and craftsmen were trained and employed by the crown for one end: the glorification of the state in the person of the King, who had declared himself to be the state. But the world was different, too, in that it had been enriched by the work of the independent and individualistic genius of François Mansart.

#### MAJOR WORKS

Château de Coulommiers (1618); Château de Berny (1623); facade of the Church of the Feuillants, Paris (1623–29); Hôtel Bouthillier, Paris (1630); Convents of the Visitation, rue Saint-Antoine, Paris (1632); Hôtel de la Vrillière, Paris (1635); Additions to château of Blois (1635); Chapel of the Dames de Sainte-Marie, Chaillot, Paris (1640); château of Maisons (Maisons-Lafitte) (1642); Val-de-Grâce, Paris (1645–46); Hôtel de Nevers, Paris (1649–50); remodelling of Hôtel Carnavalet, Paris (1655–61).

**BIBLIOGRAPHY.** A.F. BLUNT, *François Mansart and the Origins of French Classical Architecture* (1941), is the only monograph on Mansart published in this period (a serious work with some personal opinions). The same author's *Art and Architecture in France, 1500–1700* (1953), contains an excellent discussion of Mansart. See also the article "Mansart, François and Jules Hardouin," in the *Encyclopedia of World Art*, vol. 9, col. 478–485 (1964), a detailed biography and a bibliography of the essential works published to 1961. LOUIS HAUTECOEUR, *Histoire de l'architecture classique en France*, vol. 2 (1948; 2nd ed., vol. 1, sect. 3, 1966), is a general history that places the architect in the framework of his time.

### Mansfield, William Murray, 1st Earl of

William Murray, 1st earl of Mansfield, chief justice of the king's bench from 1756 to 1788, was the first jurist to shape English law to meet the demands of the country's new industrialism, burgeoning international commerce, and colonial relations; the law offered few precedents for such "modern" problems before Mansfield's time. Only Sir Edward Coke (1552–1634) and Sir Matthew Hale (1609–76) rivalled Murray as chief justice. Parts of his work were published and became authoritative almost before he was off the bench. Mansfield's outstanding juristic ability succeeded not only in solving controversial suits but also in forming the law for future claims. His greatest contribution was in the field of commercial law.

**Early life and career.** William Murray was born at Scone, in Perthshire, Scotland, on March 2, 1705, the son of the 5th Viscount Stormont. Educated at Perth grammar school, Westminster School, and Christ Church, Oxford, Mansfield was called to the bar at Lincoln's Inn in 1730. In Scotland he became famous representing the city of Edinburgh when it was threatened with disfranchisement for the hanging of the English captain of the city guard by a mob. Yet his English practice remained scanty until 1737 when his eloquent speech to the House of Commons in support of a merchants' petition to stop Spanish assaults on their ships placed him in the front rank of his profession. In 1742 he was appointed solicitor general. In 1754 he became attorney general and acted as leader of the House of Commons under the Duke of Newcastle. In 1756 he was appointed chief justice of the King's Bench and was made Baron Mansfield, becoming earl of Mansfield in 1776.

**Judicial decisions.** As must be the case with any court in central position, politics followed Mansfield to the bench. Three cases reveal his characteristic aloofness from personal or popular prejudices in rendering decisions. After the burning of his house and library in 1780, during anti-Catholic riots, which involved mobs of 50,000 and the invasion of Parliament itself, Mansfield so fairly conducted the treason trial of the leader, Lord

Mansfield, oil painting by John Singleton Copley, 1783. In the National Portrait Gallery, London.

George Gordon, that an acquittal resulted. In another case involving the prosecution of the journalist John Wilkes who had published works that were declared seditious libel by the House of Commons, he rose above both popular clamour and royal pressure by careful technical work on precedents. His investigations showed that the crown's case contained legal flaws, and he felt himself forced to discharge an agitator because due process so required. A widespread legendary view that Mansfield abolished slavery in England with one judicial decision, while it took a civil war in the United States, is unfounded. As a property-minded man of commerce, Mansfield sought, with all of his high tactical powers, to avoid any slavery issue. Even his judgment in the so-called Somerset case (1772), involving James Somersett who was bought in Virginia and attempted to run away after arriving in London, decided only that an escaping slave could not be forcibly removed from England for retributive punishment in a colony. This, as Benjamin Franklin protested, by no means implied abolition of "a detestable commerce" or of slavery in the colonies—both encouraged by the British laws until statutory changes in 1807 and 1833.

Mansfield's permanent stamp upon Anglo-American law lies in commercial law. When he mounted the bench, at the start of the Seven Years' War that was to fasten Britain's grasp upon America, India, and international trade, English law was land-centred and landbound in outlook and entrenched in professional tradition. Reform was imperative. Mansfield's vision and ambition reached beyond the continental model of a special body of rules for commerce and banking. He sought to make the international law of commerce not a separate branch but an integral part of the general law of England, both common law and equity, using the leverage thus gained to pry loose from feudalism whole blocks of other rules that had little or no direct commercial bearing. An important part of this brilliant venture succeeded.

In the area of bills of exchange (drafts), promissory notes, and the then still novel bank check, Mansfield, following standard international practice, shaped the law in sweeping judgments, each typically canvassing the whole relevant situation and its reasons. But Mansfield also established a new area of jurisprudence. Marine insurance, then a new industry, was centred in London and was a weapon of competition and Cold War. Mansfield did not build here on models; he created the entire discipline.

He was not always successful. In 1765, he ruled that a merchant's or banker's confirmed credit, or promise to

Contribution to commercial law

accept drafts drawn from abroad, was enforceable "without consideration"—i.e., without any bargained-for return. This decision was viewed as a flat attack on the whole legal doctrine of "consideration," and that doctrine was reaffirmed in its entirety by the House of Lords. He suffered a second defeat in his effort to make documents transferring hand interpretable by "plain intention," so that such intention could not be frustrated by technical rules giving unmeant effect to words. His decision in this area was reversed in 1772 (one of only six reversals during his 32 years of active service). But he triumphed in his expansion of the idea that a man should turn back or turn over any value received by mistake or wrongdoing or under other circumstances making it inequitable for him to retain it. The remedy he devised was a fictitious assumption of a "promise" to pay over (in modern times the fiction was discontinued and replaced by the term "restitution").

Three times during his career Mansfield held positions as a member of the cabinet, entrusting the great seal of his office to a committee, so that he could retain the chief justiceship regardless of changes in administration, but still exert political power. In 1783 he declined cabinet office, preferring to serve as speaker of the House of Lords. He resigned as chief justice in 1788 and died on March 20, 1793.

Assessment Despite his long tenure, the "father of commercial law" had almost no cases dealing with the substance of modern commercial law: mercantile contracts for the sale of wares. But he had chosen to make commercial law and general law a single whole. When commercial sales cases did arise, they came, ironically, before judges who thought in terms of haystacks and of horses, and the central area of commercial law in England was for more than a century given a flavour of land and manure rather than of commerce.

## Manšūr, al-

Abū Ja'far al-Manšūr, the second caliph of the 'Abbāsīd dynasty, which was descended from 'Abbās (an uncle of Muḥammad), is generally regarded as the real founder of the 'Abbāsīd caliphate. His regnal title, al-Manšūr, meant Made Victorious (by God).

Al-Manšūr was born between 709 and 714 at al-Ḥumaymah, in modern Jordan, the home of the 'Abbāsīd family after their emigration from the Hejaz in 687-688. His father, Muḥammad, was a great-grandson of 'Abbās; his mother was a Berber slave.

Shortly before the overthrow of the Umayyads, the first dynasty of caliphs, by an army of rebels from Khorāsān, many of whom were influenced by propaganda spread by the 'Abbāsīds, the last Umayyad caliph, Marwān II, arrested the head of the 'Abbāsīd family, al-Manšūr's brother Ibrāhīm. Al-Manšūr fled with the rest of the family to Kūfah in Iraq, where some of the leaders of the Khorāsānian rebels gave their allegiance to another brother of al-Manšūr, Abū al-'Abbās as-Saffāh, Ibrāhīm having died in captivity. As-Saffāh was the first 'Abbāsīd caliph.

Because his brother died in 754, after only five years as caliph, it was upon al-Manšūr that the main burden of establishing the 'Abbāsīd caliphate fell. Al-Manšūr had played an important part in wiping out the last remnants of Umayyad resistance. During his brother's caliphate he led an army to Mesopotamia, where he received the submission of a governor after informing him of the death of the last Umayyad caliph. In Iraq itself, the last Umayyad governor had taken refuge with his army in a garrison town. Promised a safe-conduct by al-Manšūr

and the Caliph, the Governor surrendered the town, only to be executed with a number of his followers.

A danger to al-Manšūr's caliphate came from a number of revolts by ambitious army commanders. The most serious of these was the revolt in 754 of al-Manšūr's uncle, 'Abd Allāh, who thought he had better claims to the caliphate than his nephew. The danger was only averted with the help of Abū Muslim, one of the chief organizers of the revolt against the Umayyads.

Al-Manšūr was largely responsible for cutting the 'Abbāsīds free from the movement that had brought them to power. While his brother was still caliph, al-Manšūr was involved in the murder of several leading personalities in that movement. Upon becoming caliph himself, one of his first acts was to bring about the death of the man who had helped him become caliph, Abū Muslim. These acts served both to remove potential rivals and to dissociate the 'Abbāsīds from their "extremist" supporters.

Perhaps in reaction to this policy, a number of revolts broke out, in which some of the pre-Islamic religions of Iran were involved. In 755 in Khorāsān, a certain Sunbadh, described as a magi (here probably meaning a follower of the Mazdakite heresy, not an orthodox Zoroastrian), revolted, demanding vengeance for the murdered Abū Muslim. Another group connected with the name of Abū Muslim, the Rāwandīyah, was charged with belief in the transmigration of souls and holding al-Manšūr to be their god. Because of these excesses, al-Manšūr had to suppress them, probably in 757-758. Finally, in 767 al-Manšūr had to put down another revolt in Khorāsān, the leader of which was accused of claiming to be a prophet.

Probably the most frustrated of those who had worked against the Umayyads were those who had believed they were fighting for a leader from among the descendants of the Prophet Muḥammad's closest male relative, 'Alī. When it became clear that the 'Abbāsīds had no intention of handing over power to an 'Alid, these groups again moved into opposition. Al-Manšūr's consequent harsh treatment of the 'Alids led to a rebellion in 762-763, which was quickly put down.

Al-Manšūr's achievement, however, was not based simply upon military power. His most lasting monument is the great city of Baghdad, upon which work began, at his command, in 762. The decision to build Baghdad was probably in part due to the restlessness of the chief towns in Iraq, Basra and, especially, Kūfah, but, in part, too, it was a statement by al-Manšūr that the 'Abbāsīds had come to stay. It was significant that he considered taking some material for the construction of Baghdad from the ruins of Ctesiphon, the capital of the last native Iranian dynasty.

Another reason for the construction of the new capital was the need to house the rapidly growing bureaucracy, developed by al-Manšūr under the influence of Iranian ideas in an attempt to provide a more stable basis for 'Abbāsīd rule.

By these political and military measures al-Manšūr firmly established the 'Abbāsīd caliphate. Furthermore, he arranged the succession in favour of his son, al-Mahdī, and every future 'Abbāsīd caliph could trace his descent directly to al-Manšūr.

Al-Manšūr is described as a tall, lean man, with a brown complexion and a sparse beard. There are a number of anecdotes designed to illustrate the simplicity of his life, his tightfistedness, his love of poetry, and his objection to music. He died in October 775 on his way to Mecca to perform the pilgrimage and was buried near the holy city.

**BIBLIOGRAPHY.** The only study of al-Manšūr's caliphate as a whole is in THEODOR NOLDEKE, *Sketches from Eastern History* (1892, reprinted 1963). For a general survey of the 'Abbāsīd rise to power and the early years of their rule, see the article "'Abbāsīds" by B. LEWIS in the *Encyclopaedia of Islam*, new ed, vol. 1, pt. 1 (1960). The *Encyclopaedia of Islam* should also be consulted for more information on specific details of al-Manšūr's life and caliphate (see especially the articles "Baghdād" and "al-Barāmīka").

Construction of Baghdad

Early years

## Mantegna, Andrea

Andrea Mantegna, a 15th-century painter, engraver, and possibly also a sculptor, was the first fully Renaissance artist of northern Italy. His art and his attitude toward Classical antiquity, moreover, provided a model for other artists, among them Giovanni Bellini in Venice and Albrecht Dürer in Germany. By placing the Virgin and saints of the S. Zeno altarpiece (1459) in a unified space continuous with its frame, Mantegna introduced new principles of illusionism into Sacra Conversazione paintings (*i.e.*, paintings of the Madonna and Child with saints).

Perhaps of even greater significance were his achievements in the field of fresco painting. Mantegna's invention of total spatial illusionism by the manipulation of perspective and foreshortening began a tradition of ceiling decoration that was followed for three centuries. Mantegna's portraits of the Gonzaga family in their palace at Mantua (1474) glorified living subjects by conferring upon them the over life-size stature, sculptural volume, and studied gravity of movement and gesture normally reserved for saints and heroes of myth and history.

Anderson—Allnar

"St. James Led to Martyrdom" (destroyed during World War II), fresco by Andrea Mantegna, 1453–55. Formerly in the Eremitani Church, Padua, Italy.

**Formative years in Padua.** Mantegna's extraordinary native abilities were recognized early. Most likely born in 1431, the second son of a woodworker near the town of Vicenza, Mantegna was legally adopted by Francesco Squarcione by the time he was ten years old and possibly even earlier.

A teacher of painting and a collector of antiquities in Padua, Squarcione drew the cream of young local talent to his studio, which some of his protégés, such as Mantegna and the painter Marco Zoppo, later had cause to regret. In 1448, at the age of 17, Mantegna dissociated himself from Squarcione's guardianship to establish his own workshop in Padua, later claiming that Squarcione had profited considerably from his services without giving due recompense. The award to Mantegna of the important commission for an altarpiece for the church of Sta. Sofia (1448), now lost, demonstrates his

precocity, since it was unusual for so young an artist to receive such a commission. Mantegna himself proudly called attention to his youthful ability in the painting's inscription: "Andrea Mantegna from Padua, aged 17, painted this with his own hand, 1448."

During the following year (1449), Mantegna worked on the fresco decoration of the Ovetari Chapel in the Eremitani Church in Padua. The figures of SS. Peter, Paul, and Christopher in the apse, his earliest frescoes in this chapel, show to what extent he had already absorbed the monumental figure style of Tuscany. In the "St. James Led to Martyrdom" in the lowest row on the left wall, painted sometime between 1453 and 1455, both Mantegna's mastery of *di sotto in su* (from below to above) perspective and his use of archaeologically correct details of Roman architecture are already apparent. The perspective scheme with a viewpoint below the lower frame of the composition exaggerates the apparent height of the scene with respect to the viewer and lends an aspect of grandiose monumentality to the triumphal arch.

In the two scenes from the life of St. Christopher united in a single perspective on the right-hand wall, Mantegna extended his experiments in illusionism to the framing element by painting a highly realistic column on the front plane. The meticulously detailed column divides the scene in two while appearing to exist in a realm totally apart from the pictorial space, a realm shared with the observer. This extension of illusionistic principles to the elements surrounding a picture anticipates Mantegna's S. Zeno altarpiece, where the carved half columns of the frame about the painted piers (vertical members) on the front plane of the picture space, so that the frame architecture serves as the "exterior" of the temple-pavilion architecture depicted in the painting. In this way the sphere of intense ideality inhabited by the Virgin is conjoined to the beholder's own space by a brilliant combination of physical and optical devices. Unfortunately, all Mantegna's frescoes in the Ovetari Chapel except "The Assumption" and "The Martyrdom of St. Christopher" episodes were destroyed by a bomb during World War II.

The environment of the city of Padua, where Mantegna lived during the major formative years of his life (from about age 10 to about age 30), exerted a strong influence on his interests, ideas, painting style, and concept of himself. Padua was the first centre of Humanism in northern Italy, the home of a great university (founded in 1222), and renowned as a centre for the study of medicine, philosophy, and mathematics. With the influx of scholars from all over Europe and Italy, an atmosphere of internationalism prevailed. From the time of the 14th-century poet Petrarch, Padua had experienced a rapidly growing revival of interest in antiquity, and many eminent Humanists and Latin scholars had resided there. Increasing interest in and imitation of the culture of ancient Rome produced a climate in which feverish collecting of antiquities and ancient inscriptions—even if only in fragmentary form—flourished. Mantegna's friendly relations with several Humanists, antiquarians, and university professors are a matter of record, and hence he may be seen as one of the earliest Renaissance artists to fraternize from a position of intellectual equality with such men. In this way Mantegna's life-style contributed to the early 16th-century ideal of the artist as a man so intimately familiar with antique history, mythology, and literature as to be able to draw easily from these highly respected sources.

The experience of the Paduan milieu was thus decisive for the formation of Mantegna's attitude toward the classical world, which may perhaps be characterized best as double faceted. On the one hand, Mantegna's search for accurate knowledge of Roman antiquity was reflected both in his depiction of specific monuments of Roman architecture and sculpture and in his creation of a vocabulary of antique forms that became the language of antique revival for more than a generation of northern Italian painters and sculptors after the mid-1450s. On the other hand, through a process of artistic synthesis, Mantegna sensed the forces and significances below the surfaces of Roman grandeur. The architectural backgrounds

of pictures in the Ovetari Chapel such as the "St. James Before Herod" and the "St. James Led to Martyrdom," as well as of the two paintings of St. Sebastian in Vienna and Paris, were infused with a brooding harshness and severity against which the suffering of the Christian saints takes on the added tragic implication of an impending cultural clash that was to separate and alienate the Christian and pagan worlds. In Mantegna's century, overcoming the experience of alienation from antiquity through the study and revitalization of its architectural and sculptural vocabulary was an obsessive theme. That the Roman world still existed in Italy in ruins only served to increase the sudden sense of cultural loss that struck the 15th century. By his thoroughgoing description of antique forms coupled with an instinctive sense of the political realities that underlay their original creation, Mantegna lent great impetus to the antique revival movement at midcentury.

Mantegna's starting point had been a still earlier form of antique revival—the monumental Tuscan figure style brought to Venice by the Florentine painter Andrea del Castagno in 1442. Mantegna presumably saw Castagno's frescoes of evangelists and saints in the church of S. Zaccaria during a visit to Venice in 1447. His Venetian connections were strengthened by his marriage in 1453 to Nicolosia, daughter of Jacopo Bellini and sister of Giovanni and Gentile Bellini, who became the leading family of painters in Venice during the following decade. Jacopo Bellini's studies in perspective and drawings of fantastic architectural settings based on antique architecture would have interested his new son-in-law, who very likely had studied such drawings during his earlier visit to Venice.

Though Mantegna might have been expected to join the Bellini studio, he preferred to pursue his independent practice in Padua, where the overwhelming artistic influence on him for the preceding few years had come from the wealth of sculpture produced by the Florentine Donatello for the high altar of S. Antonio (finished by 1450). Giovanni Bellini's response to Mantegna's style has been termed a dialogue, but Mantegna's reaction to Donatello's works might more aptly be called a struggle or even a dialectic. The frame and painted architecture of Mantegna's S. Zeno altarpiece answered the challenge posed by Donatello's Padua altar, for example. Mantegna's art always retained echoes of Donatello's sculpture in its hard, even metallic, surfaces, revealing an essentially sculptural approach that was somewhat softened only in the 1490s.

**Years as court painter in Mantua.** Mantegna has been characterized as strongly jealous of his independence, yet by entering the service of the marquis of Mantua, Ludovico Gonzaga, in 1459, he was forced to submit to limitations on his freedom of travel and acceptance of commissions from other patrons. Despite such limitations, Mantegna journeyed to Florence and Pisa in 1466–67, where he renewed contact with works of art by Donatello, Fra Filippo Lippi, Paolo Uccello, and Andrea del Castagno. During this decade (1460–70) Mantegna produced his finest small-scale works, such as "The Circumcision" and the Venice "St. George."

The Gonzaga patronage provided Mantegna a fixed income (which did not always materialize) and the opportunity to create what became his best known surviving work, the so-called Camera degli Sposi (Wedding Chamber), or Camera Picta (Painted Room), in the Palazzo Ducale at Mantua (1474), in which he developed a self-consistent illusion of a total environment.

Earlier practitioners of 15th-century perspective delimited a rectangular field as a transparent window onto the world and constructed an imaginary space behind its front plane. In the Camera degli Sposi, however, Mantegna constructed a system of homogeneous decoration on all four walls of the room, mainly by means of highly realistic painted architectural elements on walls and ceilings, which from ground level convincingly imitate three-dimensionally extended shapes. Though the ceiling is flat, it appears concave. Mantegna transformed the small interior room into an elegant open-air pavilion, to which the room's real and fictive occupants (actually one

and the same, since the beholders must have been members of this very court) were transported from deep within an essentially medieval urban castle.

Directly above the centre of the room is a painted oculus, or circular opening to the sky, with putti (little angels) and ladies around a balustrade in dramatically foreshortened perspective. The strong vertical axis created by the oculus locates the spectator at a single point in the centre of the room, the point from which the observer's space blends with that of the frescoed figures that are thrust out toward him by the narrow shelf of space provided for them on the fireplace wall.

The realism of the perspective handling of the oculus made it the most influential illusionistic *di sotto in su* ceiling decoration of the early Renaissance. Its implications for the future of ceiling decoration were largely unrealized, however, until the time of Correggio, a major north Italian painter of the early 16th century, who employed the same type of illusionism in a series of domes in Parma, Italy. Furthermore, the idea of total spatial illusion generated by Mantegna was not fully exploited until inventors of ingenious schemes of ceiling decoration in the Baroque era (the 17th century), such as Giovanni Lanfranco and Andrea Pozzo, utilized a basically identical concept of total illusion dependent upon the location of a hypothetical viewer standing at a single point in the room.

While at the Gonzaga court, Mantegna attained a position of great respect if not veneration. His close relations with his patron Ludovico were a unique phenomenon at such an early date. As one might expect, the signatures of Mantegna's paintings reveal intense pride in his accomplishments as a painter. Other than this there are only a few legal records of disputes with his neighbours (from which Ludovico had to rescue him) to provide tentative evidence for the painter's irascible and contentious personality during his later years. An empathetic viewer may draw many subjective conclusions as to Mantegna's thoughts and emotions by looking carefully at his paintings. But Ludovico died in 1478, followed soon after by Mantegna's son Bernardino, who had been expected to carry on his father's studio. Mantegna's financial situation was so bad that, in 1484, he was forced to ask for help from the powerful Florentine merchant Prince Lorenzo de' Medici and even contemplated moving to Florence. Ludovico's son Federico outlived his father by only a few years, and, with the accession of young Gianfrancesco II in 1484, the financial conditions of patronage improved.

Though many of Mantegna's works for the Gonzaga family were subsequently lost, the remains of nine canvases depicting a Roman triumphal procession, the "Triumph of Caesar," begun around 1486 and worked on for several years, still exist. In these paintings, reflecting the classical tastes of his new patron, Gianfrancesco, Mantegna reached the peak of his late style. Perhaps it was this new imaginative synthesis of the colour, splendour, and ritualistic power of ancient Rome that brought about Pope Innocent VIII's commission to decorate his private chapel in the Belvedere Palace, Rome (destroyed 1780), which Mantegna carried out in 1488–90.

Notwithstanding ill health and advanced age, Mantegna worked intensively during the remaining years of his life. In 1495 Gianfrancesco ordered the "Madonna della Vittoria" to commemorate his supposed victory at the Battle of Fornovo. In the last years of his life, Mantegna painted the "Parnassus" (1497), a picture celebrating the marriage of Isabella d'Este to Gianfrancesco Gonzaga in 1490, and "Wisdom Overcoming the Vices" (1502), for Isabella's *studiolo* (a small room in the Gonzaga palace at Mantua embellished with fine paintings and carvings of mythological subjects intended to display the erudition and advanced taste of its patron). A third canvas intended for this program, with the legend of the god Comus (Louvre), was unfinished when Mantegna died on September 13, 1506, and was completed by his successor at the Gonzaga court, Lorenzo Costa.

A funerary chapel in S. Andrea at Mantua was dedicated to Mantegna's memory. Decorated with frescoes, in-

Marriage to Nicolosia Bellini

The unique perspective of the Camera degli Sposi frescoes

Maturity of Mantegna's late style

cluding a dome painted (possibly by Correggio) with paradise symbols related to Mantegna's "Madonna della Vittoria," it was finished in 1516. No other 15th-century artist was dignified by having a funerary chapel dedicated to him in the major church of the city where he worked, which attests to the high stature Mantegna came to enjoy in his adopted city.

#### MAJOR WORKS

**PAINTINGS:** Ovetari Chapel frescoes (1448–55; Eremitani Church, Padua); "The Agony in the Garden" (c. 1450; National Gallery, London); "The Virgin with Sleeping Child" (c. 1450; Staatliche Museen Preussischer Kulturbesitz, Berlin); "The Man of Sorrows with the Virgin and Saints" ("The St. Luke Polyptych," 1454; Brera, Milan); "St. George" (c. 1455–60; Accademia, Venice); "Madonna Enthroned with Saints" (1456–59; S. Zeno Maggiore, Verona); "The Crucifixion" (1456–59; Louvre, Paris); "St. Sebastian" (c. 1459; Kunsthistorisches Museum, Vienna); "The Adoration of the Shepherds" (c. 1460; Metropolitan Museum of Art, New York); "Portrait of Cardinal Lodovico Mezzarota" (c. 1460; Staatliche Museen Preussischer Kulturbesitz, Berlin); "Portrait of a Man" (c. 1460; National Gallery of Art, Washington, D. C.); "Triptych with the Adoration of the Magi, the Circumcision, and the Ascension" (c. 1465; Uffizi, Florence); "The Death of the Virgin" (c. 1465; Prado, Madrid); "St. Sebastian" (c. 1465; Louvre); "The Dead Christ" (c. 1466; Jacob M. Heimann Gallery, New York); frescoes of the Camera degli Sposi (1473–74; Palazzo Ducale, Mantua); "The Mourning over the Dead Christ" (c. 1475?; Brera, Milan); "The Madonna of the Caves" (c. 1484?; Uffizi); "Triumph of Caesar" (begun c. 1486; Hampton Court Palace, England); "St. Sebastian" (c. 1490–1500; Ca d'Oro, Venice); "Madonna della Vittoria" (1495; Louvre); "Parnassus" (1497; Louvre); "Wisdom Overcoming the Vices" (1502; Louvre).

**ENGRAVINGS:** "Battle of the Sea Gods" (c. 1490); "Bacchanal" (c. 1490); "Madonna and Child" (c. 1490); "The Entombment" (1490s); "The Risen Christ Between St. Andrew and Longinus" (1490s). Prints of all are in the British Museum.

**BIBLIOGRAPHY.** PAUL KRISTELLER, *Andrea Mantegna* (1901), the first monograph on Mantegna in English, is a tremendous effort of scholarly achievement and synthesis. Many of Kristeller's conclusions remain unchallenged and all subsequent biographers have relied heavily on this book. IJSE BLUM, *Andrea Mantegna und die Antike* (1936), is a thorough analysis of the appearance of antique motifs in Mantegna's work with identification of his sources. There is some subsequent work on this aspect in English but none supplanting this. ERICA TIETZE-CONRAT, *Mantegna* (1955), is the best modern monograph in English, including a catalog of works, attributed works, drawings and engravings (fully illustrated). MILLARD MEISS, *Andrea Mantegna As Illuminator: An Episode in Renaissance Art, Humanism and Diplomacy* (1957), an essential book for evaluating Mantegna's achievement in classical revival, explores hitherto uncharted areas such as the artist's activity in the field of miniature painting and his contributions to the revival of classical epigraphy. See also the same author's "Toward a More Comprehensive Renaissance Palaeography," *Art Bulletin*, 42:97–112 (1960), a continuation of his research in this area. GIOVANNI PACCAGNINI, *Mantegna: La Camera degli Sposi* (1957), is a monograph on Mantegna's best known work by the leading Italian authority, who also wrote *Andrea Mantegna* (1961), the catalog of the Mantegna show in the Palazzo Ducale, Mantua, 1961 (with a good bibliography through 1961). See also his article in the *Encyclopedia of World Art*, vol. 9, col. 486–498 (1964), an excellent summary of the artist's life and works including accounts of disagreement among scholars and a fair reflection of the latest consensus. PHYLLIS and KARL LEHMANN, *Samothracian Reflections: Aspects of the Revival of the Antique* (1972), contains an essay on Mantegna's "Parnassus" that will most likely stand as the definitive analysis for many years to come.

(W.S.Sh.)

## Manuel I of Portugal

King of Portugal from 1495 to 1521, Manuel I was called the Fortunate. His reign saw the opening of the sea route to India, the discovery of Brazil, the establishment of Portuguese power at Goa (in India), the first Portuguese contact with China, and the concentration of trade with the East at Lisbon.

Manuel was also fortunate to have reigned at all; he was the 9th child of Dom Fernando, who was the younger

brother of Afonso V. Manuel was born at Alcochete on May 31, 1469; his father died a year later. King Afonso had one of Manuel's sisters married to his heir, John II, and another to the powerful Duke of Bragança. On his accession John II had Bragança executed on a charge of treason and later murdered Manuel's only surviving brother on suspicion of conspiracy. But John extended his protection to the boy Manuel, making him duke of Beja. On the death of his own son in 1491, John recognized Manuel as his heir. Although he later contemplated legitimizing his remaining son Jorge, he finally left the crown to Manuel.

As king, Manuel at once pardoned the banished Braganças and restored their confiscated estates. But the monarchy soon acquired vast new wealth as Vasco da Gama's voyage around Africa opened Portuguese trade with the East. In March 1500 Manuel sent Pedro Álvares Cabral with 13 ships to establish trade relations with the Indian princes. Cabral, sailing in the western Atlantic, sighted Brazil, sent back a ship to report the discovery, and continued around the Cape of Good Hope to India where he set up trading posts (*feitorias*) at Calicut, Cochin, and Cannanore, all on Malabar coast of southwestern India. Although half his ships were lost, the venture was profitable. In 1502 da Gama took 20 ships and brought back gold as tribute from East Africa. Manuel was already wealthy by 1503. Meanwhile, João Fernandes Lavrador reached what was probably Labrador in 1499, and Gaspar Côrte-Real discovered Newfoundland in 1500. The Brazilian coast was explored, though trade was virtually confined to the dyewood after which Brazil is named.

Manuel's claims to these newly discovered lands were confirmed by the Papacy and recognized by the Spanish, with whom Manuel maintained close relations. His three queens were Spanish. The first was Isabella, eldest daughter of cosovereigns Ferdinand and Isabella and widow of John II's heir. As a condition of the marriage, Manuel was to expel the Jews, many thousands of whom had been admitted by John II on their expulsion from Spain in 1492. Thus in December 1496 Manuel ordered Jews and free Muslims to quit Portugal within ten months. On their assembly in Lisbon, every attempt was made to force their conversion. Some were allowed to leave, but the rest were "converted" under the promise that no inquiry should be made into their beliefs for 20 years.

Manuel and Isabella became heirs to the Spanish crowns on her brother's death. They visited Toledo and Saragossa to receive oaths of allegiance in 1498, but the possibility of the union of the crowns ended when Isabella died in the same year while giving birth to their son Miguel, who died in infancy. In October Manuel married Isabella's younger sister Maria, by whom he had nine children.

The consolidation of Portuguese influence in the East can be dated from the foundation of the fortress at Cochin in 1503 and its successful defense by Duarte Pacheco Pereira (1504). Manuel sent Dom Francisco de Almeida as the first viceroy of Portuguese India in 1505. Albuquerque, who succeeded Almeida as governor, conquered Goa in 1510, and Malacca on the Malay Peninsula in 1511, bringing the distribution of oriental spices under Portuguese control. By 1513 the Portuguese had reached China.

The crusading aspect of the expansion reached its apogee with Albuquerque, who nourished grandiose schemes for blockading the Red Sea and capturing Mecca. Duarte Galvão's attempts to persuade other European courts to join a crusade met with little response. The arrival of an Abyssinian envoy at Manuel's court in 1514 suggested an alliance with the Christian negus (king) of that country and Manuel appointed Galvão ambassador to Abyssinia. But the mission was delayed by Galvão's death, and the crusading vision faded with the death of Albuquerque off Goa (December 1515). Manuel was no warrior. It was the Duke of Bragança who conquered Azamor in Morocco (1513).

The Indian traffic added enormously to the size and splendour of Manuel's court. John II had cowed the ambitious nobles. Manuel converted them into a palace aris-

Voyages to  
the East

Heir to the  
Spanish  
crown

ocracy, paying pensions to some 5,000 persons. Despite the brilliance of his age, Manuel appears in somewhat low relief. Most of the heroes of the day had made their mark under John II. Manuel was industrious, temperate, fond of music and display, and extravagant. He resided chiefly at Lisbon, where he built the waterside palace (near the present-day Terreiro do Paço), and at Sintra. The playwright-goldsmith Gil Vicente wrote for the court, which became a centre of minor poetry and painting. Manuel founded the palace-monastery of the Jerónimos at Belém and built the Tower of Belém; the architecture typical of the reign has been called "Manueline" only since the 19th century.

Under Manuel the public administration was increasingly centralized. A committee of royal officials revised town charters granted by previous rulers, standardized local privileges, and rationalized taxes. In 1515 Manuel ordered his council to revise the code of laws: his *Ordenações Manuêlinas* were issued in 1512 and revised in 1521. The judiciary was enlarged, and royal *corregedores* were appointed to all districts. This carried forward the process of neo-Roman absolutism and assured the rise of the judicial class. Manuel also excepted the church and the military orders of knighthood from certain obligations. He severely punished those responsible for the massacre of Jews in 1506. Manuel married Eleanor of Austria, sister of the emperor Charles V, in 1518, and had one daughter by this marriage. He died at Lisbon in December 1521, and was buried in the Jerónimos monastery.

**BIBLIOGRAPHY.** Chronicles of Manuel's reign were written by the humanists DAMIAO DE GOIS (1566-67), and JERONIMO DE OSSORIO (1571). There is an outline of the reign in English by ELAINE SANCEAU, *The Reign of the Fortunate King, 1495-1521* (1969).

## Mao Tse-tung

As China emerged from a half century of revolution as the world's most populous nation and a compelling model of modernization for Asian and African countries, Mao Tse-tung (in Pin-yin romanization, Mao Ze-dong), its principal revolutionary thinker and for many years its unchallenged leader, must be accorded a critical place in the story of the country's resurgence. To be sure, he did not play a dominant role throughout the whole struggle. In the early years of the Chinese Communist Party, he was a secondary figure, though by no means a negligible one, and even after the 1940s (except perhaps during the Cultural Revolution) the crucial decisions were not his alone. Nevertheless, looking back over the whole period since the foundation of the Chinese Communist Party in 1921, Mao Tse-tung can fairly be regarded as the principal architect of the new China.

Mao Tse-tung, 1966.

**Early years.** Born on December 26, 1893, in the village of Shao-shan, Hunan Province, Mao was the son of a former poor peasant who had become affluent as a

farmer and grain dealer. He grew up in an environment in which education was valued only as training for keeping records and accounts. From the age of eight he attended his native village's primary school, where he acquired a basic knowledge of the Confucian Classics. At 13, he was forced to leave and begin working full time on his family's farm. Rebelling against paternal authority, Mao left his family to study at a higher primary school in a neighbouring county and then at a secondary school in the provincial capital, Ch'ang-sha. There he came in contact with new ideas from the West, as formulated by such political and cultural reformers as Liang Ch'i-ch'ao and the Nationalist revolutionary Sun Yat-sen. Scarcely had he begun studying revolutionary ideas when a real revolution took place before his very eyes. On October 10, 1911, fighting against the Manchu dynasty broke out in Wu-ch'ang, and within 12 days the revolt had spread to Ch'ang-sha.

Enlisting in a unit of the revolutionary army in Hunan, Mao spent six months as a soldier. While he probably had not yet clearly grasped the idea that, as he later put it, "political power grows out of the barrel of a gun," his first brief military experience at least confirmed his boyhood admiration of military leaders and exploits. In primary school days, his heroes had included not only the great warrior-emperors of the Chinese past but Napoleon and George Washington as well.

The spring of 1912 saw the birth of the new Chinese Republic and the end of Mao's military service. For an entire year he drifted from one thing to another, trying in turn a police school, a soap-making school, a law school, a business school, studying history in a secondary school, and then spending some months reading many of the classic works of the Western liberal tradition in the provincial library. This period of groping, rather than indicating any lack of decision in Mao's character, was actually a reflection of China's situation at the time. The abolition of the official civil service examination system in 1905 and the piecemeal introduction of Western learning in so-called modern schools had left young people in a state of uncertainty as to what type of training, Chinese or Western, could best prepare them for a successful career or for service to their country.

Mao eventually graduated from the First Provincial Normal School in Ch'ang-sha in 1918. While officially an institution of secondary level rather than of higher education, the normal school offered a high standard of instruction in both Chinese history, literature, and philosophy and Western ideas. While at the school Mao Tse-tung also acquired his first experience in political activity by helping to establish several student organizations. The most important of these was the New People's Study Society, founded in the winter of 1917-1918, some of whose members were later to join the Communist Party and to follow Mao's leadership to the final Communist victory in 1949.

From the normal school in Ch'ang-sha Mao went to Peking University, China's leading intellectual centre. The half year he spent in Peking working as a librarian's assistant was of disproportionate importance in shaping his future career, for it was then that he came under the influence of the two men who were to be the principal figures in the foundation of the Chinese Communist Party: Li Ta-chao and Ch'en Tu-hsiu. Moreover, he found himself at Peking University precisely during the months leading up to the so-called May Fourth Movement of 1919, which was to a considerable extent the fountainhead of all the changes that were to take place in China in the ensuing half century.

In a limited sense, May Fourth Movement is the name given to the widespread and intense student demonstrations protesting against the Paris Peace Conference's decision to hand over former German concessions in Shantung to Japan instead of returning them to China. But the term also evokes a period of rapid political and cultural change, beginning in 1915, that resulted in the Chinese radicals' abandonment of Western liberalism for Marxism-Leninism as the answer to China's problems and the subsequent founding of the Chinese Communist Party in

Movement

1921. This period also saw the shift from the difficult and esoteric classical written language to a far more accessible vehicle of literary expression patterned on colloquial speech. At the same time, a new and very young generation moved to the centre of the political stage. To be sure, the demonstration on May 4th was launched by Ch'en Tu-hsiu, but the students soon realized that they themselves were the main actors. In an editorial published in July 1919, Mao wrote:

The world is ours, the nation is ours, society is ours. If we do not speak, who will speak? If we do not act, who will act?

Since then, his generation has never ceased to regard itself as responsible for the nation's fate, and, indeed, its members are still in power today, both in Peking and in Taipei.

During the summer of 1919 Mao Tse-tung helped to establish in Changsha a variety of organizations that brought the students together with the merchants and the workers—but not yet with the peasants—in demonstrations aimed at forcing the government to oppose Japan. His writings at the time are filled with references to the “army of the red flag” throughout the world and to the victory of the Russian Revolution, but it was not until the winter of 1919–20, after fleeing from Hunan, where he had led a campaign against the military ruler there, that he became committed to Marxism. He spent that winter in Peking reading translations of Marxist writings, which, he said,

built up in me a faith in Marxism from which, once I had accepted it as the correct interpretation of history, I did not afterwards waver.

**Mao and the Chinese Communist Party.** In June 1920, after a change of governors in Changsha, Mao returned to his native province as principal of the primary school, and in September or October of that year he organized a small Communist group there. That winter he married the first of his three wives, Yang K'ai-hui, the daughter of his former ethics teacher. Although his duties at the school occupied most of his time, he managed to keep up his political activities on a part-time basis. He did attend, in the summer of 1921, a meeting of representatives from the other Communist groups in China, along with two delegates from the Moscow-based Comintern (Communist International), and helped to found the Chinese Communist Party. In 1923, when the young party entered into an alliance with Sun Yat-sen's Kuomintang (Nationalist Party) in order more effectively to fight the inefficient and oppressive regime in Peking, Mao abandoned his job as principal to become a professional revolutionary and political leader.

In 1923–24, he lived mostly with his wife and two infant sons in Shanghai, where he was a leading member of the local Kuomintang organization, as well as of the Chinese Communist Party. In the winter of 1924–25, he returned to his native village of Shaoshan for a rest. There, after witnessing demonstrations by peasants stirred into political consciousness by the shooting of several dozen Chinese by foreign police in Shanghai (May and June 1925), Mao suddenly became conscious of the revolutionary potential inherent in the peasantry. Although born in a peasant household, he had, in the course of his student years, adopted the Chinese intellectual's traditional view of the workers and peasants as ignorant and dirty. His conversion to Marxism had forced him to revise his estimate of the urban proletariat, but he continued to share Marx's own contempt for the backward and amorphous peasantry. Now, however, he turned back to the rural world of his youth as the source of China's regeneration. Following the example of other Communists working within the Kuomintang who had already begun to work with peasants, Mao began to channel the spontaneous protest movements of the Hunanese peasants into a growing network of peasant associations.

**The Communists and the Kuomintang.** Pursued by the military governor of Hunan, Mao was soon forced to flee his native province once more and returned for another year to an urban environment—this time to Canton, the main power base of the Kuomintang, then led by Chiang

Kai-shek since the death of Sun Yat-sen in March 1925. But, though he lived in Canton, Mao still focussed his attention on the countryside. Apart from editing the Kuomintang's leading organ, the *Political Weekly*, and attending the Second Kuomintang Congress in January 1926, Mao served at the Peasant Movement Training Institute, set up in Canton under the auspices of the Kuomintang, as principal of the sixth training course. Although Chiang Kai-shek still declared his allegiance to the “world revolution” and wished to avail himself of Soviet aid, he was determined to remain master in his own house. He therefore expelled most Communists from responsible posts in the Kuomintang in March 1926. Mao, however, stayed on at the institute from May to October of that year. He remained there because of the common bond of nationalism he shared with Chiang, in spite of Chiang's suspicion of the Communists. As it turned out, most of the young peasant activists Mao trained were shortly at work strengthening the position of the Communists against the Kuomintang.

In July 1926, Chiang Kai-shek set out on a Northern Expedition aimed at unifying the country under his own leadership and overthrowing the conservative government in Peking as well as other dissident warlords. At the close of the training session in October, Mao once more returned to Hunan, where, in January and February 1927, he conducted an investigation into the peasant movement, which led him to conclude that in a very short time several hundred million peasants in China would “rise like a tornado or tempest—a force so extraordinarily swift and violent that no power, however great, will be able to suppress it.” Strictly speaking, this prediction proved to be false. Revolution in the shape of spontaneous action by hundreds of millions of peasants did not sweep across China “in a very short time,” or indeed at all. Chiang Kai-shek, who was bent on an alliance with the propertied classes in the cities and in the countryside, turned against the worker and peasant revolution, and in April of 1927 he went so far as to massacre the very Shanghai workers who had delivered the city to him. Stalin's strategy for carrying out revolution in alliance with the Kuomintang collapsed, and the Chinese Communist Party was virtually annihilated in the cities and decimated in the countryside. But in a broader and less literal sense, Mao's prophecy was justified. In August 1927 Mao led a few hundred peasants who had survived the autumn harvest uprising to a base on the Ching-kang Shan (Ching-kang Mountains) and embarked on a new type of revolutionary warfare in the countryside in which the Red Army, rather than the unarmed masses, would play the central role. But it was only because a large proportion of China's hundreds of millions of peasants sympathized with and supported this effort that Mao Tse-tung was able in the course of the civil war to encircle the cities from the countryside and thus defeat Chiang Kai-shek and gain control of the country.

**The road to power.** Mao's 22 years in the wilderness can be divided into four phases. The first of these is the initial three years when Mao Tse-tung and Chu Teh, the commander in chief of the army, successfully developed the tactics of guerrilla warfare from base areas in the countryside. These activities, however, were regarded even by their protagonists, and still more by the Central Committee in Shanghai (and by the Comintern in Moscow), as a holding operation until the next upsurge of revolution in the urban centres. In the summer of 1930 the Red Army was ordered by the Central Committee to occupy several major cities in south central China in the hope of sparking a revolution by the workers. When it became evident that persistence in this attempt could only lead to further costly losses, Mao disobeyed orders and abandoned the battle to return to the base in southern Kiangsi. During this year Mao's first wife was executed by the Kuomintang and he married Ho Tzu-chen, with whom he had been living since 1928 and who bore him five children.

The second phase (the Kiangsi period) centres on the founding of the Chinese Soviet Republic, November 1931, in a portion of Kiangsi Province, with Mao as

chairman. Since there was little support for the revolution in the cities, the promise of ultimate victory now seemed to reside in the gradual strengthening and expansion of the base areas. The Soviet regime soon came to control a population of several million; the Red Army, now grown to a strength of some 200,000, easily defeated large forces of inferior troops sent against it by Chiang Kai-shek in the first four of the so-called encirclement and annihilation campaigns. But it was unable to stand up against Chiang's own elite units, and in October 1934 the major part of the Red Army, Mao, and his pregnant wife all abandoned the base in Kiangsi and set out for the northwest of China, on what is known as the Long March.

The Kiangsi period of 1931–1934 is by far the most obscure and controversial in the history of Chinese Communism and in Mao's own career. There is wide disagreement among specialists as to the extent of Mao's real power, especially in the years 1932–34, and as to which military strategies were his or other party leaders'. But the majority view appears to be that, in the last years of the Chinese Soviet Republic, Mao functioned to a considerable extent as a figurehead with little control over policy, especially in military matters, and that he achieved de facto leadership over the party (though not the formal title of Chairman of the Central Committee) only at the Tsunyi Conference of January 1935 during the Long March.

In any case, when a few thousand troops who had survived the perils of the Long March arrived in the northwest in the autumn of 1935, events were already moving toward the third phase in Mao's rural odyssey, which was to be characterized by a renewed united front with the Kuomintang against Japan and by the rise of Mao to unchallenged supremacy in the party. In August 1935 both the Comintern at its Seventh Congress in Moscow and the Chinese Communists from one of their halts during the Long March proclaimed the principle of an anti-Fascist united front, and in May 1936 the Chinese Communists for the first time accepted the prospect that such a united front might include Chiang Kai-shek himself, and not merely dissident elements in the Nationalist camp. The so-called Sian incident of December 1936, in which Chiang Kai-shek was kidnapped by military leaders from northeastern China who wanted to fight Japan and recover their homelands rather than participate in civil war against the Communists, accelerated the evolution toward unity. By the time the Japanese began their attempt to subjugate all of China in July 1937, the terms of a new united front between the Communists and the Kuomintang had been virtually settled, and the formal agreement was announced in September 1937.

In the course of the anti-Japanese war, the Communists broke up a substantial portion of their army into small units and sent them behind the enemy lines to serve as nuclei for guerrilla forces which effectively controlled vast areas of the countryside, stretching between the cities and communication lines occupied by the invader. As a result, they not only expanded their military forces to somewhere between 500,000 and 1,000,000 at the time of the Japanese surrender but also established effective grass-roots political control over a population which may have totalled as many as 90,000,000. It has been argued that the support of the rural population was won purely by appeals to their nationalist feeling in opposition to the Japanese. This certainly was fundamental, but Communist agrarian policies likewise played a part in securing broad support among the peasantry.

During the years 1936–1940, Mao Tse-tung had, for the first time since the 1920s, the leisure to devote himself to reflection and writing. It was then that he first read in translation a certain number of Soviet writings on philosophy and produced his own account of dialectical materialism, of which the best known portions are those entitled "On Practice" and "On Contradiction." More important, Mao produced the major works which synthesized his own experience of revolutionary struggle and his vision of how the revolution should be carried forward in the context of the united front. On military matters, there was

first *Strategic Problems of China's Revolutionary War*, written in December 1936 to sum up the lessons of the Kiangsi period (and also to justify the correctness of his own military line at the time), and then *On Protracted War* and other writings of 1938 on the tactics of the anti-Japanese war. As to his overall view of the events of these years, Mao adopted an extremely conciliatory attitude toward the Kuomintang in his report entitled *On the New Stage* (October 1938), in which he attributed to it the leading role both in the war against Japan and in the phase of national reconstruction which would follow it. By the winter of 1939–40, however, the situation had changed sufficiently so that he could adopt a much firmer line, claiming leadership for the Communists. This was spelled out somewhat more openly in *The Chinese Revolution and the Chinese Communist Party*, written primarily for party members, than in *On New Democracy*, which was aimed at a wider audience, but otherwise the argument in both pieces was similar. Internationally, the Chinese revolution was a part of the world proletarian revolution directed against imperialism (whether it be British, German, or Japanese); internally, the country should be ruled by a "joint dictatorship of several parties" belonging to the anti-Japanese united front. For the time being, Mao felt, the aims of the Communist Party coincided with the aims of the Kuomintang, and therefore Communists should not try to rush ahead to socialism and thus disrupt the united front. But neither should they have any doubts about the ultimate need to take power into their own hands in order to move forward to socialism. During this period, in 1939, Mao divorced his second wife and married a well-known film actress, Lan P'ing, known today as Chiang Ch'ing.

The issues of Kuomintang-Communist rivalry for the leadership of the united front are related to the continuing struggle for supremacy within the Chinese Communist Party, for Mao's two chief rivals—Wang Ming, who had just returned from a long stay in Moscow, and Chang Kuo-t'ao, who had at first refused to accept Mao's political and military leadership—were both accused of excessive slavishness toward the Kuomintang. But perhaps even more central in Mao's ultimate emergence as the acknowledged leader of the party was the question of what he had called in October 1938 the "Sinification" of Marxism—its adaptation not only to Chinese conditions but to the mentality and cultural traditions of the Chinese people.

Mao could not claim the first-hand knowledge of how Communism worked within the Soviet Union possessed by many other leading members of the Chinese Communist Party nor the ability which some of them enjoyed to read Marx or Lenin in the original. He could and did claim, however, to know and understand China. The differences between him and the Soviet-oriented faction in the party came to a head at the time of the so-called Rectification Campaign of 1942. This program aimed at giving a basic grounding in Marxist theory and Leninist principles of party organization to the many thousands of new members who had been drawn into the party in the course of the expansion since 1937. Among the materials for study were writings by Lenin, Stalin, and Georgi Dimitrov, the Bulgarian Comintern leader. But a second and equally important aspect of the movement was the elimination of what Mao called "foreign dogmatism"—in other words, blind imitation of Soviet experience and obedience to Soviet directives.

The Rectification Campaign of 1942 has been bitterly denounced since the early 1960s by Soviet spokesmen as an attempt to purge the Chinese Communist Party of all those elements genuinely imbued with "proletarian internationalism" (i.e., devotion to Moscow). It is therefore not surprising that, as Mao's campaign in the countryside moved into its fourth and last phase—that of civil war with the Kuomintang—Stalin's lack of enthusiasm for a Chinese Communist victory should have become increasingly evident. Looking back on this period in 1962, when the Sino-Soviet conflict had come to a head, Mao declared:

In 1945 . . . , Stalin blocked the Chinese revolution, saying

The  
anti-  
Japanese  
war

Writings,  
1936–1940

Fourth  
phase—  
civil war

that we must not fight a civil war but must collaborate with Chiang Kai-shek. Otherwise, the Chinese nation would perish. At that time, we did not apply this, and the revolution was victorious. After the victory of the revolution, he [Stalin] again suspected that China would be like Yugoslavia, and I would turn into a Tito.

This account of Stalin's attitude is substantiated by a whole series of public gestures at the time, culminating in the fact that when the People's Liberation Army took Nanking in April 1949, the Soviet ambassador was the only foreign diplomat to accompany the retreating Nationalist government to Canton. Stalin's motives were obviously those described by Mao in the above passage; he did not believe in the capacity of the Chinese Communists to achieve a clear-cut victory, and he thought they would be a nuisance if they did.

**Formation of the People's Republic of China.** Nevertheless, when the Communists did take power in China, both Mao and Stalin had to make the best of the situation. In December 1949 Mao, now chairman of the Chinese People's Republic, travelled to Moscow, where, after two months of arduous negotiations, he succeeded in persuading Stalin to sign a treaty of mutual assistance accompanied by limited economic aid. Before the Chinese had time to profit from the resources made available for economic development, however, they found themselves dragged into the Korean War in support of the Moscow-oriented regime in P'yongyang. Only after this baptism of fire did Stalin, according to Mao, begin to have confidence in him and believe he was not first and foremost a Chinese nationalist.

Emphasis  
on  
centralized  
planning

Until several years after Stalin's death, the Chinese continued to go about "building socialism" in a way essentially similar to that which had been followed in the Soviet Union; *i.e.*, based on centralized planning with an emphasis on heavy industry, especially in the form of large capital-intensive enterprises built with Soviet assistance. Mao later described this policy as unfortunate but inevitable in view of the Chinese Communists' lack of experience in economic development. In the countryside, too, the stages of land reform, followed in due course by collectivization, were similar to those in the Soviet Union, though the details were somewhat different. Throughout the first half decade of the Chinese People's Republic, Mao rarely appeared in public. Apart from speeches welcoming foreign diplomats and official decrees which he signed as Chairman of the Chinese People's Republic, very few statements were issued in his name. On July 31, 1955, however, he suddenly emerged from this ceremonial role with an important speech calling for acceleration in forming agricultural cooperatives, which differed markedly from the provisions of the five-year plan officially adopted only the day before. This marked the beginning of a four-year period during which Mao constantly and actively sought to promote his own policies in every sphere, often against the opposition of senior comrades.

**Mao's re-emergence, 1955-59.** In the winter of 1955-56, Mao Tse-tung edited a three-volume compilation of materials on the "Socialist High Tide" in China's countryside, designed to illustrate the advantages of rapid collectivization. In the spring of 1956, three months after Nikita Khrushchev, then first secretary of the Soviet Communist Party, made a secret speech denouncing Stalin's purges of the Party after 1934, Mao proclaimed the policy of "letting a hundred flowers bloom"—that is, the freedom to express many diverse ideas—designed to prevent the development of a similar repressive political climate in China. The uprisings of October 1956 in Poland and Hungary against Soviet domination did not induce him to retreat from this policy; instead, he pressed on even more boldly in his celebrated speech of February 27, 1957, "On the Correct Handling of Contradictions among the People." It was evident at the time that the Hundred Flowers policy was never intended as a liberalization policy in the usual sense of the term. But neither was the invitation to "bloom" merely a trap to snare those with dissident opinions. Mao's hope was that the intellectuals and specialists, whom he had hailed

Hundred  
Flowers  
speech

in January 1956 as indispensable to the development of China's economy, would be more likely to support the regime wholeheartedly if the party demonstrated that it did not regard itself as infallible and was willing to listen to criticism. Mao soon discovered, however, that he had miscalculated. Far from contenting themselves with denouncing particular defects in the system, the critics called into question the most fundamental principle of the system itself, namely, leadership by the Communist Party.

Mao, therefore, in the autumn of 1957, turned his attention from the elite to the masses. If the specialists were not yet sufficiently "red," he would remold them by sending them to work at the grass-roots level. Meanwhile, he would rely primarily on the creativity of the rank and file as the agent of modernization. Mao was pushed in this direction by his disappointment with the intellectuals but economic necessity played an even greater role in the genesis of the new policies known as the Great Leap Forward. In the face of dwindling Soviet assistance, Mao concluded that China's economic development could best be assured by emphasizing small labour-intensive enterprises, which would require a substantial degree of local initiative, rather than capital-intensive programs. These policies were put into effect in the spring and summer of 1958 in the framework of the "people's communes," which spread rapidly throughout the Chinese countryside.

Great Leap  
Forward

There was still an element of Leninist orthodoxy in the system that emerged at this time, namely, party leadership. The kind of leadership involved, however, went against the grain of Leninism, essentially an elitist philosophy in which the intellectuals lead the workers and the workers lead the more backward peasants. In handing over control of both political and economic affairs to party secretaries at the commune level, who were often peasants themselves, Mao made a decisive departure from Leninism. He was quite right when he said later that 1958 had marked the end of Chinese reliance on the Soviet model.

**Setback and retirement.** The Great Leap Forward, while its economic effects were not wholly negative, did disorganize industrial production. The disruption of the countryside caused by the overhasty introduction of the communes, combined with a series of natural disasters, also led to a severe food shortage. As a result, opposition from Mao's colleagues forced him to retreat from these bold policies and accept a more orthodox approach to economic problems, stressing centralized planning and material incentives. In the autumn of 1959 the Minister of Defense, P'eng Te-huai, was removed from his post because he had criticized Mao's economic approach too openly, but in the years 1960-1962 it was P'eng's policies rather than Mao's that were applied by the party leadership. Mao's retirement in 1959 from the post of Chairman of the Chinese People's Republic was not a consequence of these setbacks, for it had been announced within the party at the end of 1957. Nevertheless, although Mao remained Chairman of the Communist Party, he was less in the public eye until the mid-1960s. Meanwhile, Lin Piao, P'eng Te-huai's successor as Minister of Defense, was turning the People's Liberation Army into a "great school of Mao Tse-tung's thought," thereby laying the foundations for Mao's comeback.

It is from this period that one may date serious disagreement and rivalry between Mao Tse-tung and Liu Shao-ch'i, who replaced Mao as chairman of the Republic. Though, in some respects, their approach to revolution in the 1920s and 1930s was different (Liu adopting a more orthodox view stressing the role of the urban proletariat), there was clearly an effective political alliance between them from the early 1940s. In 1945, at the Seventh Congress of the Chinese Communist Party, it was Liu who made the speech hailing Mao Tse-tung's thought as the guide to all the party's work, and in 1958 he supported Mao fully on the question of rapid economic development. He did not agree, however, on the decentralized and loosely coordinated pattern of development which characterized the Great Leap Forward, and begin-

Rivalry  
with Liu  
Shao-chi

ning in 1960 he came into conflict with Mao through his support of a more orthodox, Soviet-type model.

Socialist  
Education  
Movement

At the 10th Plenary Session of the Central Committee in September 1962, Mao issued the call, "Never forget the class struggle!" In the spring of 1963 he translated this into action by launching a Socialist Education Movement, which, in his view, would prevent China from "changing colour" and becoming "revisionist" like the Soviet Union. The movement became a battlefield for the opposing concepts of revolution held by Mao, on the one hand, and the leaders of the party organization, Liu Shao-ch'i and Teng Hsiao-p'ing, on the other. In the autumn of 1963 Teng produced a new directive to guide the movement, heavily imbued with Leninist elitism as compared to Mao's original draft, and in the autumn of 1964 Liu revised the directive further in an attempt to reach a compromise between Mao's views and Teng's. In January 1965 Mao intervened once more with a new and still more radical directive, denouncing the danger of "revisionism" in the Central Committee, but he was already moving toward the idea that a completely new form of political action was required—the gigantic and unprecedented undertaking that was to be called the Great Proletarian Cultural Revolution.

**The Cultural Revolution.** Mao concluded that the Socialist Education Movement had become merely another rectification movement similar to that of 1942. There had been many such campaigns since 1949, and the party cadres were adapting themselves to them: they would go through the prescribed motions, produce the necessary self-criticism, then continue acting as they had before. This time the party as a whole, and not merely individual elements in it, would have to be disciplined and re-molded.

It is still difficult to assess the consequences of the gigantic upheaval of the years 1966–69, although the general pattern of the movement is clear enough. First came the phase of Red Guard violence, in which the party organization was attacked and party officials beaten up by young zealots loyal to the Chairman, discreetly guided and supported by the army. From January 1967 to September 1968 came the "seizure of power" by revolutionary committees in the various provinces, comprising an alliance of former party cadres, young Red Guard and "revolutionary rebel" activists, and representatives of the People's Liberation Army. Then followed a period of "tidying up," symbolized by the Ninth Congress of the Chinese Communist Party in April 1969, and the attempt to reanimate the party organizations at all levels by retaining most of the previous membership but altering the spirit of the party bureaucracy and its relations with the masses.

While the Cultural Revolution can hardly be seen as the logically inevitable outcome of Mao's previous ideas and career, he so thoroughly identified himself with this attempt to transform the whole spirit and structure of Chinese society that assessment of the man and his life work must begin with it. Like many earlier episodes in Mao's life, the Cultural Revolution was full of contradictions. The most basic of these was that between the extraordinary development of the Mao cult, the call to be "boundlessly loyal to Chairman Mao," on the one hand, and the effort to promote spontaneity and grass-roots initiative on the other. Mao himself would no doubt have claimed that, in the struggle with the entrenched party bureaucracy, he had no alternative but to throw his own personal prestige and charisma into the balance. Moreover, he would have argued, if one is to extirpate the roots of bureaucracy, which lie in the attitude of arrogant superiority (and that attitude in China has always characterized those who could boast of a certain amount of book learning, from the mandarins of the past to modern party cadres and technical experts), the only solution lies in promoting ideas simple enough to be grasped by the people and a type of education adapted to the needs of the people.

There is a considerable element of truth in this official Maoist view of the Cultural Revolution. But at the same time, Mao's well-intended goal of increasing the general

level of education and culture was pursued in such a way as to paralyze advanced research and humiliate those who possessed high levels of expertness, thus inhibiting the development and use of skills that Mao described as essential to China's progress. And the cult of Mao and of Mao's thought, while giving the average man the conviction that he understood the most essential philosophical truths and the confidence to speak up and participate actively in the affairs of society, also had stultifying and impoverishing effects on intellectual life as a whole. When these considerations are added to the toll of violence of the years 1966–69, it is very hard to take a wholly positive view of the Cultural Revolution.

Mao died in Peking on September 9, 1976.

**Assessment.** In attempting to view not only Mao's later policies but his life as a whole, his profound contribution to China's national resurgence is indubitable. Although it was not Mao's achievement alone, in view of the central role he played from the 1940s until his death, he must be given a large portion of the credit. To what extent the policies he promoted during the Great Leap Forward, and subsequently during the Cultural Revolution, contributed to China's economic development or international prestige is, of course, subject to debate. Nonetheless, there was substantial economic progress, and the new China which he led and symbolized became a factor to be reckoned with in international affairs as it had not been in modern times.

More ambiguous was his message to the world at large. To Asia, Africa, and Latin America he offered China's experiences as a model of "people's war," which may be an appropriate solution in some circumstances but a source of division, dogmatic hair-splitting, and unnecessary sacrifice in others. To students and others in the advanced industrial societies of Europe and North America, he offered inspiration in the shape of a call to root out selfishness, bureaucratism, and the enslavement of man to the machine, but no infallible recipe for achieving these ends. The Chinese revolution and Mao's political theories will stand as landmarks in history, but whether or not they offer an effective solution to the problems of other countries remains to be seen. Mao himself recognized this fact when he said that a thousand years hence not only he but Marx might appear somewhat out of date.

**BIBLIOGRAPHY.** Two well-documented biographies of Mao Tse-tung are STUART R. SCHRAM, *Mao Tse-tung*, rev. ed. (1967); and JEROME CH'EN, *Mao and the Chinese Revolution* (1965). The account of Mao's life by ROBERT PAYNE, *Portrait of a Revolutionary: Mao Tse-tung* (1961), is somewhat more impressionistic but draws on the author's personal encounters with Mao. The most vivid account of Mao's youth is his own autobiography, as recounted to EDGAR SNOW in 1936 and published in *Red Star over China* (many editions from 1937). Other important books dealing with aspects of Mao's rise to power are BENJAMIN I. SCHWARTZ, *Chinese Communism and the Rise of Mao* (1951, reprinted in paperback 1967), dealing primarily with the late 1920s and early '30s; and CHALMERS A. JOHNSON, *Peasant Nationalism and Communist Power: The Emergence of Revolutionary China 1937–1945* (1962).

Regarding Mao Tse-tung's thought, the most complete collection of source materials available in English is to be found in the four-volume *Selected Works of Mao Tse-tung*, published by the Foreign Languages Press in Peking, supplemented by *Selected Readings from the Works of Mao Tse-tung*, published by the Foreign Languages Press in 1967, which duplicates some of the items in the *Selected Works* but also contains several important speeches made after 1949. The official version of the *Selected Works* is incomplete and has been extensively rewritten. The first attempt to compile a complete variorum edition of Mao's writings down to 1949 in Chinese was the 10-volume set of *Collected Writings of Mao Tse-tung* published in 1971–72 in Tokyo under the editorship of MINORU TAKEUCHI. Mao's talks and letters from 1956 to 1971 were published in English in 1974 as *Chairman Mao Talks to the People* (British title *Mao Tse-tung Unrehearsed*), ed. by STUART R. SCHRAM. Two contrasting interpretations are that of STUART R. SCHRAM (ed.), *The Political Thought of Mao Tse-tung*, rev. ed. (1969); and that of ARTHUR A. COHEN, *The Communism of Mao Tse-tung* (1964). A later work on Mao's thought is FREDERIC E. WAKEMAN, *History and Will: Philosophical Perspectives of Mao Tse-tung's Thought* (1973).

War"

## Maps and Mapping

Maps and charts are representations of features on the earth's surface drawn to scale. Globes are maps presented on the surface of a sphere. The definition can be extended to include representations of the moon, Mars, and other bodies for which increasing data are becoming available. Star charts and related celestial plats, long used for navigation and astronomical studies, might also be included.

In order to imply the elements of accurate relationships, and some formal method of projecting the spherical subject to a map plane, further qualifications might be applied to the definition. The tedious and somewhat abstract statements resulting from attempts to define maps and charts precisely are more likely to cause confusion than clarity. The terms map, chart, and plat are used somewhat interchangeably. The connotations of use, however, are distinctive: charts for navigation purposes (nautical and aeronautical), plats (in a property-boundary sense) for land-line references and ownership, and maps for general reference.

Cartography is the art and science of making maps and charts. As such, it is allied with geography in its concern with the broader aspects of the earth and its life. In early times cartographic efforts were more artistic than scientific and factual. As man explored and recorded his environment, the quality of his maps and charts improved. These lines of Jonathan Swift were inspired by early maps:

So geographers, in Afric maps,  
With savage pictures fill their gaps,  
And o'er unhabitable downs;  
Place elephants for want of towns.

Topographic maps are graphic representations of natural and man-made features of parts of the earth's surface plotted to scale. They show the shape of land and record elevations above sea level, lakes, streams and other hydrographic features, roads and other works of man. In short, they provide a complete inventory of the terrain and important information for all activities involving the use and development of the land. They provide the bases for specialized maps, and data for compilation of generalized maps of smaller scale.

Nautical charts are maps of coastal and marine areas, providing information for navigation. They include depth curves or soundings or both; aids to navigation such as buoys, channel markers, and lights; islands, rocks, wrecks, reefs and other hazards; and significant features of the coastal areas, including promontories, church steeples, water towers, and other features helpful in determining positions from offshore.

Aeronautical charts provide essential data for the pilot and air navigator. They are, in effect, small-scale topographic maps on which current information on aids to navigation have been superimposed. To facilitate rapid recognition and orientation, principal features of the land that would be visible from an aircraft in flight are shown to the exclusion of less important details.

This article is organized into the following sections:

### I. History of cartography

Maps and geography in the ancient world

The oldest maps

Greek maps and geography

The Roman period

Medieval maps and charts

The age of discovery and exploration

Revival of Ptolemy

Maps of the discoveries

18th century to the present

The new cartography

The rise of national surveys

International Map of the World (IMW)

World War II and after

### II. Map making

Elements of maps and charts

Design and planning

Map scales and classifications

Map projections

Development of reference spheroids

Geographic and plane coordinate systems

Basic data for compilation

Map and chart symbolization

Types and uses of maps and charts

World status of mapping and basic data

Types of maps and charts available

Government and other mapping agencies

International organizations

Modern map-making techniques

Compilation from existing materials

Map production from original surveys

Basic control surveys, satellites

Aerial photography

Photogrammetric mapping procedures

Final steps in map preparation

Automation in mapping

Map revision and maintenance

## I. History of cartography

Centuries before the Christian era, Babylonians drew maps on clay tablets, of which the oldest specimens found so far have been dated about 2300 BC. This is the earliest positive evidence of graphic representations of parts of the earth; it may be assumed that map making goes back much further and that it began among nonliterate peoples. It is logical to assume that men very early made efforts to communicate with each other regarding their environment by scratching routes, locations, and hazards on the ground, and later on bark and skins.

The earliest maps must have been based on personal experience and familiarity with local features. They doubtless showed routes to neighbouring tribes; where game, water, salt and other necessities might be found; and the locations of enemies and other dangers. Nomadic life stimulated such efforts by recording ways to cross deserts and mountains; the relative locations of summer and winter pastures; and dependable springs, wells, and other vital information.

Markings on cave walls associated with paintings by primitive man have been identified by some archaeologists as attempts to show the game trails of the animals depicted, though there is no general agreement on this. Similarly, networks of lines scratched on certain bone tablets could possibly represent hunting trails, but there is definitely no conclusive evidence that the tablets are indeed maps.

There are, however, numerous examples of not yet literate peoples showing surprising aptitudes in depicting essential features of their localities and travels. During Capt. Charles Wilkes's exploration of the South Seas in the 1840s, a friendly islander drew a good sketch of the whole Tuamotu Archipelago on the deck of the captain's bridge. In North America the Pawnee Indians were reputed to have used star charts painted on elk skin to guide them on night marches across the plains. Montezuma is said to have given Cortés a map of the whole Mexican gulf area painted on cloth, while Pedro de Gamboa reported that the Incas used sketch maps and cut some in stone to show relief features. Many specimens of early Eskimo sketch-maps on skin, wood, and bone have been found.

### MAPS AND GEOGRAPHY IN THE ANCIENT WORLD

**The oldest maps.** The earliest specimen that is indisputably a portrayal of land features thus far discovered is the Babylonian tablet previously referred to; certain land drawings found in Egypt and paintings discovered in early tombs are nearly as old. It is quite probable that these two civilizations developed their mapping skills more or less concurrently and in similar directions. Both were vitally concerned with the fertile areas of their river valleys and therefore doubtless made surveys and plats soon after settled communities were established. Later they made plats for the construction of canals, roads, and temples—the equivalent of today's engineering plans.

A tablet unearthed in Iraq some years ago shows the earth as a disk surrounded by water with Babylon as its centre. Aside from this specimen, dating from about 1000 BC, there appear to have been rather few attempts by Babylonians and Egyptians to show the form and extent of the earth as a whole. Their map making was preoccupied with more practical needs, such as the establishment of boundaries. Not until the time of the Greek philosopher-geographers did speculations and conclusions as to the nature of the earth begin to take form.

clay  
tablets

Maps in  
the New  
World

**Greek maps and geography.** The Greeks were outstanding among peoples of the ancient world for their pursuit and development of geographic knowledge. The shortage of arable land in their own region led to maritime exploration and the development of commerce and colonies. By 600 BC Miletus, on the Aegean, had become a centre of geographical knowledge, as well as of cosmographical speculation.

Hecataeus, a scholar of Miletus, probably produced the first book on geography about 500 BC. A generation later Herodotus, from more extensive studies and wider travels, expanded upon it. A historian with geographic leanings, Herodotus among the other things recorded an early circumnavigation of Africa by Phoenicians. He also improved on the delineation of the shape and extent of the then-known regions of the world and declared the Caspian to be an inland sea, opposing the prevailing view that it was part of the "northern oceans" (Figure 1).

accurate enough to show relative locations on the very small-scale, rudimentary maps that existed.

The eighth volume was a most important contribution, containing instructions for preparing maps of the world and discussions on mathematical geography and other fundamental principles of cartography. Ptolemy's map of the world as it was then known marked the culmination of Greek cartography, as well as a compendium of accumulated knowledge of the earth's features at that time (Figure 2).

**The Roman period.** Although Ptolemy lived and worked at the time of Rome's greatest influence, he was a Greek and essentially a product of that civilization, as was the great library at Alexandria. His works greatly influenced the development of geography, which he defined in map-making terms: "representation in picture of the whole known world, together with the phenomena contained therein." This had considerable influence in direct-

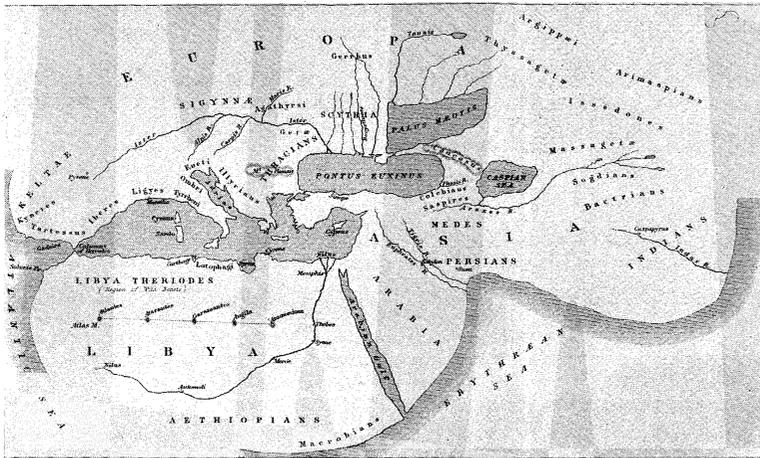

Figure 1: Herodotus' map of the world.

Although Hecataeus regarded the earth as a flat disk surrounded by ocean, Herodotus and his followers questioned the concept and proposed a number of other possible forms. Indeed, the philosophers and scholars of the time appear to have been preoccupied for a number of years with discussions on the nature and extent of the world. Some modern scholars attribute the first hypothesis of a spherical earth to Pythagoras (6th century BC) or Parmenides (5th century). The idea gradually developed into a consensus over many years. In any case by the mid-4th century the theory of a spherical earth was well accepted among Greek scholars, and about 350 BC Aristotle formulated six arguments to prove that the earth was, in truth, a sphere. From that time forward, the idea of a spherical earth was generally accepted among geographers and other men of science.

About 300 BC Dicaearchus, a disciple of Aristotle, placed an orientation line on the world map, running from west to east through Gibraltar and Rhodes. Eratosthenes, Marinus of Tyre, and Ptolemy successively developed the reference-line principle until a reasonably comprehensive system of parallels and meridians, as well as methods of projecting them, had been achieved.

**The age of Ptolemy.** The greatest figure of the ancient world in the advancement of geography and cartography was Claudius Ptolemaeus (Ptolemy; AD 90–168). An astronomer and mathematician, he spent many years studying at the library in Alexandria, the greatest repository of scientific knowledge at that time. His monumental work, the *Guide to Geography* (*Gēographikē hyphēgēsis*), was produced in eight volumes. The first volume discussed basic principles and dealt with map projection and globe construction. The next six volumes carried a listing of the names of some 8,000 places and their approximate latitudes and longitudes. Except for a few that were made by observations, the greater number of these locations were determined from older maps, with approximations of distances and directions taken from travellers. They were

ing scholars toward the specifics of map construction and away from the more abstract and philosophical aspects of geography.

One fundamental error that had far-reaching effects was attributed to Ptolemy—an underestimation of the size of the earth. He showed Europe and Asia as extending over half the globe, instead of the 130 degrees of their true extent. Similarly, the span of the Mediterranean ultimately was proven to be 20 degrees less than Ptolemy's estimate. So lasting was Ptolemy's influence that 17 centuries later Columbus underestimated the distances to Cathay and India partly from a recapitulation of this basic error.

A fundamental difference between the Greek and Roman philosophies was indicated by their maps. The Romans were less interested in mathematical geography and tended toward more practical needs for military campaigns and provincial administration. They reverted to the older concepts of a disk-shaped world for maps of great areas because they met their needs and were easier to read and understand.

The Roman general Marcus Vipsanius Agrippa constructed a map of the world, prior to Ptolemy's time, based on surveys of the then-extensive system of Roman military roads. References to many other Roman maps have been found, but very few actual specimens survived the Dark Ages. It is quite probable that the Peutinger Table, a parchment scroll showing the roads of the Roman world, was originally based on Agrippa's map, as subjected to several revisions through medieval times.

**The fall of Rome.** The tragic turn of world events during the first few centuries of the Christian era wrought havoc to the accumulated knowledge and progress of mankind. As with other fields of science and technology, progress in geography and cartography was abruptly curtailed. After Ptolemy's day, there even appears to have been a retrogression, as exemplified by the Roman trend away from the mathematical approach to mapping.

Ptolemy's  
fundamental  
error

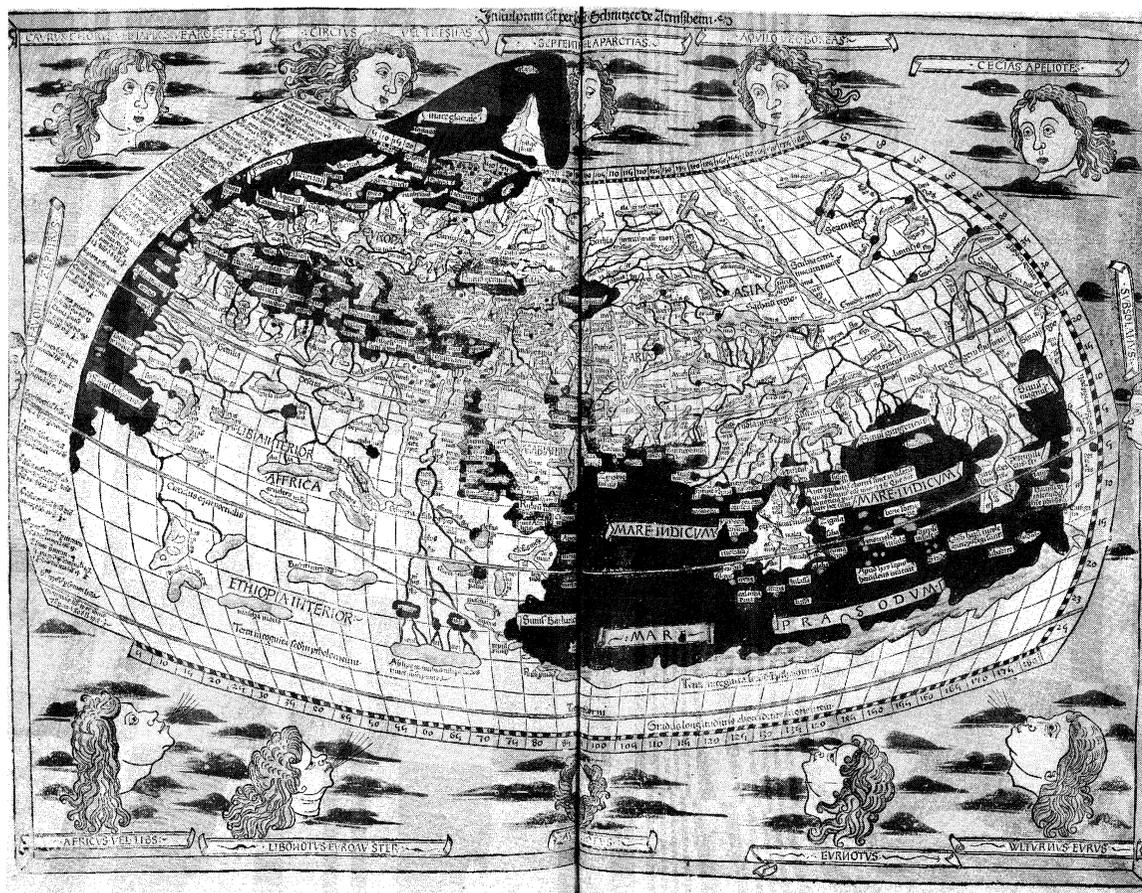

Figure 2: Ptolemy's map of the world, as printed at Ulm, 1482.

Great accumulations of documents and maps were destroyed or lost, and the survival of a large part of Ptolemy's work was probably due to its great prestige and popularity. The only other major work on mapping to survive was Strabo's earlier treatise, albeit with some changes from recopying. Few of the maps and related works of the ancient world have come down to us in their original forms. The tendencies to revise and even recapitulate, when copying manuscripts, is readily understood. Doubtless, the factual content was improved more often than not, but a residual confusion remains when the specimen at hand may be either a true copy of an ancient document or a medieval scholar's version of the subject matter.

#### MEDIEVAL MAPS AND CHARTS

Progress in cartography during the early Middle Ages was slight. The medieval map maker seems to have been dominated by the church, reflecting in his work the ecclesiastical dogmas and interpretations of Scripture. In fact, during the 6th century Constantine of Antioch created a "Christian topography" depicting the earth as a flat disk. Thus, the Roman map of the world, along with other concepts, continued as authoritative for many centuries. A contemporary Chinese map shows that country occupying most of the world, while the Roman Empire dominates most other maps produced during early Christian times.

Later medieval map makers were clearly aware of the earth's sphericity, but for the most part, maps remained small and schematic, as exemplified by the T and O renderings, so-named from the stylized T-form of the major water bodies separating the continents and the O as the circumfluent ocean surrounding the world. The orientation with east at the top of the map was often used, as the word (orientation) suggests.

Toward the end of the medieval period a significant advance in cartography was achieved in the portolan sea charts. Named for the portolano, or pilot book listing

sailing courses, ports, and anchorages, they were much in demand for the increasing trade and shipping. Genoa, Pisa, Venice, Majorca, and Barcelona, among others, cooperated in providing information garnered from their pilots and captains. From repeated revisions, and new surveys by compass, the portolan charts eventually surpassed all preceding maps in accuracy and reliability.

Many specimens of portolan charts have survived. Though primarily of areas of the Mediterranean and Black Sea, some covered the Atlantic as far as Ireland, and others the western coast of Africa. Their most striking feature is the system of compass roses (Figure 3), showing directions from various points, and lines showing shortest navigational routes.

Another phenomenon of the late Middle Ages was the great enthusiasm generated by the travels of Marco Polo in the 1270s and 1280s. New information about faraway places, and the stimulation of interest in world maps, promoted their sale and circulation. Marco Polo's experiences also kindled the desire for travel and exploration in others and were, perhaps, a harbinger of the great age of discovery and exploration.

During Europe's Dark Ages Islamic and Chinese cartography made progress. The Arabs translated Ptolemy's treatises and carried on his tradition. Two Islamic scholars deserve special note. Ibn Haukal wrote a *Book of Ways and Provinces* illustrated with maps, and al-Idrisi constructed a world map in AD 1154 for the Christian king Roger of Sicily, showing better information on Asian areas than had been available theretofore. In Baghdad astronomers used the compass long before Europeans, studied the obliquity of the ecliptic, and measured a part of the earth's meridian. Their sexagesimal (based on 60) system has dominated cartography since, in the concept of a 360-degree circle.

Chinese map making, like so many other aspects of art and science, developed independently. The oldest known Chinese map is dated about AD 1137. Most of the area had been mapped in crude form before the arrival of the

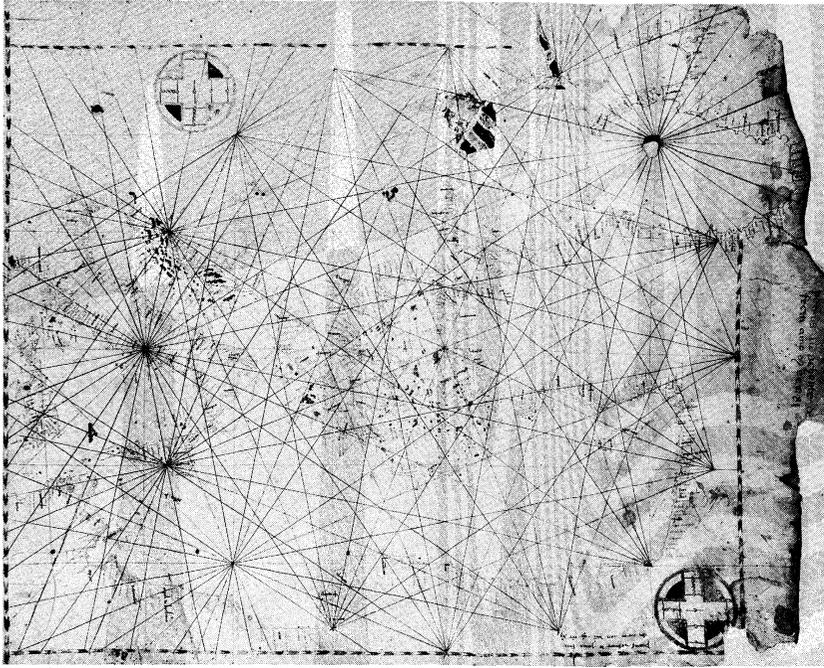

Figure 3: Portolan chart of the eastern Mediterranean area by Petrus Vesconte, 1311.

Europeans. The Jesuit missionaries of the 16th century found enough information to prepare an atlas, and Chinese maps thereafter were influenced by the West.

#### THE AGE OF DISCOVERY AND EXPLORATION

**Revival of Ptolemy.** The fall of Byzantium sent many refugees to Italy, among them scholars who had preserved some of the old Greek manuscripts, including Ptolemy's *Geography*, from destruction. The rediscovery of this great work came at a fortunate time. The recent development of a printing industry capable of handling map reproduction, made possible its circulation far beyond the few scholars who otherwise would have enjoyed access to it. This, together with a general reawakening of scholarship and interest in exploration, created a golden era of cartography.

The *Geography* was translated into Latin about 1405. Although it had not been completely lost (the Arabs had preserved portions of it) recovery of the complete work, with maps, greatly stimulated general interest in cartography. About 500 copies of Ptolemy were printed at Bologna in 1477, followed by other editions printed in Germany and Italy. The printing process, in addition to permitting the wide diffusion of geographic knowledge, retained the fidelity of the original works. By 1600, 31 Latin or Italian editions had been printed.

**Maps of the discoveries.** Progress in other technologies such as navigation, ship design and construction, instruments for observation and astronomy, and general use of the compass tended continuously to improve existing map information, as well as to encourage further exploration and discovery. Accordingly, geographic knowledge was profoundly increased during the 15th and 16th centuries. The great discoveries of Columbus, da Gama, Vespucci, Cabot, Magellan, and others gradually transformed the world maps of those days. "Modern" maps were added to later editions of Ptolemy. The earliest was a map of northern Europe drawn at Rome in 1427 by Claudius Claussön Swart, a Danish geographer. Cardinal Nicholas Krebs drew the first modern map of Germany, engraved in 1491. Martin Waldseemüller of St. Dié prepared an edition with more than 20 modern maps in 1513. Maps showing new discoveries and information were at last transcending the classical treatises of Ptolemy.

**Characteristics of new maps.** The most important aspect of postmedieval maps was their increasing accuracy, made possible by continuing exploration. Another signif-

icant characteristic was a trend toward artistic and colorful rendition, for the maps still had many open areas in which the artist could indulge his imagination. The cartouche, or title block, became more and more elaborate, amounting to a small work of art. Many of the map editions of this age have become collector's items. The first map printings were made from woodcuts. Later, they were engraved on copper, a process that made it possible to reproduce much finer lines. The finished plates were inked and wiped, leaving ink in the cut lines. Dampened paper was then pressed on the plate, and into the engraved line work, resulting in very fine impressions. The process remained the basis of fine map reproduction until the comparatively recent advent of photolithography.

The *Cosmographiae*, textbooks of geography, astronomy, history, and natural sciences, all illustrated with maps and figures, first appeared in the 16th century. One of the earliest and best known was that of Petrus Apianus in 1524, the popularity of which extended to 15 more editions. That of Sebastian Münster, published in 1544, was larger and remained authoritative and in demand until the end of the century, reflecting the general eagerness of the times for learning, especially geography.

**Cartographers of the discoveries.** The foremost cartographer of the age of discovery was Gerardus Mercator of Flanders. Well-educated and a student of Gemma Frisius, of Louvain, a noted cosmographer, he became a maker of globes and maps. His map of Europe, published in 1554, and his development of the projection that bears his name, made him famous. The Mercator projection (see below *Cylindrical projections*) solved an age-old problem of navigators, enabling them to plot bearings as straight lines.

Other well-known and productive cartographers of the Dutch-Flemish school are Abraham Ortelius of Antwerp, who prepared the first modern world atlas in 1570, and Jadocus Hondius. Early Dutch maps were among the best for artistic expression, composition, and rendering. Juan de la Cosa, the owner of Columbus' flagship, "Santa María," in 1500 produced a map recording Columbus' discoveries, the landfall of Cabral in Brazil, Cabot's voyage to Canada, and da Gama's route to the Indies. The first map showing North and South America clearly separated from Asia was produced in 1507 by Martin Waldseemüller. An immense map, 4½ by 8 feet, printed in 12 sheets, it is probably the first map on which the name America appeared, indicating that Waldseemüller was impressed

Printing  
of  
Ptolemy's  
*Geog-  
raphy*

Mercator

by the account written by the Florentine navigator Amerigo Vespucci.

In 1529, Diego Ribero, cosmographer to the king of Spain, made a new chart of the world on which the vast extent of the Pacific was first shown. Survivors of Magellan's circumnavigation of the world had arrived in Seville in 1522, giving Ribero much new information.

The first known terrestrial globe that has survived was made by Martin Behaim at Nürnberg in 1492. Many others were made throughout the 16th century. The principal centres of cartographic activity were Spain, Portugal, Italy, the Rhineland, the Netherlands, and Switzerland. England and France, with their growing maritime and colonial power, were soon to become primary map and chart centres. Capt. John Smith's maps of Virginia and New England, the first to come from the English colonies, were published in London in 1612.

#### 18TH CENTURY TO THE PRESENT

**The new cartography.** A reformation of cartography that evolved during the 18th century was characterized by scientific trends and more accurate detail. Monsters, lions, and swash lines disappeared and were replaced by more factual content. Soon, the only decorative features were in the cartouche and around the borders. The map interiors contained all the increasing information available, often with explanatory notes and attempts to show the respective reliabilities of some portions.

Application of science to map making

Where map makers formerly had sought quick, profitable output based on information obtained from other maps and reports of travellers and explorers, the new French cartographers were scientists, often men of rank and independent means. For expensive ventures, such as the triangulation of two degrees of a meridian to determine the earth's size more accurately, they were subsidized by the king or the French Academy. Similar trends were developing across Europe.

The new cartography was also based on better instruments, with the telescope playing an important part in raising the quality of astronomical observations. Surveys of much higher orders of accuracy were now feasible. The development of the chronometer (an accurate timepiece) made the computation of longitude much less laborious than before; much more information on islands and coastal features came to the map and chart makers.

**The rise of national surveys.** The development in Europe of power-conscious national states, with standing armies, professional officers, and engineers, stimulated an outburst of topographic activity in the 18th century, reinforced to some extent by increasing civil needs for basic data. Many countries of Europe began to undertake the systematic topographic mapping of their territories. Such surveys required facilities and capabilities far beyond the means of private cartographers who had theretofore provided for most map needs. Originally exclusively military, national survey organizations gradually became civilian in character. The Ordnance Survey of Britain, the Institut Géographique National of France, and the Landestopographie of Switzerland are examples.

In other countries, such as the United States, where defense considerations were not paramount, civilian organizations—e.g., the U.S. Geological Survey and the National Ocean Survey—were originally assigned responsibility for domestic mapping tasks. Only when World War II brought requirements for the mapping of many foreign areas did the U.S. military become involved on a large scale, with the expansion of the Oceanographic Office (navy), Aeronautical Chart Service (air force), and the U.S. Army Topographic command.

Surveys of colonies

Elaborate national surveys were undertaken only in certain countries. The rest of the world remained largely unmapped until World War II. In some instances colonial areas were mapped by military forces, but except for the British Survey of India, such efforts usually provided piecemeal coverage, or generalized and sketchy data. Some important national surveys will be outlined briefly.

**France.** The work in France was organized by the French Academy, and in 1748 the *Carte Géométrique de la France*, comprising 182 sheets, was authorized. Most of

the field observations were accomplished by military personnel. The new map of France as a whole, drawn after the new positions had been computed, caused Louis XV to remark that the more accurate data lost more territory than his wars of conquest had gained. Napoleon, an ardent map enthusiast, planned a great survey of Europe on a 1:100,000 scale, which was well under way when he was overthrown.

**Britain.** During the 18th century Britain became the foremost maritime power of Europe, and the Admiralty sponsored many developments in charting as well as improvements in navigation facilities. Because of the Admiralty's prestige, other maritime nations accepted its proposal that Greenwich be the prime meridian for longitude reference. Other achievements in early oceanography were Edmond Halley's magnetic chart that has been continuously revised from new data. Later similar charts for currents, tides, and prevailing winds were developed.

French progress in mapping stimulated the English to start a national survey, which was completed in 1787. The Ordnance Survey was organized in 1791, and the first sheet, on the scale of one inch to the mile, was published in 1801. Over a century ago the original coverage was completed and a new series, of six inches to the mile, was begun; England was soon the best mapped country in the world. An earlier "first" was John Ogilby's *Britannia* published in 1675, an atlas of road strip maps plotted by odometer and compass, presaging the modern road map.

**Other countries.** A survey of Spain was started in the 18th century. Surveys of several German principalities were combined into the Reichskarte at 1/100,000 scale after unification. A topographic survey of Switzerland was begun in 1832. An Austrian series was started in 1806, from which the Specialkarte, later considered the most detailed series of Europe, were derived. In China, under the Communist regime, survey and cartography groups have provided coverage of much of the country with a new 1:50,000-scale map series. Japan established an Imperial Land Survey in 1888. By 1925, topographical coverage of the home islands, with a scale of 1:50,000, was complete.

**International Map of the World (IMW).** The International Geographical Congress in 1891 proposed that the participating countries collaborate in the production of a 1:1,000,000 scale map of the world. Specifications and format were soon established, but production was slow in the earlier years, since it was first necessary to complete basic surveys for the required data, and during and after World War II, there was little interest in pursuing the project. The intention to complete the series was recently re-established, however, and many countries have returned to the task.

**World War II and after.** World War I, and to a much greater extent World War II, brought great progress in mapping, particularly of the unmapped parts of the earth; an appraisal by the U.S. Air Force indicated that less than 10 percent of the world in 1940 was mapped in sufficient detail for even the meagre requirements of pilot charts. A major program of aerial photography and reconnaissance mapping, that became known as the trimetrogen method, was developed. Vast areas of the unmapped parts of the world were covered during the war years, and the resulting World Aeronautical Charts have provided generalized information for other purposes since that time. Many countries have used the basic data to publish temporary map coverage until their more detailed surveys can be completed.

World Aeronautical Charts

**International cooperation.** The Cold War atmosphere of the 1940s and 1950s promoted a continuation of militarily oriented mapping activity. Both NATO and Warsaw Pact countries continued to improve their maps; NATO developed common symbols, scales, and formats, so that maps could be readily exchangeable among the forces of member countries. Postwar economic development programs, in which maps were needed for planning road, railroad, and reservoir constructions, also stimulated much work. The United Nations provides advisory assistance in mapping to countries wishing it.

Among other collaborations, the Inter-American Geo-

detic Survey, in which the U.S. Army provides instruction and logistic support for mapping, was organized. Although this cooperation primarily involved Latin American countries, similar arrangements were made with individual countries in other parts of the world. Cooperation and exchange of data in hydrographic surveys, aeronautical charting, and other fields has continued.

*The remaining tasks.* Although some terrain data are available for practically all of the world, the data for many sectors remain sketchy. Surveys by the several countries active there are in progress in Antarctica, but the continent will not be completely mapped for some years. The goal of most countries is to achieve adequate coverage for general development needs. Much remains to be done. Even in countries like the U.S. that have not yet completed the initial coverage, many of the areas mapped in earlier years are already in need of revision. Thus, even when mapping is completed, requirements for greater detail and revision will continue to make demands upon the funds available.

*Recent technology.* Aerial photography, which permits accurate and detailed work within feasible cost ranges, has dominated basic mapping in recent years. During World War I aerial photography was used for reconnaissance mapping, and after the war rapid progress was made in optics, cameras, plotting devices, and related equipment. By World War II much of the highly sophisticated equipment now currently in use had been designed. Electronic distance-measuring devices have made field surveys easier and more accurate, while much improved circle graduation has made theodolites (transits) lighter as well as more precise. Computers and automation, which together have transformed the mapping procedures of yesterday, are described below in the section *Modern map-making techniques*.

## II. Map making

### ELEMENTS OF MAPS AND CHARTS

**Design and planning.** Map design is a twofold process: (1) the determination of user requirements, with attendant decisions as to map content and detail, and (2) the arrangement of content, involving publication scale, standards of treatment, symbolizations, colours, style, and other factors. To some extent, user requirements obviously affect standards of treatment, such as publication scale. Otherwise, the latter elements are largely determined on the basis of efficiency, legibility, aesthetic considerations, and traditional practices.

In earlier productions by individual cartographers or small groups, personal judgments determined the nature of the end product, usually with due respect for conventional standards. Map design for large programs such as the various national map series of today, is quite formal by comparison. In most countries, the requirements of official as well as private users are carefully studied, in conjunction with costs and related factors, when considering possible changes or additions to the current standards.

Requirements of military agencies often have a decisive influence on map design, since it is desirable to avoid the expense of maintaining both civil and military editions of maps. International organizations and committees are additional factors in determining map design. The fact that development of changes in design and content of national map series may become rather involved induces some reluctance to change, as does the fact that map stocks are usually printed in quantities intended to last for ten or more years. Also, frequent changes in treatments result in extensive overhauls at reprint time, with consequent inconsistencies among the standing editions.

Planning for the production of a national series involves both technical and program considerations. Technical planning involves the choice of a contour interval (the elevation separating adjacent contour lines, or lines of constant elevation), which in turn determines the height of aerial photography and other technical specifications for each project. The sequence of mapping steps, or operational phases, is determined by the overall technical precedures that have been established to achieve the most efficiency.

The program aspects of planning involve fiscal allotments, priorities, schedules, and related matters.

Production controls also play important roles in large programs, where schedules must be balanced with capacities available in the respective phases to avoid backlogs, or dormant periods between the mapping steps. Considering that from authorization to final printing, topographic maps may require two years or more to complete, the importance of careful planning is evident. Many factors, including the weather, can converge to cause delays.

**Map scales and classifications.** Map scale refers to the size of the representation on the map as compared to the size of the object on the ground. The scale generally used in architectural drawings, for example, is  $\frac{1}{4}$  inch to one foot, which means that one quarter of an inch on the drawing equals one foot on the building being drawn. Scale models of buildings, railroads, and other objects may be one inch to several feet. Maps cover more extensive areas and it is usually convenient to express the scale by a representative fraction or proportion, as 1/63,360, 1:63,360, or "one-inch-to-one-mile." The scale of a map is smaller than that of another map when its scale denominator is larger: thus, 1:1,000,000 is a smaller scale than 1:100,000. Most maps carry linear, or bar, scales in one or more margin or in the title blocks.

In rare instances, reference may be made to the areal scale of a map, as opposed to its more normal linear scale. In such cases, the denominator of the fractional reference would be the square of the denominator of the linear scale.

The linear scale may vary, particularly on maps of quite small scale. Variations in the scale of a map because of the spherical surface it represents may, for practical purposes, be considered as nil. On maps of very large scale, such as 1:24,000 such distortions are negligible (considerably less than variations in the paper from fluctuations of humidity). Precise measurements for engineering purposes are usually restricted to maps of that scale or larger. As maps descend in scale, and distortions inherent to their projection of the spherical surface increase, less accurate measurements of distances may be expected.

Maps may be classified according to scale, content, or derivation. The latter refers to whether a map represents an original survey or has been derived from other maps or source data. Some contain both original and derived elements, usually explained in their footnotes. Producing agencies, technical committees, and international organizations, have variously classed maps as large, medium, or small scale. In general, large scale means inch-to-mile and larger, small scale, 1:1,000,000 and smaller, leaving the intermediate field as medium scale. As with most relative terms, these can occasionally lead to confusions but are useful as one practical way to classify maps.

The nature of a map's content, as well as its purpose, provides a primary basis of classification. The terms aeronautical chart, geologic, soil, forest, road, weather, etc., map, make obvious their respective contents and purposes. Maps are therefore often classified by the primary purposes they serve. Topographic maps usually form the background for geologic, soil, and similar thematic maps and provide primary elements of the bases upon which many other kinds of maps are compiled.

**Map projections.** A great variety of map projections has been devised to provide for the various properties that may be desired in maps. In effect, a projection is a systematic method of drawing the earth's meridians and parallels on a flat surface. Some projections have equal-area properties, while others provide for conformal delineations, in which, for small areas, the shape is practically the same as it would be on a globe. Only on a globe can areas and shapes be represented with true fidelity. On flat maps of very large areas, distortions are inevitable. These effects may be minimized by selecting the projection best suited to the purpose of the map to be produced.

Most types of projection can be grouped according to their geometrical derivations as cylindrical, conic, or azimuthal (Figure 4). A few cannot be so related, or are combinations of these. Terms such as network, graticule, or grid might have been preferable to describe the transposition of meridians and parallels from globe to flat sur-

Types of classification

Study of user requirements

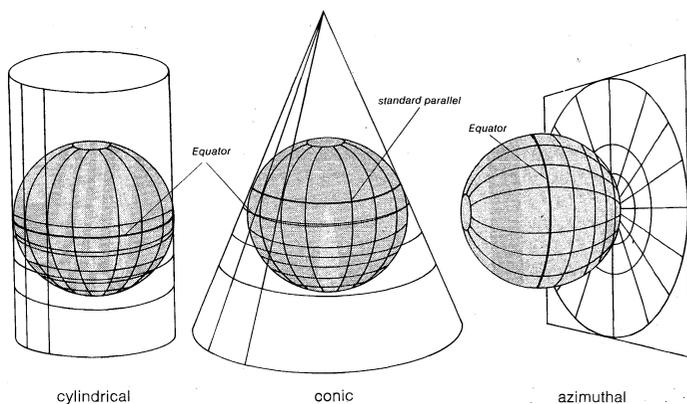

Figure 4: Derivations of basic projections.

face, since few systems are actually derived by projection, and, most in fact have been formulated by analytical and mathematical processes. The term projection however, is well established and has some merit in helping the layman to understand the problems and solutions. Tables for the construction of the commonly used projections have been developed by mapping agencies.

**Cylindrical projections.** These projections treat the earth as a cylinder, in which parallels are horizontal lines and meridians appear as vertical lines. The familiar Mercator projection is of this class and has many advantages in spite of great distortions it causes in the higher latitudes. Compass bearings may be plotted as straight segments on these projections, which have been traditionally used for nautical charts. On cylindrical projections places of similar latitude appear at the same height. Parallels and meridians may, if desired, be omitted from the body of the map and simply indexed at the margins, while lettering can be placed horizontally rather than in a curve. Among the variations of cylindrical projections is the Transverse Mercator, in which the axis of the cylinder is parallel to the Equator, a treatment which has advantages in drawing maps that are long in the north-south direction.

**Conic projections.** This group is derived from a projection of the globe on a cone drawn with the point above either the North or South Pole and tangent to the earth at some standard or selected parallel. Occasionally the cone is arranged to actually intersect the earth at two closely spaced standard parallels. A polyconic projection, used in large-scale map series, treats each band of maps as part of a cone tangent to the globe at the particular latitude.

**Azimuthal, or zenithal, projection.** These picture a portion of the earth as a flattened disk, tangent to the earth at a specified point, as viewed from a point at the centre of the earth, on the opposite side of the earth's surface, or from a point somewhere out in space. If the perspective is from the centre of the earth the projection is called gnomonic; if from the far side of the earth's surface, it is stereographic; if from space, it is called orthographic (Figure 5).

Modified from I. Fisher and O.M. Miller, *World Maps and Globes*

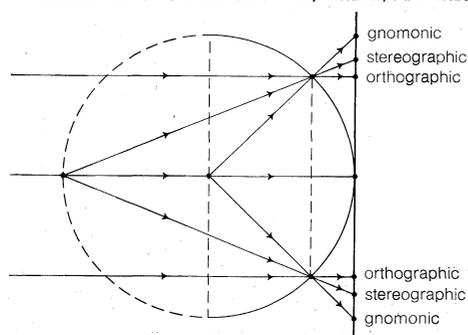

Figure 5: Basis of gnomonic, stereographic, and orthographic projections.

A type of projection often used to show distances and directions from a particular city is the Azimuthal Equidistant. Such measurements are accurate or true only from the selected central point to any other point of interest.

The polar projection is an azimuthal projection drawn to show Arctic and Antarctic areas. It is based on a plane perpendicular to the earth's axis, in contact with the North or South Pole. It is limited to 10 or 15 degrees from the poles. Parallels of latitude are concentric circles, while meridians are radiating straight lines.

**Development of reference spheroids.** Tables from which map projections of the more familiar kinds may be plotted have been available for some years and have been based on the best determinations of the size and shape of the earth available at the time of their compilation. The dimensions of Clarke's Spheroid (by the British geodesist Alexander Ross Clarke) of 1866 have been much used in polyconic and other tables. A later determination by Clarke in 1880 reflected the several geodetic surveys conducted during the interim. An International Ellipsoid of Reference was adopted by the Geodetic and Geophysical Union in 1924 for worldwide application.

With the recent development of electronic distance-measuring systems, greater progress has been made in geodetic surveys. With satellite observation and international collaborations now in progress, an accurate determination of the size and shape of the earth should be made during the next few years. It will then be possible to adjust all existing primary geodetic surveys and astronomical observations to a single world datum.

**Geographic and plane coordinate systems.** The standard geographic coordinate system of the world involves latitudes north or south of the Equator and longitudes east or west of the Prime Reference Meridian of Greenwich. Map and control point references are stated in degrees, minutes, and seconds carried to the number of decimal points commensurate with the accuracy to which locations have been made.

Geodetic surveys, being of extensive areas, must be adjusted for the earth's curvature and reductions made to mean sea level for scale. The computations are therefore somewhat involved. As a convenience for engineers and surveyors, many countries have established official plane coordinate systems for each province, state, or sector thereof. By this means, all surveys can be "tied" to control points in the system, without transposition to geographic coordinates.

In large countries such as the United States, two basic projections are commonly selected to provide systems with minimum distortions for each state or region. For those long in N-S dimension, the Transverse Mercator is generally used, while for those long in E-W direction, the Lambert conformal (intersecting cone) projection is usually employed. In the case of large-size regions, two or more zones may be established to limit distortions. Positions of geodetic control points have been computed on the plane coordinate systems and have been made available in published lists.

**Basic data for compilation.** Maps may be compiled from other maps, usually of larger scale, or may be produced from original surveys and photogrammetric compilations. The former are sometimes referred to as derived maps and may include information from various sources, in addition to the maps from which they are principally drawn. Most small-scale series, such as the International Map of the World and World Aeronautical Charts, are compiled from existing information, though new data are occasionally produced to strengthen areas for which little or doubtful information, exists. Thus, compiled maps may contain fragments of original information, while those representing original surveys may include some existing data of higher order, such as details from a city plat.

Road maps, produced by the millions and familiar to everyone, are compiled from road surveys, topographic maps, and aerial photography. City maps often represent original surveys, made principally to control engineering plans and construction. Some are, however, compiled from enlargements of topographic maps of the area.

projection

Notations regarding the sources from which they were drawn are usually carried on compiled maps. This sometimes includes a reliability diagram showing the areas for which good information was available and those that may be less dependable. Comments regarding certain features or areas, that the editor may deem helpful to the user, may be made in the map itself.

Maps reflecting original surveys, such as a national topographic map series, carry standard marginal information. Date of aerial photography, process and instrumentation employed, notes regarding control and projection, date of field edit, and other information may be included. References to the availability of adjoining maps and those of other scales or series may also be included. Marginal ticks for intervals of plane coordinate systems, military grids, and other reference features are also shown and appropriately labelled.

**Map and chart symbolization.** Symbols are the graphic language of maps and charts that has evolved through generations of cartographers. The symbols doubtless had their origins as simple pictograms that gradually developed into the conventions now generally used.

**Standardization.** Early cartographers recognized that common usages and conventions would minimize confusion and to some extent simplify compilation and engraving. Efforts in this direction were made over the years, but cartographers, being artists of a sort, preferred to vary their styles, and effective standardization was not achieved until comparatively recent times. National agencies in most countries established conventions with due regard to practices in other countries. International Map of the World agreements, NATO conventions, the efforts of the United Nations and of international technical societies, all aid standardization.

Symbols may be broadly classed as planimetric or hypsographic, or may be grouped according to the colours in which they are conventionally printed. Black is used for names and culture, or works of man; blue for water features, or hydrography; brown for relief, or hypsography; green for vegetation classifications; and red for road classes and special information. There are variations, however, particularly in special-purpose series, such as soil and geologic maps. Symbols will also vary, perforce, due to limitations of space in the smaller scales, and the feasibility of drawing some features to actual size in maps of larger scales. Legends explain the less obvious symbols on many maps, while explanatory sheets or booklets are available for most standard series, providing general data as well as symbol information. When less familiar symbols are used on maps they are often labelled to avoid misunderstanding. The general located-object symbol, with label, is often used in preference to specific symbols for such objects as windmills and lookout towers for similar reasons.

**Relief treatments.** Planimetric features (those shown in "plan," such as streams, shorelines, and roads) are easier to portray than shapes of land and heights above sea level. Mountains were shown on early maps by sketchy lines simulating profile or perspective appearance as envisioned by the cartographer. Little effort was made at true depiction as this was beyond the scope of available information and existing capabilities. Form lines and hachures, among other devices, were also used in attempting to show the land's shape. Hachures are short lines laid down in a pattern to indicate direction of slope. When it became feasible to map rough terrain in more detail, hachuring developed into an artistic speciality. Some hachured maps are remarkable for their detail and fidelity, but much of their quality depends on the skill of draftsman or engraver. They are little used now, except where relief is incidental.

Contours are by far the most common and satisfactory means of showing relief (see Figure 6). Contours are lines that connect points of equal elevation. The shorelines of lakes and of the sea are contours. Such lines were little used until the mid-19th century, mainly because surveys had not generally been made in sufficient detail for them to be employed successfully. Mean sea level is the datum to which elevations and contour intervals are generally re-

ferred. If mean sea level were to rise 20 feet the new shoreline would be where the 20-foot contour line is now shown (assuming that all maps on which it is delineated are reasonably accurate).

By courtesy of U.S. Geological Survey

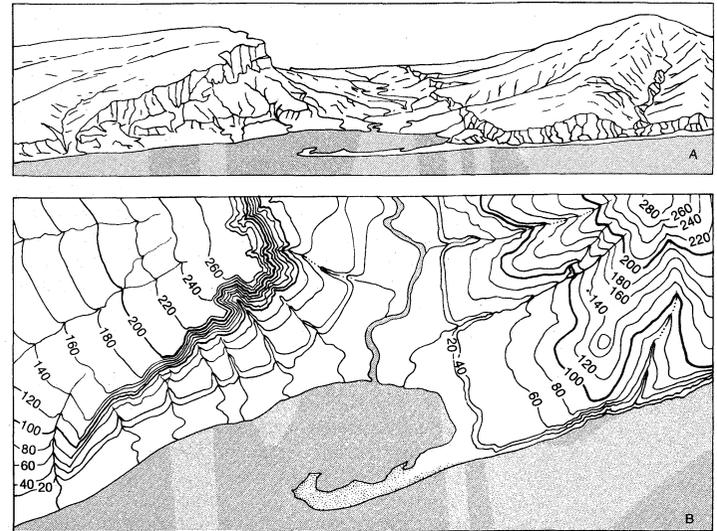

Figure 6: Landscape shown in perspective A is represented with the aid of contour lines on map B.

The quality of contour maps, until recent times, depended largely on the sketching skill of the topographer. In earlier days funds available for topographic mapping were limited, and not much time could be spent in accurate placement. Later, the accurate location of more control points became feasible. An approximate scale of reliability is therefore indicated by the date of a topographic survey, taking into account the respective situations that existed in various countries. Modern surveys, being based on aerial photos and accurate plotting instruments, are generally better in detail and accuracy than earlier surveys. The personal skill of individual topographers, long a factor in map evaluations, has therefore been substantially eliminated.

Hill shading, or shaded relief, layer or altitude tinting, and special manipulations of contouring are other methods of indicating relief. Hill shading requires considerable artistry, as well as the ability to visualize shapes and interpret contours. For a satisfactory result, background contours are a necessary guide to the artist. Hypsographic tinting is relatively easy, particularly since photomechanical etching and other steps can be used to provide negatives for the respective elevation layers. Difficulty in the reproduction process is sometimes a deterrent to the use of treatments involving the manipulation of contours.

**Terrain models.** In the past, three-dimensional maps were laboriously constructed for studies in military tactics and for many other purposes. They were costly to produce, as contour layers had to be cut and assembled, filled with plaster and painted, after which streams, roads, etc., had to be drawn on the surface. Lettering then was applied and models of large structures, such as buildings and bridges, were added. In view of the time and cost involved in such productions they were sparingly used until recent years when better production methods and materials became available. During and after World War I a process was developed and improved whereby an aluminum sheet was "raised" by tapping along the contours copied on its surface. When the contours selected for tapping were completed, the sheet became, in effect, a mold for shaping plastic sheets to its convolutions. The map was printed on plastic sheets prior to the thermal process of shaping them to the mold. Sets of relief maps were soon produced in this manner for use in schools, military briefings, and many other activities.

During and after World War II the production of plastic relief maps was greatly expanded, while the processes and equipment were further improved and refined. Most

Hachuring

Pantograph-router

significant among these developments was a pantograph-router, which cuts a model from plaster or other suitable material, as the selected contours are followed by the operator on a topographic map. This eliminated the distortions inherent in shaping metal sheets by the tapping process. Selected topographic maps are now published in limited relief editions for military instruction, special displays, and general classroom instruction.

Most relief maps are exaggerated severalfold in the vertical scale. The earth is remarkably flat, when viewed in actual scale, and many significant features would hardly be distinguishable on a map without some vertical exaggeration. Mt. Everest, for example, is actually only one-seventh of 1 percent of the earth's radius in height, or only one-third of an inch at a scale of 1:1,000,000. For this reason, relief is usually shown at five, or even ten times actual scale, depending upon the nature of the area represented. This exaggerated relief scale is always explained in the map legend.

**Nomenclature.** All possible places and features are identified and labelled to assure maximum map usefulness. Some names must be omitted, particularly from maps of smaller scales, to avoid overcrowding and poor legibility. The editor must decide which names may be eliminated, while arranging placements so that a maximum number may be accommodated.

Geographic names are the most important, and sometimes the most troublesome, part of the map nomenclature as a whole. Research on existing maps and related documents for a given area may reveal different names for the same features, variations in spelling, or ambiguous applications of names. The field engineer often finds that local usage is confused and sometimes controversial. Various types of official organizations have been established to study the problems submitted and decide the forms and applications that are to be used in government maps and documents. This function is exercised in the U.S. by the Board on Geographic Names and in the United Kingdom by the Permanent Committee on Geographical Names.

Toponymics

The science of place-names, or toponymics, has become a significant specialty since World War II, and efforts have been made to establish uniform usages and standards of transliteration throughout the world. Renewed interest in completing the remaining sheets of the International Map of the World, collaborations resulting from military alliances, and efforts of committees of international scientific societies and the United Nations have all contributed to these efforts.

At the local levels, however, there are different kinds of problems. The larger scales of most basic topographic map series permit the naming of quite minor hilltops, ridges, streams, and branches, for which designations can be obtained locally. In sparsely settled country, few names in actual use may be obtained for minor features, while in other areas, inquiries may reveal inconsistencies and confusions in both spelling and application of local names. In some areas, for example, local residents may tend to refer to small streams by the name of the present occupant of the headwater area. The occupants of opposite sides of a mountain sometimes refer to it by different names. In coastal areas the waterman and landsman may use different references for the same features.

A prime opportunity for resolving these problems is presented when a topographic map of an area is prepared for publication. By extensive inquiry and documentation and research of local records and deeds, the appropriate form and application of nearly all names can be determined. Publication and distribution of the map as an official document may then tend to solidify local usage and eliminate the confusions that previously existed.

Lettering

Lettering is selected by the map editor in styles and sizes appropriate to the respective features and the relative importance of each. For topographic maps and most others that follow conventional practice, four basic styles of lettering are used in the Western world. The Roman style is generally used for place-names, political divisions, titles, and related nomenclature. Italic is used for lakes, streams, and other water features. Gothic styles are usu-

ally applied to land features such as mountains, ridges, and valleys. Man-made works such as highways, railroads, and canals are usually labelled in slope Gothic capitals, but other distinctive styles are often used for these, together with descriptive notes.

The relative importance of map features is reflected in the different sizes of lettering selected to label them. The most prominent places and features are usually shown in capitals, while lesser ones are labelled with lowercase lettering. In the labelling of cities, however, uppercase lettering is often reserved for state or province capitals. County seats are also labelled in this manner on topographic maps of the U.S. For other towns, where lowercase lettering is in order, the sizes selected reflect their relative importance.

#### TYPES AND USES OF MAPS AND CHARTS

**World status of mapping and basic data.** Before World War I, only a few countries such as Britain, France, and Germany had detailed maps covering their whole national areas. Now many countries have completed coverage of their territories, while others have carried out small-scale coverage and are beginning engineering surveys in selected areas.

It has been demonstrated that the full potential of map usage in a country, state, or province is not realized until some time after complete coverage has become available. When a modern, detailed map replaces an earlier issue, annual distribution can increase dramatically.

**Status of world topographic mapping.** Topographic maps provide the basic data for many other kinds, as well as working bases for thematic maps showing geology, soils, and vegetation types. The progress of such mapping in the various parts of the world is therefore a primary indicator of the status of cartography in general. A United Nations survey of the status of world mapping was recently completed. Inquiries were made to the mapping organizations of all member nations regarding the extent of their respective map coverage, publication scales, and related data.

Less than 20 percent of the world's land area is now covered by maps at scales of 1:50,000 and larger. Some of such coverage is culturally obsolescent or of low structural quality. An additional 40 percent is covered by medium-scale topographic maps; *i.e.*, up to 1:250,000 (about four miles to the inch). Some of this is inferior coverage at medium scales, lacking in geodetic control and topographic detail. This is the case with much of China, but most of the mapping is quite adequate for purposes of reconnaissance and as source information for smaller scale maps.

This provides a general indication of the relative reliability of data contained in such world series maps as the 1:1,000,000 scale aeronautical charts and International Maps of the World. Areas of doubtful information are left blank or are drawn with broken lines. In spite of this dearth of reliable data, most of the IMW sheets have been compiled, and most of the aeronautical pilotage charts have been published, to provide navigation continuity across water areas as well as over unmapped parts of the world.

In some areas, however, large-scale topographic maps are not required. Australia, for example, has large-scale coverage only of its populated coastal areas, in the east; in the "outback" areas 1:250,000 scale maps are considered adequate for all foreseeable needs, and a program for their production is well under way. Likewise, large areas of tundra, as in Siberia, deserts in many parts of the world, and other sparsely populated areas may be adequately served with medium- or small-scale coverage until specific development sites require engineering maps.

**Nautical charts.** Nautical chart coverage of the world leaves much to be desired. Good progress has been made, however, on areas bordering the continents and islands. The Arctic, Antarctic, South Pacific, and South Atlantic oceans are the most deficient in good chart coverage. The Defense Mapping Agency, through agreement with the British Admiralty and other chart-producing countries, maintains worldwide coverage that is constantly updated.

International Hydrographic Bureau

The National Ocean Survey maintains charts of U.S. coastal waters. The International Hydrographic Bureau, based at Monaco, attempts to stimulate cooperation in improvement of hydrographic data in general. This organization's Bathymetric Chart of the Oceans shows existing knowledge and is revised from time to time, as new data are accumulated (see also HYDROGRAPHIC CHARTING).

**Aeronautical charts.** Coverage of reliable quality parallels the availability of topographic maps that provide the essential terrain and cultural data. For this purpose, good 1:250,000 scale maps contain sufficient information for clearance safety and position identification.

**Geodetic surveys.** Until recently, the progress of geodetic triangulation, the basic survey method, was more or less limited to areas either covered by good topographic maps or scheduled for mapping. Preparations for cadastral surveys, where land partition problems abound, have occasionally led to early geodetic programs. Coastal and other surveys also require good basic control to be fully effective; however, it is again the developed and heavily populated areas that are encompassed with the best geodetic surveys. Electronic distance-measuring systems have accelerated the progress of geodetic surveys during the 1960s and have extended continental schemes over many ocean areas. International cooperation on satellite triangulation is now in progress, with the prospect that existing triangulation of the continents may soon be tied together and adjusted into a single world datum. The Inter-American Geodetic Survey has made progress in the Americas.

**Aerial photography.** In addition to other applications, aerial photography provides a useful supplement to topographic maps. Indeed, where maps are not available, aerial photographs invariably serve as map substitutes, in spite of inherent distortions and lack of elevation data. Most of the world is covered by aerial photography.

During World War II the U.S. Air Force photographed vast areas of the world, providing reconnaissance maps that were used as bases for aeronautical charts. Much of this information now forms the basis for small-scale map coverage in still remote areas. The system of photography and mapping became known as the trimetrogon process. In it, three wide-angle cameras are used to photograph the terrain from horizon to horizon across the line of flight, from an elevation of 20,000 feet. Detail is usually discernible and plottable for several miles on each side of the line of flight, and occasional points, required for photo-triangulation, can be identified farther out. With higher flight capabilities, wider angle cameras, and lenses of fine resolution the progress of aerial photography has been accelerated. Films have been much improved for fineness of emulsion grain and scale stability. Satellite photography, and high-altitude flights with super-wide-angle cameras, are now under way in the remaining areas of the world. Infrared and colour film developments have greatly improved photo-interpretation capabilities, providing much better delineations for coastal charts, geologic maps, timber and soil classifications, and other thematic mapping.

**Types of maps and charts available.** Although the range of maps and charts now available in many countries is so wide that a complete listing is impractical, any list of principal types would have to include aeronautical (worldwide and national); congressional or political districts; population distribution; geologic (various scales); highways (national and secondary political units); historical; hydrographic (coastal areas; inland waters; foreign waters); national forests; forest types; public land survey plats; soil; topographic and related (national and foreign areas).

The National Atlas of the United States of America, published by the Geological Survey in 1970 contains contributions from all of that country's mapping agencies. Summaries are provided of all thematic and economic data of interest. The atlas also indicates where more detailed information or large-scale specialized maps may be obtained. Many countries have centres where detailed information on existing map series and related data may be obtained. In the U.S. this service is performed by the Map Information Office of the U.S. Geological Survey, which publishes and distributes indexes of each state

showing map coverage and ordering information. Summary data on geodetic control and aerial photography are also maintained.

The situation is less complex in other countries, where mapping activities are concentrated in one or two organizations; e.g., Ordnance Survey in Britain and Institut Géographique National in France. The main agencies can advise where maps produced by others may be obtained. Technical societies maintain large map reference libraries and are prime sources of information, as are the map sections of national libraries and museums.

**Government and other mapping agencies.** The following are the primary agencies of selected countries having advanced mapping programs.

Principal Mapping Agencies of Selected Countries	
Australia	Division of National Mapping, Department of National Development
Brazil	Servico Geográfico do Exercito
Canada	Surveys and Mapping Branch, Department of Energy, Mines and Resources
Chile	Instituto Geográfico Militar
France	Institut Géographique National
Germany, West	Institut für Landeskunde Geodäsie
Iran	Army Geographic Department and National Geographic Organization
U.K.	Ordnance Survey and Directorate of Overseas Surveys
U.S.S.R.	Glavnoye Upravlenie Geodezii i Kartografii

Military agencies play large roles in the mapping activities of many countries. Frequently, a small cadre of officers administers the mapping facilities, while most of the production personnel are civilian. Many countries, such as Iran and the U.S., have both civilian and military organizations that collaborate in developing their respective programs and in performing the actual mapping.

Most countries have private and commercial organizations that produce maps. The widely distributed road maps noted earlier, are printed by a few large producers who, in cooperation with others, compile the maps. Very large-scale maps, for road construction and other engineering works, are produced under contract by a number of mapping companies. Some local highway departments have their own photogrammetric units to provide or supplement such productions. City surveys, and maps for real-estate developments, tax records, power lines, etc., are largely produced by commercial organizations.

Large societies, such as the American Geographical Society, the National Geographic Society, and the Royal Geographical Society, play important roles, in addition to being centres of reference as noted above. The National Geographic Society produces popular small-scale maps of the various regions of the world. The American Geographical Society has compiled many maps, most notably a 1:1,000,000 coverage of Hispanic America on standards similar to the International Map of the World. Technical societies, such as the American Congress on Surveying and Mapping, American Society of Photogrammetry, American Society of Civil Engineers, and others, lend their support to mapping programs and activities. They issue technical papers, and hold frequent meetings where new processes and instrumentation are discussed and displayed. *The Manual of Photogrammetry* and *Journal* produced by the American Society of Photogrammetry, *Photogrammetria*, published by the International Society of Photogrammetry, and the *Journal of Surveying and Mapping* of the American Congress on Surveying and Mapping, are prime examples of important contributions that societies make to the overall progress of mapping.

**International organizations.** Many societies and other types of organizations are now engaged in activities associated with maps and mapping. In general, they encourage cooperation through meetings and articles in their journals; some are more directly concerned with the dissemination of information on the progress of particular kinds of mapping and charting. Standardizations of map treatments and conventional signs, as well as the promotion of progress in technical processes are further objectives of such groups.

Tri-metrogon process

The work of geographic societies

*The United Nations Office of Cartography.* This organization plays an important role in all of the activities noted above. It maintains records of progress on the International Map of the World and performs related services formerly handled by the Central Bureau of the IMW. Technical assistance in the development of mapping facilities and programs is provided on request. Occasional regional meetings are arranged for groups of countries having similar problems while the journal *World Cartography* publishes related papers.

*Inter-American Geodetic Survey.* This organization is a special unit of the U.S. Corps of Engineers, organized to forward the completion of geodetic surveys and mapping in the Americas. Through technical training and assistance with programs, geodetic surveys in Central and South America have been greatly advanced in recent years. Training in photogrammetry is offered and has promoted the establishment of mapping facilities and programs in many of the collaborating countries.

*Pan American Institute of Geography and History.* This organization has sponsored regular meetings and consultations on cartography, much in the manner of scientific societies. The consultations are held in different countries each year.

*International Hydrographic Bureau.* This organization was founded in 1921 in Monaco, where it has been headquartered through the years. It serves as a clearinghouse for information related to hydrography and charting and maintains a Bathymetric Chart of the World, which is revised periodically to include data furnished by the maritime nations participating in their programs and conferences. Other organizations that promote progress in the various aspects of mapping and charting are the International Association of Geodesy, the International Cartographic Association, the International Civil Aviation Organization, the International Geographical Union, the International Federation of Land Surveyors, the International Society for Photogrammetry, and the International Union of Geodesy and Geophysics.

#### MODERN MAP-MAKING TECHNIQUES

**Compilation from existing materials.** The preparation of derived maps—*i.e.*, maps that are compiled from other maps or existing data—involves the search for, and evaluation of, all extant data pertaining to the subject area. Depending on the nature of the map to be compiled, a thoroughgoing research includes boundary references, historical records, name derivations, and other materials. Selection of the most authentic items, on the frequent occasions when some ambiguities are detected, requires careful study and references to related materials. The sources finally selected may require some adjustment or compromise in order to fit properly with adjacent data. When it becomes evident that some sources are of questionable reliability, the cartographer explains this in the margin of his compilation. Sometimes this is placed in the body of the map where the doubtful features or delineations are located.

When selected materials have been assembled, they are reduced to a common scale and copied on the compilation base, often in differentiating colours for the respective features. Reductions to a common scale are usually made by photography but may be made by projection and traced directly on the drawing. Minor adjustments may have to be made, during compilation, even though the source materials are of good quality. In particular, the need to make appropriate generalizations, omitting some details in smaller scale maps, requires much study and judgment.

Except for the new methods of preparing final colour separation plates by scribing (described below), rather than by drafting or copper-plate engraving, compilation processes have changed little over the years. Automatic-focussing projectors and better illumination have made the tracing of selected data at compilation scale easier. Better and more extensive facilities for photoreduction and copying, improved light tables, and a wider choice of drafting materials and instruments have all served to facilitate compilation. The basic chores of research, selec-

tion of best data, and adjustment of these into the compilation, however, remain essentially the same.

*Scale conversions.* The preparation of small-scale maps from large ones is sometimes simpler than the process just described, which pertains to compilation from a miscellany of differing sources. The relatively straightforward preparation of 1:62,500 scale maps from those of the 1:24,000 scale series, for example, may require little more than photoreduction and colour-separation drafting, or scribing. Even in this case some generalizations, as well as omission of a few of the least important details, are in order. To avoid the considerable expense involved in such scale conversions, straight photoreduction of colour separation plates appears to be a promising procedure.

Larger reductions from one map series to another—1:62,500 to 1:250,000 for instance—are more of a problem, since the need for generalization is greater and the omission of many details is involved. The considerable differences in road and other symbol sizes also create displacement problems.

The component maps are reduced, and the negatives are cut and assembled into a mosaic on a clear sheet of plastic, the master negative of which provides guide copy for the several colour-separation plates required, which are then completed for reproduction as described below in *Colour-separation processes*. More often, however, it is necessary to make an intermediate compilation, rather than burden the draftsman with too many adjustments to be made while following copy on the colour-separation plates. The intermediate scale for initial reduction of the component maps provides better legibility than direct photography to reproduction scale. This negative mosaic is copied on a metal-mounted drafting board. A compiler then inks the whole map, usually in three or more contrasting colours. He also draws roads and other symbols at the intermediate size, so that they will reduce to proper dimensions at reproduction scale, and makes the necessary displacement adjustments. Minor features and terrain details to be omitted on the new map are not inked in. The drawing is now ready for photoreduction to the final colour-separation plates, providing much better copy for the draftsman or engraver than direct reduction in one step would have produced.

Most smaller scale map series are prepared from large-scale maps as described above. In earlier days, original reconnaissance surveys were made at small scales such as 1:192,000 for publication at 1:250,000. Ideally, the small-scale series of maps should be compiled progressively from those of larger scale and greater detail. Most countries, however, started their mapping programs with relatively small-scale reconnaissance surveys because of economic considerations. Later, affluence and technical competence permitted mapping at larger scales, with better accuracy.

*Thematic maps.* Geologic, soil, and other thematic maps usually have a topographic base from which woodland tints and road classification printings have been omitted. Such a map therefore has a topographic background printed in subdued colours, on which the geologic or soil patterns are overprinted in prominent colours. Small-scale thematic maps, showing weather patterns, vegetation types, and a large amount of economic and other information are of similar origin. Backgrounds are drawn from appropriate outline maps of provinces, countries, or regions of the world, while overlaying subject matters are compiled from specialized sources of information.

*Generalization.* The generalization of detail is a problem that frequently confronts the cartographer, both in original mapping and in reducing the scale of existing maps. There are two principal reasons for taking such liberties (or topographic license in the case of the original mapping). The primary purpose is to avoid overcrowding and the resulting poor legibility. In addition, the degree of generalization or detail should be as consistent as possible throughout the map. Generalizations in some parts, and excessive detail in others, confuse the user and make the map's reliability suspect. Effective generalization requires good judgment based on seasoned knowledge and experience.

grounds

In approaching such problems as the thousands of islets in the Stockholm archipelago, or the thousands of small lakes in the Alaskan tundra areas, when the map scale will accommodate only a small number, the cartographer may decide to draw the features in groupings that reflect the patterns shown in the large-scale source maps or aerial photos. This is difficult and at best presents the nature of the respective areas rather than a literal portrayal. There is also the possibility that the source maps may already have been generalized by some omissions to accommodate to their own scales. Another device is to note, in appropriate text or marginal references, that many minor lakes or islets are omitted because of scale. Such areas may also be symbolized and explained. The "pattern" representation noted above is actually a form of symbolization.

Intricate coastlines are also extremely difficult to generalize consistently. Here again, the purpose is to omit minor details while retaining the main features and their distinguishing characteristics. These, and many equally perplexing questions arise in preparing maps of very small scale from any source. The problems of equalization of detail are also present in such cases. The topographer of earlier days had the equalization problem between areas close at hand and those viewed distantly. In addition, the topographer had to deal with terrain on the far sides of obscuring features.

Photogrammetrists—that is, persons who compile original maps from aerial photos—have similar problems when, for example, one side of a ridge is seen in more detail than the opposite side. Indeed, in steep terrain, parts of the far sides of some mountains are not seen at all. Appropriate steps must be taken in such cases to avoid differing renditions on opposite sides of the mountain. This may be accomplished by adding in field completion of the manuscript map the segments not seen by the photogrammetrist; or additional aerial photography, patterned to cover the obscured sectors, may be requested.

**Map production from original surveys.** The instrumentation, procedures, and standards involved in making original surveys have all improved remarkably in recent years. Geodetic, topographic, hydrographic, and cadastral surveys have all been facilitated by the application of electronics and computer sciences. At the same time, superior optics and more refined instruments, in general, have enhanced the precision of observations and accuracies of the end products.

The improved quality of surveys has increased the reliability of maps and charts based on them. In turn, the greater output of basic data has accelerated the production of maps and charts, while parallel improvements in processing steps have increased the volume and improved the final product. In a sense, the production of maps from original surveys parallels the process steps after a compilation is made from derived sources. This phase is sometimes referred to as map finishing and involves editing, colour separation, and printing. In original surveys for topographic maps and nautical charts, however, the end products are provided for in all the process steps leading to the completed basic manuscript. The manuscript scale is, for example, selected to accommodate the plotting instruments involved, as well as the final rendering for printing. In early years, it was usual to choose a manuscript scale somewhat larger than that prescribed for publication. This was to allow for some generalization and line refinement in the final reduction. Thus, maps to be published at 1:62,500 scale were plotted in the field at 1:48,000 or thereabouts. With modern photogrammetric instruments, plotting is at reproduction scale.

Maps are not directly derived from geodetic surveys, and only land-line plats are produced from cadastral surveys. Accordingly, the primary original map and chart productions are those from topographic and hydrographic surveys. The surveys are somewhat similar, as the nautical chart is, in effect, a topographic map of the coast, with generalized topography offshore interpolated from depth soundings.

A variety of electronic devices are used to determine

a survey ship's precise location while taking soundings, which are also made with electronic equipment. Both hydrographic and topographic surveys now employ aerial photography and precise plotting instruments to develop the base map. In order to simplify the description of modern map-making techniques, the process developed for topographic mapping will be described below, with comments where procedures for nautical charts differ significantly. Both processes start by expanding upon the basic control previously established from geodetic surveys.

**Basic control surveys, satellites. Geodetic surveys.** These surveys involve such extensive areas that allowance must be made for the earth's curvature. Baseline measurements for classical triangulation (the basic survey method that consists of accurately measuring a base line and computing other locations by angle measurement) are therefore reduced to sea-level length to start computations, while corrections are made for spherical excess in the angular determinations. Geodetic operations are classified into four "orders," according to accuracy, the first-order surveys having the smallest permissible error. Primary triangulation is performed under rigid specifications to assure first-order accuracy.

**Satellite triangulation.** Efforts are now underway to extend and tie together existing continental networks by satellite triangulation so as to facilitate the adjustment of all major geodetic surveys into a single world datum and determine the size and shape of the earth spheroid with much greater accuracy than heretofore. At the same time, current national networks will be strengthened, while the remaining amount of work to be done may be somewhat reduced. Satellite triangulation became operational in the U.S. in 1963 with observations by Rebound A-13, launched that year, and some prior work using the Echo 1 and Echo 2 passive reflecting satellites. A satellite specifically designed for geodetic work, Pageos 1, was launched in 1966.

Many countries are collaborating in developing arrangements for the worldwide program underway in the early 1970s. Existing systems will be adjusted and extended to meet all needs for precise locations.

**Control extension surveys.** A first requirement for topographic mapping of a given area is an adequate pattern of horizontal and vertical control points, and an initial step is the assembly of all such existing information. This consists of descriptions of points for which positions of latitude and longitude and elevations above mean sea level have been determined. They are occasionally located at some distance from the immediate project, in which case it is necessary to expand from the existing work. This is usually done on second- or third-order standards, depending upon the length of circuits involved.

Between the very early maps of the U.S. and those of the early 1970s, there is a steady increase in reliability, approximately reflected by their dates of survey. The control on which mapping was based suggests a similar evolution. Some years ago, control points were much farther apart. Also on establishing the control points, and in working from them, systematic procedures were not always followed by surveyors working under difficult conditions.

Today, extensions from existing control points are not required as frequently and can be performed much more accurately when they are required. Existing networks are being continually increased, while modern systems and instrumentation enable the photogrammetrist to bridge greater distances. Electronic distance-measuring equipment has improved the quality of second- and third-order control surveys and greatly reduced the number of traverse stations formerly required. An airborne system is one of the methods developed to facilitate the extension of existing networks of control. It involves the use of aluminum-alloy observation towers and special trucks to move them without disassembly. Helicopters are used extensively both for rapid transport and for hovering over points otherwise difficult to intersect.

Similar advantages now facilitate vertical control extensions. Automatic instruments make levelling by classical methods easier and more reliable. Elevation meters ex-

Use of

devices in  
ship  
surveys

Networks  
of control  
points

tend determinations over roads at low cost, while vertical bridging enables the photogrammetrist to extend the available elevation data to the extent that further control can often be dispensed with. Refinements in altimeters, and methods of calibrating the air column with high- and low-based recording controls, permit the use of barometric means of extending vertical values.

The National Ocean Survey in recent years has hoped to increase the density of horizontal control to the extent that no location in the U.S. will be farther than 50 miles from a primary point, and advances anticipated in analytical phototriangulation suggest that the envisioned density of control may soon suffice insofar as topographic mapping is concerned. Existing densities of control in Britain and much of western Europe are already adequate for mapping and cadastral surveys.

**Aerial photography.** In 1851 Aimé Laussedat of France compiled some map data based upon measurements of photographs taken from a balloon, the earliest known application of photography to mapping. Little progress was made in the science, however, until World War I, by which time better lenses and cameras and better aircraft to carry them were available. By World War II most advanced countries were using photogrammetry. Since then there have been continuous advances in optics, films, and precision instruments for mapping and specialized photo-interpretations.

**Precision lenses and cameras.** The evolution of these important elements has increased the efficiency of plotting instruments, as well as the accuracy of the final product. For many years wide-angle lenses were not available. This focussed attention on multiple-lens arrangements, such as the trilens cameras of World War I, and three-camera devices of World War II. Other experimental arrangements included a nine-lens camera used successfully in coastal mapping. This phase of camera design tapered off with the development of lenses with a 90-degree angle of view, and particularly with the recent design and production of super-wide-angle lenses. Wide-angle lenses are important to mapping for two main reasons: first, they reduce the number of overlapping stereoscopic photographs to be oriented and plotted from, as well as the amount of control required, and second, they provide a more precise determination of vertical values and contouring because of the wider base of stereoscopic perception. At present, precision lenses are reasonably distortion free.

**Photography for mapping.** There is a tendency in most governments to utilize military-training efforts and expenditures to secure map photography free, or at minimum cost. This has proved to be false economy in most civilian mapping operations, because the specialized requirements of photography for mapping are better met by commercial or other civilian agencies especially equipped and experienced. Furthermore, military priorities may be such that immediate advantage cannot be taken of the few opportunities for optimum photography that are available; that is, when skies are cloudless, foliage minimum, shadows minimum, and no smog or haze is present.

**Flight patterns.** Stereoscopic aerial photographic coverage requires an overlap in successive exposures of about 60 percent. These overlaps form the stereoscopic models by which the terrain is mapped with any of a variety of instruments. A side overlap of 10 to 15 percent is also required along the flight lines for maximum efficiency in mapping. This assures adequate coverage and minimizes the number of supplemental control points needed, so that each one may serve in three or four models.

The flight plan is furnished to the contractor, or photographic crew, on the best existing map of the area to be covered. Later, when the actual photography is assembled, suitable controlling points in the overlap areas are selected and marked. The elevations or positions or both required for mapping are then obtained by field parties. In order to hasten the survey, a random pattern of controlling points is often obtained by the field engineers while extending the basic control. This eliminates one field operation, but the elevations of more points have to be obtained, and these are not likely to be in the best positions

for the photogrammetrist. The contour intervals designated for areas to be mapped determine the flight heights for aerial photography. The various systems have factors of capability varying from 500 to 1,200 times the contour interval. Thus, the higher order systems can draw 20-foot contours satisfactorily with aerial photographs taken at 24,000 feet above the mean ground elevation. Mapping is generally more economical at higher altitudes, since fewer models will be involved and less supplemental control required. The clarity of features diminishes with height, however, and about 25,000 feet (7,500 metres) is the current limit for cameras with six-inch focal-length lenses, used in mapping. Wider angle and shorter focal-length lenses require lower altitudes, unless their resolving powers are of higher orders.

**Coastal mapping.** Coastal features can be more readily identified and delineated when photography with infrared and colour films supplements the normal black and white photography. Shoals and other shallow areas are also more clearly defined and mapped. It is therefore now routine practice to obtain the additional types of photographs simultaneously.

Infra-red and colour photographs have also been found quite helpful in other activities, such as determining vegetation types and identification of areas where insects or disease may be affecting crops or woodlands. Tentative outlines of soil types and area geology can also be made through close study of aerial photographs of two or more kinds.

**Photomosaics and orthophotos.** Aerial photographs have always been used in field and office for a variety of purposes. Radial distortions due to relief, however, are often a great inconvenience and may render the photograph useless. Photomosaics, in which much of the distortion has been removed, are therefore assembled. This is a laborious process, involving enlargements and reductions of the photography, cutting and fitting of pieces to a controlling framework, while avoiding appreciable offsets of roads and other features.

A recently developed device known as the orthophotoscope greatly reduces distortion by producing a picture from stereoscopic models. The principle has been further developed, as part of an automatic system of mapping.

**Photomaps.** Aerial photos contain great amounts of detail that it is not feasible to include in a standard topographic map. Some military maps during World War II were printed with the standard topographic map on one side of the paper and the reproduction of a photomosaic of the same area on the other side. These maps were received with enthusiasm by the users. More recently, military and civilian agencies have produced some topographic maps with photo-backgrounds in colours. These have been found quite helpful to military and civilian personnel for rapid identification of position and recognition of nearby features. Thus far, civilian production has been reserved for areas difficult to portray by standard symbolization, such as swamp areas where the normal use of the swamp symbol over an extensive area would become meaningless, and some way of showing the actual variations of vegetation and swamp characteristics needs to be adopted. In view of the favourable response by both military and civilian users, it appears that this type of map will be increasingly produced, although it is more expensive than other types.

**Photogrammetric mapping procedures.** *Preparation of base sheets.* Manuscripts are usually prepared on coated plastic sheets which facilitate later process steps. All available controls for the area are plotted, and projection lines are drawn. Plotting is frequently done automatically by an instrument called a coordinatograph, which is directed by paper or magnetic tapes containing the coordinate values for each point and projection intersection. Edges from adjoining sheets are transferred to the base, together with pertinent notes regarding features common to both maps. If coastal areas are involved, appropriate features of the nautical chart are copied to the base so that they can be joined and duplication of work avoided. Topographic maps now carry offshore depth curves and other helpful information when it is

Wartime  
lens  
improve-  
ments

Ortho-  
photoscope

available from charts of the area. After the quadrangle name and other identifications have been applied, the sheet is ready for stereomapping.

*Preparation of diapositives.* Meanwhile, the photo laboratory has prepared transparent positive prints (diapositives) of the aerial photographs on glass or film. For some instruments, the plates are made in reduction printers designed for the respective plotters. For the higher order instruments, prints are prepared by contact printing or in a one-to-one projection printer. The diapositives must be geometrically accurate and of the highest photographic quality.

*Control points.* Pairs of diapositives are mounted in the same relative position as that in which the pictures were taken. The overlapping projected images from the diapositives form a stereoscopic model. To compile map detail from aerial photography, each stereoscopic model must be oriented to the correct horizontal and vertical data by means of control points. Preferably, vertical control points should be available near the corners of each model, but a random pattern is usable if difficult terrain limits field operations.

*Stereomapping.* A variety of instruments are available for stereocompilation, from the elaborate and precise first-order instruments to those designed for reconnaissance or incidental purposes, such as, for example, the plotters using paper prints of aerial photos (see also SURVEYING).

After the relative and absolute orientations have been established for the several models in a strip of photography, the mapping proceeds, one model at a time. Planimetry (those areas having no indication of contour) is compiled first, and then the contours are plotted, so they can be fitted properly to the streams, roads, etc. Usually, the planimetry is scribed after all the models of the sheet have been plotted in pencil. The planimetry is then contact printed by the compiler onto another base on which contours are drawn. This separation simplifies later steps by providing more legible copy, in differentiating colours, for field and office operations. After all discernible roads, railroads, fences, buildings, drainage, woodland outlines (often on a separate overlay), and contours have been delineated, the bases are ready for field review. A number of spot elevation readings are also made, on mountaintops and other features, that may be shown on the final map. This is desirable for the user's convenience when rather few elevations established by control parties are available for publication. The stereoreadings are printed in brown, while those of higher order are shown in black.

*Final steps in map preparation.* *Field completion and editing.* After the stereo-operator has mapped all the features visible in the aerial photography, the manuscripts are contact printed on coated plastic sheets for review by the field engineer. He examines the whole map, adding such details as houses, trails, and fences that were not visible or were overlooked by the stereo-operator. Political lines such as state, county, and township limits are located, as are geographic and other names in local use. Roads are classified, and woodland outlines are checked.

Contour accuracy is tested if the operator has noted areas that may be weak. The determination of names involves extensive local inquiry, as do political lines, and both may require research of records.

In remote areas, it is more efficient to combine the above activities with supplemental control survey to avoid the extra field phase. Then, the photos must be carefully examined and annotated for the compiler, while buildings must be encircled or pricked. Roads are classified and political lines located in the usual manner and noted on the photos or overlays.

Handling  
corrections

Field corrections are applied to the original manuscripts. They must be scribed (engraved) on the originals so that guide copies can be prepared by contact printing for final colour-separation scribing. At this time all factual detail is carefully checked. Editing may proceed, to conserve time, while the colour-separation scribing is in progress. The editor reviews all names, boundaries, and related data, comparing them to information thereon that may be

available from other sources. The editor's function is to see that the map conforms to standard conventions, is clear and legible, and free of errors.

Controversial names, or those found to be in confused or ambiguous spelling or usage, are documented and referred to an appropriate official body. The designation of type styles and sizes as well as placement of lettering is another function of the map editor.

*Colour-separation processes.* Because modern topographic maps are printed in several colours, separate plates must be prepared for each. Some of the earliest maps were printed from woodcuts, usually in a single colour. Various hand processes were developed through the years, culminating in the fine rendering of copper-plate engraving, which dominated the map production industry for many years. The process became obsolete, however, with increased production demands and the development of efficient printing presses. After World War II engraving on glass, and later on coated plastic sheets, was developed to a point that recovered the fineness of copper engraving. These methods of engraving have become firmly established in map production throughout the world.

In the negative engraving or scribing process, guide copy is printed on several sheets of plastic coated with an opaque paint, usually yellow. The scribe follows copy on the respective plates, by engraving through the coating. Because arc light can pass only through the engraving scratches, the completed engravings are, in effect, negatives from which the press plates are made. The finest lines, such as intermediate contours, are engraved 0.002 inch in width, with a phonograph needle in freehand holder. Heavier lines, such as index contours, engraved at 0.007 inch may require a small tripod to assure that the scribe is perfectly vertical. Gravers for double-lined roads, others for buildings, and templates, or patterns, for a variety of symbols are used. Woodland and similar boundaries and shorelines are contact printed and etched on their respective coated sheets, and the areas of the woodland or water are then peeled off, leaving open windows for their respective features. If portions of scrub, orchard, or vineyard are contained in the "woodland" plate, negative sections for these are stripped into their respective locations. Press plates are then processed from the negatives.

A combined-colour proof is then made by successively exposing the several completed negatives to a sensitized white plastic sheet that serves for the final checking and review of all aspects of the map. After all corrections have been made the negatives are ready for the reproduction process.

*Map reproduction.* Nearly all map printing is now done by rotary offset presses, using flexible aluminum-alloy printing plates. The system uses surface plates (very slightly raised or recessed), as opposed to the letter-press and intaglio processes, which involve greater image heights and depths respectively. In the printing sequence inking goes from the plate to a rubber blanket to the paper. Thus, the printing plate is positive, or right reading, as is the printed map. The negatives from which the printing plates are prepared are accordingly left reading. This is the process for so-called surface plates. To retain fineness of line on very long runs (10,000 or more impressions) some map printers prefer "etched" plates, prepared from film positives. Both may be considered essentially surface plates, however, since the respective raise or recess is quite small.

Presses are of many varieties and makes. Huge multicolour types are used in large plants, printing several colours at a time. In effect, a multicolour press is several presses built into one. Each unit has three cylinders for plate, rubber blanket, and paper, as well as rollers for water and ink. Presses with automatic feed may run as many as 6,000 impressions per hour, while hand-fed types are limited to about 2,500 per hour.

*Automation in mapping.* During the 1960s there was much interest in the automation of mapping processes, and considerable progress was made in this area. Achievements in the fields of electronics, high-speed digital com-

Scribing  
process

puters, and related technologies provided a favourable period for such progress. In Britain, a set of procedures utilizing automatic elements, known as the Oxford System, is in the development stage.

#### Automatic plotting

Some success was also achieved in the difficult area of automatic plotting. Instruments now available can automatically scan a stereo model and generate approximate profiles, from which contours may be interpolated. Some steps, however, must still be very closely monitored or else performed completely by the operator. Contouring interpolated from a profile scan is still inferior to an operator's delineation. This contouring will meet some less exacting requirements for elevation data, and there is every indication of future progress and refinement. The need for human intervention when automatic devices get "lost" is not a decisive drawback, as one operator can monitor several machines. The reduction of tedious and repetitive steps for stereo-operators offers a significant advancement.

Coordinatographs with high repeat accuracies now facilitate the automatic plotting of control points and projection intersections. Line work can also be drafted or scribed automatically by the same process, but the respective features must first be coded to provide the necessary input tapes. Automatic colour scanning and discrimination is not yet operational, so it is necessary for an operator to trace the various features on the manuscript to code them. Obviously, little is to be gained by automatic scribing until the input can be provided automatically. Coded line-work can be displayed on a cathode-ray tube and corrected with light-pen, but at present it is much simpler to check and correct the manuscript or finished drawing. Systems of automatic type placement at present offer only marginal advantages over conventional methods. In short, automation is advancing but will not be fully operational in a practical sense for some time.

An aspect of automation that is developing rapidly concerns graphic data acquisition, storage, and retrieval. Data banks are being accumulated by specialized users of topographic information, often to produce thematic maps showing soil types, vegetation classifications, and a variety of other information. Such data banks are usually organized in two parts, one for line work, such as boundaries, and the other for descriptive information, or classifications. Assuming that the necessary inputs have been made to the data bank, special plats can be generated speedily. Examples of such graphics include profiles showing elevations along a selected radio propagation path and cross sections for earthwork on roads and other construction.

**Map revision and maintenance.** It is well recognized by map makers and users alike that periodic revisions are necessary to maintain the usefulness of maps and charts. Aeronautical and nautical charts are revised on relatively short cycles because of changes in aids to navigation, call signals, wrecks, or channel changes. For topographic maps, however, a ten-year cycle is considered adequate, except for those areas that change rapidly.

#### BIBLIOGRAPHY

**Techniques:** Until recent years most technical dissertations on the various aspects of mapping were contained in the manuals of official producing agencies. "Topographic Instructions of the United States Geological Survey," *Bull. U.S. Geol. Surv.* 788 (1928); and the *Hydrographic Manual of the U.S. COAST AND GEODETIC SURVEY* (1960), are prime examples. Bulletins of technical societies, such as *Surveying and Mapping*, *Photogrammetria*, and *The Military Engineer*, carry articles on all aspects of procedures and techniques. Many countries have cartographic societies whose bulletins carry current information. The following are typical of the texts available on techniques; most include comprehensive bibliographies: E.J. RAISZ, *General Cartography*, 2nd ed. (1948); *Principles of Cartography* (1962); E. IMHOF, *Gelände und Karte* (1950); T.W. BIRCH, *Maps: Topographical and Statistical*, 2nd ed. (1964); F. REIGNIER, *Les Systèmes de projection*, 2 vol. (1957); A.D. MERRIMAN, *An Introduction to Map Projections* (1947); W. CHAMBERLAIN, *The Round Earth on Flat Paper*, 2nd ed. (1947); and E. ARNBERGER, *Handbuch der thematischen Kartographie* (1966).

**History:** The history of cartography was somewhat neglected until the mid-19th century when the first great collec-

tions of early maps were published. Treatises on the historical aspects of cartography are enumerated in W.W. RISTOW and C.E. LEGEAR (comps.), *A Guide to Historical Cartography*, rev. ed. (1970). The essential aspects of the subject are well covered in the following; many contain references for further study: R.A. SKELTON, *Decorative Printed Maps of the 15th to 18th Centuries* (1952, reprinted 1966), and with L. BAGROW, *History of Cartography* (1964, orig. pub. in German, 1944); C. BRICKER and R.V. TOOLEY, *A History of Cartography: 2500 Years of Maps and Mapmakers* (1969); G.R. CRONE, *Maps and Their Makers*, 3rd ed. (1966); L.A. BROWN, *The Story of Maps* (1949), *Map Making* (1960); C.H. HAPGOOD, *Maps of the Ancient Sea Kings: Evidence of Advanced Civilization in the Ice Age* (1966); R. LISTER, *How to Identify Old Maps and Globes* (1965); E. LYNAM, *The Mapmaker's Art* (1953), historical essays on maps of early England through the age of discovery.

(C.F.F.)

## Maranhão

Maranhão (Estado do Maranhão), one of Brazil's 22 states (*estados*), lies in the northern part of the country immediately south of the Equator and to the southeast of the Amazon Basin. It had a population of over 3,000,000 at the 1970 census. Almost two-thirds of its 126,897 square miles (328,663 square kilometres) consists of a low, heavily wooded region, bordered by the Atlantic Ocean to the north. To the east and southeast lies Piauí state and to the west the states of Goiás and Pará (for a related physical feature see AMAZON RIVER).

**Physiography.** The higher plateaus in the southern section of the state are extensions of Brazil's northeastern massif (mountainous mass); the highest point, the Serra da Cinta, is 4,373 feet (1,333 metres) in altitude.

From these highlands a number of river systems run generally northeastward into the Atlantic. Several of them form a delta region around the capital city of São Luis (population about 242,000 [1970 est.]), which stands on an island. The delta is bounded to the west by dense mangrove forests and to the east by areas of quicksand. The rivers are navigable for much of their course, cutting through arable soils that support farming and cattle raising, the economic mainstays of Maranhão. The climate is hot and moist. There is a wet and a relatively dry season but never a rainless one.

**History.** Tupinambá Indians inhabited the Maranhão region when Europeans first explored the coasts in 1500 and when the region was included in land grants, known as captaincies, made by the Portuguese crown in 1534. In the decades that followed, rival European powers attempted to take possession of the territory. The first settlement was established by the French in 1594; later, in 1612, they also founded a colony on São Luis Island. The French were expelled by the Portuguese in 1615, but the Dutch succeeded in holding São Luis from 1641 to 1644.

In 1621, Maranhão and adjoining regions were united as the Estado do Maranhão, which remained independent of the southern captaincies and of Portuguese colonial administration until 1774, when the territory was formally made part of the Portuguese colony of Brazil.

In 1823 Maranhão adhered to the newly independent empire of Brazil and, in 1889, to the newly proclaimed republic.

Throughout its history, Maranhão lay in the shadow of the more populous and westernized states of Brazil along the southern coast. It was settled mainly by Jesuit missionaries, who Catholicized the Tupinambás and introduced the pattern of agriculture and cattle raising that continues to characterize the domestic economy.

**The contemporary state.** The people of Maranhão represent a blend of Tupinambás, white Europeans (mainly Portuguese), and the descendants of African slaves. There has been considerable racial intermarriage through the centuries, though in interior regions descendants of the original Indian population, known as caboclos, remain.

Portuguese is the main written and spoken language, but it has been enriched by indigenous languages, just as Portuguese culture has been supplemented by local folklore. Most of the population is Catholic; São Luis is the seat of the archdiocese.

The landscape

Language and religion

The state is administered by a governor elected for a four-year term and by a number of secretaries of state. The legislative assembly consists of 21 deputies. There is a court of justice and there are a number of lesser judges.

*The economy.* Maranhão is still an economically underdeveloped region, dependent largely on agriculture and cattle raising. The major industry is the extraction of oils and essences from plants. Palm oils from the babassu nut is a major export item, as is rice. A fast-growing food-processing industry employs an increasing number of persons. Deposits of the aluminum ore bauxite on Turiaçu Island are undeveloped; in 1956 oil was discovered in the interior, near the Goiás border, but has yet to be exploited. Further exploration has centred in the offshore Barreirinhas Basin east of São Luis. By 1970 this area had produced only small quantities of natural gas at Espigão.

*Transportation.* Itaqui Quay on São Luis Island is one of several modern shipping points on Maranhão's coasts, and the navigable river system permits extensive shipment from ports deep in the interior. A 250-mile-long railway links São Luis with Teresina, the capital of Piauí state. The road network, with a total length of about 19,000 miles, of which only about 300 are paved, is rudimentary. There are nine commercial airports, of which São Luis is by far the most important.

*Health and welfare.* Medical facilities and health standards are relatively good throughout the state. Occasional outbreaks of tropical disease rarely reach epidemic proportions. The state supports primary, secondary, and university education, in addition to which there are four independent colleges, a number of technical institutes, and private educational institutions at lower levels.

*Culture.* Cultural institutions include the Maranhão Academy of Letters and the Instituto Histórico e Geográfico do Maranhão. The most famous Maranhense writer was Antônio Gonçalves Dias (1823–64), a poet in the romantic tradition versed in Maranhense lore whose "Song of Exile" is justly renowned. The folk traditions of the state are rich and varied. The different cultural influences are typified by the blending of such elements as the native *boi-bumbá*, or "cow dance," with Catholic traditions in the festivals of the church year. (P.N.deS.)

## Marat, Jean-Paul

Known during his life as a physician, surgeon, journalist, and politician, Jean-Paul Marat has been considered by later generations as a leading exponent of the most radical tendencies of the French Revolution. Marat was born at Boudry, near Neuchâtel, Switzerland, on May 24, 1743. After obscure years in France and other European countries, he became a well-known doctor in London in the 1770s, and published a number of books on scientific and philosophical subjects. His *Essay on the Human Soul* (1771) had little success, but *A Philosophical Essay on Man* (1773) was translated into French and published in Amsterdam (1775–76). His early political works included *The Chains of Slavery* (1774), an attack on despotism addressed to British voters, in which (according to some) he first expounded the notion of an "aristocratic" or "court" plot, which was to be the principal theme of so many of his great speeches and articles.

Returning to the Continent in 1777, Marat was appointed physician to the personal guards of the Comte d'Artois (later Charles X), youngest brother of Louis XVI of France. At this time he seemed mainly interested in making a reputation for himself as a successful scientist. He wrote articles and experimented with fire, electricity, and light. His paper on electricity was honoured by the Royal Academy of Rouen in 1783. At the same time, he built up a practice among upper middle class and aristocratic patients. In 1783 he resigned from his medical post, probably intending to concentrate on his scientific career. In 1780 he published his *Plan de législation criminelle* ("Plan for Criminal Legislation"). Considered subversive, it was immediately suppressed by French authorities. It may be that this episode was the origin of his bitterness against the existing system, but he had already

assimilated the ideas of such critics of the *ancien régime* as Montesquieu and Jean-Jacques Rousseau and was corresponding with the American Revolutionary leader Benjamin Franklin. More serious, perhaps, was Marat's failure to be elected to the Academie des Sciences. Some historians, notably the American Louis Gottschalk, have concluded that he came to suffer from a "martyr complex," imagining himself persecuted by powerful enemies. Thinking that his work entitled him to a greater glory even than Sir Isaac Newton, he joined the opponents of the established social and scientific order. In the first weeks of 1789—the year that saw the beginning of the French Revolution—he published his pamphlet "Offrande à la Patrie" ("Offering to our country"), in which he indicated that he still believed that the monarchy was capable of solving France's problems. In a supplement published a few months later, though, he remarked that the King was chiefly concerned with his own financial problems and that he neglected the needs of the people; at the same time he attacked those who proposed the British system of government as a model for France.

Giraudon

Marat, portrait by J. Boze, 1793. In the Museum of the History of Paris.

Beginning in September 1789, as editor of the newspaper *L'Ami du Peuple* ("The Friend of the People"), Marat became an influential voice in favour of the most radical and democratic measures, particularly in October, when the royal family was forcibly brought from Versailles to Paris by a mob. He particularly advocated preventive measures against aristocrats, whom he claimed were plotting to destroy the Revolution. Early in 1790 he was forced to flee to England after publishing attacks on Jacques Necker, the King's finance minister; three months later, he was back, his fame now being sufficient to give him some protection against reprisal. He did not relent but directed his criticism against such moderate revolutionary leaders as the Marquis de Lafayette, the Comte de Mirabeau, and Jean-Sylvain Bailly, mayor of Paris (a member of the Academie des Sciences); he continued to warn against the émigrés, royalist exiles who were organizing counter-revolutionary activities and urging the other European monarchs to intervene in France and restore the full power of Louis XVI.

In July 1790 he declared to his readers:

Five or six hundred heads cut off would have assured your repose, freedom, and happiness. A false humanity has held your arms and suspended your blows; because of this millions of your brothers will lose their lives.

The National Assembly sentenced him to a month in prison, but he went into hiding and continued his campaign. When bloody riots broke out at Nancy in eastern France, he saw them as the first sign of the counter-revolution.

In 1790 and 1791, Marat gradually came to the view

Attacks on the aristocracy

Early scientific work

Activities  
in the  
National  
Convention

that the monarchy should be abolished, but did not say so publicly before the establishment of the republic in September 1792. As a delegate to the National Convention (beginning also in September 1792), he advocated such reforms as a graduated income tax, state-sponsored vocational training for workers, and shorter terms of military service. Though he had often advocated the execution of counter-revolutionaries, Marat seems to have had no direct connection with the wholesale massacres of suspects that occurred in the same month. His articles in *L'Ami du Peuple* and his speeches before the Jacobin Revolutionary club encouraged a feeling of class consciousness among the ordinary people of Paris. He had opposed France's declaration of war against antirevolutionary Austria in April, but, once the war had begun and the country was in danger of invasion, he advocated a temporary dictatorship (probably under his fellow Parisian leader Georges Danton) to deal with the emergency.

Actively supported by the Parisian people both in the chamber and in street demonstrations, Marat quickly became one of the most influential members of the Convention. Attacks by the conservative Girondin faction early in 1793 made him a symbol of the Montagnards, or radical faction. In April the Girondins had him arraigned before a Revolutionary tribunal. His acquittal of the political charges brought against him (April 24) was the climax of his career and the beginning of the fall of the Girondins from power. On July 13, Charlotte Corday, a young Girondin supporter from Normandy, was admitted to Marat's room on the pretext that she wished to claim his protection and stabbed him to death in his bath (he took frequent medicinal baths to relieve a skin infection). Marat's dramatic murder at the very moment of the Montagnards' triumph over their opponents caused him to be considered a martyr to the people's cause. His name was given to 21 French towns and, later, as a gesture symbolizing the continuity between the French and Russian revolutions, to one of the first battleships in the Soviet Navy.

nation

**BIBLIOGRAPHY.** LOUIS REICHTHAL GOTTSCALK, *Jean Paul Marat: A Study in Radicalism* (1927), remains the best biography. Selected articles and extracts have been recently published, with introduction and notes, by MICHEL VOVELLE, *Marat Textes choisis* (1963). Marat's scientific works are exposed in AUGUSTE CABANES, *Marat inconnu, l'homme privé, le médecin, le savant, d'après des documents nouveaux et inédits*, 3rd ed. (1920). Two other biographies of Marat (in French) provide detailed information on his political career: ALFRED BOUGEART, *Jean-Paul Marat, l'ami du peuple*, 2 vol. (1865); and JEAN MASSIN, *Marat* (1960).

(J.Vi.)

## Marbles

Marbles, most simply, are rocks that are used in many classic sculptures and buildings. Though technically the term (from the Greek *marmaros*, "stone" or "boulder") is restricted to granular limestones and dolomites (*i.e.*, rocks composed of calcium-magnesium carbonate) that have been recrystallized under the influence of heat, pressure, and aqueous solutions, commercially, it includes all decorative calcium-rich rocks that can be polished, as well as certain serpentines (*verd antiques*).

Petrographically marbles are massive rather than thin-layered and consist of a mosaic of calcite grains that rarely show any traces of crystalline form under the microscope. They are traversed by minute cracks that accord with the rhombohedral cleavage (planes of fracture that intersect to yield rhombic forms) of calcite. In the more severely deformed rocks, the grains show stripes and may be elongated in a particular direction or even crushed.

Marbles often occur interbedded with such metamorphic rocks as mica schists, phyllites, gneisses, and granulites and are most common in the older layers of the earth's crust that have been deeply buried in regions of extreme folding and igneous intrusion (see MOUNTAIN-BUILDING PROCESSES). The change from limestones rich in fossils into true marbles in such metamorphic regions is a common phenomenon; occasionally, as at Carrara, Italy, and

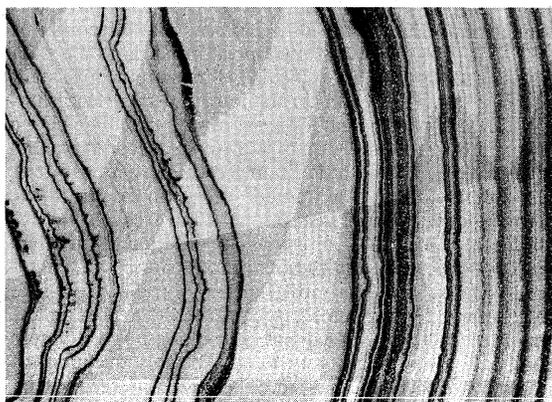

at Bergen, Norway, recrystallization of the rock has not completely obliterated the organic structures.

Most of the white and gray marbles of Alabama, Georgia, and western New England, and that from Yule, Colorado, are recrystallized rocks, as are a number of Greek and Italian statuary marbles famous from antiquity, which are still quarried. These include the Parian marble, the Pentelic marble of Attica in which Phidias, Praxiteles, and other Greek sculptors executed their principal works, and the snow-white Carrara marble used by Michelangelo and Antonio Canova and favoured by modern sculptors. The exterior of the National Gallery of Art in Washington, D.C., is of Tennessee marble, and the Lincoln Memorial contains marbles from Yule, Colorado, Alabama (roof transparencies), and Georgia (Lincoln statue).

Even the purest of the metamorphic marbles, such as that from Carrara, contain some accessory minerals, which, in many cases, form a considerable proportion of the mass. The commonest are quartz in small rounded grains, scales of colourless or pale yellow mica (muscovite and phlogopite), dark shining flakes of graphite, iron oxides, and small crystals of pyrite.

Composi-  
tion,  
properties,  
and colour

Mexican onyx marble showing concentric banding.

Many marbles contain other minerals that are usually silicates of lime or magnesia. Diopside is very frequent and may be white or pale green; white bladed tremolite and pale green actinolite also occur; the feldspar encountered may be a potassium variety but is more commonly a plagioclase (sodium-rich to calcium-rich) such as albite, labradorite, or anorthite. Scapolite, various kinds of garnet, vesuvianite, spinel, forsterite, periclase, brucite, talc, zoisite, wollastonite, chlorite, tourmaline, epidote, chondrodite, biotite, sphene, and apatite are all possible accessory minerals. Pyrrhotite, sphalerite, and chalcocopyrite also may be present in small amounts.

These minerals represent impurities in the original limestone, which reacted during metamorphism to form new compounds. The alumina represents an admixture of clay; the silicates derive their silica from quartz and from clay; the iron came from limonite, hematite, or pyrite in the original sedimentary rock. In some cases the original bedding of the calcareous sediments can be detected by mineral banding in the marble. The silicate minerals (*q.v.*), if present in any considerable amount, may colour the marble; *e.g.*, green in the case of green pyroxenes and amphiboles; brown in that of garnet and vesuvianite and yellow in that of epidote, chondrodite, and sphene. Black and gray colours result from the presence of fine scales of graphite.

Bands of calc-silicate rock may alternate with bands of marble or form nodules and patches, sometimes producing interesting decorative effects, but these rocks are particularly difficult to finish because of the great difference in hardness between the silicates and carbonate minerals (*q.v.*).

Later physical deformation and chemical decomposition of the metamorphic marbles often produces attractive coloured and variegated varieties. Decomposition yields hematite, brown limonite, pale green talc, and, in particu-

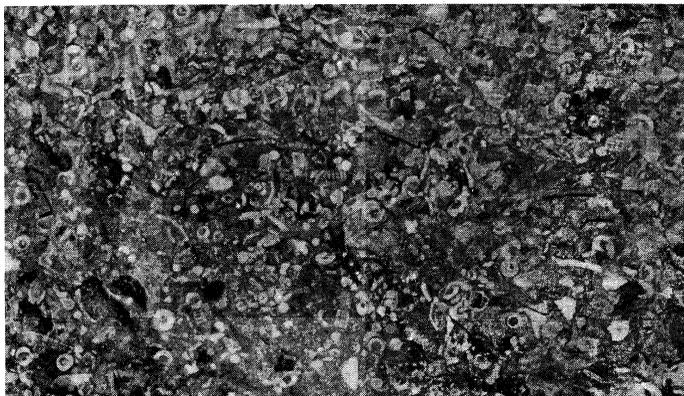

lar, the green or yellow serpentine derived from forsterite and diopside, which is characteristic of the ophicalcites or verd antiques. Earth movements may shatter the rocks, producing fissures that are afterward filled with veins of calcite; in this way the beautiful brecciated, or veined, marbles are produced. Sometimes the broken fragments are rolled and rounded by the flow of marble under pressure.

Onyx  
marble and  
alabaster

The so-called onyx marbles consist of concentric zones of calcite or aragonite deposited from cold-water solutions in caves and crevices and around the exits of springs (see CAVES AND CAVE SYSTEMS; SPRINGS AND WELLS). They are, in the strict sense, neither marble nor onyx, for true onyx is a banded chalcedony composed largely of silicon dioxide. Onyx marble was the "alabaster" of the ancients, but alabaster is now defined as gypsum, a calcium sulfate rock. These marbles are usually brown or yellow because of the presence of iron oxide.

Well-known examples include the *giallo antico* ("antique yellow marble") of the Italian antiquaries, the reddish-mottled Siena marble from Tuscany, the large Mexican deposits at Tecali near Mexico City and at El Marmol, California, and the Algerian onyx marble used in the buildings of Carthage and Rome and rediscovered near Oued-Abdallah in 1849.

Fossiliferous marble containing fossils of crinoidal debris, bryozoans, and shell fragments.

Unmetamorphosed limestones showing interesting colour contrasts or fossil remains are used extensively for architectural purposes. The Paleozoic rocks (from 225,000,000 to 570,000,000 years in age) of Great Britain, for example, include "madrepore marbles" rich in fossil corals and "encrinital marble" containing crinoid stem and arm plates with characteristic circular cross sections. The shelly limestones of the Purbeck Formation, England, and the Sussex marble, both of Mesozoic age (from 225,000,000 to 65,000,000 years ago), consist of masses of shells of freshwater snails embedded in blue, gray, or greenish limestone. They were a favourite material of medieval architects and may be seen in Westminster Abbey and a number of English cathedrals. Black limestones containing bituminous matter, which commonly emit a fetid odour when struck, are widely used; the well-known *petit granit* of Belgium is a black marble containing crinoid stem plates, derived from fossil echinoderms (invertebrate marine animals).

Uses of  
marbles

Marbles are used principally for buildings and monuments, interior decoration, statuary, table tops, and novelties. Colour and appearance are their most important qualities. Resistance to abrasion, which is a function of cohesion between grains as well as the hardness of the component minerals, is important for floor and stair treads. The ability to transmit light is important for statuary marble, which achieves its lustre from light penetrating from 0.5 to 1.5 inches from where it is reflected at the surfaces of deeper lying crystals. Brecciated, coloured marbles, onyx marble, and verd antique are used principally for interior decoration and for novelties. Statuary marble, the most valuable variety, must be pure white and of uniform grain size. For endur-

ance in exterior use, marble should be uniform and non-porous to prevent the entrance of water that might discolour the stone or cause disintegration by freezing. It also should be free from impurities such as pyrite that might lead to staining or weathering. Calcite marbles that are exposed to atmospheric moisture made acid by its contained carbon dioxide, sulfur dioxide, and other gases maintain a relatively smooth surface during weathering; but dolomite limestone may weather with an irregular, sandy surface from which the dolomite crystals stand out.

The principal mineral in marbles is calcite, and the fact that this mineral varies in hardness, light transmission, and other properties in various directions has a number of practical consequences in the preparation of some marbles. Calcite crystals are doubly refractive—they transmit light in two directions and more light in one direction; slabs prepared for uses in which translucency is significant are therefore cut parallel to that direction. The bending of marble slabs has been attributed to the directional thermal expansion of calcite crystals on heating. Some faces of calcite crystals are less rapidly soluble than others and a number of marble tombstones from the 1800s, cut so as to expose the less soluble faces, have withstood weathering (*q.v.*) better than those not so prepared.

Quarrying

The use of explosives in the quarrying of marble is limited because of the danger of shattering the rock. Instead, channelling machines that utilize chisel-edged steel bars make cuts about two inches wide and several feet deep. Wherever possible, advantage is taken of natural joints already present in the rock, and cuts are made in the direction of easiest splitting, which is a consequence of the parallel elongation of platy or fibrous minerals. The marble blocks outlined by joints and cuts are separated by driving wedges into drill holes. Mill sawing into slabs is done with sets of parallel iron blades that move back and forth and are fed by sand and water. The marble may be machined with lathes and carborundum wheels and is then polished with increasingly finer grades of abrasive (see also MINING AND QUARRYING).

Even with the most careful quarrying and manufacturing methods, at least half of the total output of marble is waste. Some of this material is made into chips for terrazzo flooring and stucco wall finish. In various localities it is put to most of the major uses for which high-calcium limestone is suitable.

**BIBLIOGRAPHY.** The several uses of marble and its extraction from the earth are discussed in OLIVER BOWLES, *The Stone Industries*, 2nd ed. (1939); "Marble," *Inf. Circ. U.S. Bur. Mines 7829* (1958); and T.N. DALE, "The Commercial Marbles of Western Vermont," *Bull. U.S. Geol. Surv.* 521 (1912). In a more specialized vein, the properties of carbonate minerals and the deformation that produces marbles are treated in H.W. FAIRBAIRN with supplementary chapters by FELIX CHAYES, *Structural Petrology of Deformed Rocks*, 2nd ed. (1949); and D.L. GRAF and J.E. LAMAR, "Properties of Calcium and Magnesium Carbonates and Their Bearing on Some Uses of Carbonate Rocks," *Economic Geology and the Society of Economic Geologists: Fiftieth Anniversary Volume*, pp. 639-713 (1955).

## Marcel, Gabriel

A French philosopher, dramatist, and critic of literature, drama, and music, Gabriel Marcel achieved fame as a thinker by his sensitive exploration of personal experience and relations, his evocative description of the human condition, and his affirmation of communion between man and transcendent reality.

**Early life and influences.** Marcel was born in Paris on December 7, 1889. His father, Henry Marcel—a government official, diplomat, and distinguished curator—was a man of wide cultural interests and contacts. Gabriel's mother died suddenly when he was four, leaving him with a sense of deep personal loss and yet of a continuing mysterious presence; the event made death and the irrevocable an early urgent concern for him. He was brought up by his maternal grandmother and his aunt—a devoted woman of stern upright character, who became his father's second wife, and who had a major influence

on his early development. An only child, he was, much to his distress, the centre of constant familial attention and care; and despite his brilliant scholastic achievements, his family's incessant demands for ever better academic performance, together with the rigid, mechanical quality of his schooling, filled him with a lifelong aversion toward depersonalized, forced-fed modes of education. He found some consolation in travelling to foreign places on his vacations, and when his father became French minister to Sweden he accompanied him. These vacations were the beginning of his lifelong passion for travel and of the fulfillment of a deep inner urge to make himself at home in the new and to explore the unfamiliar. In later life he became versed in several foreign languages and literatures and played a significant role in making contemporary foreign writers known in France.

H. Roger-Viollet

Gabriel Marcel, 1951.

Religion played no role in Marcel's upbringing. His father was a lapsed Catholic and cultured agnostic, who never bothered to have him baptized, and his aunt-stepmother, of nonreligious Jewish background, was converted to a liberal, humanist type of Protestantism. Reason, science, and the moral conscience were held to be sufficient guides, superseding traditional religion. Despite abundant parental love and solicitude, Marcel, in later life, looked back to this period as one of spiritual "servitude" and "captivity" that impelled him (without his knowing it) into a personal religious quest and to a philosophical inquiry into the conditions of religious faith.

**Areas of his work.** His search took three paths: music, drama, and philosophy. Hearing, playing, and composing music assumed an important role in the shaping of Marcel's mind from an early age, and composers such as J.S. Bach and Mozart played a more decisive role in his spiritual development than did great religious writers such as Augustine and Blaise Pascal. As a composer, his favourite mode was improvisation on the piano, for him a communion with a transcendent reality and not the mere expression of his private feelings and impressions. Only a small number of Marcel's improvisations have been transcribed or recorded; in 1945, however, he became a composer in the ordinary sense, devoting himself to the scored musical interpretation of poetry, ranging from that of Charles Baudelaire to that of Rainer Maria Rilke.

Playwriting provided another early and significant mode of expression. Gabriel wrote his first play at the age of eight. His father's accomplished reading-aloud of plays at home, Gabriel's own invented dialogues with imaginary brothers and sisters, or some peculiar innate cast of mind may have stimulated him to this precocious pursuit. His own family situation had provided the living matrix for his later dramatic presentations of intertwined and irreconcilable aspirations, frustrations, and conflicts of definitely individual characters. The dramatic delineation of the chaotic and unpleasant aspects of human

life complemented the expression of a transcendent harmony in his music; and both touched on key experiences and themes which were to be explored later in his philosophical meditations. They were unconsciously concrete illustrations of his philosophy before the fact, not deliberately contrived examples after the fact; they dealt with what were to be Marcel's main philosophical concerns as they emerged in the dramatic spiritual crises and relations of his full-dimensional real-life characters, not with a disingenuous manipulation of animated concepts as in the conventional "play of ideas."

Marcel dealt with themes of spiritual authenticity and inauthenticity, fidelity and infidelity, and the consummation or frustration of personal relationships in his early plays, such as *La Grâce*, *Le Palais de sable*, *Le Coeur des autres*, and *L'Iconoclaste*. In *Le Quatuor en fa dièse* his musical, philosophical, and dramatic dispositions merge to render vividly the sense of the interpenetration of persons whose lives are bound up with one another. He appended one of his most significant philosophical essays ("On the Ontological Mystery") to the play *Le Monde cassé*, in which "the broken world" of the title is displayed in the empty life and relations of the charming, despairing, and yet still hoping woman who is its protagonist.

**Philosophical development.** Philosophy, an early passion with Marcel, was the only subject that aroused his whole-hearted participation during his preparatory education. At 18, he was at work on his thesis for a diploma in higher studies, "The Metaphysical Ideas of Coleridge in Their Relations with the Philosophy of Schelling," and he studied philosophy at the Sorbonne. Although he passed examinations to become a teacher of philosophy in secondary schools (1910), he never completed his doctoral dissertation—on the necessary conditions for the intelligibility of religious thought. He taught philosophy only intermittently, usually earning his living as a publisher's reader, editor, writer, and critic.

At first, philosophy for Marcel meant a highly abstract type of thought that sought to transcend the everyday empirical world. Gradually, over a long period of probing and searching, he came to shape a concrete philosophy that sought to deepen and restore the intimate human experience left behind by abstract thought. This philosophical "conversion" occurred when he was working for the French Red Cross, during World War I, trying to trace soldiers listed as missing. In place of the information on file cards he came to see real, though invisible, persons—presences—and to share in the agony of their grieving relatives. What Marcel called his "metapsychical" experiments—investigations of possible communications by means of telepathy, clairvoyance, prophecy, and spiritualism—also played a role in his philosophical conversion. For him these experiences convincingly challenged the conventional naturalistic and materialistic bent of contemporary philosophy, indicating a realm beyond that of ordinary sense-experience, and promising freedom from conformist biases and prohibitions in his philosophical quest.

Originally Marcel intended to express his philosophical reflections in the conventional treatise form, but as he came to see his philosophical vocation as essentially exploratory and the philosopher's situation to be always in search and en route (*homo viator*), he abandoned this format as too didactic. Instead he published his philosophical workbooks, his day-to-day journals of philosophical investigations (such as *Metaphysical Journal*), and the later shorter philosophical diaries in *Being and Having* and *Présence et Immortalité*. He also wrote essays on particular themes and occasions (as in *Homo Viator*); these were usually a more rounded development of themes explored initially in various journal entries, such as exile, captivity, separation, fidelity, and hope, which were also a response to the particular situation of the French people during the German occupation of 1940 to 1944.

The decisive event in Marcel's spiritual life was his conversion to Roman Catholicism on March 23, 1929. The culmination of years of philosophical inquiry into the

Conversion  
to  
Catholicism

meanings and conditions of personal existence and faith, the action represented his realization that he had to choose a particular form of faith, that there is no faith in general. Despite his apparent affinity with Protestantism, which seemed more in keeping with his essentially non-conformist character and his need for intellectual freedom, he chose Catholicism, which he came to understand as a universal faith, not a special ecclesiastical institution or a partisan, exclusivist stance. After that decisive occasion he continued as an independent philosopher with a specific spiritual disposition, never as a theological apologist or spokesman for an official Catholic philosophy. And he continued in his plays, as well as in his philosophy, to explore and illuminate the dark and negative aspects of human existence.

**Basic themes and method.** Marcel's contribution to modern thought consisted of the exploration and illumination of whole ranges of human experience—trust, fidelity, promise, witness, hope, and despair—which have been dismissed by predominant schools of modern philosophy as not amenable to philosophical consideration. These explorations were buttressed by a remarkable reflective power and intellectual rigour, a metaphysical capacity *par excellence*.

His early central concept of "participation," the direct communion with reality, was gradually elaborated to elucidate everything from the elemental awareness of one's own body and sense-perception to the relation between human beings with ultimate being. The full, open relation between beings, thus conceived, is essentially "dialogical," the relation between an *I* and a *thou*, between the whole of a person and the fullness of what he confronts—another being, a "presence," and a "mystery," rather than an "object" of detached perception, thought, and expression. Such a relation requires an opening up to what is other than oneself, *disponibilité* (approximately "availability," "readiness," "permeability") and also an entering into, involvement, or *engagement*—dispositions demonstrable in everyday existence. The opposite is also ubiquitous—the refusal to open up and engage oneself, to give credit, to trust or hope, the disposition toward negation, despair, or even suicide. This possibility, for Marcel, is an essential characteristic of the human condition: man may deny as well as affirm his existence and either fulfill or frustrate his need to participate in being.

Marcel's method of thought and expression in dealing with these matters is an open, intuitive one. He probes the meaning of such terms as hope, fidelity, or witness and sketches the reality that they indicate through a sensitive description of the mind, action, and attitude of the hoper, faithful one, or witness. He makes use of concrete metaphors, and real-life instances to evoke and embody the difficult-to-express experiences and realities he is exploring.

Contributions to  
Phenomenology

In his own unique way, Marcel was an outstanding example of one of the central emphases of mid-20th century philosophy—Phenomenology (see PHENOMENOLOGY). Marcel's use of this intuitive method was original and was developed independently of the work of the great German Phenomenologist Edmund Husserl and his followers, just as his notion of the *I-thou* relation was developed independently of Martin Buber and other dialogical thinkers, and just as his exploration of Existential themes occurred long before his reading of Kierkegaard and the bursting forth of Existential philosophy on the mid-20th-century European scene. Marcel may justly be called the first French Phenomenologist and the first French Existential philosopher (though he deprecated the term Existentialism).

Marcel was married in 1919 to Jacqueline Boegner (died 1947), whom he called "the absolute companion of my life." Their only child was an adopted son, Jean-Marie, the relation to whom may have inspired Marcel's later reflections on "creative paternity" and the spirit of adoption.

Marcel was the recipient of many honours and awards, among them the Grand Prix de Littérature of the Académie Française (1948), membership in the Académie des Sciences Morales et Politiques (1952), and the Goethe

Prize (1956). He was an officer and commander of the Légion d'Honneur. He was Gifford Lecturer at Aberdeen (1949–50), and William James Lecturer at Harvard (1961). He died October 8, 1973, in Paris.

#### MAJOR WORKS

**PLAYS:** *La Grâce* and *Le Palais de sable*, published together under the title *Le Seuil invisible* (1914); *Le Quatuor en fa dièse* (1920); *Le Cœur des autres* (1921); *L'Iconoclaste* (1923); *Un homme de Dieu* (1925, new ed. 1950; *A Man of God*, 1952); *La Chapelle ardente* (1925, new ed. 1950; *The Funeral Pyre*, 1952); *Le Regard neuf* (1931); *Le Mort de demain* (1931); *Le Monde cassé* (1933); *Le Chemin de crête* (1936; *Ariadne*, 1952); *Le Dard* (1936); *Le Fanal* (1936); *Les Points sur les i* (1938); *La Soif* (1938; retitled *Les Coeurs avides*, 1952); *L'Horizon* (1945); *Colombyre, La Double Expertise*, and *Le Divertissement posthume*, all three published, with a reprint of *Les Points sur les i*, in *Théâtre comique* (1947); *L'Emissaire* and *Le Signe de la croix*, published together in *Vers un autre royaume* (1949); *Rome n'est plus dans Rome* (1951); *A Man of God* (1952; U.S. edition, *Three Plays*, 1958) includes *A Man of God*, *Ariadne*, and *The Funeral Pyre*, and preface of "The Drama of the Soul in Exile"; *Mon temps n'est pas le vôtre* (1955); *Croissez et multipliez* (1955); *La Dimension Florestan* (1958); *Le Secret est dans les îles*, includes *Le Dard*, *L'Emissaire*, and *La Fin des temps* (1967).

**WRITINGS ON THE THEATRE:** *L'Heure théâtrale: de Giraudoux à Jean-Paul Sartre* (1959); *Théâtre et religion* (1959); *Regards sur le théâtre de Claudel* (1964).

**PHILOSOPHICAL WRITINGS:** *Journal métaphysique* (1927; *Metaphysical Journal*, 1952); "Position et approches concrètes du mystère ontologique," first published as an appendix to *Le Monde cassé* (1933, separate editions 1949 and 1967; "On the Ontological Mystery," in *The Philosophy of Existence*, 1948); *Etre et avoir* (1935; *Being and Having*, 1949), new ed. in 2 vol., *Journal métaphysique 1928–1933 and Réflexions sur l'irreligion et la foi* (1968); *Du refus à l'invocation* (1940; *Creative Fidelity*, 1964), new ed. entitled *Essai de philosophie concrète* (1967); *Homo Viator: prolégomènes à une métaphysique de l'espérance* (1945, enlarged ed. 1963; *Homo Viator: Introduction to a Metaphysics of Hope*, 1951); *La Métaphysique de Royce* (1945; *Royce's Metaphysics*, 1945); *Le Mystère de l'être*, lectures of 1949–50 printed in 2 vol., *Réflexion et mystère* and *Foi et réalité* (1951; *The Mystery of Being*, 2 vol., 1950–51); *Les Hommes contre l'humain* (1951; *Men Against Humanity or Man Against Mass Society*, 1952); *Le Déclin de la sagesse* (1954; *The Decline of Wisdom*, 1954); *L'Homme problématique* (1955; *Problematic Man*, 1962); *Présence et immortalité* (1959; *Presence and Immortality*, 1967); *Fragments philosophiques 1909–1914* (1962; *Philosophical Fragments, 1901–1914*, 1965); *La Dignité humaine et ses assises existentielles* (1964; lectures pub. orig. in English, *The Existential Background of Human Dignity*, 1963); *Paix sur la terre: deux discours, une tragédie* (1965); *Pour une sagesse tragique et son au-delà* (1968).

## Marconi, Guglielmo

Guglielmo Marconi, a distinguished Italian physicist, was the inventor of a successful system of radio telegraphy. Applying the principles of electromagnetism, as elucidat-

ed by others, to the problem of transmitting messages through space, Marconi exploited the commercial possibilities of electrical communication without wires to an unlimited number of receivers at the same time.

By courtesy of the Library of Congress, Washington, D.C.

Marconi, c. 1908.

Marconi was born in Bologna on April 25, 1874. His father was Italian, his mother Irish. Educated first in Bologna and later in Florence, Marconi then went to the technical school in Leghorn, where, in studying physics, he had every opportunity for investigating electromagnetic wave technique, following the earlier mathematical work of James Clerk Maxwell and the electrical experiments of Heinrich Hertz, who first produced and transmitted radio waves, and Sir Oliver Lodge, who conducted experiments on lightning and electricity.

In 1894 Marconi began experimenting at his father's estate near Bologna, using comparatively crude apparatus: an induction coil for increasing voltages, with a spark discharger controlled by a Morse key at the sending end and a simple coherer (a device designed to detect radio waves) at the receiver. After preliminary experiments over a short distance, he first improved the coherer; then, by systematic tests, he showed that the range of signalling was increased by using a vertical aerial with a metal plate or cylinder at the top of a pole connected to a similar plate on the ground. The range of signalling was thus increased to about 1½ miles, enough to convince Marconi of the potentialities of this new system of communication. During this period, he also conducted simple experiments with reflectors around the aerial to concentrate the radiated electrical energy into a beam instead of spreading it in all directions.

Receiving little encouragement to continue his experiments in Italy, he went, in 1896, to London, where he was soon assisted by Sir William Preece, the chief engineer of the post office. Marconi filed his first patent in England in June 1896 and, during that and the following year, gave a series of successful demonstrations, in some of which he used balloons and kites to obtain greater height for his aerials. He was able to send signals over distances of up to four miles on the Salisbury Plain and to nearly nine miles across the Bristol Channel. These tests, together with Preece's lectures on them, attracted considerable publicity both in England and abroad; and in June 1897 Marconi went to La Spezia, where a land station was erected and communication was established with Italian warships at distances of up to 12 miles.

There remained, however, much skepticism about the useful application of this means of communication and a lack of interest in its exploitation. But Marconi's cousin Jameson Davis, a practicing engineer, financed his patent and helped in the formation of the Wireless Telegraph and Signal Company, Ltd. (changed in 1900 to Marconi's Wireless Telegraph Company, Ltd.). During the first

years, the company's efforts were devoted chiefly to showing the full possibilities of radiotelegraph. A further step was taken in 1899 when a wireless station was established at South Foreland, England, for communicating with Wimereux in France, a distance of 31 miles; in the same year British battleships exchanged messages at 75 miles.

In September 1899, Marconi equipped two U.S. ships to report to newspapers in New York City the progress of the yacht race for the America's Cup. The success of this demonstration aroused worldwide excitement and led to the formation of the American Marconi Company. The following year the Marconi International Marine Communication Company, Ltd., was established for the purpose of installing and operating services between ships and land stations. In 1900 also, Marconi filed his now famous patent No. 7777 for Improvements in Apparatus for Wireless Telegraphy. The patent, based on earlier work in wireless telegraphy by Sir Oliver Lodge, enabled several stations to operate on different wavelengths without interference.

Marconi's great triumph was, however, yet to come. In spite of the opinion expressed by some distinguished mathematicians that the curvature of the earth would limit practical communication by means of electric waves to a distance of 100–200 miles, Marconi succeeded in December 1901 in receiving at St. John's, Newfoundland, signals transmitted across the Atlantic Ocean from Poldhu in Cornwall, England. This achievement created an immense sensation in every part of the civilized world; and, though much remained to be learned about the laws of propagation of radio waves around the earth and through the atmosphere, it was the starting point of the vast development of radio communications, broadcasting, and navigation services that took place in the next 50 years, in much of which Marconi himself continued to play an important part.

During a voyage on the U.S. liner "Philadelphia" in 1902, Marconi received messages from distances of 700 miles by day and 2,000 miles by night. He thus was the first to discover the fact that, because some radio waves travel by reflection from the upper regions of the atmosphere, transmission conditions are sometimes more favourable at night than during the day. This is due to the fact that the upward travel of the waves is limited in the daytime by absorption in the lower atmosphere, which becomes ionized—and so electrically conducting—under the influence of sunlight. In 1902 also, Marconi patented the magnetic detector in which the magnetisation in a moving band of iron wires is changed by the arrival of a signal causing a click in the telephone receiver connected to it. During the ensuing three years, he also developed and patented the horizontal directional aerial. Both of these devices improved the efficiency of the communication system. In 1910 he received messages at Buenos Aires from Clifden in Ireland over a distance of about 6,000 miles, using a wavelength of about 8,000 metres (26,000 feet). Two years later, Marconi introduced further innovations which so improved transmission and reception that important long-distance stations could be established. This increased efficiency made it possible for Marconi to send the first radio message from England to Australia in September 1918.

In spite of the rapid and widespread developments then taking place in radio and its applications to maritime use, Marconi's intuition and urge to experiment were by no means exhausted. In 1916, during World War I, he saw the possible advantages of shorter wavelengths that would permit the use of reflectors around the aerial, thus minimizing the interception of transmitted signals by the enemy and also effecting an increase in signal strength. After tests in Italy (20 years after his original experiments with reflectors), Marconi continued the work in Great Britain and, on a wavelength of 15 metres, received signals over a range of 20–100 miles. In 1923 the experiments were continued on board his steam yacht "Elettra," which had been specially equipped. From a transmitter of one kilowatt at Poldhu, Cornwall, signals were received at a distance of 1,400 miles, much louder than those from

tions  
of short  
waves

Caernarvon in Wales on a wavelength several hundred times as great and with 100 times the power at the transmitter. Thus began the development of shortwave wireless communication that, with the use of the beam aerial system for concentrating the energy in the desired direction, constitutes the basis of nearly all modern long-distance radio communication. In 1924 the Marconi company obtained a contract from the post office to establish shortwave communication between England and the countries of the British Commonwealth.

A few years later Marconi returned to the study of still shorter waves of about a half metre. At these very short wavelengths a parabolic reflector of moderate size gives a considerable increase in power in the desired direction. Experiments conducted off the coast of Italy on the yacht "Elettra" soon showed that useful ranges of communication could be achieved with low-powered transmitters. In 1932, using very short wavelengths, Marconi installed a radiotelephone system between the Vatican City and the pope's palace at Castel Gandolfo. In later work Marconi once more demonstrated that even radio waves as short as 55 centimetres (22 inches) are not limited in range to the horizon or to optical distance between transmitter and receiver.

Marconi received many honours and several honorary degrees: awarded the Nobel Prize for Physics (1909) for the development of wireless telegraphy; sent as plenipotentiary delegate to the peace conference in Paris (1919), in which capacity he signed the peace treaties with Austria and with Bulgaria; created marchese and nominated to the Italian senate (1929); and chosen president of the Royal Italian Academy (1930).

Marconi died in Rome on July 20, 1937, and was accorded a state funeral by the Italian government. At his own wish he was buried in his native town of Bologna.

**BIBLIOGRAPHY.** W.J. BAKER, *A History of the Marconi Company* (1970), a history of the development of radio communications from early experiments over a few miles to the transmission of colour-television programs using artificial Earth satellites—includes a brief review of scientific discoveries prior to 1896 and a photograph of Marconi's first transmitter used in his earliest experiments in Italy in 1895; GEORGE G. BLAKE, *History of Radio Telegraphy and Telephony* (1926), a well-illustrated historical account of various schemes that were advanced to exploit radio communication since the earliest observations of electrical phenomena; JOHN A. FLEMING, *The Principles of Electric Wave Telegraphy and Telephony*, 4th ed. (1919), a comprehensive technical treatise describing the development of radio communications from laboratory experiments on electrical oscillations to early radio telegraphy and telephony; and "The Coming of Age of Long-Distance Radiotelegraphy and Some of Its Scientific Problems," *Jl. R. Soc. Arts*, 70:66-78, 82-96 (1921), a discussion by an associate of Marconi of early transmission experiments and of the first transatlantic signal in 1902; WILLIAM T. O'DEA, *Radio Communication*, pt. 1, *History and Development* (1934), a brief, illustrated account from experiments with spark discharges in 1780 to the development of thermionic valves and their application to sound broadcasting and television; RADIO ENGINEERING LABORATORIES, INC. ## Marcus Aurelius

Marcus Aurelius Antoninus, Roman emperor from AD 161 to 180, has symbolized, for many generations in the West the Golden Age of the Roman Empire, that period in which a thoroughly organized world state was headed by a conscientious and self-sacrificing monarch who carried out in daily practice the precepts of Stoicism, a philosophy that alone among pagan creeds provided a moral justification for a life spent in public service. His claim to the attention of subsequent ages has been the greater because, with the exception of Cicero, he is the only figure of classical antiquity whose individual personality can still be apprehended through his writings: the *Meditations*, or "soliloquies," and some of his private correspondence. Although the rosy picture of Rome's Golden Age has come under challenge in every particular and a more critical eye has been

Marcus Aurelius, bas-relief depicting his triumphal entry into Rome in a quadriga. In the Palazzo dei Conservatori, Rome.

Allinari

turned upon the Emperor who symbolized it, his personality and achievement, even after 18 centuries, are still worth discussing.

**Period of youth and apprenticeship.** His name at his birth on April 26, 121, was Marcus Annius Verus. His paternal grandfather was already consul for the second time and prefect of the city, which was the crown of prestige in a senatorial career; his father's sister was married to the man who was destined to become the next emperor and whom he himself would in due time succeed; and his maternal grandmother was heiress to one of the most massive of Roman fortunes. Marcus thus was related to several of the most prominent families of the new Roman establishment, which had consolidated its social and political power under the Flavian emperors (69-96); and, indeed, the ethos of that establishment is relevant to his own actions and attitudes. The governing class of the first age of the Roman Empire, the Julio-Claudian, had been little different from that of the late Republic—it was urban Roman (despising outsiders), extravagant, cynical, and amoral; the new establishment, however, was largely of municipal and provincial origin—as were the emperors around whom it revolved—cultivating sobriety and good works and turning more and more to piety and religiosity.

The child Marcus was, thus, clearly destined for social distinction. How he came to the throne, however, remains a mystery. In 136 the emperor Hadrian inexplicably announced as his eventual successor a certain Lucius Ceionius Commodus (henceforth L. Aelius Caesar), and in that same year young Marcus was engaged to Ceionia Fabia, the daughter of Commodus. Early in 138, however, Commodus died and later, after the death of Hadrian, the engagement was annulled. Hadrian then adopted Titus Aurelius Antoninus (the husband of Marcus' aunt) to succeed him as the emperor Antoninus Pius, arranging that Antoninus should adopt as his sons two young men, one the son of Commodus and the other Marcus, whose name was then changed to Marcus Aelius Aurelius Verus. Marcus thus was marked out as a future joint emperor at the age of just under 17, though as it turned out he was not to succeed till his 40th year. It is sometimes assumed that in Hadrian's mind both Commodus and Antoninus Pius were merely to be "place warmers" for one or both of these youths.

The long years of Marcus' apprenticeship under Antoninus are illuminated by the correspondence between him and his teacher Fronto. Though the main society literary figure of the age, Fronto was a dreary pedant whose blood ran rhetoric; but he must have been less lifeless than he now appears, for there is genuine feeling

Family

Apprenticeship under Antoninus

and real communication in the letters between him and both of the young men. It was to the credit of Marcus, who was intelligent as well as hardworking and serious-minded, that he grew impatient with the unending regime of advanced exercises in Greek and Latin declamation and eagerly embraced the *Diatribai* ("Discourses") of a religious former slave, Epictetus, an important moral philosopher of the Stoic school. Henceforth, it was in philosophy that Marcus was to find his chief intellectual interest as well as his spiritual nourishment.

Meanwhile, there was work enough to do at the side of the untiring Antoninus, with learning the business of government and assuming public roles. Marcus was consul in 140, 145, and 161. In 145 he married his cousin, the Emperor's daughter Annia Galeria Faustina, and in 147 the *imperium* and *tribunicia potestas*, the main formal powers of emperorship, were conferred upon him; henceforth he was a kind of junior co-emperor, sharing the intimate counsels and crucial decisions of Antoninus. (His adoptive brother, nearly 10 years his junior, was brought into official prominence in due time.) On March 7, 161, at a time when the brothers were jointly consuls (for the third and the second time, respectively), their father died.

**Period as full Roman emperor.** The transition was smooth as far as Marcus was concerned; already possessing the essential constitutional powers, he stepped automatically into the role of full emperor (and his name henceforth was Emperor Caesar Marcus Aurelius Antoninus Augustus). At his own insistence, however, his adoptive brother was made co-emperor with him (and bore henceforth the name Emperor Caesar Lucius Aurelius Verus Augustus). There is no evidence that Lucius Verus had much of a following, so that a ruthless rival could have easily disposed of him, though to leave him in being as anything less than emperor might have created a focus for disaffection. It is most probable, however, that Marcus' conscience impelled him to carry out loyally what he believed to have been the plan by which alone he himself had eventually reached the purple. For the first time in history the Roman Empire had two joint emperors of formally equal constitutional status and powers; but, although the achievement of Lucius Verus has suffered by comparison with the paragon Marcus, it seems probable that the serious work of government was done throughout by Marcus and was the more arduous in that it was done during most of his reign in the midst of fighting frontier wars and combatting the effects of plague and demoralization.

**His statesmanship.** For constructive statesmanship or the initiation of original trends in civil policy, Marcus had little time or energy to spare. The field most congenial to him seems to have been the law. Numerous measures were promulgated and judicial decisions made, clearing away harshnesses and anomalies in the civil law, improving in detail the lot of the less-favoured—slaves, widows, minors—and giving recognition to claims of blood relationship in the field of succession. Marcus' personal contribution, however, must not be overstated. The pattern of ameliorating legislation was inherited rather than novel, and the measures were refinements rather than radical changes in the structure of law or society; Marcus was not a great legislator, but he was a devoted practitioner of the role of "ombudsman." Moreover, there was nothing specifically Stoic about this legal activity; and in one respect the age of Antoninus Pius and Marcus signalizes a retrogression in the relationship of law to society, for under them there either began, or was made more explicit, a distinction of classes in the criminal law—*honestiores* and *humiliores*, with two separate scales of punishments for crime, harsher and more degrading for the *humiliores* at every point.

Marcus' claim to statesmanship has come under critical attack in numerous other ways; for example, in the matter of Christian persecution. Though Marcus disliked the Christians, there was no systematic persecution of them during his reign. Their legal status remained as it had been under Trajan and Hadrian: Christians were *ipso*

*facto* punishable but not to be sought out. This incongruous position did little harm in times of general security and prosperity, but when either of these were threatened, the local population might denounce Christians, a governor might be forced to act, and the law, as the central authority saw it, must then run its course. The martyrdoms at Lyons in 177 were of this nature, and, though it appears that Christian blood flowed more profusely in the reign of Marcus the philosopher than it had before, he was not an initiator of persecution.

**His military campaigns.** In 161 Syria was invaded by the Parthians, a major power to the East. The war that followed (162–166) was nominally under the command of Verus, though its successful conclusion, with the overrunning of Armenia and Mesopotamia, was the work of subordinate generals, notably Gaius Avidius Cassius. The returning armies brought back with them a plague, which raged throughout the empire for many years and—together with the German invasion—fostered a weakening of morale in minds accustomed to the stability and apparent immutability of Rome and its empire.

In 167 or 168 Marcus and Verus together set out on a punitive expedition across the Danube, and behind their backs a horde of German tribes invaded Italy in massive strength and besieged Aquileia, on the crossroads at the head of the Adriatic. The military precariousness of the empire and the inflexibility of its financial structure in the face of emergencies now stood revealed; desperate measures were adopted to fill the depleted legions, and imperial property was auctioned to provide funds. Marcus and Verus fought the Germans off with success; but in 169 Verus died suddenly, and doubtless naturally, of a stroke. Three years of fighting were still needed, with Marcus in the thick of it, to restore the Danubian frontier; and three more years of campaigning in Bohemia were enough to bring the tribes beyond the Danube to peace, at least for a time.

A more intimate contact with the thoughts pursued by Marcus during the troubling involvements of his reign, though not what would have been historically most valuable, his day-to-day political thoughts, can be acquired by reading the *Meditations*. To what extent he intended them for eyes other than his own is uncertain; they are fragmentary notes, discursive and epigrammatic by turn, of his reflections in the midst of campaigning and administration. In a way, it seems, he wrote them to nerve himself for his daunting responsibilities. Strikingly, though they comprise the innermost thoughts of a Roman, the *Meditations* were written in Greek—to such an extent had the union of cultures become a reality. In many ages these thoughts have been admired; the modern age, however, is more likely to be struck by the pathology of them, their mixture of priggishness and hysteria. Marcus was forever proposing to himself unattainable goals of conduct, forever contemplating the triviality, brutishness, and transience of the physical world and of man in general and himself in particular; otherworldly, yet believing in no other world, he was therefore tied to duty and service with no hope, even of everlasting fame, to sustain him. Sickly all through his life and probably plagued with a chronic ulcer, he took daily doses of a drug; the suggestion has been made that the apocalyptic imagery of passages in the *Meditations* betrays the addict. More certain and more important is the point that Marcus' anxieties reflect, in an exaggerated manner, the ethos of his age.

The *Meditations*, the thoughts of a philosopher-king, have been considered by many generations one of the great books of all times. Though they were Marcus' own thoughts, they were not original. They are basically the moral tenets of Stoicism, learned from Epictetus: the cosmos is a unity governed by an intelligence, and the human soul is a part of that divine intelligence and can therefore stand, if naked and alone, at least pure and undefiled, amidst chaos and futility. One or two of Marcus' ideas, perhaps more through lack of rigorous understanding than anything else, diverged from Stoic philosophy and approached that Platonism that was itself then turning into the Neoplatonism into which all pagan philosophies,

Appointment of his brother as co-emperor

The *Meditations*

Treatment of Christians during his reign

His Stoic philosophy

except Epicureanism, were destined to merge. But he did not deviate so far as to accept the comfort of any kind of survival after death.

At the same time that Marcus was securing his trans-Danubian frontiers, Egypt, Spain, and Britain were troubled by rebellions or invasions. By 175, the general Avidius Cassius, who earlier had served under Verus, had virtually become a prefect of all of the eastern provinces, including control of the important province of Egypt. In that year, Avidius Cassius took the occasion of a rumour of Marcus' death to proclaim himself emperor. Marcus made peace in the north with those tribes not already subjugated and prepared to march against Avidius; but the rebel general was assassinated by his own soldiers. Marcus used the opportunity to make a tour of pacification and inspection in the East, visiting Antioch, Alexandria, and Athens—where, like Hadrian, he was initiated into the Mysteries of Eleusis (though that esoteric religious cult does not seem to have impinged at all upon his philosophical views). During the journey the empress Faustina, who had been with her husband in the Danubian wars as well, died. Great public honours were bestowed upon her in life and in death, and in his *Meditations* Marcus spoke of her with love and admiration. The ancient sources accuse her of infidelity and disloyalty (complicity, in fact, with Avidius Cassius), but the charges are implausible.

In 177 Marcus proclaimed his 16-year-old son, Commodus, joint emperor. Together they resumed the Danubian wars. Marcus was determined to pass from defense to offense and to an expansionist redrawing of Rome's northern boundaries. His determination seemed to be winning success when, on March 17, 180, he died at his military headquarters, having just had time to commend Commodus to the chief advisers of the regime.

**Criticism and evaluation.** Marcus' choice of his only surviving son as his successor has always been viewed as a tragic paradox. Commodus turned out badly, though two things must be borne in mind: emperors are good and bad in the ancient sources according as they did or did not satisfy the senatorial governing class, and Commodus' rapid calling off of the northern campaigns may well have been wiser than his father's obsessive and costly expansionism. But those who criticize Marcus for ensuring the accession of Commodus are usually under the misapprehension that Marcus was reverting to crude dynasticism after a long and successful period of "philosophic" succession by the best available man. This is historically untenable. Marcus had no choice in the matter: if he had not made Commodus his successor, he would have had to order him to be put to death.

Marcus was a statesman, perhaps, but one of no great calibre; nor was he really a sage. In general, he is a historically overrated figure, presiding in a bewildered way over an empire beneath the gilt of which there already lay many a decaying patch. But his personal nobility and dedication survive the most remorseless scrutiny; he counted the cost obsessively, but he did not shrink from paying it.

#### BIBLIOGRAPHY

*Ancient sources:* Scriptores Historiae Augustae, *Vita M. Antonini philosophi*, the standard and reasonably reliable life from the set of late Latin biographies of emperors; DIO CASSIUS, book lxxi, which survives only in Byzantine excerpts; FRONTO, *Epistulae*, which presents the correspondence (of which it is important to use the modern edition by M.P.J. VAN DEN HOUT, 1954); EUSEBIUS, *Historia ecclesiastica*, v, 1—the account of the martyrs of Lyons; and A.S.L. FARQUHARSON (ed.), *The Meditations of the Emperor Marcus Antoninus*, 2 vol. (1944), the full annotated edition.

*Modern biographies:* Farquharson's edition contains a brief biography (vol. 1, pp. 256–268); the fullest treatment (in German) is by P. VON ROHDEN and H. VON ARNIM in *Pauly-Wissowa Real-Encyclopädie*, vol. 1, pp. 2279–2309 (1894), still fundamental in spite of its date. ANTHONY BIRLEY, *Marcus Aurelius* (1966), is a more recent biography in English; A.S.L. FARQUHARSON also produced a wider-ranging study: *Marcus Aurelius: His Life and His World*, ed. by D.A. REES (1951). The general history of the principate by ALBINO GARZETTI, *L'impero da Tiberio agli Antonini* (1960), places Marcus' reign in its historical setting and contains a useful bibliogra-

phy. G.R. STANTON, "Marcus Aurelius, Emperor and Philosopher," *Historia*, 18:570–587 (1969), well represents a skeptical current in points of view about Marcus.

*Chronological problems:* For more detail on the controversial problems of the chronology of the reign, see the papers of C.H. DODD in *Numismatic Chronicle*, 11:209–350 (1911), 13:162–199, 276–321 (1913), and 14:34–91 (1914); W. ZWIKKER, *Studien zur Markussäule* (1941); and J. MORRIS, "The Dating of the Column of Marcus Aurelius," in *Journal of the Warburg and Courtauld Institutes*, 15:33–47 (1952).

## Margaret of Denmark, Norway, and Sweden

Margaret, queen of Denmark, Norway, and Sweden, medieval Scandinavia's most remarkable ruler, brought external and domestic peace to the three countries she united under her rule. The daughter of King Valdemar IV of Denmark, she was born in 1353 in Sjøborg.

By courtesy of the Nationalmuseum Arkivet, Stockholm

Margaret, detail of her tomb effigy (recumbent) in the cathedral of Roskilde, Denmark.

She was only six years old when she was betrothed to Haakon, king of Norway and son of King Magnus Eriksson of Sweden and Norway. The betrothal, intended to counter the dynastic claims to the Scandinavian thrones by the dukes of Mecklenburg and the intrigues of certain aristocratic factions within the Scandinavian countries, was imperilled by the renewal in 1360 of the old struggle between Valdemar of Denmark and Magnus of Sweden. But military reverses and the opposition of his own nobility forced Magnus to suspend hostilities in 1363. The wedding of Margaret and Haakon took place in Copenhagen in the same year.

Haakon's aspirations to become king of Sweden were thwarted when he and his father were defeated soon afterward by Albert of Mecklenburg, who bore the Swedish crown from 1364 to 1389. Haakon, however, succeeded in keeping his Norwegian kingdom, and it was there that Margaret spent her youth, under the tutelage of Märta Ulfsdotter, a daughter of the Swedish saint, Bridget. Margaret early displayed her talent as a ruler: she soon overshadowed her husband and appears to have exercised the real power. The couple's only child, Olaf, was born in 1370.

After her father's death in 1375, Margaret succeeded, over the objections of the Mecklenburgian claimants, in getting Olaf elected to the Danish throne. Following her husband's death in 1380, Margaret also ruled Norway in her son's name. Thus began the Danish-Norwegian union that lasted until 1814. Margaret was successful in securing and extending her sovereignty: in 1385 she won

Choice of  
Commodus  
as  
successor

Rise to  
power

back the economically important strongholds on the west coast of Scandia from the Hanseatic League, and for a time she was also able to safeguard Denmark's southern borders by agreement with the counts of Holstein.

Margaret and Olaf, who came of age in 1385, were on the point of making war on Albert to enforce their claims to the Swedish throne when Olaf died unexpectedly in 1387. Deploying all her diplomatic skill, Margaret consolidated her position, becoming regent of both Norway and Denmark and, in the absence of an heir, adopting her six-year-old nephew, Erik of Pomerania. She then joined forces with the Swedish nobles, who had risen against the unpopular King Albert in a dispute over the will disposing of the lands of Bo Jonsson Grip, the powerful chancellor. By the Treaty of Dalaborg of 1388, the nobles proclaimed Margaret Sweden's "sovereign lady and rightful ruler" and granted her the main portion of Bo Jonsson Grip's vast domains. Defeating Albert in 1389, Margaret took him captive and released him only after the conclusion of peace six years later. His supporters, who had allied themselves with pirate bands in the Baltic Sea, did not surrender Stockholm until 1398.

Margaret was now the undisputed ruler of the three Scandinavian states. Her heir, Erik of Pomerania, was proclaimed hereditary king of Norway in 1389 and was elected king of Denmark and Sweden (which also included Finland) in 1396. His coronation took place the following year in the southern Swedish town of Kalmar, in the presence of the leading figures of all the Scandinavian countries. At Kalmar the nobility manifested its opposition to Margaret's increasing exercise of absolute power. The two extant documents disclose traces of the struggle between two political principles: the principle of absolute hereditary monarchy, as expressed in the so-called coronation act, and the constitutional elective kingship preferred by some nobles, as expressed in the so-called union act. The Kalmar assembly was a victory for Margaret and absolutism; the union act—perhaps the medieval Scandinavian document most debated by historians—denoted a plan that failed.

Despite Erik's coronation, Margaret remained Scandinavia's actual ruler until her death. Her aim was to further develop a strong royal central power and to foster the growth of a united Scandinavian state with its centre of gravity located in Denmark, her old hereditary dominion. She succeeded in eliminating the opposition of the nobility, in curbing the powers of the council of state, and in consolidating the administration through a network of royal sheriffs. In order to secure her position economically, she levied heavy taxes and confiscated church estates and lands exempt from dues to the crown. That such a policy succeeded without fatal strife to the union testifies to her strong political position as well as to her diplomatic skills and her ruthlessness. By adroitly using her relations to the Holy See, she was able to strengthen her influence over the church and on the politically important episcopal elections.

Margaret's political acumen was also evident in foreign affairs. Her main goals in this area were to put an end to German expansion to the north and to extend and secure Denmark's southern borders, goals she tried to achieve through diplomatic means. An armed conflict did, however, break out with Holstein, and during the war Margaret died unexpectedly at Flensburg in 1412.

One of Scandinavia's most eminent monarchs, she was able not only to establish peace in her realms but also to maintain her authority against the aspirations of German princes and against the superior economic power of the Hanseatic League. The united kingdom that she created and left as a legacy, whose cementing factor was a strong monarchy, remained in existence until 1523, albeit not without interruptions.

**BIBLIOGRAPHY.** The first study of Queen Margaret based on modern critical principles is KRISTIAN ERSLEV, *Dronning Margrethe og Kalmarunionens Grundlaeggelse* (1882), still a work of great value. The most debated event during Margaret's reign has been the foundation of the Kalmar Union in 1397. Among the contributions to this discussion the following titles are recommended: LAURITZ WEIBULL,

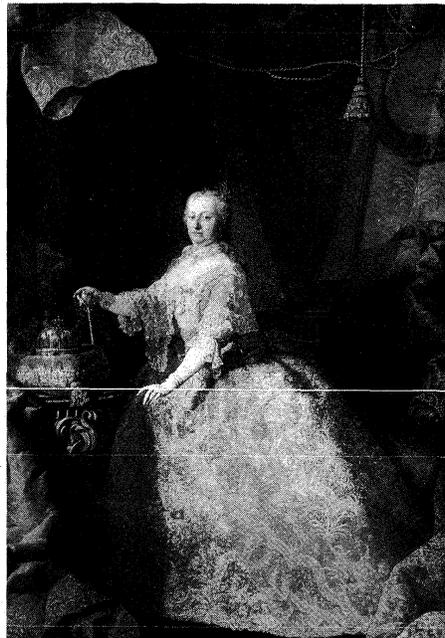

"Unionsmötet i Kalmar 1397," *Scandia*, pp. 185–222 (1930); GOTTFRID CARLSSON, "Kalmarunionen," *Svensk Historisk Tidskrift*, pp. 405–481 (1930); and *Sveriges historia till våra dagar*, vol. 3, pt. 1 (1941); ERIK LONNROTH, *Sverige och Kalmarunionen 1397–1457* (1934); and HALVDAN KOTH *Dronning Margareta og Kalmarunionen* (1950). Margaret's financial policy is the topic of J. ROSEN, "Drottning Margareta svenska räfst," *Scandia*, pp. 169–246 (1950). MICHAEL LINTON, *Drottning Margareta* (1971), throws new light on Margaret's methods of diplomacy.

## Maria Theresa, Empress

The archduchess of Austria, queen of Hungary, queen of Bohemia, and wife of the Holy Roman emperor Francis I, Maria Theresa was a key figure in the power politics of 18th-century Europe. To the Habsburg monarchy, a dynastic agglomeration of disparate lands, she gave a measure of unity. A princess of engaging naturalness, she was one of the most capable rulers of her house and, according to one historian, "the most human of the Habsburgs."

Maria Theresa, oil painting by Martin van Meytens (1695–1770). In Schönbrunn Palace, near Vienna.

She was born in Vienna on May 13, 1717, the eldest daughter of the emperor Charles VI and Elizabeth of Brunswick-Wolfenbüttel. The death of an only son prompted Charles, the only living prince of his line, to promulgate the so-called Pragmatic Sanction, a royal act, eventually recognized by most powers, whereby female issue was entitled to succeed to the domains of the Habsburgs. (Since nearly every major European nation coveted some part of the Habsburg domains, their consent to the Pragmatic Sanction must be taken as nothing more than an act of convenience.) Theresa thus became a pawn on Europe's political chessboard. In 1736 she married Francis Stephen of Lorraine. Because of French objections to the union of Lorraine with the Habsburg lands, Francis Stephen had to exchange his ancestral duchy for the right of succession to the Grand Duchy of Tuscany. The marriage was a love match, and 16 children were born to the couple, of whom ten survived to adulthood.

On October 20, 1740, Charles VI died, and the war of succession he had striven so hard to forestall broke out before the end of the year. Charles left the Habsburg state at the lowest point of its prestige, its coffers empty, its capital beset by unrest. The naïve courage with which Maria Theresa assumed her heritage (and made her husband coregent) astounded Europe's chancelleries. Her

ment

refusal to negotiate with Frederick II (later the Great) of Prussia, who had invaded Silesia, her most prosperous province, appalled the senescent councillors of her late father. Her successful appearance before the refractory Hungarian Estates, ending with an appeal for a mass levy of troops, gave her a European reputation for diplomatic skill. When the elector Charles Albert of Bavaria—one of the princes who had joined Frederick in assaulting Habsburg territories—was elected emperor, Maria Theresa was mortified; that dignity, little more than titular by then, had in practice been hereditary in her family for 300 years. Upon the death of the “usurper” (1745), she secured for her husband, Francis, the imperial crown, which the law denied to women.

Domestic reforms

For some brief years she had indulged her youthful zest for horseback riding, dancing, and music making. She adored the Italian poet Metastasio and the composers who used his masques and librettos and remained partial to Italianate music throughout her life. From the mid-1740s on, however, her outlook on life became decidedly more puritanical. During the campaigns of the War of the Austrian Succession, her generals and ministers came to know both her autocratic temper and the thorough attention she gave to all matters, important or trivial. Realizing the need for a sizable standing army and in order to maintain one, she accepted the plans of Count Friedrich Wilhelm Haugwitz—the first in a succession of remarkable men of intellect she was to draw into her council. In the face of the opposition of many noblemen, she managed to reduce drastically (except in Hungary) the powers of the various dominions’ estates, which had held the monarchy’s purse strings since time immemorial. In the further process of abolishing tax exemptions held by the great landowners, who dominated those assemblies, she hit on the notion of a “God-pleasing equality.” Yet she did not question the justice of the manorial lord’s claim on the labour of his hereditary subjects. Only many years later did peasant riots in famine-stricken Bohemia, as well as the reported cruelty of Hungarian magnates, cause her to limit the use of forced labour. “The peasantry must be able to sustain itself as well as pay taxes . . .,” she wrote. Practical, if not always fiscal, considerations, rather than doctrinaire humanitarianism, guided all of Maria Theresa’s reforms. An enlarged central administration—from which the judiciary was separated in 1749—and a repeatedly reorganized treasury required knowledgeable civil servants and judges; and their training was, to her mind, the sole purpose of higher education. She approved drastic changes that her physician, the Dutchman, Gerhard van Swieten, carried through at the universities (such as the introduction of textbooks, the linking of the medical school of the University of Vienna with the embryonic public health service, and the sovereign’s right to veto the election of deans by the faculties) even as he took them out of the hands of the Jesuits, to whose Society she herself was devoted. (She was the last of the Catholic monarchs to close its establishments.) Deeply pious, strictly observant, and intolerant to the point of bigotry, she was moving, nonetheless, toward subordinating the church to the authority of the state.

Change of alliances

Neither the peace of 1745 (by which Austria ceded Silesia to Prussia) nor the peace of 1748 (which ended Maria Theresa’s war with the rest of her enemies) ended her efforts to modernize the army. The dazzling ideas of her new chancellor, Wenzel Anton von Kaunitz, fired her determination to recover Silesia, indeed, to destroy Prussia. In a famous “reversal of alliances” (1756) she threw over England, the old ally and “banker” of the Habsburgs, and allied herself with France, their ancient foe. Moreover, she had entered into a treaty with Russia, a newcomer to European rivalries. She paid but scant attention to the global ramifications of the ensuing Seven Years’ War. When its end sealed the loss of Silesia and left the monarchy with a mountain of debts, she became a champion of peace. As late as 1779 she single-handedly frustrated another full-scale war with Prussia, risked by her self-opinionated firstborn, Joseph II, who on his father’s demise had become coregent in the Habsburg dominions (and been elected emperor).

Though Francis had not been a faithful husband, Maria Theresa never wavered in her love, and his sudden death in 1765 plunged her into prolonged grief. She emerged from it, her zeal for activity nowise impaired. A new public-debt policy, the settlement of the empty spaces of Hungary, the drafting of a penal code to supplant the tangle of local systems, and a kind of poor law—these were but some of the innovations in which she herself took a hand, with her common sense doing service for the book learning she lacked. In step with the enforced retreat of the church from secular affairs, she came to feel that it was incumbent on the state to control the intellectual life of its subjects. It was she who institutionalized government censorship; on the other hand, it was she, too, who launched plans for compulsory primary education.

Although Maria Theresa pedantically supervised her children’s upbringing and education, she was to experience many disappointments in connection with them. Of her sons, only Leopold of Tuscany (later Emperor Leopold II), though difficult as a child, lived up to her hopes. Her special affection belonged to Maria Christina, who was allowed to marry for love and on whom Maria Theresa showered vast gifts of money. Three of her daughters, married off to unprepossessing Bourbons—in Parma, Naples, and France—again and again irritated their mother with their strong will or their follies; to her dying day she bombarded one of these, Queen Marie-Antoinette of France, with practical advice, moral exhortations, and dire warnings of the future. But it was the running conflict with Joseph that clouded the years of her widowhood most. His flirting with the “new philosophy” of the Enlightenment frightened her, his admiration of Frederick the Great offended her, and his foreign enterprises filled her with trepidation. There were threats of abdication on both his part and hers. When Joseph, supported by Kaunitz, pressured her into agreeing to share in the (first) partition of Poland in 1772, she loudly bewailed the immorality of the action. And while she had shrugged off ridicule on such occasions as her setting up a public-morals squad (the “chastity commission” of popular parlance) or, prude though she was, her enlisting the help of Louis XV’s mistress, Madame de Pompadour, in order to obtain the French alliance, the accusation of “lachrymose hypocrisy” raised in foreign courts during the Polish affair distressed her. Grown enormously stout and in poor health, she spent more and more of her time in suburban Schönbrunn, whose palace owed its reconstruction to her initiative. She was still trying to hold off the approach of the new age. Ironically, her own pragmatic reforms had smoothed the road to the enlightened despotism that was to mark the reign of her successor. She died on November 29, 1780, in the Hofburg, the vast Habsburg palace in Vienna.

**BIBLIOGRAPHY.** A. VON ARNETH, *Geschichte Maria Theresias*, 10 vol. (1863–79), is still the basic chronicle. Sentimental biographies abound; the most informative is EUGEN GUGLIA, *Maria Theresia: Ihr Leben und ihre Regierung*, 2 vol. (1917). J.F. BRIGHT’s primarily diplomatic study, *Maria Theresa* (1897), is useful. By far the most judicial appraisal of Maria Theresa’s domestic policies is to be found on pp. 1–118 of C.A. MACARTNEY, *The Habsburg Empire 1790–1918* (1968). *Empress Maria Theresa*, by ROBERT PICK (1966), covers her life up to 1757 and contains a valuable bibliography. PRINCE J.J. KHEVENHULLER’S diaries, 1748–73, published as *Aus der Zeit Maria Theresias*, 7 vol., ed. by KHEVENHULLER and SCHLITZER (1907–25), are indispensable. So are two memoirs of Maria Theresa reissued as *Maria Theresias politisches Testament* (1952). The various collections of Maria Theresa’s surviving letters to her children, her friends, and some of her servants—notably *Marie Antoinette: Correspondance secrète entre Marie-Thérèse et le Cte. de Mercy-Argenteau, avec les lettres de Marie-Thérèse et de Marie-Antoinette*, ed. by ARNETH and GEOFFROY, 3 vol. (1874–75)—offer splendid views of her behaviour and her thinking.

(R.Pi.)

## Marine Sediments

Marine sediments are deposits of materials that are brought to the oceans from the continents by rivers, ice, and winds. They consist of the remains of marine organisms, products of submarine vulcanism, chemical precipi-

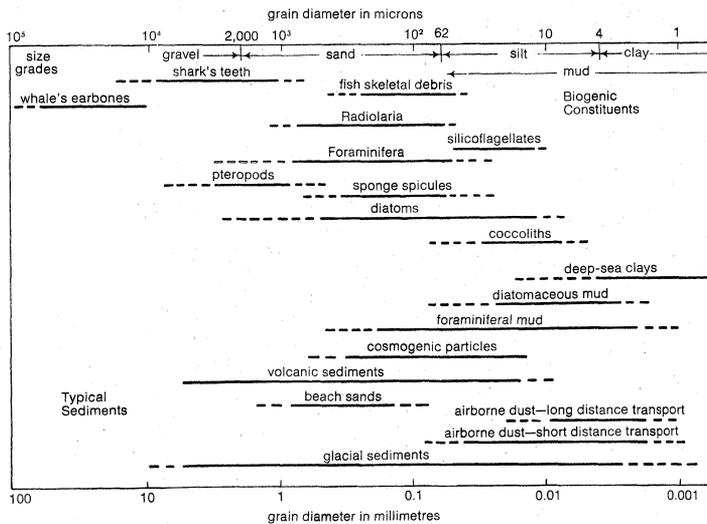

Figure 1: Grain diameters for sediment size grades and typical size ranges for biogenic constituents and typical marine sediments.

tates from sea water, sediments derived from land areas, and materials from outer space. The great bulk of marine sediments consists primarily of the residues of rock weathering and soil formation on land. Rivers contribute between 20,000,000,000 and 30,000,000,000 tons of solid sediment and 4,000,000,000 tons of dissolved material to the oceans each year. Man also contributes to the sedimentary accumulation; 10,000,000 tons of wastes are dumped annually into the Atlantic Ocean from the New York City area. This is probably the largest single source of sediment entering directly into the Atlantic from North America. Man's artifacts—in the form of beverage bottle fragments, worked wood, ships' ballast, and cinders—are found in sediment cores recovered from the ocean floor. These provide a time datum or reference surface that is used to determine sedimentation rates in areas of rapidly accumulating marine sediments.

Marine sediments presently are accumulating at various rates over two-thirds of the earth's surface. In the geologic past they occupied even more of the surface. From sedimentary rocks now exposed on land, geologists reconstruct past conditions on the earth's surface, its paleogeography. Fossils have provided most of this information, but the physical properties of the sediments themselves also provide valuable clues. The study of modern marine sediments provides information on sedimentary processes that is necessary if reasonable interpretations of ancient environments are to be made.

For further information on these ancient environments, see PALEOGEOGRAPHY and STRATIGRAPHIC BOUNDARIES; for additional details on marine sediments and their components, see CLAY MINERALS and SEDIMENTARY ROCKS; see also RIVER DELTAS, CONTINENTAL SHELF AND SLOPE, and OCEAN BASINS for treatment of the present depositional sites of marine sediments.

#### SEDIMENT TYPES

Marine sediments are aggregates of particles in which sea water occupies the interstices. They are classified by the grain size and the origin of the particles of which they are composed. Thus, on the basis of their dominant grain size, deposits can be characterized as boulders, gravels, sands, silts, and clays, or as such combinations of these forms as sandy silts or silty sands. Grain diameters of these size grades and the size ranges of some typical sediments are given in Figure 1. Sands are common on beaches, where boulders and gravels may also be found; but mixtures of silts and clays (muds) are the commonest sediment types over most of the ocean bottom.

When classified on the basis of their origins, the constituents of sediments are called lithogenous when they consist of silicate minerals and rock fragments derived from land areas; biogenic when they are the skeletal remains of

marine organisms; hydrogenous when they are the precipitates from sea water; and cosmogenic when they are primarily meteoritic in origin. Silicate minerals of lithogenous character dominate the general composition of marine sediments (Table 1). Most minerals in igneous and

metamorphic rocks form at high temperatures and pressures and are not stable when exposed to surface conditions, especially in the presence of oxygen and liquid water. Many rocks break down by means of an array of physical and chemical processes known as weathering, partially dissolve, and finally reform as more stable minerals that are transported to the ocean.

The mineral quartz is abundant in most igneous and metamorphic rocks, and because it is relatively stable it is a common constituent of sediments. Other common minerals in sediments include feldspars and micas, neither of which is as stable as quartz, and clay minerals, which are produced and altered during one or more steps of the weathering process. Table 2 lists the amounts of various

Table 2: Sources of Sediments

sediment types contributed annually to the sea. Most lithogenous particles are carried to the ocean by rivers; the smaller particles are transported in suspension and the coarser materials (about 10 percent of the total) are transported along the river bottom as part of the bed load. It is assumed that the annual additions of dissolved calcium carbonate and silica are removed from the ocean by organisms through shell formation.

An unknown amount of lithogenous material is carried to the ocean by winds that blow across mountains and deserts, pick up dust, and blow it out to sea. The occurrence of buff-coloured grains coated with iron oxide, in sediments downwind from deserts, attests to the local importance of wind transport. The phenomenon appears to be especially important in mid-latitudes of the Northern Hemisphere. In the Southern Hemisphere, where there is less land area and much less desert area, wind-blown dust is far less important as a constituent of marine sediments. High mountains without plant cover are sources of windblown dust that may contain bits of grasses or shells of one-celled plants called diatoms that grow in lakes.

Asia contributes by far the largest amount of lithogenous sediment to the ocean. This is because of its mountainous

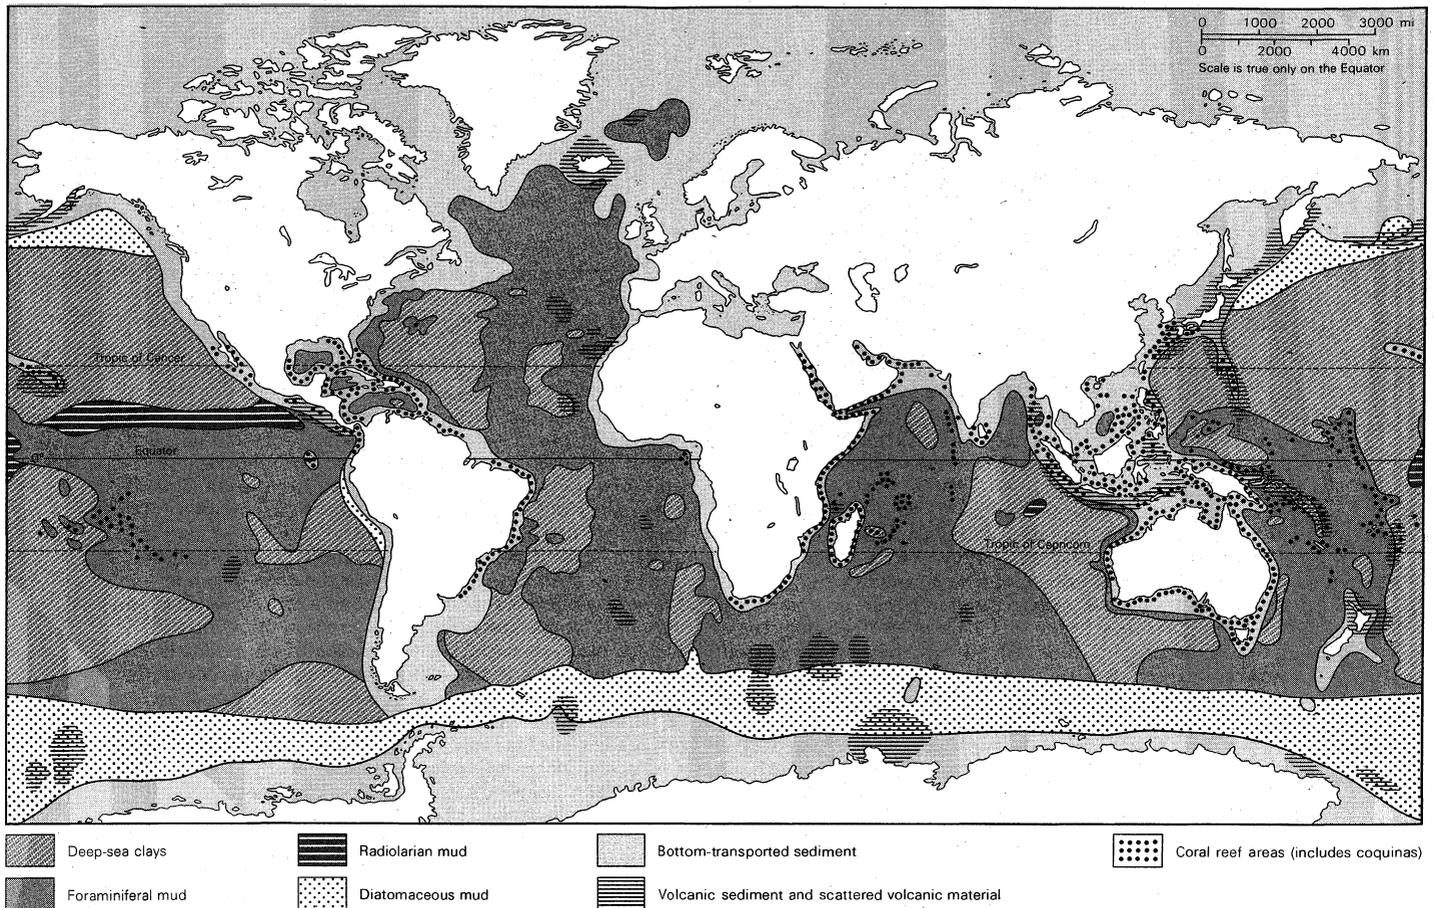

Figure 2: World distribution of marine sediments.

terrain, relatively low rainfall, and limited plant cover. In addition, the long history of agriculture increases soil erosion, especially in semi-arid regions.

Marine organisms build their shells from dissolved silica and carbonate that originally were derived from rock weathering. These biogenic constituents are the most conspicuous components of 62 percent of the deep-ocean sediment. Wherever biogenic constituents exceed 30 percent of the total, deep ocean sediments are said to be oozes. The most abundant of the biogenic constituents are the carbonate minerals calcite and aragonite, which are precipitated by many organisms to form their shells. Calcareous or foraminiferal muds cover about 48 percent of the deep-ocean bottom (Figure 2).

Another important biogenic constituent is opal, a glass-like silicate formed by diatoms (algae) and radiolarians (protozoans). Where diatom growth is luxuriant, the sediments consist largely of their remains and are termed diatomaceous muds. Radiolarians are especially abundant in the equatorial waters of the eastern Pacific Ocean, where they form radiolarian muds (or oozes). Siliceous muds cover 14 percent of the deep-ocean floor.

Only the hard skeletal remains of marine organisms are easily recognizable in sediments. The soft flesh normally is eaten by other organisms or decomposed by bacteria. Bones and fish scales usually are broken down and only the extremely resistant sharks' teeth or rare bones, like the fist-sized earbones of whales, are recognizable.

Organic matter from these soft parts usually makes up about one percent, or less, of deep-ocean sediments and about 2 to 3 percent of nearshore sediments. Organic matter may comprise 10 percent or more of the sediment in fjords or isolated bays where sediment deposition is rapid, or where the lack of dissolved oxygen in the water keeps animals away.

Hydrogenous constituents form directly by precipitation from sea water. In areas where other types of sediment accumulate slowly, hydrogenous constituents, usually

iron-manganese nodules, form a conspicuous part of the sediment. Such nodules form extremely slowly ( $10^{-5}$  to  $10^{-6}$  centimetres per year by some determinations), and if other materials are deposited rapidly around them, the nodules are buried before they can develop to an appreciable size.

Cosmogenic materials are recognized only in deep-ocean deposits where the supply of other constituents is extremely small. These rare particles are small spheres, usually about 30 to 60 micrometres in diameter, and have an inner nucleus of iron and an oxidized magnetic crust.

**Shallow-water sediments.** Most sediments are deposited initially near their sources. Most river-borne sediment, for example, is deposited near the river mouth. On open coasts, waves and tidal currents are often strong enough to hold these deposits in suspension and move them along the continental shelf. They are finally deposited in areas where currents or wave action along the bottom are too weak to keep them in suspension. If the rate of supply exceeds the capacity of coastal ocean processes to move the sediment, large deposits form river deltas. Marine sediments deposited near continents cover about 25 percent of the ocean floor, but they probably account for 90 percent (by volume) of all sediment deposits.

Modern rates of sediment transport to the ocean may be somewhat different than rates of the geological past. Lakes gouged by continental glaciers act to trap sediment and to prevent its movement to the sea. In addition, changes in sea level following the retreat of the continental ice sheets have flooded the mouths of many rivers during the past 5,000 years, forming large estuaries. Until these lakes and estuaries are filled with sediment deposits virtually no detritus can escape to the ocean.

Areas like the Atlantic coast of the United States consequently contribute little sediment. On the other hand, many land areas now stand much higher above sea level than they did during most of the earth's history; and these contribute large amounts of sediment to the ocean, espe-

Effects of density currents

Other constituents

cially where rainfall is low and plant cover limited. Submarine canyons are the principal route for sediment movement from continental shelves and slopes onto the deep-ocean bottom. An earthquake (or other shock) triggers a massive slumping and stirring of sediment at the canyon head. Mixed with water, a dense liquid mass forms, causing a density current that moves down the canyon at speeds of a few tens of kilometres per hour. Upon reaching the base of the continental slope, the sediment-laden mass moves out onto the continental rise, a large, sediment-built structure at the base of the slope. Deposits from turbidity currents (density currents that arise by reason of their sediment content) can build outward for hundreds, even thousands of kilometres across the ocean bottom. Large sediment-built plains are common in the Atlantic Ocean, where turbidity currents can flow from the base of a continent to the Mid-Atlantic Ridge. In the northern Indian Ocean, large deposits also occur. These deposits are built from sediment discharged by the Ganges, the Brahmaputra, and other rivers of the area (Figure 2).

Turbidites, deposits formed by turbidity currents, usually consist of silts and sands but sometimes of gravels. They tend to have distinct boundaries between adjacent units. Each unit is formed by a separate flow and usually exhibits a systematic change in grain size from coarsest at the bottom to finest at the top. This graded bedding results from decreasing current strength as the density current wanes; coarsest materials are deposited when the current is at its maximum and finer materials settle out as its force decreases.

The remains of shallow-water organisms mixed with deep-water forms are characteristic of turbidites. Shallow-water organisms come from areas where the density current formed; deep-water forms were living in the area traversed by the current or where it finally deposited its load.

Sediments deposited on the continental shelves or continental rises (often referred to as hemipelagic sediments) normally accumulate too rapidly to react chemically with sea water. Individual grains often retain characteristics imparted to them in the area in which they formed. Near a coast where soils are yellow, for example, it is common to find yellowish marine sediments.

Glaciers flowing from continents into the ocean form glacial-marine deposits. At present, this occurs off Antarctica, to a lesser extent near Greenland, and off the coasts of Alaska and South America (near Tierra del Fuego). Such sediments contain a wide range of particle sizes, ranging from silt to large boulders. In general, minerals or rock fragments in glacial deposits are little altered. Despite the richness of marine life in Antarctic waters overlying present sites of deposition, the remains of marine organisms are not conspicuous in the sediments because the accumulation of lithogenous material is rapid.

Sediments deposited near coral reefs in shallow tropical waters contain abundant carbonate material. For example, calcareous, reef-derived muds occur around atolls at the northwestern end of the Hawaiian chain, as well as in the Indonesian area.

Near volcanoes, sediments contain ash (silicate glass and fine volcanic rock fragments). In areas of island arcs (*q.v.*), such as Indonesia, fragments from known volcanic eruptions can be recognized in sediments. In certain places these pyroclastic materials are still being deposited or are being moved upward to the surface by organisms more than 100 years after the eruption.

**Deep-ocean sediments.** About 75 percent of the ocean bottom is covered by slowly accumulating deposits called pelagic sediments. Because of the great distance between the continents and the barriers that exist in the oceans' bottom topography, these areas do not receive turbidity currents and their associated coarse-grained sediment.

Because deep-ocean sediments receive relatively little lithogenous material from the continents, they commonly contain large amounts of biogenic constituents. In areas where surface waters are fertile, opal (from diatoms and radiolarians) and calcium carbonate (from foraminiferans, coccolithophorids, pteropods, and other organ-

isms) are supplied to the sediment. These biogenic constituents are generally larger than the average rock particle and usually constitute the most conspicuous parts of the deep-ocean sediments. Shells and tests (external hard parts) are commonly dissolved or broken up by bottom-dwelling and burrowing organisms.

If biological constituents exceed 30 percent by volume, then deep ocean sediments usually are classified on the basis of their biologic constituents. Thus, a mud containing 30 percent by volume of foraminiferal tests is called a foraminiferal mud or ooze. When one genus dominates, as is often the case in a deposit, it is commonly known by the generic name, such as *Globigerina* ooze. Diatomaceous and radiolarian muds are named on the same basis. Where biogenic constituents comprise less than 30 percent of the total, the deposit is known as a deep-sea clay, brown mud, or red clay.

Foraminifera are larger and more conspicuous, but coccoliths, the minute calcite plates formed by the one-celled plant *Coccolithophorida*, are often more important quantitatively. Dissolution of carbonate from sediments is most significant at depths greater than about 4,500 metres. Thus, foraminiferal muds and other carbonate-rich sediments are most common in the shallower parts (less than four kilometres) of the deep-ocean basin. Carbonate-poor sediments, such as brown muds and red clays, are commonest at depths greater than four kilometres. Near continents, the presence of abundant lithogenous materials reduces the proportion of carbonate in the sediments.

Opal dissolves in sea water at all depths. Therefore opal-rich deposits containing diatoms or radiolarians form only where the rate of supply locally exceeds the rate of dissolution. Opal production is greatest in the fertile waters along the Equator, on the eastern margins of ocean basins, and at high latitudes.

Several hundred years may elapse before sedimentary particles come to rest on the sea floor. This is followed by thousands to millions of years of exposure at the sediment-water interface before burial. Ample time is therefore available for chemical reactions between particles and ocean waters. These waters contain abundant dissolved oxygen so that the sediments are often rust coloured and usually contain little organic matter.

The fine-grained component of deep-sea sediment consists primarily of clay minerals (*q.v.*), whose study requires special techniques such as X-ray diffraction. Clays come from the continents, blown by winds or carried by ocean currents. The importance of tropical areas as sediment sources is shown by the abundant kaolinite in the Atlantic Ocean and gibbsite in equatorial deep-ocean sediments. Both minerals are common in tropical soils where chemical alteration of rocks is rapid and intense. The abundance of chlorite in high latitude sediments provides a useful tracer for sediments moving from high latitude areas. Chlorite is a common constituent in high latitude soils where chemical alteration is less rapid and intense.

Clay mineral abundance in deep-ocean sediments suggests that near-bottom currents can move fine-grained sediments. After sediment has sunk through a few hundred metres of the ocean surface layers, it cannot be moved by surface currents. Subsurface currents can transport material as it sinks, and strong currents on the bottom can resuspend and transport sediment previously deposited. There is often a layer of muddy water a few hundred metres thick near the ocean floor that contains these resuspended particles. Near-bottom ocean currents (*q.v.*) trend north-south in all oceans, with the strongest currents paralleling continental slopes on the western side of the ocean basins. There also may be strong near-bottom currents along oceanic ridges (*q.v.*).

#### AGE DETERMINATIONS IN SEDIMENT

The ages of sedimentary deposits are determined in several ways (see DATING, RELATIVE AND ABSOLUTE). Easiest to visualize is the case in which annual layers, called varves, form as the sediment accumulates. Varved deposits (*q.v.*) form in basins where a low supply of dissolved oxygen prevents organisms from living in the sediments. In the

Classifications based on biological constituents

Clay minerals in deep-sea sediments

open ocean, layering of sediments due to seasonal changes in particle composition would be disrupted by the burrowing of the abundant worms and other bottom-dwelling (benthic) organisms.

It is often possible to determine when sediments form by their fossil content; the presence or absence of diagnostic species, or subspecies, whose range in time is known will indicate this. For short time intervals, it is sometimes possible to use changes in shell characteristics of a particular species to establish time markers that correlate widely separated sediment deposits. Temperature related changes in the coiling direction of certain foraminiferans are examples of such characteristics. The coiling directions have been related to glacial-interglacial fluctuations by some workers. Although the causes for such test changes are not always well understood, they can be extremely useful for studies of comparatively recent deep-ocean deposits. Radiolarians have been used to correlate sediments near the Antarctic and in the Pacific; and discoasters, remains of extinct one-celled plants similar to Coccolithophoridae, are useful for establishing ages of Tertiary sediments (2,500,000 to 65,000,000 years ago). Despite the utility of paleontological age determinations, these provide only relative ages or useful markers for identifying equivalent time horizons in deposits from different areas.

Radiometric dating techniques

Radiometric dating techniques utilize the decay of a radionuclide to indicate absolute age of sediments. Radionuclides decay at a fixed rate, so it is possible to determine the time elapsed since a sediment was deposited by comparing radionuclide abundance at a given depth in the sediment with the amount originally present.

Carbon-14 is often used for radiometric dating of recently deposited sediment. Formed continually in the upper atmosphere, carbon-14 occurs in a fixed amount per gram of ordinary carbon in all living things. Carbon-14 that is lost by radioactive decay while an organism is alive is made up by exchange with the atmosphere or ocean. When the organism dies, it no longer obtains carbon-14, which therefore begins to decrease at a fixed rate. After 5,600 years (the approximate half-life of carbon-14) one-half the original amount of carbon-14 remains. If analysis indicates that only one-fourth the original amount of carbon-14 remains in the sediment, the age of this carbon, and presumably the age of the sediment as well, is put at 11,200 years, or approximately two carbon-14 half-lives.

Another radiometric dating technique involves determination of the elemental abundance produced by decay of a parent radionuclide. Potassium-40, which decays to form argon-40 and calcium-40, is one example. Many minerals include potassium, of which 1.2 percent is potassium-40, a radionuclide with a half-life of  $1.3 \times 10^9$  years. Eleven percent of potassium-40 decays to form argon-40, which is not incorporated in silicate minerals; thus, a comparison of the amount of argon-40 with that of potassium-40 indicates the time elapsed since the mineral formed or was last altered. To use a radiometric technique to date sediment deposition, it is essential to analyze the minerals or other material that formed at the time the sediment was laid down. Otherwise, one obtains an average age of the mineral grains rather than the age of the sediment deposit.

Two approaches have been used to date sediment deposition. One involves glauconite, a mica-like mineral that forms in sediments; the other uses volcanic material, such as ash falls that occurred while the sediment was accumulating. Because of the long half-life of potassium-40, the technique can be applied only to older sediments; under favorable circumstances, sediments as young as 100,000 years can be dated.

Most minerals and sediments also contain uranium and thorium, which are radionuclides with long half-lives. These radionuclides and their various daughter products become separated during sediment transport and deposition, so that the equilibrium relationships are disturbed. Certain of these relationships are slowly reestablished after deposition, providing a measure of the time elapsed since the sediments were deposited. This technique has been used extensively to date sediments in the age range

between the limits of carbon-14 dating (about 30,000 years) and the limits of potassium-40-argon-40 dating (greater than 100,000 years).

#### MARINE SEDIMENTARY ROCKS

Sediments are lithified or transformed into sedimentary rocks by several processes. These include compaction—the expulsion of water and reduction of pore space, which is especially important in muds and other fine-grained sediments; cementation—the precipitation of minerals in pores or at points of grain contact, which is important in many sediments and is quite conspicuous in sands; and diagenesis—the reactions that take place within the sediment between the contained minerals and the interstitial fluids. Solutions may bring in new materials from outside the sediment, thus precipitating new minerals and changing the chemical composition of the sediment as it lithifies.

Studies of these processes in deep-ocean sediments have been handicapped by difficulties and the expense of obtaining samples of ancient sediments far below the deep-ocean bottom. Deep-ocean drilling has provided limestones and siliceous rocks in various cores. Recovery of rocks containing unusual minerals, including zeolites, clays, and carbonate minerals, show that diagenetic alteration of sediments occurs in the deep ocean. Igneous activity at or below the ocean bottom produces fluids that react with sediments to cause diagenesis. The nature of sediment diagenesis involves the consideration of geochemical equilibria at low temperatures and pressures.

Most sedimentary rocks now exposed on the continents were originally deposited in shallow water when the ocean covered continental areas. Sedimentary rocks formed from deep-ocean sediment are rare, but some do occur in regions of crustal instability where mountain building has been active. Uplifted deep-ocean sediments are found on the islands of Timor in the Indonesian region, Barbados in the West Indies, and in the Alps.

The thickness of sediment deposits in the ocean can be determined directly by drilling from specially constructed and equipped vessels, or indirectly by geophysical techniques. The latter, which have been used most extensively include seismic reflection and refraction techniques. Reflection techniques utilize an explosion to generate a sound signal that bounces off successive sediment layers. Precise determinations of the time elapsed between sending the signal and receiving the echo permit calculations of the layer thickness.

Thickness of sediments

Seismic refraction techniques also utilize an explosion to generate a signal but employ a second station at some distance to receive the signal transmitted through the ocean bottom. Sound travels at different velocities in the various layers. Precise timing of the signal arrival from the various layers provides information about layer thickness and sound velocities in each layer. Sound velocity in turn provides information about physical properties of layers that cannot be obtained from reflected signals.

Using these techniques, geophysicists have shown that marine sediments are several kilometres thick near continents; more than three kilometres thick, for instance, in the Argentine basin off South America. Away from continents, sediments are 200 to 300 metres thick in the Pacific and about a kilometre thick in the Atlantic. Deep-ocean deposits average about 450 metres thick, lying on about 1.8 kilometres of consolidated sediments or volcanic rocks (called Layer 2, or basement) and under that, about five kilometres of basalt, in part altered (called Layer 3, or the oceanic layer). Layer 3 makes up the lowest part of the oceanic crust, which lies above the earth's mantle region.

The deep-ocean bottom seems to have been constantly renewed through a process known as sea-floor spreading. Oceanic crust apparently forms at mid-oceanic ridges by volcanic and intrusive igneous activity and moves away to be destroyed eventually at oceanic trenches. In this process, overlying sediments are carried along passively, changing both depth and position relative to the ridge crest. This affects both the type of sediment deposited and the rate at which it accumulates. Volcanic or igneous activity near ridge crests produces lithogenous material

Sea-floor spreading effects

and causes a locally increased rate of sediment accumulation. Rough topography on the ridges also forms small protected areas in which these sediments collect; sediment can neither enter these small depressions at a later time nor readily escape from them. Furthermore, the shallowness of the ocean bottom near the ridges favours development of carbonate-rich sediments. Foraminiferal muds are common on the Mid-Atlantic Ridge; it is also one of the few areas where pteropods, delicate shells of planktonic gastropods, accumulate.

As the crust moves away from ridges through time, the sediment deposits are moved to greater depths where carbonate solution is most intensive, so that the most recently deposited sediment is less carbonate-rich than the older underlying sediment. The ridge topography is gradually covered by sediment accumulations. As the ocean bottom becomes deeper, turbidity currents may eventually reach the area, further changing the type of sediment deposited. Where the ocean bottom approaches a continent, the sediment deposits become thicker. Island arcs or ridges along the continental margins, as in the western Pacific Ocean, may trap sediment locally and cause an immense thickness of sediment to accumulate, up to 15 kilometres in some of the Asiatic basins. In such cases, virtually no sediment escapes to be deposited in the trench or on the deep-ocean floor seaward of the island arc (see also SEAFLOOR SPREADING; OCEANIC RIDGES).

## Maritime Law

Maritime law is the term commonly employed to denote the branch of jurisprudence that governs ships and shipping. In English-speaking countries, "admiralty" is sometimes used synonymously, although in a stricter sense that term relates to the jurisdiction and procedural law of courts whose origins may be traced to the office of Admiral. Although etymologically maritime law and "law of the sea" are identical, the former term is generally applied to private shipping law, whereas the latter, usually prefixed by "international," has come to signify the maritime segment of public international law.

### HISTORICAL BACKGROUND

**Ancient and medieval developments.** From the fact that the ancient Egyptians engaged in shipping on a wide scale, it can be inferred that they had at least rudimentary laws regulating that activity, although no trace of any has been found thus far. Nor is there anything known of any maritime laws of the Phoenicians, who succeeded the Egyptians as commercial leaders in the Mediterranean. That Rhodes was a major source of maritime law, however, is clearly indicated in two passages from the *Digest* (AD 533) of the Roman emperor Justinian. The first quotes the Emperor Antoninus (reigned AD 138–161) in a case of plunder following a shipwreck: "I am indeed lord of the world, but the Law is the lord of the sea. This matter must be decided by the maritime law of the Rhodians, provided that no law of ours is opposed

to it." The second is a statement of the basic law of "general average," which the *Digest* attributes to the Rhodians. "Average" here means any loss sustained by a vessel or its cargo. When one segment of a maritime venture is sacrificed to save the others, the average is described as general, and the owners of the property saved must help make good the loss. Thus, if cargo is jettisoned in a successful effort to refloat a grounded vessel, the owners of the vessel and of the cargo saved are obliged to bear proportionate shares of the loss sustained by the owner of the cargo singled out for sacrifice.

Rome did not become a maritime power until the Punic wars of the third century BC. From the fact that the Romans were allies of the Rhodians and from the references in the *Digest*, it is logical to assume that Roman maritime law borrowed heavily from that of Rhodes. Acknowledging Rhodes as the birthplace of maritime jurisprudence, the maritime code of the later Eastern Empire, dating from the 7th or 8th century AD, was called the "Rhodian Sea Law."

Because the Mediterranean, under Roman control, was not only the centre of the Western world but also its principal commercial highway, European maritime law evolved as a uniform, supranational, comprehensive body of law—a characteristic which, though sometimes threatened by the spread of nationalism, has never been lost completely. The barbarian invaders who moved south were not seafarers, and the principal Mediterranean seaports were thus able to maintain their independence. Moreover, the conquered peoples were permitted to keep the Roman law to which they had become accustomed, and in the field of maritime jurisprudence the transition into the Middle Ages was therefore gradual. As certain Italian cities began to outstrip the Eastern Byzantine Empire commercially, they formulated their own maritime laws, some dating as early as 1063. Trani, Amalfi, Venice, and other Italian port cities all offered their own collections of laws. Nevertheless, the next widely accepted body of sea laws was the *Consolat de Mar*, or "Consulate of the Sea," originally compiled at Barcelona in the 13th century. More elaborate than the earlier codes, the *Consolat* was followed in Spain, Provence, and the Italian cities and had a significant effect on the development of modern maritime law.

The earliest code to emerge beyond the Mediterranean was the "Rolls of Oléron," named for an island in the Bay of Biscay and apparently dating from the 12th century. Whether the Rolls were of French or of Anglo-Norman origin, they became the nucleus of the maritime law not only of England and France but also of Scotland, Flanders, Prussia, and Castile; and they are still occasionally cited as authority, even by U.S. courts. The Rolls were closely followed in the Laws of Wisby, headquarters of the Hanseatic League until 1361.

**Modern national developments.** In Continental Europe, loss of uniformity in the maritime law began with the late Renaissance and accelerated with the rise of nationalism in the 17th century, which witnessed adoption of the Maritime Code of Christian XI of Sweden (1667), the Marine Ordinances of Louis XIV of France (1681), and the Code of Christian V of Denmark (1683). Of these, the most significant were the Ordinances, prepared under Louis XIV's finance minister, Jean-Baptiste Colbert, as part of his comprehensive though unfulfilled plan for the codification of all French law. Established customs of the sea, revised to suit the times, were made part of the national law, enforceable in the French Admiralty Court, which was granted maritime jurisdiction to the exclusion of the old consular courts, whose judges had been elected by the mariners themselves.

The individuality of the maritime law—its "separation" from other types of law—was accentuated by the Ordinances, which gathered together in one code all of the criminal, private, procedural, and public laws relating to the sea. Although the French Admiralty Court failed to survive the Revolution that began in 1789, the substantive law embodied in the Ordinances was very closely followed in the *Code de Commerce*, whose adoption in 1807 meant that the maritime law was thereafter considered

The medieval maritime codes

The effect of nationalism

Origins of maritime law

simply as a branch of commercial law, with consequent diminution of the weight previously given to custom and usage. Furthermore, abolition of the Admiralty Court resulted in the trial of maritime cases by the commercial courts, on which, in the smaller ports, maritime interests might not be represented. In countries with codes based directly or indirectly on the French commercial code, civil maritime cases, as well as nonmaritime commercial disputes, are heard and decided by commercial courts.

Although the *Code de Commerce* was widely adopted in the first half of the 19th century, in some cases by choice and in others by conquest, the German Commercial Code of 1861, revised in 1897, marked a departure from French law, and revisions of the Spanish and Italian codes showed the influence of the new German law. These, in turn, had their effect in countries under Italian and Spanish influence.

Early  
English  
maritime  
courts

Although the "Pied Poudre" courts, held primarily for the settlement of disputes at English fairs and markets, also had special jurisdiction of seamen's cases, it is probable that the first English tribunals to apply maritime law, with the Rolls of Oléron as a basis, were the courts of the Cinque Ports. The High Court of Admiralty, which sat at London, and the Vice Admiralty Courts set up in the other ports, were a later development. They were named after the admiral, an officer whose duties were at first solely administrative and military but were broadened early in the 14th century to include disciplinary proceedings in such matters as piracy. The Admiralty Court is considered as dating from 1360, when for the first time the admiral was expressly granted jurisdiction in civil maritime cases. By the end of the 16th century the admiralty courts had come to exercise an extremely wide jurisdiction, reaching far beyond saltwater transportation into many areas of commercial law. But during the first half of the 17th century, the judges of the common-law courts succeeded in divesting their competitors in the Admiralty of their commercial jurisdiction and in restricting them to the adjudication of "things done upon the sea."

The Admiralty was a royal court with valuable emoluments. It functioned without the aid of juries, following procedures borrowed from the Continent that were somewhat less dilatory and cumbersome than those of the common-law courts, and applied the laws and customs of the sea to the maritime controversies that came before it. For these reasons it was preferred by the merchants and favoured by the Crown, which depended to a considerable extent on taxation of the merchants for its revenues. Its jurisdiction therefore waxed and waned with the strength or weakness of the reigning sovereign. Thus, it enjoyed wide jurisdiction under the Tudors, but its powers were severely curtailed under succeeding monarchs and governments, and were never fully restored until the passage of the first of the Admiralty Court Acts in the 19th century.

Although the powers of the English Admiralty are today quite broad, in practice it is rare for cases other than those involving marine collisions and salvage to be brought before it. Controversies respecting charter parties, ocean bills of lading, and marine insurance, for example, are more generally brought before the Commercial Court.

In the United States, the federal district courts are by statute granted original jurisdiction, "exclusive of the courts of the States," of "Any civil case of admiralty or maritime jurisdiction, saving to suitors in all cases all other remedies to which they are otherwise entitled." This means, essentially, that if a maritime claimant wishes to have his claim litigated in accordance with admiralty procedure he must invoke the admiralty jurisdiction of the district courts. However, he is free to sue in a state court, unless the defendant is a citizen of another state, in which case the suit may be tried as an ordinary civil action in the district court.

#### DISTINGUISHING FEATURES OF MARITIME LAW

**Maritime liens.** Although admiralty actions are frequently brought *in personam*, against individual or cor-

porate defendants only, the most distinctive feature of admiralty practice is the proceeding *in rem*, against maritime property, that is, a vessel, a cargo, or "freight," which in shipping means the compensation to which a carrier is entitled for the carriage of cargo.

Under American maritime law, the ship is personified to the extent that it may sometimes be held responsible under circumstances in which the shipowner himself is under no liability. The classic example of personification is the "compulsory pilotage" case. Some state statutes impose a penalty on a shipowner whose vessel fails to take a pilot when entering or leaving the waters of the state. Since the pilotage is thus compulsory, the pilot's negligence is not imputed to the shipowner. Nevertheless, the vessel itself is charged with the pilot's fault and is immediately impressed with an inchoate maritime lien that is enforceable in court.

Maritime liens can arise not only when the personified ship is charged with a maritime tort, such as a negligent collision or personal injury, but also for salvage services, for general average contributions, and for breach of certain maritime contracts.

In a proceeding *in rem*, the vessel, cargo, or freight can be arrested and kept in the custody of the court unless the owner obtains its release by posting a bond or such other security as may be required under the applicable law or as may be acceptable to the plaintiff. More frequently, however, the owner will post security to avoid a threatened arrest, and the property never has to be taken into custody. When the judgment is for the plaintiff in a proceeding *in rem*, there will be a recovery on the bond or other security if the owner of the property does not pay; or, if security has not been posted, the court will order the property sold, or the freight released, in order to satisfy the judgment. The sale of a ship by an admiralty court following a judgment *in rem* divests the ship of all pre-existing liens—and not merely those liens sought to be enforced in the proceeding *in rem*. By way of contrast, the holder of an *in personam* judgment against a shipowner can, like any judgment creditor, have the ship sold in execution of the judgment; but such a sale, unlike the sale under an admiralty judgment *in rem*, does not divest existing liens; the purchaser at the execution sale takes the ship subject to all such liens. Thus, an *in rem* proceeding has decided advantages over a proceeding *in personam* in a case in which the shipowner is insolvent.

Efforts have been made from time to time to increase the security value of ship mortgages, in order to encourage lending institutions to finance vessel construction, but these efforts have not been very successful, largely because of differences in national laws respecting the relative priorities of mortgages and maritime liens. (Under general maritime law there is a complex hierarchy of maritime liens; that is to say, in a proceeding that involves distribution of an inadequate fund to a number of lien claimants, liens of a higher rank will be paid in full in priority over liens of a lower rank; and in most countries a ship mortgage ranks lower than a number of maritime liens.) Attempts were made to harmonize some of these conflicts by international conventions signed in 1926 and 1968, but the first failed to win widespread support and as of the end of 1971, the second had not been ratified by any of the signatories.

**Contracts for the carriage of goods.** The function of ships, other than warships, pleasure craft, and service vessels of various types is of course transportation of cargoes and passengers. In the "jet age" the passenger-carrying segment of the shipping industry has lost much of its former importance, but the quantity of goods transported by water continues to grow as the world economy expands.

The great majority of the contracts governing the carriage of goods by water are evidenced either by charter parties or by bills of lading. The term charter party (a corruption of the Latin *carta partita*, or "divided charter") is employed to describe three widely differing types of contracts relating to the use of vessels owned or controlled by others. Under a "demise" or "bareboat" charter, the shipowner delivers possession of the vessel

Proceedings  
*in rem*  
and *in personam*

Ship mortgages

Charter parties and ocean bills of lading

to the charterer, who engages the master and crew, arranges for repairs and supplies, and, in general, functions in much the same way as an owner during the term of the charter. A much more common arrangement is the "time" charter, whereunder the shipowner employs the master and crew and the charterer simply acquires the right, within specified limits, to direct the movements of the vessel and determine what cargoes are to be carried during the charter period. Under both demise and time charters, the charterer pays charter hire for the use of the vessel at a specified daily or monthly rate.

The third type is the "voyage" charter, which is essentially a contract of affreightment, or carriage. Most voyage charters provide for the carriage of full cargoes on one voyage or a series of voyages, but occasionally a charterer contracts for the use of only a portion of the carrying capacity of the vessel, in which case the governing contract is described as a "space" charter. Under a voyage charter, it is customary for the master or his agent to issue a bill of lading to the shipper, who is usually the charterer, although as between shipowner and charterer the voyage charter remains the governing contract of carriage; the bill of lading serves only as a receipt and as a document of title to the goods. Ocean bills of lading are usually in order form; that is, they call for delivery to the order of the shipper or of some other designated party. Such a bill of lading may be negotiated in much the same way as a check, draft, or other negotiable instrument, which means that a bona fide purchaser of the bill of lading takes it free and clear of any defects not appearing on its face. Thus, if cargo is externally damaged on shipment but the damage is not noted on the bill of lading, the carrier will be barred from establishing that the cargo was in fact damaged before it came into the carrier's custody. Once a bill of lading issued under a voyage charter is negotiated to a bona fide purchaser, it becomes the governing contract between the carrier and the holder of the bill.

When a ship strands or collides with another vessel, substantial cargo loss or damage may result. If the casualty is found to have been caused by a sea peril or an error in navigation, there will be no liability if the goods are being carried under a statutory or contractual provision based upon the Brussels bills of lading convention of 1922, which incorporated the so-called "Hague Rules." If, however, the casualty was the result of the carrier's failure to exercise due diligence to make the ship seaworthy and to see that it was properly manned, equipped, and supplied, the carrier will be held responsible.

**Limitation of liability.** A distinctive feature of maritime law is the privilege accorded to a shipowner and certain other persons (such as charterers in some instances) to limit the amount of their liability, under certain circumstances, in respect of tort and some contract claims. In some countries, including the United States, the limit, except as to claims for personal injury and wrongful death, is the value of the ship and the earnings of the voyage on which it was engaged at the time of the casualty. On the other hand, in the United Kingdom and the other countries that have ratified the Brussels limitation of liability convention of 1957 or enacted domestic legislation embracing its terms, the limit is £28, or its equivalent, multiplied by the adjusted net tonnage of the vessel, regardless of its actual value. The basic condition of the privilege is that the party asserting it must be free from "privity or knowledge," in the words of the United States statute, or "actual fault or privity," in the words of the convention. This formula means, generally speaking, that the shipowner is entitled to limit his liability for the negligence of the master or crew, but not for his own personal negligence or that of his managerial personnel. In a sense the limited liability of shipowners may be compared to the limited liability that any investor may now achieve by incorporating his enterprise. The limited-liability idea in maritime law, however, long antedates the emergence or invention of the modern corporation or limited company; its early appearance in maritime law may be taken as a recognition of the extraordinary hazards of seaborne commerce and the need to

protect the adventurous shipowner from the crushing burden of liability—that is, in the days before even the most primitive forms of insurance had become available. Some modern commentators have suggested that the peculiar features of maritime limitation of liability have outlived their usefulness, and that the development of insurance and of the modern limited-liability company has radically altered the conditions out of which the shipowners' privilege originally grew. Although no maritime country has yet gone to the length of abolishing limitation of liability, shipowning interests appear to have become concerned about the possibility of such a development.

In most maritime countries the principle of limitation of liability was considered to be a part of the general maritime law. As it developed in continental Europe, the idea, generally stated, was that a shipowner entitled to limitation could satisfy his liability by abandoning the ship (and its pending freight) to claimants. Since the privilege of limitation was, and is, typically invoked following a large-scale maritime disaster, the abandonment theory meant that claimants got the value of the ship as it was following the disaster. If the ship had sunk or was a total loss with no freight pending, the claimants got nothing. This theory was carried over into the law of many South American countries.

Great Britain and the United States were once the only maritime countries that refused to admit the principle of limitation as part of the general maritime law. In both countries, however, the competitive needs of the shipping industry compelled its introduction by statute.

In general, the limitation law of any country will be applied by its own courts in favour of foreign shipowners as well as of citizens. From the point of view of shipowning interests, however, a major weakness of limitation law has been the fact that limitation proceedings were not given international recognition. That has meant that a shipowner whose ships moved in international trade could find himself sued in several countries as a result of one disaster and forced to set up limitation funds in each country. The Brussels convention of 1957 makes limitation decrees delivered by admiralty courts in ratifying countries internationally effective; that is, a shipowner is required to set up only one limitation fund, out of which all claims are paid, no matter in how many countries proceedings might be instituted against him. Thus, the convention, which increases the liability of shipowners in most countries, does offer in return this considerable advantage to shipowners.

**Collision liability.** Under maritime law responsibility for collision damage is based upon the fault principle: a colliding vessel will not be held responsible for damage to another ship or to a fixed object such as a bridge, wharf, or jetty unless the collision is caused by a deficiency in the colliding vessel or by negligence or a willful act on the part of its navigators. It is not always necessary, however, to establish fault by positive evidence; there is a presumption of fault when a moving vessel collides with a fixed object or with another vessel that is properly moored or anchored, and the burden of proving freedom from fault will lie with the moving vessel.

In countries that have adopted the International Convention for the Unification of Certain Rules Relating to Collisions between Vessels, signed at Brussels in 1910, the rule of "comparative negligence" governs: if each of two colliding vessels is to blame, the total damages will be divided between their owners or operators in proportion to the respective degrees of fault. In certain countries that have not ratified the Convention, such as the United States, the law is such that, if both vessels are to blame, the total damages are equally divided, regardless of the respective degrees of fault. In certain other countries that have not ratified the Convention, including most of the Latin American states, the principle of "contributory fault" governs: if both vessels are to blame, each owner or operator bears his own damages.

**Salvage and general average.** Salvage and general average are doctrines peculiar to maritime law. Under the law of salvage, strangers to the maritime venture who

Foreign  
claims

Nature of  
limitation  
of liability

succeed in saving maritime property from loss or damage from perils of the sea or other waters are entitled to an award for their efforts and have a maritime lien on the salvaged property therefor. Several elements will be taken into account in fixing the amount of the award, including the extent of the efforts required; the skill and energy displayed by the salvors, the amounts involved, including both the value of the vessel or other property employed by the salvors in rendering the service and the value of the vessel, cargo, or other property salvaged; the risks incurred by the salvors; and the degree of danger from which the property was rescued. General average (defined at the beginning of this article) is a principle still universally accepted, although there is some agitation for its abolition, principally because the accounting and other expenses incurred in administering a general average are often quite out of proportion to the amounts involved and because the same underwriters sometimes insure both hull and cargo.

**Marine insurance.** An appreciation of the part played by marine insurance is essential to an understanding of the shipping industry and the special law that governs it. Most shipowners carry hull insurance on their ships and protect themselves against claims by third parties by means of "protection and indemnity" insurance. Waterborne cargo is almost universally insured against the perils of the seas. It is impossible in a brief outline such as this to go into any of the special intricacies, which are many, of marine insurance law. Most cases of damage to a ship or its cargo resolve themselves into settlements between insurance carriers. Proposals for changes in the maritime law must always be evaluated against this background of insurance coverage, as the imposition of liabilities that cannot be insured against can discourage all but the wealthiest ocean carriers from engaging in the affected trades.

Insured  
perils

Marine insurance is the oldest known form of insurance. Indeed, the institution of general average, under which the participants in a maritime venture contribute to losses incurred by some for the benefit of all, may itself be looked on as a primitive form of mutual insurance. Hull and cargo insurance today, in fact, is usually written on forms whose wording has changed little since the 18th century. The so-called "perils" clause, enumerating the risks insured against, customarily includes not only the natural hazards to which a vessel is exposed but man-made perils such as capture or destruction by enemy forces as well. In 1898, however, Lloyd's of London underwriters inaugurated the practice of adding "Free of Capture and Seizure" (F.C.&S.) clauses to the basic policy forms, the effect of which was to remove war and similar risks from coverage. The practice has since become universal, with the result that the owner of a ship or cargo must either purchase separate war-risk insurance or else pay his marine underwriters an additional premium in return for deletion of the F.C.&S. clause.

An early type of marine liability insurance was against liability for damage that the insured vessel caused to other vessels. Such insurance was effected by the addition of a "running down" or "collision" clause to the basic hull policy insuring the owner or operator of a vessel against its loss or damage. On the theory that, if given full protection, owners and operators would not be encouraged to exercise proper care in the maintenance of their vessels and the selection of their masters and crews, hull underwriters at first refused to insure against more than 75 percent of the collision liability.

Protection  
and  
indemnity  
associa-  
tions

With the advent of steam-driven vessels of iron and steel in the 19th century, the potential liabilities of shipowners increased substantially. To protect themselves, British owners banded together in "protection and indemnity" associations, commonly known as "P. and I. Clubs," whereby they insured each other against the liabilities to which they were all exposed in the operation of their vessels. These included liability for cargo damage, personal injury, and damage to piers, bridges, and other fixed objects, and also 25 percent of the liability for damage to other vessels against which the hull underwriters refused to insure. Foreign owners soon found the P. and

I. Clubs attractive, and as of 1971 the operators of some 75 percent of the world's ocean tonnage were insured with the British clubs and their Scandinavian and Japanese affiliates.

#### INTERNATIONALISM OF MARITIME LAW

Maritime law is often thought of as being a species of international law rather than a branch of domestic or municipal law. It should not be denied that the international aspect of maritime law gives it a distinctive flavour; in doubtful cases courts of one country will often look to the precedents or statutes of another country for inspiration or guidance. Except to the extent that it may have bound itself by international conventions, however, each country has the right to adopt such maritime laws as it sees fit. Although many such laws are common to most maritime countries, others are not, though there is a growing tendency to restore the international uniformity in the maritime law achieved during the Middle Ages. In many areas, the lead has been taken by the International Maritime Committee, more commonly known by its French name, Comité Maritime International (CMI), which is composed of the maritime law associations of 31 nations. The work of the Comité consists principally of drafting international conventions relating to subjects of maritime law. When such a draft is prepared, it is submitted to the Belgian government, which then convenes a diplomatic conference at which the CMI draft is discussed and amended as the official delegates may decide. If the revised draft wins approval at the conference, it is then submitted to the national governments for possible ratification. Although many of these conventions have failed to be widely ratified, others have been highly successful.

The international regulations for the prevention of collisions at sea, first adopted at an international conference held in Washington in 1889 and revised at maritime safety conferences held in London in 1914, 1929, 1948, and 1960, are recognized by all of the maritime countries. The regulations are, in effect, an international code of navigation. In other fields much has been accomplished to ensure international uniformity through private agreements voluntarily adhered to by affected interests; the York-Antwerp Rules of General Average, first promulgated in 1890 and most recently amended in 1950, are the best known example of such agreements; although they do not technically have the force of law, nevertheless, by incorporation in charter parties and bills of lading, they determine the rights and obligations of the parties as effectively as any statute.

tions

**BIBLIOGRAPHY.** E. BENEDICT, *The Law of American Admiralty*, vol. 1-4, 6th ed. by A.W. KNAUTH (1940-41) and vol. 5-6B, 7th ed. by A.W. and C.R. KNAUTH (1968-69), is the standard American text on admiralty practice. Included in *British Shipping Laws* are K. MCGUFFIE, P.A. FUGEMAN, and P.V. GRAY, *Admiralty Practice* (1964); N. SINGH, *International Conventions of Merchant Shipping* (1963); and the following standard British texts: SIR JOSEPH ARNOULD, *The Law of Marine Insurance and Average*, 15th ed. by LORD CHORLEY and C.T. BAILHACHE, 2 vol. (1961); T. CARVER, *Carriage by Sea*, 11th ed. by R.P. COLINVAUX, 2 vol. (1964); R. LOWNDES and G.R. RUDOLPH, *The Law of General Average*, 9th ed. by J.F. DONALDSON, C.T. ELLIS, and C.S. STAUGHTON (1964); and R.G. MARSDEN, *The Law of Collisions at Sea*, 11th ed. by K. MCGUFFIE (1961). G. RIPERT, *Droit Maritime*, 4th ed., 3 vol. (1950-53), is the most respected modern French text on maritime law. G. GILMORE and C.L. BLACK, JR., *The Law of Admiralty* (1957), is the leading modern, single-volume text on American maritime law. SIR WILLIAM R. KENNEDY, *Civil Salvage*, 4th ed. by K. MCGUFFIE (1958), is the leading text on salvage law. J.W. GRIFFIN, *The American Law of Collision* (1949), is the standard American text on the law of marine collision. SIR THOMAS E. SCRUTTON, *Scrutton on Charter Parties and Bills of Lading*, 17th ed. by SIR WILLIAM L. MCNAIR, SIR ALAN A. MOCATTA, and M.J. MUSTILL (1964), is the best known work on the subject. M.J. NORRIS, *The Law of Seamen*, 3rd ed. (1970), is a widely used American text. F.R. SANBORN, *Origins of the Early English Maritime and Commercial Law* (1930), is an excellent inquiry into the sources of English maritime law. J.H. WIGMORE, *A Panorama of the World's Legal Systems* (1936), contains a fascinating account of the origins and early development of maritime law.

T.L. MEARS, "The History of the Admiralty Jurisdiction," in *Select Essays in Anglo-American Legal History*, vol. 2 (1907), offers a fair survey.

(N.J.H.)

## Marius, Gaius

Gaius Marius, with a middle class (equestrian) background, was the first man in the late Roman Republic (Cicero, from the same town, Arpinum, was the second) to achieve striking success as what the Romans called a new man by breaking into the conservative governing class of the exclusive Roman aristocracy. The main facts of Marius' public career are certain, but the explanation is often baffling because no good history of his period survives from antiquity. What does survive is biased, sometimes for him, more often against him.

**Early career.** Born c. 157 BC near Arpinum, in southern Latium, he was a strong and brave soldier and a skillful general, popular with his troops; but he showed little flair for politics and was not a good public speaker. As an equestrian, he lacked the education in Greek normal to the upper classes. He was superstitious and overwhelmingly ambitious; and because he failed, despite his great military success, to force the aristocracy to accept him, he suffered from an inferiority complex that may help explain his jealousy and vindictive cruelty. As a young officer-cadet, along with Jugurtha (later king of Numidia), on Scipio Aemilianus' staff in the Numantine War in Spain (134 BC), he, like Jugurtha, made an excellent impression on his commanding officer. Marius' family enjoyed the patronage of more than one noble family, in particular the distinguished and inordinately conceited Caecili Metelli, then at the height of their political power; they backed his candidacy for tribune (defender) of the plebs (common people) in 119. As tribune, Marius proposed a bill affecting procedure in elections and legislative assemblies by narrowing the bridges—the gangway across which each voter passed to fill in and deposit his ballot tablet—as a result of which there was no longer room on the gangway for observers, normally aristocrats, who abused their position to influence an individual's vote. When the two consuls tried to persuade the Senate to block the bill, Marius threatened them with imprisonment, and the bill was carried.

Marius showed himself no unprincipled candidate for popular favour, for he vetoed a popular corn bill; and the following years offered him little promise of a conspicuous career. He failed to secure the aedileship (control of markets and police) and was only just elected praetor (judicial magistrate) for the year 115 after bribing heavily, for which he was lucky to escape condemnation in court. The next year he governed Further Spain, campaigned successfully against bandits, and laid a foundation for great personal wealth through mining investments. After that, he made a good marriage into a patrician family that, after long obscurity, was on the point of strong political revival. His wife was Julia, sister of Julius Caesar, father of the later dictator.

When the command in the war against Jugurtha (who was now Numidian king) was given to Quintus Metellus, brother of Metellus Delmaticus, who had opposed his election reform law, as consul in 109, Marius was invited to join Metellus' staff; his quarrel with the Metelli had evidently been patched up. After defeating Jugurtha in pitched battle, Metellus was less successful in later guerrilla warfare, and this failure was exaggerated by Marius in his public statements when at the end of 108 he returned to Rome to seek the consulship (chief magistracy) after a quarrel with Metellus that may have been exaggerated in the pro-Marian tradition. Marius was elected on the equestrian and popular vote and, to Metellus' bitter chagrin, appointed by a popular bill to succeed Metellus at once in the African command.

In recruiting fresh troops, Marius broke with custom, because of a manpower shortage, by enrolling volunteers from outside the propered classes, which alone had previously been liable for service. In Africa he kept Jugurtha on the run, and in 105 Jugurtha was captured, betrayed by his ally, King Bocchus of Mauretania—not to Marius

himself but to Sulla, considered a rather seedy young aristocrat, who had joined Marius' staff as quaestor in 107. Sulla had the incident engraved on his seal, provoking Marius' jealousy.

The victory, however, was Marius', and he was elected consul again for 104—at the start of which year he celebrated a triumph and Jugurtha was executed—in order to take command against an alarming invasion of the Cimbri and Teutones, who had defeated a succession of Roman armies in the north, the last in disgraceful circumstances in 105. For this war, Marius used fresh troops raised by Rutilius Rufus, consul in 105, and excellently trained in commando tactics by gladiatorial instructors. With them, Marius defeated the Teutones at Aquae Sextiae (modern Aix-en-Provence, France) in 102 and in 101 came to the support of the consul of 102, Quintus Lutatius Catulus, who had suffered a serious setback; together they defeated the Cimbri at the Vercellae, near modern Rovigo in the Po Valley, and the danger was over. This was the apex of Marius' success. He had been consul every year since 104, and he was elected again for 100. With Catulus he celebrated a joint triumph, but already there was bad feeling between them. Marius claimed the whole credit for the victory; Catulus and Sulla gave very different accounts in their memoirs.

Marius had always had equestrian support, not only because his origins lay in that class but also because wars are bad for trade, and Marius had brought serious wars to an end. The Roman populace liked him for not being an aristocrat. He had the further support of his veterans, for it was in their interest to stick closely to their general. Marius perhaps did not realize the potency of their force, one that Sulla, Caesar, and Octavian employed with overpowering effect later.

**Fall from power.** The year 100 saw Marius fail disastrously as a politician. Saturninus was tribune for the second time, and Glaucia was praetor; given the poverty of surviving sources, it is extremely difficult to understand either their political aims or Marius' relationship to them. The three shared a common hatred of Metellus, who, as censor in 102, had tried to remove Saturninus and Glaucia from the Senate; and in 103 Saturninus had carried a bill, evidently in Marius' interest, for the settlement of veterans in Africa. Now, with the inevitability of civil disorder—for the Roman populace opposed his measures—Saturninus introduced bills for land distribution of Cimbric territory in the north to Romans living in the country, and probably to Italians, and for the settlement of veterans, evidently including allied troops, in colonies overseas. This bill may have included a powerful command for Marius to supervise the resettlement of the veterans—empowering him to give Roman citizenship to a certain number of the new settlers in each colony.

Marius had already violated the law by granting citizenship on the battlefield to two cohorts of Italians (Carmertes) who fought under him against the Cimbri in 101, and conceivably Saturninus and Marius were agreeable to a program of extensive enfranchisement of Italians by means of the new colonial settlements. A breach between them occurred, possibly because Marius, in his jealous way, thought that Saturninus was stealing some of his own thunder or possibly because Saturninus' lawlessness had reached a pitch that no self-respecting consul could tolerate.

First the land and colonial bill was passed, but with blatant illegality; it required senators to take an oath within five days to observe it. After misleading statements about his own intention, Marius took the oath. Metellus refused, however, presumably because of the way in which the bill had been carried, and, forestalling condemnation in the treason court, he retired to Greece; later he was officially exiled. At the tribunician elections for 99, Saturninus was re-elected together with a pretender who, already heavily discredited, claimed to be the son of Tiberius Gracchus. At the consular elections, with Glaucia as a candidate, Marcus Antonius, the orator, was elected, and Gaius Memmius, a man with an excellent popular record, was murdered. In the ensuing pandemonium the Senate passed the "last decree," calling on the consuls to

Rise to power

Failure as a politician

Election to the consulship

Reputation  
as a  
betrayor

save the state. Through Marius' action Saturninus and Glauca were captured on the Capitol and imprisoned in the Senate house; then a mob stripped off the roof and stoned them to death. Although this was no responsibility of Marius, he was smeared as a man who betrayed not only his enemies but also his friends.

**Later years.** Rather than attend the inevitable recall of Metellus from exile, Marius went to the east in 99 and there met Mithradates VI of Pontus. He was elected to a priesthood (the augurship) but wisely withdrew his candidature for the censorship of 97. A background figure in the not fully unravelled politics of the 90s, successfully opposing an attempt in 95 to disenfranchise men to whom he had given citizenship under the terms of Saturninus' colonial bill, though the law itself had been shelved, in 92 he supported the equites in a scandalous prosecution and condemnation of his old associate Rutilius Rufus (in fact a model administrator) for alleged misgovernment of Asia.

Marius was now beginning to show his age. In an Italian rebellion (the Social War) of 90, he campaigned under the consul Rutilius Lupus, a soldier far his inferior. In 88, when the tribune Sulpicius Rufus proposed the transfer of the Asian command from the consul Sulla to Marius, presumably on the ground that Marius alone was sufficiently experienced to conduct such a critical war, there was violent public opposition to Sulla in Rome. Sulla went to his army in Campania and marched with it on Rome. Sulpicius' measures were rescinded, and Marius was exiled.

After a series of near catastrophes, all much embroiled in the telling, Marius escaped safely to Africa. In 87, when Sulla was fighting in Greece, disorder in Rome led to the consul Cinna being dismissed. Marius landed in Etruria, raised an army, sacked Ostia, and, joining forces with Cinna, captured Rome; both were elected consuls for 86, Marius for the seventh time. Hideous massacre followed as Marius ordered the deaths of Marcus Antonius, Lutatius Catulus, Publicus Licinius Crassus, and other distinguished men whom he considered to have behaved with treacherous ingratitude toward him. By this time he was hardly sane, and his death, on January 13, 86 BC, was a godsend for both enemies and friends alike. If the outcome of his proscriptions was considered to be less disastrous than that of the later proscriptions of Sulla, it was only because they lasted for a shorter time.

Marius' only son died as consul fighting against Sulla in 82. His widow survived until 69 and received the unusual honour, for a woman, of a public funeral oration by her nephew Julius Caesar, who later won great popularity by restoring to the Capitol Marius' trophies, which Sulla had removed.

Marius was commemorated by the name Mariana given to Uchi Majus and Thibaris (two African settlements) and to a colony in Corsica, and by the Fossa Mariana, a canal dug by his soldiers at the mouth of the Rhône River.

## Marketing and Merchandising

Marketing in its most general definition is the directing of the flow of goods and services from producers to consumers or users. It is not confined to any particular type of economy, since goods must be marketed in all economies and societies except perhaps the most primitive. Nor is marketing a function only of profit-oriented business;

even such service institutions as hospitals, schools, and museums, engage in some forms of marketing.

### THE FUNCTIONS OF MARKETING

In Western business organizations the marketing function was once seen as encompassing only sales and advertising and perhaps, also, marketing research. The purpose of the staff engaged in marketing was primarily to maximize sales volume. More recently the marketing manager's responsibilities have broadened to include all activities relating to the firm's customers, including product development, customer communications, and customer services; in some firms, the principal marketing executives have even been given authority over credit, physical distribution, public relations, and research and development. In a few firms, the integrated marketing concept has been pushed to the point where the head of marketing becomes the chief executive officer. The emphasis on marketing has been most conspicuous in industries serving the general consumer, such as retail store chains and manufacturers of foods, toiletries, and household appliances. Service industries, such as hotels, banks, and insurance companies, have been slower in taking it up. Airline transportation companies have been notably more customer oriented than the railroads. These tendencies have been visible in most of the leading industrial countries, although they have been pushed farthest in the U.S.

The activities involved in marketing account for a large proportion of consumer expenditures. Studies made in the U.S. estimate the proportion at between 40 and 60 percent of total final sales value of all tangible goods. This includes the buying and selling expenses of producers; of wholesalers' and retailers' margins; and of all other promotional, storage, and transportation expenses. The proportion has increased through the years: in 1870 in the U.S., 88 persons were employed in distribution for every 1,000 employed in production; in 1950, 407 persons were employed in distribution for every 1,000 in production. But if marketing increases in significance with the growth of an industrial economy, it also plays a large part in those less-developed economies where distribution is in the hands of myriads of small tradesmen.

**Types of goods and channels of distribution.** It is common to distinguish between consumer goods, which are sold directly to consumers, and industrial goods, which are used by their purchasers to produce other goods and services. Consumer goods are sometimes classified according to the way in which they are purchased. "Convenience goods" are purchased with a minimum of searching; the consumer is familiar with the assortments offered, the goods are readily accessible on shelves or in display racks, and there is little to be gained from more extended shopping. "Shopping goods" are those for which the customer searches; he compares the prices, qualities, and styles available in a number of stores, perhaps not even knowing specifically what he wants to buy. "Specialty goods" have particular characteristics that encourage customers to make special efforts to find them, and price may be a minor consideration. Some students of marketing distinguish a fourth classification of unsought goods—those customers do not want, or do not know are available, or are not looking for.

Staple groceries, such as white bread and pancake syrup, are convenience goods in most U.S. supermarkets but might be considered specialty goods in France or Italy. Long, crusted "French" bread, or the various pastas (from *agnellotti* to *tortellini*), may be shopping goods in Nashville, Tennessee, or Fort Worth, Texas, but they are convenience goods in Rome. A common electric rice cooker is a convenience good in Tokyo but not in New York City. Major items of household furniture and appliances tend, however, to be shopping goods wherever the assortments offered are wide enough to permit a meaningful choice for the customer.

Goods move to the final consumer through various channels of distribution. Raw materials pass from the extractive industries (forestry, fishing, mining, and agriculture) to manufacturing establishments. Finished prod-

marketing

Con-  
venience  
goods  
and  
shopping  
goods

ucts may be sent directly to the retailer or, less often, to the consumer, but as a rule they flow from the manufacturer to one or more wholesalers before they reach the retailer and, finally, the consumer. Although legal possession of goods generally accompanies their physical transfer from one party to another, this is not always the case; in consignment selling the seller retains ownership while the goods are in the hands of the wholesaler or retailer; that is, until the merchandise is sold to the final user or consumer.

In less developed countries, channels of distribution tend to be simpler than in the more highly industrialized nations. There are notable exceptions, however. Cacao beans in Nigeria and several other West African nations are collected by a Cocoa Marketing Board that licenses trading firms to process the commodity. Because of the large numbers of small producers, these agents work through middlemen who, in turn, employ sub-buyers who may have "runners" to bring in the produce from remote areas. Japan's marketing organization was until recently characterized by lengthy channels of distribution and a multiplicity of wholesalers. It was not unusual for a product to pass through at least five separate wholesalers before it reached a retailer: a general wholesaler, a basic product specialty wholesaler, a special wholesaler, a regional wholesaler, and a local wholesaler. A move toward efficiency and direct selling by manufacturers is compressing the length of these channels in Japan, as it is in Switzerland, Great Britain, West Germany, and most other highly industrialized nations.

**Marketing as a business function.** Businessmen whose primary concern is the marketing of goods usually distinguish four basic functions in their work: (1) pricing, (2) product determination, (3) distribution, and (4) promotion. More recently a fifth function has been added, marketing research. Product determination consists of establishing the assortments of goods to be produced, as well as their qualities and physical characteristics. Such determinations are usually made in concert with the company's manufacturing, engineering, and finance departments. Promotion includes both personal selling and advertising, and is intimately related to the culture in which it is found. The provision of information is an important element in promotion, but the type and degree of selling pressure varies considerably from one country to another. Marketing research is concerned with the gathering, processing, and analyzing of market information. It is an aid in the evaluation of actions already taken, as well as a guide to future planning and budgeting.

In developing its marketing strategy a firm must determine what its best potential markets are and then select the means by which it will try to sell to them. The means are various, and the individual firm will concentrate on the specific combination (or "marketing mix") that seems to yield the most successful results.

#### RETAILING

For thousands of years most goods were sold in marketplaces or by peddlers. In tropical Africa, hawkers still walk the streets of cities and towns crying out their wares, or cycle from village to village. Marketplaces are still the chief form of retail selling in the villages of many countries. During the Renaissance, market stalls in certain localities became fixed and eventually grew into stores. Many artisans' workshops expanded their retail facilities.

Chains of retail stores are known to have operated in China several centuries before Christ. In 1643 a chain of pharmacies was founded in Japan. Mercantile operations of a chain-store character were carried on by the Fugger family of Germany in the 15th century, and a chain of outposts was developed in Canada by the Hudson's Bay Company following its charter in 1670. The chain store as it is known in much of the world today, however, is generally believed to stem from the founding of the Great Atlantic & Pacific Tea Company (A & P) in New York City in 1859.

The prototypes of present-day department stores existed in Japan as early as the 17th century, but not until horse-drawn buses encouraged the growth of central business

districts did the department store take hold in the Western world. Au Bon Marché in Paris developed from a large specialty store to a department store about 1860. Retailers in the U.S. soon followed. By World War I department stores modelled after the French example existed in large cities throughout the world, including cities in Argentina, Mexico, and Egypt.

Small independent merchants, however, still form the majority of retailers in most countries of the non-Communist world. (Most retail outlets in the Communist countries are nationalized.) According to the U.S. Census of Business, 97 percent of the 1,577,302 retail firms existing in the U.S. in 1967 were single-establishment companies. They accounted for 60 percent of total sales.

**Chain stores and supermarkets.** Centrally managed chains of stores have many advantages over independently managed retail enterprises: they can buy at more favourable terms; employ specialized buying personnel who have a wide knowledge of the supply markets; cut operating costs by integrating wholesaling and retailing functions; maintain lower inventories relative to sales; feature special price reductions on selected items; consolidate their advertising for stores in a single area; and try out new merchandising methods in one store at a time. There are also disadvantages in the chain structure. Personal interest, drive, creativity, and the will to serve the customer are often much weaker in chain operations than among independent retailers. Public sentiment has often been hostile to chains: at one time chain-store tax laws were in effect in 29 states of the U.S.; a Danish law prohibited retailers from owning more than a single store per municipality; the Poujadist movement in France in the late 1950s and early 1960s brought political pressure to bear in favour of small business and against the retail chain.

The importance of retail chains varies from country to country. In western Europe in 1960, the estimated share of total retail sales made by chains (excluding consumer cooperatives and department stores) ranged from 0.7 percent in Austria to 25.6 percent in Great Britain. In Portugal, Spain, and parts of Italy, low purchasing power and the undeveloped structure of commerce and industry inhibited the growth of retail chains. In other countries, including Austria and Denmark, they were impeded by the antichain legislation of the 1930s. The strong position of consumer cooperatives in the Scandinavian countries made the spread of retail chains difficult.

Retailing in Communist countries is almost entirely in the hands of chains. The retail stores are often tied to wholesale establishments covering a municipality, a region, or even an entire country; in some cases, the integration extends back to producers. The degree of autonomy granted managers of individual stores also varies. Store managers in Hungary in the 1970s had a larger degree of operational autonomy than did their counterparts in China, where the tendency was to centralize managerial decisions.

Supermarkets do not always belong to chains, but in the U.S., Great Britain, France, Italy, West Germany, and other highly industrialized countries the chains include about 90 percent of them. Supermarkets are large stores dealing in groceries, meats, produce, dairy products, baked goods, and household sundries; they are organized departmentally and operate primarily on a self-service basis. Supermarkets in the U.S. commonly handle a broad assortment of toilet goods; those in France and Italy stock wines and other alcoholic beverages; and many Swiss supermarkets sell clothing and quantities of cut flowers.

The pattern of supermarket development was set in the U.S. in 1930 when Michael Cullin opened the first unit of what was to become the King Kullen chain of supermarkets. Other independent food stores followed Cullin's lead. The major food chains gradually began to convert their service stores—most of which handled only dry groceries—into supermarkets in the mid-1930s. During the two decades following World War II, when the rate of growth of supermarket chains in the U.S. was at its peak, tens of thousands of small independent food re-

Distribution in Africa and Japan

The advantages of chain stores

From peddlers to chain stores

Supermarkets

tailers were driven out. Similar developments occurred at a later date in other countries. In France, for instance, the number of supermarkets increased from approximately 50 in 1960 to 1,500 by 1970; in the latter year, 13,000 small specialty shops were forced to close.

Many operators of individual supermarkets, superettes (small stores), and chains with only a few retail outlets have successfully fought the expansion of large chains by banding together into retail cooperatives. The cooperatives service their members by joint buying, warehousing, store delivery, and common advertising and other promotional aids. Retail cooperatives have been strong among foodstores in the Pacific coast states of the U.S., and in western Europe in nonfoods, particularly textiles.

Voluntary chains of retailers sponsored by wholesalers are common in many countries. In western Europe in the 1960s, there were at least four huge wholesaler-sponsored chains of retailers, each including 15,000 stores or more. The 30,000 "Spar" retailers were located in 10 countries, each store using the same name and, as a rule, offering the same brands of products. Wholesaler-sponsored chains offer the same types of services for their retailer clients as do the financially integrated retail chains.

**Department stores and discount houses.** Department stores are large retail stores that carry a wide variety of merchandise, particularly apparel and accessories, and some home furnishings. In western Europe and Japan, department stores also sell food on a large scale. They are organized in departments, each with its own merchandising, control, promotion, and service. Some departments—such as beauty parlors, restaurants, pet shops, and shoes—that have special merchandising or operational problems may be leased to outside firms.

Although department stores seldom account for more than five to eight percent of total retail sales, they draw large numbers of customers in urban areas. The most influential department stores offer fashion leadership; one example is the promotion of contemporary-style furniture by the Nordiska Kompaniet (NK) department-store group of Sweden. Recreation and entertainment are often used to attract customers, as in the Japanese department stores that offer exhibitions, sideshows, and other diversions, generally without charge.

Giant department stores have also spawned chain organizations, sometimes through mergers with other department stores within the same country or by opening branch units within a region but also by expanding to other countries—for example, Sears, Roebuck and Company's operations throughout Latin America, Canada (in partnership with Simpson of that country), and Spain. Major department stores in several western European nations have branched into variety-store chains, supermarkets, specialty shops, and wholesale establishments. The laRinascente group of Italy, which began with a single department store in Milan, later developed the UPIM chain of variety stores, the SMA supermarket chain, and a buying service for other store groups, including foreign ones.

Moscow's leading department store, GUM, has a staff of well over 4,000; another Moscow department store, Children's World (*Detskii Mir*), selling a wide variety of children's items, employs more than 3,000 people. Other large department stores are located in some of Moscow's residential neighbourhoods.

The practice of "discounting," or selling merchandise below the manufacturer's list price, has existed among some segments of retailing for decades. In the years following World War II, large numbers of retail stores in the U.S. adopted this policy, made possible by reducing services and often locating in low-rent shopping districts. The initial growth was in "hard goods" or consumer durables, particularly electrical household appliances. Other goods were added later, until the discount houses (as these establishments came to be known) became essentially department stores featuring reduced prices and minimal services. Specialty discount operations have also grown significantly in foods, pharmaceutical items, forms of hardware, and other lines, usually through a chain-store organization. Some "closed-door"

discount houses restrict sales to a special membership, often based upon a group affiliation.

Discount houses appeared also in Canada, France, Mexico, Sweden, Great Britain, West Germany, and elsewhere. They have been most successful in countries that are well supplied with consumer goods and in which retailing is highly competitive. In some countries their growth has been inhibited by pressures from suppliers, governmental agencies, other retail organizations, and labour unions.

**Consumer cooperatives.** Consumer cooperatives are retail stores owned and operated by consumers for their mutual benefit. Most espouse the principles of the first cooperative store established in Rochdale, England in 1844. These include open membership, one vote per member, limited customer services, and a sharing of the profits among members in the form of rebates, generally related to the amounts of their purchases.

Consumer cooperatives have flourished in western and northern Europe, particularly in Denmark, Finland, Iceland, Norway, Sweden, and Great Britain. The Communist countries have their own forms of consumer cooperative, usually integrated into the national distributive systems. In the Soviet Union, for example, consumer cooperatives have a near monopoly of retail sales in the villages. A number of the newer countries have tried to encourage the growth of consumer cooperatives as a means of lowering prices and of counteracting foreign-business influence.

**Nonstore retailing.** Some retailers have no stores. The three principal types of nonstore retailers are catalog houses, itinerant retailers, and vending-machine operators.

The largest catalog houses in the world—Sears, Roebuck and Company and Montgomery Ward & Company Inc.—were founded in the U.S. during the latter part of the 19th century. They began by selling exclusively by mail order through catalogs, although today both firms do more than half their business in their retail stores. They also sell through catalog order stations in their retail stores, catalog stations located at other points, and by telephone. Other department stores and larger specialty stores frequently supplement their store operations with mail and telephone orders, often in response to advertising.

Following World War II, mail-order specialists grew rapidly in West Germany, Great Britain, and a few other highly industrialized countries. The firms of Quelle and Neckermann in West Germany also do a considerable part of their business in retail stores, in catalog service outlets, and by telephone. Development of a mail-order operation requires an efficient transportation network and a secure means of transmitting payments; in many countries these are lacking.

Itinerant retailers contact their customers in homes, at places of work, or in streets and other public places. Some sell by soliciting customers on a door-to-door basis; others work through merchandise "clubs" or personal introductions. In less-developed countries they hawk their wares in the streets. In the 1960s about 19 percent of retail businesses in Italy were itinerant in nature.

Vending-machine operations are usually carried on in sites owned by other businesses (including retail stores), by institutions, and by transportation agencies. In the U.S., vending machines deal mainly in food for immediate consumption. In other countries—Sweden, for example—vending machines have developed as a supplementary channel to retail stores where hours of business are restricted by law. High costs of manufacturing, installation, and operation have limited the expansion of vending-machine retailing.

#### WHOLESALE

Wholesaling consists of selling to other business firms, either for resale or for business use, usually in bulk and at less than retail prices. A wholesaler is an independent merchant operating one or more wholesale establishments. Manufacturers may engage in wholesaling through their sales branches, and retailers may also do so intern-

How department stores vary

Mail-order selling

Kinds of wholesalers

ally through chain-store warehouses, although they are not classed as wholesalers.

Wholesalers are of two kinds: full-service and limited-service. Full-service wholesalers are generally the more important in terms of sales volume; they perform a variety of services for their customers: stocking inventories, operating warehouses, supplying credit, employing salesmen to aid customers, and making deliveries. Full-service wholesalers who carry broad assortments of merchandise such as groceries are called general-line wholesalers; those who sell only narrow lines of goods, such as coffee and tea, or cigarettes, are called specialty wholesalers.

Limited-service wholesaling has emerged in West Germany, the U.S., and other industrialized countries as a way of reducing the costs of service. Examples of limited-service wholesalers are "cash-and-carry" outlets, usually handling only fast-moving merchandise; "drop shippers," who ship goods directly from the manufacturer to the retailer; "truck jobbers," who sell and deliver directly from their vehicles, often for cash; and the "rack jobber," who handles the requirements of supermarkets in certain nonfood lines, such as housewares or toiletries.

In less-developed countries, wholesalers often dominate trade; they are the main elements in the distribution systems of many countries in Latin America, the Far East, and tropical Africa. In those countries the business activities of wholesalers may extend to manufacturing or retailing or branch out into nondistributive ventures, such as real estate, moneylending, or transportation. Until the latter half of the 1950s Japan was a country of wholesaling where even fairly large manufacturers and retailers relied principally on wholesalers as their intermediaries, but in more recent years, as in the U.S. almost a century earlier, Japanese wholesalers have decreased in importance. Even in the most highly industrialized nations, however, wholesalers remain essential to the operations of large numbers of small retailers.

In Communist countries, wholesaling performs basically the same functions as in other economies. Some capital goods pass directly from the producer to the user; in other cases, goods may move through one or more layers of wholesalers. The latter are usually supervised by trade ministries at the national or regional level.

Brokers and agents

Manufacturers may use agents in marketing their products. Agent middlemen, unlike merchant wholesalers, do not take title to the goods they sell; nor, as a rule, do they take physical possession of them. The three principal types of agent middlemen are brokers, manufacturers' agents, and sales agents.

Brokers, most commonly found in the food industries, may represent either a buyer or a seller, but most frequently the latter. Relationships are usually temporary, and brokers often represent a number of manufacturers of noncompeting products on a commission basis.

Manufacturers' agents, on the other hand, represent their principals on a continuous basis. As a rule, they sell only part of a manufacturer's output, sometimes in areas where the manufacturer cannot support full-time salesmen. Compensation is usually by commission.

Sales agents sell all of a manufacturer's output, and generally have considerable freedom in setting prices. Sometimes they function in effect as a manufacturer's marketing department, even though they work on a straight commission basis. Sales agents often feed back market and product information to their principals and play an active role in product development.

#### MARKETING GOODS TO INDUSTRY

Many goods are sold for use in producing other goods and services. These include buildings, land, machinery, component parts, semifinished goods (such as textiles, steel sheets, and other products that will undergo further processing), raw materials, and such supplies as coal, oil, or janitorial services.

Industrial channels

The marketing of goods and services to manufacturers differs markedly from marketing to final consumers. Industrial purchasers often employ professional purchasing agents backed up by engineers, testing laboratories, and production specialists. Such purchasers are generally fa-

miliar with competitive products, and are prepared to negotiate. They are also more concentrated geographically: the purchasing decisions of automobile manufacturers are made in centres such as Detroit, Paris, and Turin, Italy; data-processing equipment for large-scale financial operations is sold mainly in such cities as Tokyo, London, New York, and Geneva and Zürich, Switzerland.

The demand for industrial goods is further distinguished by its dependence upon the demand for consumer goods that are the final products. Thus, the prosperity of the steel industry depends upon conditions in the automobile industry. Similarly, the industrial demand for screws, nuts, bolts, drafting supplies, and circuits is largely derived from the purchases of the general public.

A prevalent practice in industrial marketing is reciprocity—that is, a two-way buying agreement, often inferred rather than overtly stated. It is difficult for a seller not to buy from his own customers, if they produce items he needs. Three-way reciprocal combinations also exist, generally where there are circular relations among buyers; for example, A buys from B, and B buys from C, so A places pressure on B to persuade C to buy from A. Reciprocal buying arrangements may become even more complex.

Customers for industrial goods may be classified into three groups: users, original-equipment manufacturers, and middlemen. Users make use of the goods in their businesses—for example, the manufacturer who purchases a metal-stamping press to produce parts for his finished goods. Original-equipment manufacturers incorporate the purchased goods into their final products—for example, the television manufacturer who buys his tubes and transistors. Industrial middlemen are essentially wholesalers who distribute industrial goods from the manufacturers to users, to original equipment manufacturers, and to other middlemen. Industrial goods wholesalers include mill-supply houses, steel warehouses, machine-tool dealers, paper jobbers, and chemical distributors; different industries often have different names for middlemen who perform similar functions.

#### MARKETING FARM PRODUCTS

Channels of distribution for agricultural products follow the same general scheme as those for other goods. Individual farmers, however, often produce in relatively small quantities for the market—e.g., cocoa beans in Ghana, or milk in Wisconsin—and therefore the production of separate farmers often has to be assembled as the first stage in marketing it. This is done by three principal types of middlemen: wholesale merchants, who buy and resell to processors or other merchants; merchandise agents and brokers, who do not take title to the goods and usually do not have possession of them; and such special types as commission buyers, auctioneers, and livestock concentration yards.

Assemblers of agricultural products

The auction is one of the more colourful features of agricultural marketing. Major auctions, as a rule, are devoted to a particular product indigenous to a region, such as cut flowers in San Remo, Italy, cheese in Alkmaar, The Netherlands, and tobacco in Winston-Salem, North Carolina. Although sellers at the auctions are usually the producers, they may be assemblers reselling to a higher echelon of assemblers or to industrial users, retailers, or even consumers.

Farmers' cooperative associations are found throughout the world. Governments have encouraged them in order to stabilize the supply of agricultural products and raise farm productivity and incomes. In addition to marketing the farms' output, these cooperatives often purchase supplies, obtain loans, encourage research, and offer a host of services ranging from irrigation to insurance. Many cooperatives pool their members' products and market them as a single batch. Swedish cooperatives handle almost all milk production, most of the output of livestock and eggs, and a large percentage of the timber. In the U.S. in the 1960s, cooperatives marketed over 20 percent of farm production and handled about 20 percent of the farm supply business.

In recent decades the less-developed countries have giv-

en particular encouragement to the development of agricultural cooperatives. Most sugarcane in India is sold to sugar factories through cooperative societies sponsored and administered by the state governments. The Commodity Marketing Boards of West African countries are government-supervised organizations regulating the buying and selling of peanuts, palm kernels and oil, cocoa, cottonseed and lint, and other exported commodities. The boards attempt to secure the most favourable terms for the purchase, grading, export, and sales of the commodities. Cooperatives are also frequently used in Communist countries to market the farms' products and to handle many of the functions of supply in rural districts.

#### MARKETING RESEARCH

The analysis of marketing problems

Marketing research has been defined as the application of the scientific method to the solution of marketing problems. It studies people as buyers, sellers, and consumers, examining their attitudes, preferences, habits, and purchasing power. Marketing research is also concerned with the channels of distribution, with promotion and pricing, and with the design of the products and services to be marketed. Although there is hardly a form of commercial activity that does not use marketing research with some frequency, it finds its widest application in manufacturing—probably because manufacturing is further removed from the ultimate consumer than are most service industries, public utilities, and wholesale and retail enterprises.
