Peking

Peking (Bei-jing in Pin-yin romanization) is both a very old and a very new city—old and rich in its cultural and artistic heritage but new and thriving since 1949 as the capital of the People's Republic of China. Few cities in the world have served for so long as the political headquarters and cultural focus of a country as immense as China. The city has constituted an integral part of the history of China over the past eight centuries, and there is scarcely a building of any age in Peking that has not made its contribution toward the evolution of the country. As Peking is itself a China in miniature, it is impossible to understand China without a knowledge of this ancient city, which in 1970 had a population of 7,600,000 and a metropolitan area of 6,900 square miles (17,800 square kilometres).

More than 2,000 years ago, a site near present-day Peking was already an important military and trading centre for the northeastern frontier of China. Not until the Mongol dynasty (AD 1279 to 1368) was a successor city—called Ta-tu—to become the administrative capital of China. During the reign of the first emperor of the Ming dynasty (1368 to 1644), Nanking became the capital, and the old Mongol capital was renamed Pei-p'ing (Peace in the North); the third Ming emperor, however, restored it as the Imperial seat of the dynasty and gave it a new name, Peking (Northern Capital). It remained the capital until the 20th century, when, after the successful campaign of the Chinese Nationalist troops against warlords in Peking in 1927, Nanking was selected as the national capital, and Peking once again resumed its old name—Pei-p'ing—a name still used by the Nationalist government in Taiwan.

In spite of frequent political changes in China, the city throughout the earlier decades of the 20th century remained the most flourishing cultural centre in the nation. Peking's importance was never fully realized, however, until the city was chosen as the capital of the People's Republic of China in 1949, and this new political status has over the past two decades added much vitality to the ancient city. Indeed, few cities in the world have ever experienced such rapid growth in population and geographic area, as well as in industrial and other activities. Combining both historical relics of an ancient culture and new urban construction under a socialist system, Peking has become the showplace of modern China.

HISTORY

With but few interruptions, Peking has been the capital of China for some 700 years, and in the number of years as the Imperial capital it is exceeded only by Ch'ang-an (Hsi-an) in Shensi Province and Lo-yang in Honan Province. In prehistoric times the area around Peking was inhabited by some of the earliest human beings of whom we have knowledge. Between 1918 and 1939, the fossil remains of Peking man (formerly *Sinanthropus pekinensis*; now known as *Homo erectus pekinensis*), who lived about 500,000 years ago, and of Upper Cave man, who lived about 50,000 years ago, were unearthed at Chou-k'ou-tien, a village 34 miles southwest of Peking.

While long periods in Peking's early history necessarily remain blank, it is certain that, some 3,000 years ago, Neolithic communities settled down on or near the site where Peking now stands. During the Warring States period (481–221 BC) of the Chou dynasty (from about 1122 to 221 BC), one of the powerful feudal states, the kingdom of Yen, established its capital named Chi near the present city of Peking; this was the first capital city to be associated with the site. The city was destroyed by the troops of Shih Huang Ti, founder of the Ch'in dynasty (221 to 206 BC).

Chi—the capital of Yen

During the Ch'in dynasty, the Yen capital was incorporated into one of the 36 prefectures then established throughout the country. A new town was built during the Han dynasty (206 BC to AD 220) and was known as Yen. But, throughout the Han dynasty and the turbulent centuries that followed, the place remained a provincial town, witnessing most of the time the fateful struggle between the Han Chinese to the south and the nomadic Hsiung-nu, or Huns, to the north.

During the period of Three Kingdoms (AD 220 to 264), the city was again called Yen. The northern border of ancient China ran close to the present city of Peking, and northern nomadic tribes frequently broke in from across the border. Thus the area that was to become Peking became an important strategic as well as a local political centre.

For nearly 300 years (from the end of the Chin dynasty in 317 to the beginning of the Sui dynasty in 581), the northern territory, including the site where Peking now stands, was largely under the control of invading nomads. It was not until the T'ang dynasty (618 to 907) that it was recovered by the Han people and known as Yu-chou. By the middle of the T'ang dynasty, measures were taken to prevent the nomadic Tangut tribes of Tibet, the Hsi Hsia and the Khitans (a Manchurian people), from raiding the border lands and the local capital. The position of Yu-chou consequently became increasingly important. On the fall of T'ang China, a number of states emerged in North China. One of these states was established by the Khitans; after destroying the city of Yu-chou, the Khitans established the Liao kingdom (947 to 1125) and built one of their capitals on approximately the same site, calling it Nan-king (the Southern Capital) to distinguish it from other capitals in their Manchurian homeland (also distinct from the modern Nanking or Nan-ching in the Yangtze Valley). The Liao capital was bounded by a square wall, almost 14 miles in circumference and some 32 feet high. It had eight gates and enclosed a fine Imperial palace in the centre, which indicated the strong influence of Chinese city planning.

In the middle of the 12th century, when the Juchen, a Manchurian people from the Amur Valley, defeated the Liao and established the state of Chin, the Liao capital was rebuilt as the new Chin capital and renamed Chung-tu (Central Capital). Chung-tu under the rule of the Juchen (Golden Tartars) was constructed on a larger scale, with spendidly decorated palaces and halls.

Between 1211 and 1215 the Mongols, under the leadership of Genghis Khan, one of the great conquerors of

history, repeatedly attacked and finally took the city from the Chin. In the battle the palaces of Chung-tu were set on fire and blazed for over a month. When all China fell to the Mongol hordes, Kublai Khan (1215 to 1294), a successor to Genghis Khan and founder of the Yüan dynasty (1279 to 1368), determined to build a new capital at Peking, abandoning the old city of Karakorum in Mongolia. In 1272 he named the new capital Ta-tu (Great Capital); under Mongol control it became for the first time the political centre of all China.

The Mongol capital of Ta-tu

Ta-tu was larger than any of its forerunners and was rebuilt slightly northeast of the old site. The square of the outer wall measured about 18 miles in length and enclosed an area of more than 20 square miles. The city walls were built with pounded earth, and once a year labourers were called in to repair them with mud. The Imperial Palace, which was approximately to the west of the existing one, was situated in the southern half of the capital city. The chief palace architect at the time was an Arab, appointed by Kublai Khan. The city of Ta-tu exemplified the imposing and variegated architecture of the Mongol period. The square walls and the 12 gates were all modelled on the Chinese plan, but the inner chambers and living quarters were often in the style of Mongolia or of Central Asia. It was at this time that a canal, the T'ung-hui Canal, was dug and connected to China's Grand Canal so that boats transporting the tribute rice from the provinces south of the Yangtze could sail into one of the new lakes inside the city. Ta-tu, which had magnificent Imperial palaces and treasures drawn from every corner of the country, was the scene of stupendous feasts given by the khan (ruler) on state occasions. These characteristics and the well-organized post-stages on the roads leading to the city astounded Marco Polo (*q.v.*), the Venetian traveller who visited Ta-tu in the 1280s.

In the middle of the 14th century, Chu Yüan-chang headed a peasant revolt that overthrew the Mongol dynasty and established the Ming dynasty (1368 to 1644). He moved the capital to Chin-ling, near his own hometown in Anhwei Province, and called it Nanking; Ta-tu was renamed Pei-p'ing (Northern Peace) and was placed under his son's rule. On Chu's death (1399) the throne should have passed to his grandson in Nanking, but his son, Prince Yen, who ruled Pei-p'ing, usurped the throne. In consequence, in 1403 the city was renamed Peking (Northern Capital), and in 1420 it was officially made the capital city of the Ming dynasty.

The 15th-century city

Peking in the Ming period grew on a yet grander scale than under the Mongols. The present city walls, moats, palaces, and temples were mostly built in the 15th century. The old city of Ta-tu, including the palaces, was largely demolished. The new city was situated further south, thus leaving the northern part of the Mongol city derelict while at the same time slicing off one gate from the east and west walls, respectively. In 1553, an outer city wall was begun, to include the increasing number of inhabitants living outside the city, but, when the entire construction was subsequently found to be too costly, the plan was abandoned on the completion of the south wall, thus producing the present shape of the walled city. Unlike the city wall of pounded earth of Mongol times, the walls of the Ming city were faced with a layer of bricks, in order to prevent weathering.

In 1644 Peking was taken over by Li Tzu-ch'eng, who led a peasant uprising against the Ming regime. Li's army held it for only 40 days, for the Manchus were simultaneously preparing an incursion south of the Great Wall, and—thanks to the treachery of a Ming general who opened the gate—they swept down on the city. Peking fell intact and in the same year was declared the Manchu capital by Shun-chih, the first emperor of the Ch'ing (also known as Manchu) dynasty (1644 to 1911).

Peking remained superficially the same throughout Ch'ing times. The city plan was unaltered, though many palaces, temples, and pavilions were added outside the walls to the west, notably the Yüan Ming Yüan (old Summer Palace), built in the 17th century, and the Yi Ho Yüan (new Summer Palace), built in the late 19th century. The old Summer Palace was completely destroyed by fire in 1860 by the allied British and French troops in Peking during the "Arrow" War (1856–60). In the same year, as a result of the treaties of Tientsin in 1858, a permanent British embassy was established in the city, and a legation quarter, situated to the southeast of the palace ground, was reserved for British and other embassies. The legation quarter was besieged for nearly two months by the Boxer rebels in 1900.

After the revolution of 1911, Peking remained the political centre of the Republic of China until 1928, when the Nationalists moved the capital to Nanking, at which time Peking was renamed Pei-p'ing once again. The city was occupied by the Japanese from 1937 to 1945. In 1949, when the Communists established the People's Republic of China, Peking (with its old name restored) was chosen as the capital of the new regime.

THE CONTEMPORARY CITY

Physical organization. *The city site.* Peking is situated at the northern apex of the triangular North China Plain and lies at an elevation of between about 100 and 130 feet above sea level. To the north lies the fringe of the Mongolian Plateau; to the northeast rises the mountain range of the Yen Shan (Yen Mountains), part of which forms the eastern part of the concave arc that circles the Peking lowland from the northeast to the southwest and that is known to geologists as the "Bay of Peking."

The city was built at the mouth of this embayment, which opens onto the great plain to the south and east, and between two rivers, the Yung-ting and the Ch'ao-pai, which eventually join to empty into the Gulf of Chihli, some 100 miles to the southeast of Peking. Peking is a natural gateway on the long-distance land communication route between the North China Plain and the northern ranges, plains, and plateaus. To the south of the city the plain spreads out for about 400 miles until it merges into the lower valley and the delta of the Yangtze. On the east the plain is bounded by the sea, except for the break caused by Shantung Hills; on the west it is flanked by the T'ai-hang Shan, which constitute the eastern edge of the plateau of loess (loamy material deposited by wind). Since Peking stands at the apex of the triangle, routes running across the great plain naturally converge on the city.

Since the dawn of Chinese history, the Yen Shan range has constituted a formidable barrier between the North China Plain to the south, the Mongolian Plateau to the north, and the Liao Ho (Liao River) Plain in the southern region of the Northeast (formerly Manchuria). A few passes, however, cut through the ranges—the most important being Nan-k'ou, Ku-pei-k'ou, and Shan-hai-kuan—and are so situated that all roads leading from Mongolia and the Northeast to the North China Plain are bound to converge on Peking. For more than 700 years, therefore, Peking has been an important terminus of the caravan routes leading to and from the vast Central Asian hinterland.

The metropolitan district

Since the early 15th century, the city of Peking and its surrounding territories have been organized as a metropolitan district of enormous size, having a governor—formerly appointed by the emperor himself—equal in rank to a provincial governor. This special district organization was continued by the Ch'ing dynasty and by the People's Republic of China. The present metropolitan boundary was established in 1959 and covers a territory of approximately 6,600 square miles. The metropolis consists of eight *ch'u* (municipal districts) in the centre and nine annexed *hsien* (counties) in peripheral areas. It may be divided into three concentric zones, based on urban functions. The central zone coincides with the walled city; it is mainly occupied by old palaces, government buildings, commercial districts, and old residential areas and makes up roughly 0.4 percent of the total metropolitan area. Four of the *ch'u* lie within the walled city. The second zone, the near suburb, comprises three *ch'u* immediately surrounding the walled city; it provides sites for new factories, schools, government buildings, and workers' dormitories. The outer fringe of this zone is intensively cultivated and supplies vegetables and fruits to

the population of the central zone. The near suburb accounts for 7.6 percent of the metropolitan area. The third zone, the far suburb, consists of one *ch'u* and nine annexed *hsien*. This zone constitutes 92 percent of the metropolitan area and functions as the economic base—supplying coal, lumber, construction material, dairy products, water, and some grain crops to the urban population in the central zone and the near suburb. The far suburb of Peking is mainly under the administration of people's communes.

The environment. Though the distance from Peking to the Gulf of Chihli is only about 113 miles, the general air circulation in Peking is mainly from the northwest throughout the year. Maritime effects on Peking's weather are meagre. The climate is clearly of the continental monsoon type that occurs in the temperate zone. Winters are cold and dry because of the Siberian air that passes over the Mongolian Plateau and moves southward into China proper. In summer the warm and humid air from the southeast often penetrates into North China, bringing Peking most of its annual precipitation.

Local topography has a great effect on Peking's climate. Being located in the lowland area and shaded by mountains, the city is a little warmer in winter than other areas of China on the same latitude; it has only five months in a year in which the mean monthly temperature is lower than 50° F (10° C). Wind direction in Peking is also influenced by topography, with changes occurring from day to night. Generally, there are more southerly winds in the day but northerly or northwesterly winds at night.

Temperature and rainfall

Based on meteorological data from 1841 to 1956, the annual mean temperature of the city was 53° F (about 12° C). The coldest month was January, when monthly mean temperatures were 24° F (about −4° C), and the warmest month was July, when the monthly mean was 79° F (26° C). In an average year, there are 132 days of freezing temperature in Peking (between October and March); the mean amount of precipitation is 25 inches (635 millimetres), with 75 percent of the annual total falling in the summer months from June to August. July is ordinarily the wettest month of the year, with monthly mean precipitation averaging about nine inches.

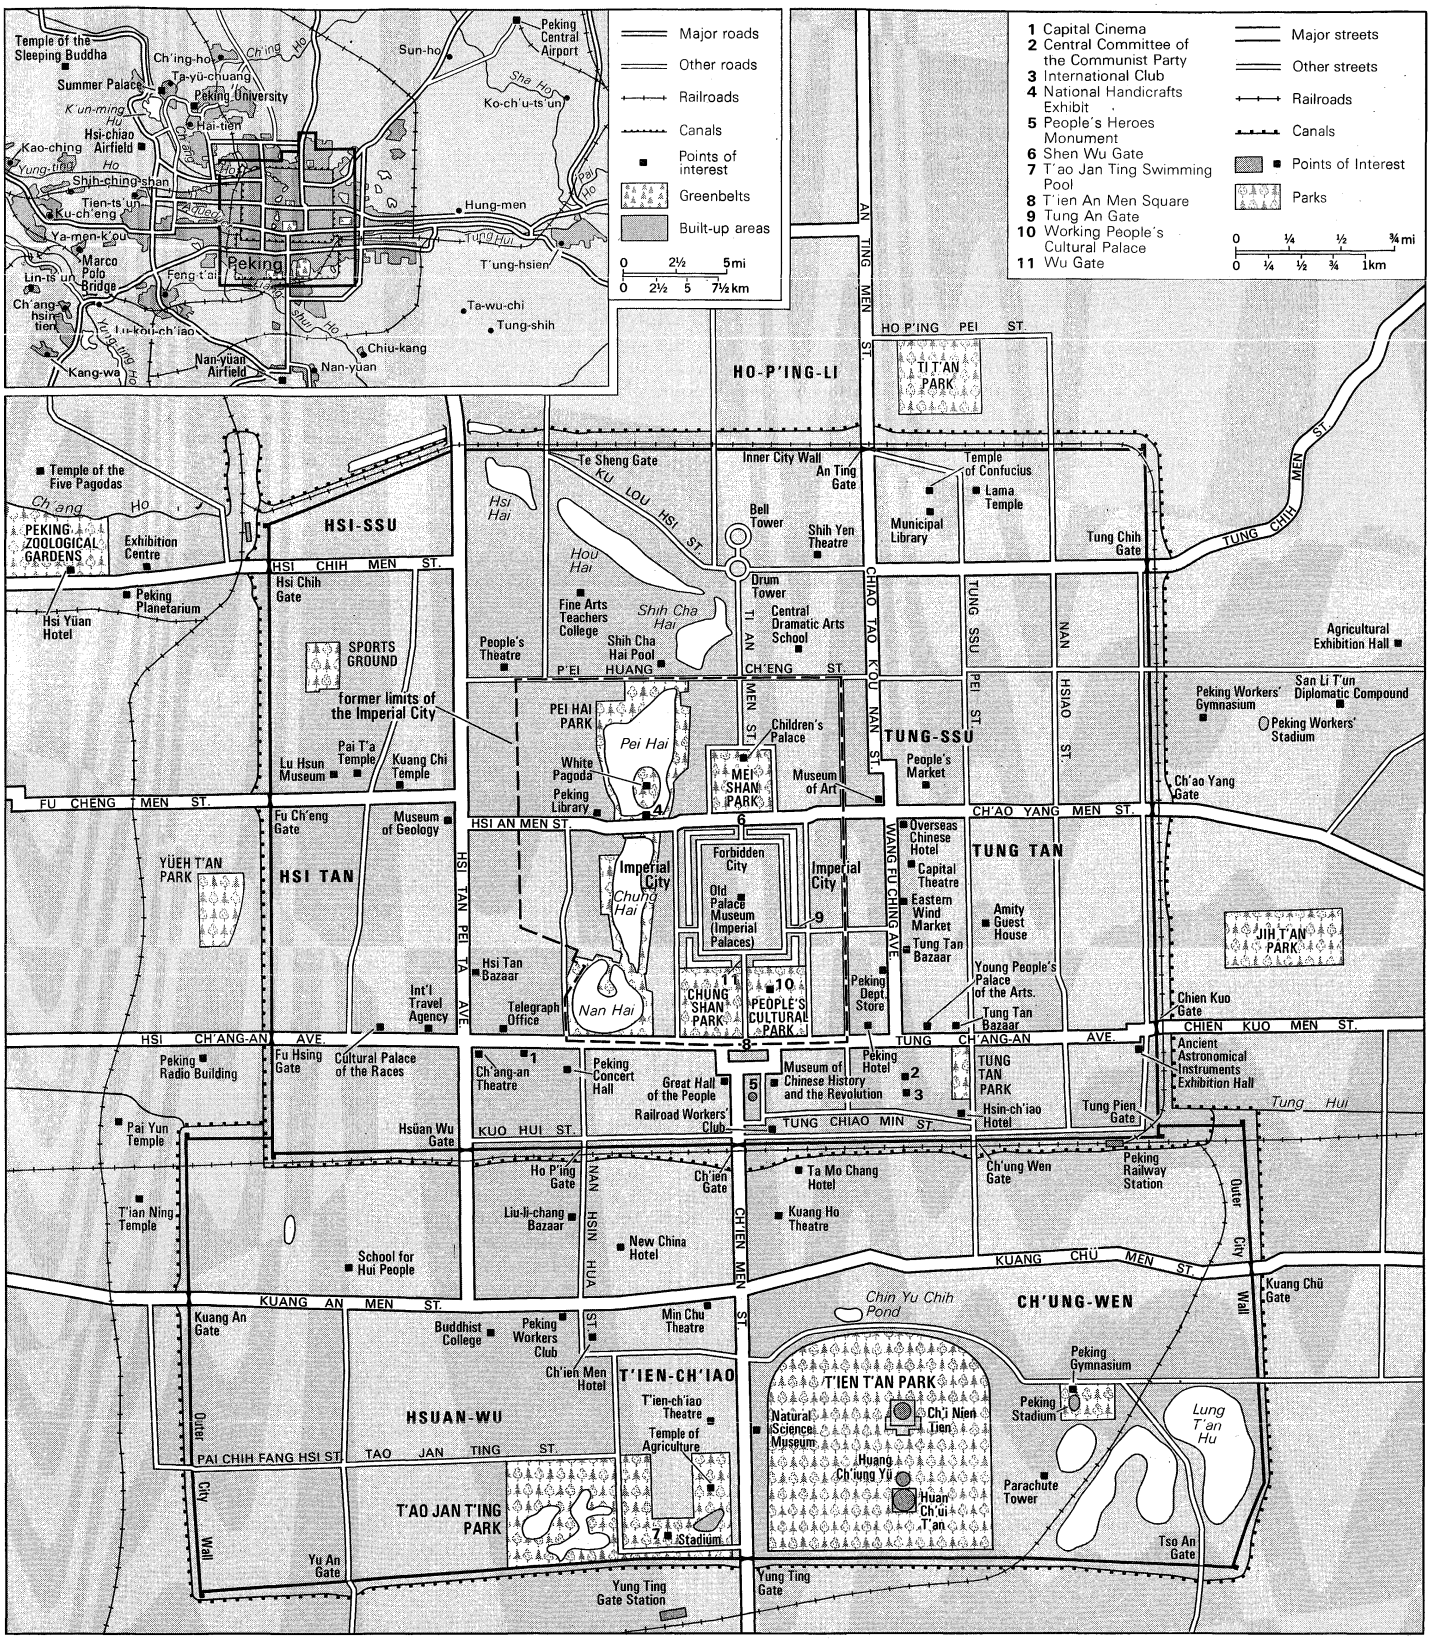
One of the characteristics of Peking's rainfall is its variability. In 1959—an extremely wet year for Peking—the total precipitation amounted to 55 inches, whereas in 1891—an extremely dry year—only seven inches of rainfall was recorded. The average number of rainy days is about 80, and the average relative humidity for the city is 57 percent.

Winter in Peking is long and usually begins in October, when northwesterly winds gradually gain strength. Until March, this seasonal wind system dominates Peking; coming from the Mongolian desert, the wind is cold and dry, bringing little snow or other precipitation. The monthly mean temperature from December to February is below 32° F (0° C), and during this period it is not unusual for a daily mean temperature of 14° F (−10° C) or lower to last for days. Spring, the windiest season, is short and rapidly becomes warm. Total precipitation from March to May is less than three inches. Mainly because of the prevailing high winds, the evaporation rate in spring averages 24 inches—about nine times the total spring precipitation—and frequently is sufficient to cause droughts that are harmful to agriculture. In addition to being the season of torrential rains, summer is rather hot, with the average temperature for June, July, and August being above 75° F (24° C). Autumn begins in late September and is a pleasant, though short, season when the sky is clear and the temperature comfortable.

Vegetation

The mountain areas of Peking belong to the temperate deciduous forest zone, while the plains area belongs to the wooded steppe zone. Because of continuous deforestation by man for several centuries, however, only the mountain areas in the northeast and the western parts of the metropolitan area are still covered with mixed forests, composed mainly of pines, oaks, and Manchurian birch. Different types of forest, divided into vertical zones, can be seen at higher elevations. On the lower slopes of many hills to the west of the city, human activities have resulted in the disappearance of forest cover so that only bushes and shrubs dot the landscape. On sunny slopes at altitudes of between about 2,300 and 5,600 feet, a variety of species occurs, including Manchurian birch (*Betula mandshurica*), Dahurian birch (*Betula davurica*), trembling poplar (*Populus tremula*), Mongolian oak (*Quercus mongolica*), and Liaotung oak (*Quercus liaotungensis*). Between 5,600 and 6,250 feet above sea level, the mixed forest of truncated maple (*Acer truncatum*) and trembling poplar replaces all other species. Above 6,250 feet, goat willow (*Salix caprea*) becomes the dominant tree. A larger part of the plain areas of Peking has been either cultivated or occupied by various settlements so that it is for the most part bare of any natural vegetation. Occasionally, some small groves of planted trees may be seen near graveyards or in the vicinity of villages; these are mainly composed of mixed woods consisting of oil pine, Chinese juniper, Chinese cypress, willow, elm, and Chinese locust.

The city plan. The city proper of Peking essentially consists of two walled cities, the northern inner city and the southern outer city. The inner city, also known as Tatar City, lies approximately on the site of the Mongol city of Ta-tu; it is in the form of a square, with walls nearly 15 miles in length. The outer city, also known as the Chinese City, was added during the region of the Ming emperor Chia-ching (1521 to 1566); it is in the form of an oblong adjoining the inner city, with walls 14 miles in length, including four miles of the southern wall of the inner city. Within the inner city is the former Imperial City, also in the form of a square, which has red plastered walls six and a half miles in length. Within the Imperial City, in turn, is the moated "Forbidden City," with walls two and a quarter miles long. The Forbidden City contains the Imperial Palaces, which have been converted into a museum.

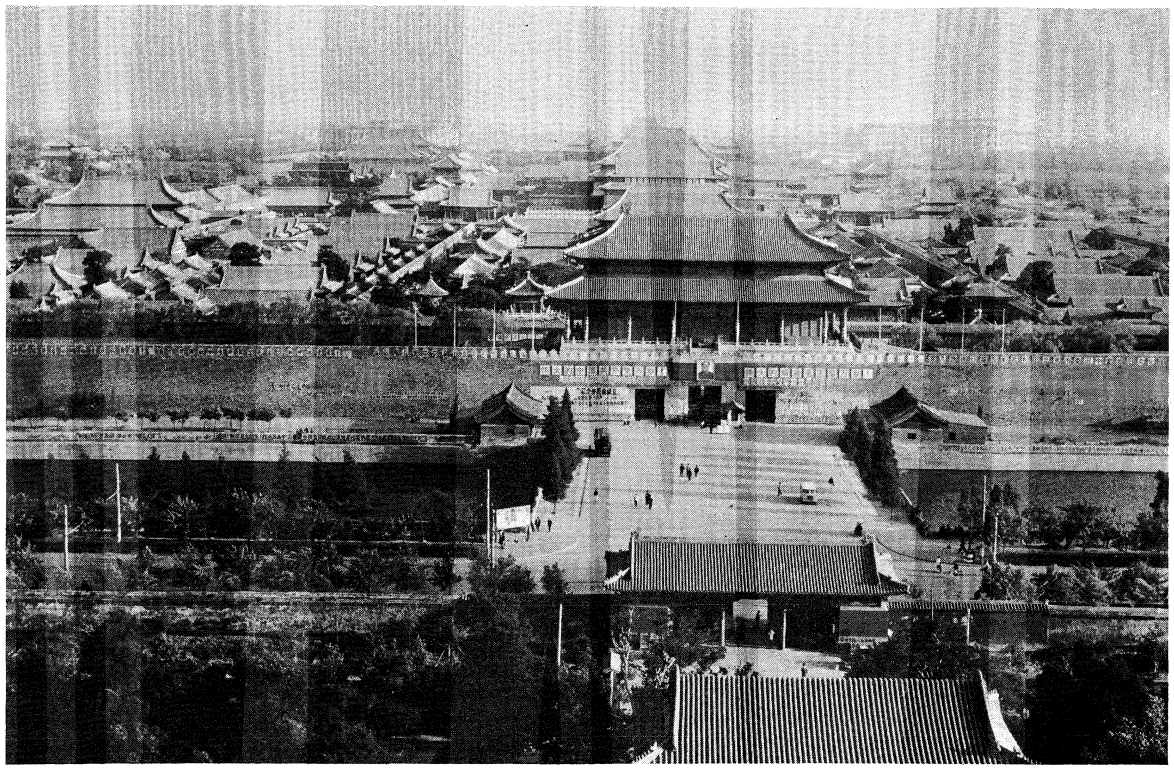


Peking represents, better than any other existing city, the heritage of Chinese architectural achievement. During each dynasty in which Peking was the capital, care was consistently taken to preserve tradition unchanged when the city was rebuilt or remodelled. Few cities in the world can thus rival Peking in the regularity and harmony of its city plan.

The north–south axis

The plan is composed about a single straight line, drawn north and south through the centre of Peking, on which the internal coherence of the city hinges. All the city walls, important city gates, main avenues and streets, religious buildings, and daily shopping markets are systematically arranged in relation to this central axis. Because the central axis has historically signified the authority of the ruling dynasty, many official buildings, public grounds, and city gates are located along this line. From north to south this line passes through the Chung Lou (Bell Tower); the Ku Lou (Drum Tower); Mei Shan (Coal Hill) Park; the Forbidden City, including the Imperial Palaces; T'ien An Men Square; Ch'ien Men (Front Gate); T'ien-ch'iao (section of town); and Yung Ting Men (Gate of Eternal Stability).

The symmetrical layout of the city to the east and west of this line is quite striking. In front of the palaces, the Temple of the Imperial Ancestors (now the People's Cultural Park) on the east side of the axis is balanced by the Altar of Earth and Harvests (now the Chung Shan Park) on the west. Farther away from the palaces, the Tung Tan (East Bazaar) is balanced by the Hsi Tan (West Bazaar); these form the main business districts. In the outer city, the T'ien T'an (Temple of Heaven) Park and the Ti T'an (Altar of the Earth) Park are similarly situated on both sides of the axis. Of the 16 city gates constructed in Ming times, seven are located on each side of the north–south line, and two are situated on the line itself.



The main avenues of Peking, whether running north–south or east–west, connect the gates on the opposite walls and divide the whole city into a rectangular grid. Within the walls, buildings are constructed around a courtyard or series of courtyards, with every important building facing south. Buildings often stand behind one another along a north–south line, with small courtyards in between. The prevailing southern orientation of buildings has its climatic functional basis and also appears to

The city of Peking and (inset) its metropolitan area.

have been sanctified or conventionalized early in the Bronze Age in connection with ancestral ceremonies and with the worship of Heaven and Earth.

Since 1949, the greatest change in the city's appearance has been the extension of its streets immediately outside the old city walls. On the west side of the old city, an area extending about a mile out from the Fu Hsing Men has become a new extension of the Hsi Ch'ang-an Avenue and is used primarily for government offices. To the north, government offices are situated in an area of approximately the same width. Toward the Summer Palace, to the northwest, is an area where the most important universities and research institutes of the country are located. To the north of the city, the outlying districts between An Ting Men and Te Sheng Men are being developed as a new housing area adjoining the educational district in the

Forbidden City as seen from Mei Shan. The Great Hall of the People on T'ien An Men Square is visible in the background at right and the Museum of Chinese History and the Revolution at left.
Paolo Koch—Rapho Guillumette

northwest. Plans call for factories to be located around the east and south suburbs, although the southern suburbs still retain a predominantly rural aspect.

Rail communications

Transportation. Peking is the railroad centre of China, forming the terminus of four major lines and three local lines in the national railroad network. The four major lines radiating from Peking provide connections with Shenyang (Liaoning Province), Shanghai Municipality, Wu-han (Hupeh Province), and Pao-t'ou (Inner Mongolian Autonomous Region), respectively, each city being a major national industrial and commercial centre. The local lines are of regional importance and serve outlying districts within the metropolitan area; they are the Peking–Ku-pei-k'ou line to the north, the Peking–T'ung-hsien line to the east, and the Peking–Ta-tai line to the west. Peking is linked by direct express with several other large urban centres, such as Tsingtao (in Shantung), T'ai-yüan (in Shansi), Sian (in Shensi), Lan-chou (in Kansu), Ch'ang-ch'un (in Kirin), and Man-chou-li (in Heilungkiang). Under international agreements, Peking is also periodically connected by express train with Moscow; P'yŏngyang, North Korea; Ulaanbaatar, Mongolian People's Republic; and Hanoi, North Vietnam.

There are four major railroad stations in the city: Peking, Hsi Chih Men, Te Sheng Men, and Tung Pien Men. Peking Station, completed in 1959, is by far the largest and most important of these; located almost two miles from the heart of the city near the eastern end of the main thoroughfare, Tung Ch'ang-an Avenue, it has the capacity to serve more than 200,000 people a day and is the terminal and transfer point for all express lines. The new facilities were built to replace the Ch'ien Men Station (now the Railroad Workers' Club), built in 1906 outside the front gate of the inner city. The new station has more than 2,800,000 square feet of floor space in its central concourse and two wings, while its 18 waiting rooms can accommodate 14,000 people at one time. The roof of the beamless concourse is constructed in the form of a hyperbolic shell supported on four columns; it reaches the height of a ten-story building. Platform No. 1, at which the international trains pull in, is wide enough to hold a military review and is equipped with cinematographic and television facilities. The other three stations are mainly for local commuting trains.

While railroads connect Peking with distant cities, highways are the principal means of communication with communities within a 125-mile radius. There are 12 major highways radiating from the city, along which regular bus services run to Tientsin (in the Tientsin Municipality, an autonomous area in Hopeh Province), Chou-k'ou-tien, Nan-k'ou, the Ming Tombs (all in the Peking Municipality), and T'ang-shan and Ch'eng-te (in Hopeh). Five major bus depots are located in the walled city.

Peking is also the centre of China's civil airlines. The nation's major air routes radiate from Peking to Shanghai, Canton (in Kwangtung Province), Ch'eng-tu (Szechwan), Chungking (Szechwan), Urumchi (Sinkiang Uighur Autonomous Region), Harbin (Heilungkiang), K'unming (Yunnan), Nan-ning (Kwangsi Chuang Autonomous Region), Lhasa (Tibetan Autonomous Region), and Hsi-ning (Tsinghai).

Peking's intracity communications and commuting services are provided by a network of a city-owned system of buses and trolleys. The public transport system carries about 2,000,000 riders every day. The city's population is served by almost 120 routes with a route mileage of about 1,250 miles and by more than 1,000 buses and 430 trolleys. At places to which a large number of people are carried, such as the Shih-ching-shan steel mill and the Ch'ang-hsin-tien locomotive works (both in the outlying areas), bus routes run through the plant itself. The trolley routes run through the densely populated districts of the inner and outer walled cities; the pattern is much influenced by the symmetrical arrangement of the city plan. Bus routes also run throughout the walled city and the suburban areas. Bus fares are determined by distance, and monthly passes good for both trolleys and buses are available. There are also about 200 taxicabs on the city streets. For short-distance intracity travel, bicycles are very popular, constituting the bulk of street traffic.

Demography. Since 1949, Peking has become one of the most rapidly growing urban centres in China. The population change in historical times is illustrated by Table 1.

Young people painting Maoist slogans on the pavement in front of the Ch'ien Men railway station in 1967 (now the Railroad Workers Club).
Der Stern—Black Star

Population growth

During the dynastic period, when Peking was the capital, from the 13th to the beginning of the 20th century, the population of Peking seems to have increased very slowly in numbers, but since the downfall of the Manchu dynasty it has increased at an accelerating rate. The rapid increase during the four decades from 1910 to 1949 may be attributed to several factors. First, the rural disorder on the North China Plain during the rule of the warlords caused extensive migration to the walled city of Peking; second, the loss of Manchuria to Japan in 1931 made Peking a shelter for thousands of refugees from the northeastern provinces; third, the establishment of numerous institutes of higher education, sponsored by the government or by foreign missionaries, stimulated the growth of the student population in a city that was a cultural as well as a political capital.

Table 1: Peking Population Growth

year	population
1280	401,000
1578	707,000
1913	728,000
1916	801,000
1930	1,300,000
1936	1,551,000
1948	1,722,000
1949	2,360,000
1953	2,768,000
1958	4,148,000
1959	6,800,000
1970	7,600,000

The phenomenal increase in Peking's population did not occur, however, until the city had resumed its role as the national capital. In 1949 Peking, with a population of 2,360,000, was the fourth largest city in the country; ten years later a total of 6,800,000 made it the second largest. This increase resulted primarily from three circumstances: the necessary migration of thousands of government workers to the new capital, the rapid rate of industrial development in the municipality, and the extension of the municipal boundary in 1959 to include large rural areas. The 1953 census indicated that Peking had 708,000 persons living in rural areas—about 25 percent of the total population of the municipality. With the expansion of the city boundary in 1958 to include nine counties within the metropolis, it is likely that at least one-third of the total population may now be considered rural.

Housing and architecture. *Housing.* To cope with the rapid growth of population, some 200,000,000 square feet of floor space of new housing was constructed in the 1950s and 1960s for office and factory workers. During the time of the first five-year plan (1953 to 1957), new housing projects were concentrated in the western outskirts of the city, where apartment buildings were erected near the newly built government offices outside the Fu Hsing Men. After 1958 the construction of a large group of multi-unit housing estates was begun in the northern outlying districts between the city gates of An Ting and Te Sheng, centring on the new residential district of Ho-p'ing-li. The Ho-p'ing-li housing development contains primary and secondary schools, nurseries, hotels, and recreational facilities, as well as more than 100 four- or five-story apartment buildings. In addition, there are many groups of single-family houses in the northern suburbs, with associated parks, theatres, and recreational centres. All these buildings are supplied with gas and water, in contrast with the older parts of the city, where the existence of old stone paving had hindered the development of modern structures and facilities.

In the area outside the city gate of Chien Kuo, to the east of the city, apartment buildings accommodate the families of office workers employed in nearby government office buildings. This area has also been selected as the new diplomatic district and contains many foreign embassies, together with a number of Western-style houses for the housing of diplomatic representatives and their families.

In the older districts inside the city walls, many dilapidated houses have been pulled down in municipal housing-renewal projects and have been replaced by multistory apartment buildings. Urban-renewal projects, however, had, by the early 1970s, been unable to match the growth of population. In consequence, many traditional house compounds—originally designed centuries ago to house officials' families during the Manchu dynasty—were repaired or renovated and subdivided to provide quarters for three or four families in each compound; each family in a compound faces a public courtyard and shares a common front gate with other families.

Workers' community housing

In order to minimize commuting traffic in the metropolis, many factories in the eastern and southern outskirts of the city have erected four-story apartment buildings for workers' living quarters. These workers' residences constitute independent communities of their own and are so located that they are easily accessible from the place of work yet are far enough away to be free from noise and smoke. Rents in these community housing units are rather low compared with the total family income of average workers. A 1965 survey by the Peking Housing Bureau of 5,000 families living in houses operated by the city or various public enterprises found that the average rent amounted to about 6 percent of each family's monthly budget.

Building types and architectural features of note. Peking's heritage of Chinese architectural achievement is exemplified by both private housing and public buildings. As the whole city was laid out upon a rectangular street pattern symmetrically arranged around a centrally located palace, almost every dwelling unit in the city is rectangular in form, with the four sides squarely facing the cardinal directions. Most houses in the inner city were designed as residences of former officials and their families, and almost every dwelling compound is surrounded by high walls, with an open courtyard in the centre flanked by houses on the eastern, western, and northern sides, usually one story high. The former residences of high-ranking officials were composed of two or three compounds, interconnected along a north–south axis.

Stepping over the high wooden gate-sill of the front gate of a large compound, the visitor will find a brick screen wall located a few feet inside the gate—a structure that was supposed to shut off the intrusion of evil spirits, as well as to prevent curious passersby from looking inside. Beyond the screen is the outer courtyard, or service courtyard, which is flanked by houses to the east and west. Here, in former days, were the kitchen and living quarters for the gatekeeper, servants, and any visiting guests and relatives. A red-painted gate leads through the north wall of the outer court into the main part of the house. This is built around three sides of the main courtyard, which, usually shaded by a large tree, was the centre of the family's life. All the windows look inward to the courtyard, and a double door opens into the courtyard from each of the three wings. The windows extend from three feet above the ground up to the deep, overhanging eaves. As they face south, the rooms in the main building get the maximum possible sunshine in winter, and the eaves provide a pleasant shade in summer, when the sun is high. The wing at the northern end of the court was intended for the head of the family and his wife. It is divided into three compartments, the central one being the living or community room, and the smaller rooms at either side being the bedroom and study. The rooms facing east and west—three on each side of the court—were for married sons and their families. This is the basic plan of all the old houses in Peking. Larger families built an extra courtyard behind the main house, for it was regarded as essential that all the existing generations should live together. Since 1949, however, as mentioned, a great many of the old-style houses have been adapted for use by several families.

While the style and architecture of private dwelling units are uniform throughout the city, the public buildings and temples are characterized by a variety of designs and structures. As the nation's political and cultural centre for some 700 years, Peking possesses more buildings of historical and architectural significance than any other contemporary city in China. Since 1949 many new government and municipal buildings, combining both traditional and Western architecture, have added to the city's landscape.

The Great Hall of the People

Perhaps the most imposing structure constructed in the heart of the city since 1949 is the Great Hall of the People, an equivalent of the Capitol, in Washington, D.C. The Great Hall is located on the southwestern side of the T'ien An Men Square and is an immense building with tall columns of gray marble set on red marble bases of floral design. It has a flat roof with a golden-yellow tile cornice over green eaves shaped like lotus petals. Its frontage is 1,100 feet long—about the equivalent of two city blocks. Its floor space is 6,062,000 square feet—more than that of all the palaces in the old Forbidden City. The grand auditorium, seating 10,000, is where the National People's Congress holds its sessions. Other components are a banquet hall for 5,000, huge lobbies, and scores of meeting rooms and offices for the standing committee of the congress. The base of the building is of pink granite, and its walls are apricot yellow. Inside the building, the ceiling and walls are rounded. The focus of the lighting system is a red star surrounded by golden sunflower petals.

Among the historical and religious structures in Peking, the T'ien T'an (Temple of Heaven), located in the outer city, is unique both for its unusual geometric layout and because it represents the supreme achievement of traditional Chinese architecture. Entering from the western gate of the temple, along a path that is about 1,600 feet in length and shaded by ancient cypresses, one comes to a raised passage about 1,000 feet long. This broad walk connects the two sets of main buildings in the temple enclosure. To the north lies the Ch'i Nien Tien (Hall of Prayer for Good Harvests) and to the south the Huang Ch'iung Yü (Imperial Vault of Heaven) and the Huan Ch'ui T'an (Circular Mound Altar). The three buildings are built along a straight line. A bird's-eye view of the enclosure would show that the wall to the south is square, while the one on the north side is semicircular. Such a pattern symbolizes the traditional Chinese belief that Heaven is round and Earth square.

The Ch'i Nien Tien, built in 1420 as a place of heaven worship for the emperors, is a lofty, cone-shaped structure with triple eaves, the top of which is crowned with a gilded ball. The base of the structure is a triple-tiered circular stone terrace more than 63,000 square feet in area. Each ring has balustrades of carved white marble, which gives the effect of lace when seen from a distance. The roof of the hall is deep blue, resembling the colour of the sky. Without the use of steel and concrete, the entire structure, 125 feet high and about 100 feet in diameter, is supported by 28 massive wooden pillars. The four central columns, called the "dragon-well pillars," represent the four seasons; there are also two rings of 12 columns each, the inner ring symbolizing the 12 months and the outer ring the 12 divisions of day and night, according to a traditional system. The centre of the stone-paved floor is a round marble slab that has a design of a dragon and a phoenix—traditional symbols of king and queen. The hall has no walls, only partitions of open latticework doors.

The Huang Ch'iung Yü, first erected in 1530 and rebuilt in 1752, is a smaller structure some 64 feet high and about 50 feet in diameter. The circular building has no crossbeam, and the dome is supported by complicated span work. Its decorative paintings still retain their fresh original colours.

South of the enclosure lies the Huan Ch'ui T'an, built in 1530 and rebuilt in 1749. The triple-tiered white stone terrace is enclosed by two sets of walls that are square outside and round inside; thus, the whole structure forms an elaborate and integrated geometric pattern. The inner terrace is 16 feet above the ground and about 100 feet in diameter; the middle terrace is about 165 feet across and the lowest terrace some 230 feet across. Each terrace is encircled by nine rings of stones. Both the Huang Ch'iung Yü and the Huan Ch'ui T'an were erected to portray the geometric structure of the heaven, as conceived by the architects of the Ming dynasty. After 1949, the whole enclosure of the T'ien T'an was repaired; it is now a public park.

The economy. One of the main differences between the Imperial capital of former times and present-day Peking is that the Imperial capital was a consumption rather than a production centre, receiving supplies of all kinds from other parts of the country. In the 1950s and 1960s, however, Peking became one of the nation's principal industrial centres. The first five-year plan emphasized the

Children sweeping the steps at the Ch'i Nien Tien, or Hall of Prayer for Good Harvests, central building of the Temple of Heaven, Peking.
Emil Schulthess—Black Star

reconstruction and industrialization of the capital city; by 1959, there were almost 100 industrial units employing 1,000 to 5,000 workers each and 15 that employed more than 5,000.

Industrial activities. Among the large industrial establishments is the Shih-ching-shan Iron and Steel Works, located about 15 miles west of the walled city. The Shih-ching-shan plant was originally started in 1920, based on local ore and anthracite in the Western Hills; after the Japanese occupation of 1937, it produced a meagre amount of pig iron. Since 1958, the plant has been enlarged with a blast furnace, a steelworks, electric furnaces, and other equipment. With an annual capacity of 1,900,000 tons of iron and 1,500,000 tons of ingot steel, it is among the largest steel plants in China. Its high-quality steel production supplies such growing Peking industries as machine building, electrical engineering, and precision instrument manufacturing. A number of smaller finishing mills have also been established to produce such items as cold-drawn bearing steel and flat spring steel for tractor and automobile accessories, seamless tubes for high-pressure boilers, and magnetic steel for machine tools and radios. Peking is also an important centre of machinery manufacture, with plants established for manufacturing cranes, locomotives, automobile parts, tractors, wheat harvesters, and mining and printing machinery. Most of these plants were built in the suburbs east and south of the walled city, where extensive tracts of level land were available and where the prevailing northwest winds would carry industrial pollutants away from the densely populated areas. With the rapid expansion of cotton cultivation in Hopeh Province in the 1950s and 1960s, Peking has also become one of China's major textile centres. Peking's textile industry includes the manufacture of cotton and woollen fabrics and piece goods, serge, and several types of synthetic fabric, including polyester and nylon. To meet the needs of agriculture in the large rural area within Peking's administrative jurisdiction, insecticides, chemical fertilizers, and plastic sheets are also produced.

Iron and steel manufacturing

As a former Imperial capital, Peking possesses a rich accumulation of art treasures, produced by a variety of arts and handicraft industries that were intimately connected with court life and Imperial needs. Today, much of the traditional handicraft industry has not only been preserved but has been reorganized and re-equipped. Among the city's well-known handicraft products are rugs and carpets, porcelain and chinaware, jade and ivory sculpture, brass ware, enamel and lacquer ware, lace, and embroidery.

Commercial activities. With the rapid growth of industry and population in the city, many service industries, operated mainly by government agencies, have also greatly expanded.

Since 1949, there has been a slow but steady increase in tourist services provided in Peking. Many new hotels and hostels have been built, and old ones have been renovated and enlarged to meet the demands of the public; among these are the International Hotel, Hsin-ch'iao Hotel, Ho-p'ing Hotel, Ch'ian Men Hotel, Nationalities Hotel, the Overseas Chinese Hotel, Tung-ssu Hotel, and the enlarged Peking Hotel. Peking now has altogether more than 300 hostels and hotels; more than a dozen of them meet international standards. The China International Travel Service, which is state-owned, especially serves foreign tourists. Its general office is located on Hsi Ch'ang-an Avenue, and it has branches in all major cities in the nation, including one in Hong Kong. It makes reservations for airline and train tickets, hotel accommodations, and can also arrange for food, interpreters, cable service, and foreign monetary exchange. The general office of the Overseas Chinese Tourist Service is located in the inner city; its main function is to take care of overseas Chinese who are touring China, and it has more than 40 branch offices throughout the country.

Banking institutions

China has a nationwide and centralized system of banking, in which The People's Bank of China, a state-owned institution, plays a key role. This bank, with its head office in the inner city, functions as the agent of the national treasury. All funds of state-owned industrial enterprises, as well as of national, provincial, and local governments, the People's Liberation Army, and the network of cooperatives, are deposited with the People's Bank. The bank centralizes the financial resources of the government and the major sectors of China's economy. It uses the working capital at its disposal for the operations of the economy and the government. The People's Bank thus acts as cashier of the national budget and of a large part of the nation's financial operations. Through its branch offices and savings account centres, the bank also serves the daily needs of people in the city and in the suburbs. Working in cooperation with the People's Bank and under its supervision are two other older banking institutions—the Bank of Communications, which has the task of financing and supervising all basic construction projects, such as new railways, and the Bank of China, which specializes in international trade and foreign exchange.

The urban economy. Although Peking has been the capital of China for hundreds of years, it is far distant from the nation's traditional key economic area, the productive Yangtze Valley. The task of feeding the large urban population in Peking—not an easy one—was facilitated by the opening and maintaining of the Grand Canal and by the use of sea transport for importing grain from the south. Since the first decade of the 20th century, railways have played an important role in bringing food supplies to the capital; with the completion of additional

trunk lines since 1949, Peking, as mentioned, has become a major railway centre. Today, food grains and industrial raw materials from almost every corner of the nation can easily be shipped to Peking. The city, however, has striven for a high degree of self-sufficiency in secondary food supplies, such as vegetables, fruits, fish, and poultry, and in a number of construction materials. The expansion of municipal boundaries in 1958 and 1959 was partially aimed at this goal, and in the early 1970s the municipality was succeeding in maintaining an adequate supply of vegetables and fruits.

Vegetables are grown by the people's communes in a six-mile-wide belt, totalling more than 35,000 acres of land, that encircles the city and is covered by a network of irrigation channels. Some 600 miles of power lines provide power for the several thousand electric pumps that have made intensive farming possible. Hothouses, where vegetables are grown in the winter months, have 17,000 compartments, each occupying an average area of 130 square feet. This large farm belt is also one of the most highly mechanized agricultural areas in China.

In the 1950s and 1960s, many state farms near Peking have converted some of the hill slopes to the west of the city into large orchards, some of which are 1,700 acres in area. Several communes have also reclaimed large areas of wasteland to the north and east of the city for fruit tree planting. At present, the city's fruit-growing region ranges from the Great Wall in the north to the Grand Canal in the south and from the Yen Shan in the northeast to the Yung-ting Ho (Yung-ting River) in the southwest. While the hill areas produce large quantities of pears, persimmons, apples, chestnuts, and walnuts, the newly reclaimed lowlands are covered with vineyards and peach orchards. There are six state farms for fruit growing within the metropolitan area; of these, the Nan-kou State Farm, north of the city, is the largest. With more than 40 varieties of fruit grown in the metropolitan area, the ripening season lasts from early May to September. Most of Peking's fruit is channelled to the retail market through two distribution centres. Some of the fruit grown around Peking is sent to canneries, and some is put into cold storage; large quantities of "Aromatic Rose" grapes are sent to the Peking winery. Part of the Peking fruit crop is shipped by train to the cities of the Northeast and Inner Mongolia.

The business districts. Because of the symmetrical layout of the city, Peking lacks the compact central business district that characterizes most cities in the Western world. Historically, the market areas of the city were situated at two street intersections to the southwest and southeast of the centrally located Imperial Palace, and today the Tung Tan and Hsi Tan districts are still major shopping centres. Since 1949, however, a number of multistory department stores have been erected along Wang-fu-ching Avenue and at Hsi Tan, supplying a wide variety of goods for daily needs. The China Department Store, a state-owned enterprise, is the largest department store in China and has branch stores in major cities throughout the country. The International Friends (Quaker) Service Center serves foreign visitors and specializes in high-quality clothes, souvenirs, and gifts. In addition to these modern establishments, there are a dozen traditional bazaars that still serve an important local function. The Peking bazaars have evolved through a long period of history, and each has developed its own reputation for special commodities and services.

Shopping facilities

The Tung Tan Bazaar, located on the busy Wang-fu-ching Avenue, is the largest bazaar in the city. It includes about 30 different trades, which are carried on in more than 600 separate stalls. The bazaar is famous for the traditional handicrafts produced in the city, such as ivory, jade, and stone carvings, antiques and curios, lacquer ware, necklaces, cloisonné (a kind of enamel work) and porcelain, gauze lanterns, Peking sweets (dried and sugared fruits, such as sugared dates, sugared lotus, and sugared apples), and preserved fruits. The bazaar contains a number of restaurants and cafés serving a variety of Chinese regional foods.

The Liu-li-chang Bazaar is located just outside the city gate of Ho P'ing in the outer city. Because colourful glazed tiles were made here in the Ming dynasty, the area acquired its present name (which means "the glazier's shop"), but during the later part of the 18th century it gradually became a market for curios, antiques, old books, paintings, works of ancient Chinese calligraphers, and paper. It is still the centre for traditional art shops. The Ch'ien-men Administrative Department of the Peking Handicrafts Company has set up a workshop there that makes reproductions of traditional Chinese paintings, ancient bronze and iron vessels and statuettes, pottery and porcelain ware, and stone and wood carvings.

Inside the city gate of Yung Ting and near the T'ien T'an is the T'ien-ch'iao Bazaar. As early as the 16th century, poor people of the city began to come to T'ien-ch'iao to buy and sell secondhand goods. Open-air markets were also held here in the evenings. After 1900, when the railway station in the southern suburbs was moved to the vicinity of the T'ien T'an, peddlers and small traders, folk artists, storytellers, and musicians began to appear in large numbers, and the place became a bustling market for fish, poultry, fruit, and vegetables, as well as a recreational area for poor people. This bazaar has some of the best food shops in the city and remains a folk-entertainment centre for the metropolis.

Paolo Koch—Rapho Guillumette

Stalls in Peking's main market.

The Hsi Tan Bazaar, established in 1932 around Hsi-tan-pei-ta Street in the western section of the city, is one of the most diverse markets in the city. The bazaar is composed of five different sections, each offering special commodities or services. The commodities include sports equipment, musical instruments, books, magazines, food supplies, hardware, and electric appliances; there is also a complete department store, as well as a number of recreational establishments.

Political and governmental institutions. As the national capital, Peking houses the most important political institutions in the nation. These include the National People's Congress, the supreme organ of state power, and the State Council, the highest executive organ of the state, which carries out the decisions of the congress. The State Council has under its jurisdiction administrative depart-

The State Council

ments, the number of which varies according to the needs of the work. They include the ministries and commissions in charge of foreign affairs, internal affairs, public security, national defense, justice, finance, culture, health, education, nationality affairs (concerning minority groups in the country), agriculture, and various branches in industry.

In addition to the above, there are some organs of state concerned with the maintenance of law and order—the People's Courts and the People's Procuratorate, both of which are located in Peking.

Peking is one of the three independent municipalities in China (the others being Shanghai and Tientsin), and there is no governmental tier between it and the central government. Peking is divided administratively into eight municipal districts in the centre and nine annexed counties in the peripheral areas. The highest organ of the municipal administration is the People's Congress of Peking Municipality. The representatives for the congress, numbering 564, are elected among groups of workers, peasants, teachers, merchants, office workers, the armed forces, public institutions, and religious circles. The congress elects the members of the Peking People's Council, the executive organ of the municipal government, including the mayor and deputy mayors. It ensures that the municipal government carries out the decisions and resolutions of the congress, discusses and approves the budget and financial statements submitted by the municipal government, and examines the report on the administrative work of the municipality. The composition of the congress in 1955 is shown in Table 2.

Table 2: Composition of the People's Congress of Peking Municipality

groups	number of deputies
Workers	168
Employees in the education and cultural fields	136
Government employees	65
Industrialists and businessmen	43
Democratic parties	30
Peasants	27
Medical and health workers	26
Engineers and technicians	26
Co-op employees	12
Dependents of veterans	12
Armed forces stationed in Peking	10
Religious groups	9
Total	564

The congress included a percentage of women, minority groups, and model workers elected by various industrial plants.

The Peking People's Council in 1955 consisted of 47 members, including the mayor and his deputy mayors. They control 47 administrative units that cover all fields of life in the city—health and sanitation, public security, education, employment, industry, etc. As a subdivision of the municipality, each district or township has its own people's council. Below the urban district are a number of street offices of the district people's council. Below street offices are residents' committees, which are self-governing welfare organizations established on a neighbourhood basis. The residents cooperate on matters of common interest, such as problems of local hygiene, culture and recreation, sports, studies in current events, and literary classes. The residents' committee is also in charge of the neighbourhood's population census, vital statistics, population movements, children's nurseries, and street beautification.

Public utilities. Peking is not on a river, and all water for municipal consumption has to be brought from elsewhere. Some water, however, comes from shallow wells, which are common throughout much of the region. These provide some villages with drinking water and supply water for irrigation.

Water supplies

From the earliest history of the city, use has been made of the rivers and springs in the neighbourhood. To the east is the Pai Ho, which, after being joined by the Sha Ho, turns southward. The tumultuous Yung-ting Ho is a large river, draining the Shansi Plateau and the northwest of Hopeh. After following a twisting course through the mountains, it reaches the Peking plain, passes under the Marco Polo Bridge, nine miles southwest of Peking, and then turns southward to meet the Pai Ho north of Tientsin. The flow of the Yung-ting Ho is irregular; in the rainy season it rises rapidly, carrying with it large quantities of silt, which raise the level of the riverbed considerably. At Marco Polo Bridge it is 50 feet above the level of the city, thus constituting a hazard when the river is in flood but facilitating canalization and irrigation. Several springs rise at the foot of Hsiang Shan (Fragrant Hills) and on the Yü-ch'üan Shan (Jade Fountain Hill), both to the northeast of the city. During the Manchu dynasty these springs were tapped by means of an aqueduct that conveyed water for the city moat and for the three lakes near the Imperial Palaces. The moat around the city walls became an important means of water distribution for the municipality.

In the early 1950s, large-scale water-conservancy projects were begun to provide more water for the expanding urban area. Two large artificial lakes have since been made: the Mi-yün Reservoir, northeast of the city, and the Kuan-t'ing Reservoir, in the northwestern mountains beyond the Great Wall. These regulate the flow of the Pai Ho and of the Yung-ting Ho upstream, storing water at times of heavy discharge and releasing it when the rivers are low. Two lesser projects have also been carried out: the construction of the Ming Tombs Reservoir, whose waters feed a hydroelectric power station and irrigate the neighbouring countryside, and a hydroelectric power station near Mo-shih-k'ou, which uses the waters of the Yung-ting Ho and feeds them back into the river through an ancient canal. The hydroelectric station at Kuan-t'ing, which has been generating electricity since 1956, is the largest source of electricity for the metropolitan area of Peking.

The Peking Water Company, which was originally formed in 1908, is responsible for supplying water for the municipality. Water is obtained from the old waterworks within the walled city, as well as from several waterworks in the suburbs; altogether, the network of mains and pipes totals nearly 1,250 miles in length and extends to every newly built residential and industrial unit, including towns and villages near the Men-t'ou-kou coal mine about seven miles from the city. Public standpipes have also been installed at regular intervals throughout the city, the suburbs, and nearby rural people's communes. The Kuan-t'ing Reservoir, the largest man-made lake in the North China Plain, supplies the metropolitan area of Peking with most of its water.

Peking is one of the few cities in China equipped with a modern sewage system. An underground sewage system was installed as early as the 15th century, when nearly 195 miles of sewage network were constructed. Later this network became clogged with effluent and silt. A new sewage system was installed in the early 1950s, which, within the walled area, was partly based on the rehabilitation of the old system. All open sewers, characteristic of many Chinese cities, were eliminated, and nearly 600 miles of new pipes were laid throughout the densely populated areas of the municipality.

The headquarters of the Peking General Post Office is located on Kung-an Street, on the east side of T'ien An Men Square. It provides more comprehensive services than the post office in any Western city, handling mail, telegrams, long-distance telephone calls, and the distribution of newspapers and magazines. There are also more than 350 branch offices and stations in the city and the suburbs. The Peking General Post Office has also set up several service centres at certain busy traffic points, such as Hsi Ch'ang-an Avenue, Ch'ien Men, Peking Railway Station, T'ien An Men, Hsi-chi, and Wang-fu-ching. The service centre at Wang-fu-ching takes subscriptions to foreign newspapers and magazines and sells single issues.

The Peking Telegraph Office is housed in the Telegraph Building on Hsi Ch'ang-an Avenue. It is open day and night for domestic and international telegrams and for

long-distance telephone calls. International telegrams can be sent to all countries throughout the world in four languages: Chinese (in Chinese standard code, in which each character is represented by four numerals), Russian (in Roman alphabet), English, and French; telegrams may also be sent in any other language agreed upon by the countries to which the telegrams are sent, provided they are written in the Roman alphabet and notice is given of the language to be used.

The telephone system

Telephones first appeared in Peking in 1900, when a small exchange was established by a foreigner. In the subsequent 50 years, more than 20,000 telephones were installed. In the 1950s the Peking Telephone Administration increased its 21 exchanges to 29, and nearly all telephones in the city became automatic. Seven of the new exchanges were installed in suburbs, serving outlying districts that have experienced rapid industrial and agricultural development. In the 1960s the original five-digit dialing system was changed to one of six digits, thus increasing the city's telephone capacity from 100,000 to 1,000,000 instruments. Public telephones are located in shops in busy streets. As a great number of households in Peking cannot be reached by phone, a neighbourhood messenger service is provided in many of these street service stations. The caller gives the name and address of the person he wants to reach, leaving his own number and the time he wants to be called with the attendant who delivers the message; attendants are usually elderly men or housewives.

Health. Chinese medical services employ two systems of medicine: traditional Chinese and Western. Peking possesses some of the best hospitals of both systems in the nation.

The Peking Union Hospital, the earliest modern hospital to be established in China, was founded in 1921 as an affiliate of the Peking Union Medical College, which from 1915 onward was supported by the China Medical Board of the Rockefeller Foundation. The hospital, now renamed Peking Hospital, is a large polyclinic combined with an institute of gynecology and pediatrics. It handles about 500,000 cases annually and is the largest hospital in Peking. Since 1949, more than 30 new hospitals, clinics, and sanitariums, together covering more than 10,000,000 square feet of floor space, have been built, and there are more than 25,000 beds available in the inner districts of the metropolitan area. Among the newly established hospitals is the Friendship Hospital, located at T'ien-ch'iao in the outer city, a gift made by the Soviet people at the time of the peak of Sino-Soviet friendship in the 1950s. Until 1960, the Soviet staff not only treated patients but also gave advanced training to Chinese medical personnel according to the latest Soviet methods.

Many hospitals are clinical teaching hospitals attached to medical schools; these include the Fu Wai Hospital of the Chinese Academy of Medical Science, located outside the city gate of Fu Ch'eng; the First Affiliated Hospital of the Peking Medical College, near the city gate of Hsi An; the Affiliated Hospital of the Research Institute of Chinese Medicine, located in the western suburban town of Hsiao-yüan; and the Affiliated Hospital of the Peking Chinese Medical College, situated on Nanhsiao Street. The largest children's hospital in China, the new Peking Children's Hospital, is situated just outside the city gate of Fu Hsing. It has 600 beds and was designed to provide a homelike atmosphere for the sick child. In the hills to the west, a sanitarium in the traditional Chinese architectural style has been built for students from Asian countries; it has accommodations for up to 300 students. The most specialized hospitals are located in the old residential districts of the city and include the Stomatological Hospital (dealing with the mouth and related diseases), the Chest Surgery Hospital, the Hospital of Plastic Surgery, the old Peking Children's Hospital, the Peking Municipal Hospital of Chinese Medicine, and the Ji-sui-tan Hospital, which specializes in traumatic (accident-related) and orthopedic surgery.

Traditional medicine

Chinese traditional medicine comprises the prescription of Chinese herb drugs and the practice of acupuncture (a medical practice encompassing therapeutics and anesthesia that involves puncturing various parts of the body with needles). Doctors in both Chinese and Western systems are trained in many universities and institutes in Peking. Students in the Western-style medical schools are taught the essentials of Chinese traditional medicine, and Chinese traditional medical students are expected to be familiar with the essentials of Western medicine. Diagnoses of difficult cases are made only after consultations with specialists of both systems.

For the rural areas of the metropolis, each county has a well-equipped county hospital located in the county seat. But the basic unit of the medical service is the health centre in the commune, which is equipped with complete clinical facilities. Medical teams of doctors, nurses, and public health personnel are sent frequently from the teaching centres in the city to the communes to assist in the general medical work and to keep the local medical staff in touch with the latest medical progress and techniques.

Education. There has been no radical change in the school system in Peking since 1949. The school system is still largely composed of six years of primary education, which is quite universal, and six years of secondary education. For preschool-age children, kindergartens and nurseries are operated by factories, business enterprises, government offices, and city block cooperatives. Their main function is to permit the mother to work so that, while some of these facilities are located in the residential neighbourhoods, many are located on the premises of particular institutions of employment. In the suburban or rural areas, kindergartens are often temporarily set up during such events as the harvest; small fees are charged that help to offset the cost of meals provided.

The schools

In the early years of the present regime, efforts were made to abolish private schools and to put all education in the hands of the state. As a result, all private schools run by missionaries were taken over by the government. It was soon realized, however, that the government could not possibly provide enough schools for the millions who demanded education. The government then reversed its policy to some degree and decided to encourage the establishment of schools by local organizations, such as factories, business concerns, collectives, and communes. In the early 1970s a major part of the finance for elementary education was met by sources other than the central government, though government subsidies to schools in difficult financial situations were also considerable.

The curriculum in the primary school is simple. The early part of primary education is largely devoted to reading, writing, and mathematics, and in the last two years of the primary school, nature study, history, geography, and physical education are added to the curriculum. Closely related to primary education are movements for the liquidation of illiteracy, the phoneticization of the Chinese writing, and simplification of Chinese characters.

The secondary schools in Peking are mainly of three types: the general middle school, the normal school, and the vocational and technical school. The general middle school is of the academic type, with a curriculum designed to prepare students for college. The normal school is to train teachers for primary schools. The vocational and technical schools, created to provide skilled workers in various fields, have developed most rapidly in the city and in the early 1970s were beginning to overtake the general middle schools in number.

Institutions of higher education

Peking's position as a centre of higher education in China has been further strengthened since 1949, and within the metropolitan area in the early 1970s there were more than 20 institutes of higher learning. A scientific and educational district has emerged in the northwestern outskirts of the city, against the background of the K'un-ming Hu (K'un-ming Lake), the Summer Palace, and the Western Hills. This area contains such prestigious institutes of higher education as Peking Univerity and Ch'ing-hua University. Founded in 1898, Peking University is one of the largest composite universities in China. The university has a faculty of 2,000 and

May Day rally in T'ien An Men Square, Peking.
Der Stern—Black Star

an enrollment of more than 10,000 students, including some 300 foreign students from 30 different countries. In 1953 the university moved from its old site at Sha-t'an, in the inner city, to the present campus, which previously belonged to the missionary-established Yen-ch'ing University. The new campus has been expanded considerably to the east and south. Ch'ing-hua University has an enrollment of 6,000, with 45 percent of the students being selected from among workers in various factories throughout the country, 40 percent from communes, and 15 percent from the People's Liberation Army.

Within the academic district are also found the People's University of China, an institute of ideological training, and the Central Institute of Nationalities which accepts students from the various autonomous regions and districts. Situated in the same area are the Peking Normal College, the Peking Medical College, and the Central Conservatory of Music. Numerous institutes of higher education are also located in this area; these include the Peking Institute of Steel and Iron, the Peking Institute of Aeronautical Engineering, the Peking Petroleum Institute, the Peking Institute of Geological Prospecting, the Peking Institute of Forestry, and the Peking Mechanical Institute of Agriculture. The Chinese Academy of Sciences, the highest research institute in the nation, is also located in this district.

Foreign-language institutions

Besides technical colleges, there are a number of foreign-language institutions in Peking where foreigners are employed to teach alongside their Chinese colleagues. The First Foreign Language Institute is the largest institute of its kind in China and has an enrollment of 2,000. The Second Foreign Language Institute was set up in 1964 for training personnel for the New China News Agency. There are also a number of small institutes of language training, run by the Ministries of Foreign Affairs and Foreign Trade and by the Peking Radio Station. The Peking Institute of Foreign Languages is an institute at the secondary level, which accepts children as young as eight years of age and enrolls about 1,000 students; 500 of them learn English, while others study French, German, Spanish, Arabic, Russian, and Japanese.

Cultural life. As the cultural focus of China for several centuries, Peking possesses what are probably the finest cultural institutions in the nation, including libraries, museums, and theatres.

To the east of T'ien An Men Square within the People's Cultural Park is found the Working People's Palace of Culture (formerly the Temple of the Imperial Ancestors), where the tablets of the emperors were displayed. The temple, like the T'ai Ho Tien (Hall of Supreme Harmony) and the Imperial Palaces in style, was built in three stone-work tiers, each with double eaves. On either side are two rows of verandas surrounding a vast courtyard large enough to hold 10,000 people. Exhibitions of economic and cultural achievements, both of China and of foreign countries, are frequently held in the three halls. Each exhibition lasts several weeks and draws hundreds of thousands of visitors. Lectures by leading scholars on science, literature, and the arts are frequently held there, and reports are presented by nationally known heroes of labour. There is also an art school for adults in the park; it has five departments—for literature, drama, music, fine arts, and dance. The park also serves as the home of amateur art groups, who specialize in dancing, orchestral music, or choral singing. Persons who are found to have particular artistic talent may be sent from here to a specialized school for further study. In the northeast corner is a sports ground that can accommodate more than 4,000 spectators. In a grove in the southeast corner is a large open space for dancing.

The Palace Museum

The Imperial Palace Museum is housed in the main buildings of the former Imperial Palaces. Many of the halls are kept as they were in dynastic times, each constituting a museum in itself; others are kept for the display

of some of the priceless treasures from China's past. The Imperial Palaces, with their golden roofs, white marble balustrades, and red pillars, stand in the heart of Peking and are surrounded by a moat and walls with a tower on each of the four corners.

The palaces consist of outer throne halls and an inner court. North of the three tunnel gates that form the front gate, called the Wu Men (Meridian Gate), a great courtyard lies beyond five marble bridges. Further north is a massive double-tiered hall, the T'ai Ho Tien (Hall of Supreme Harmony), once the throne hall. A marble terrace rises above the marble balustrades that surround it, upon which stand beautiful, ancient bronzes in the shapes of cauldrons, cranes, turtles, compasses, and ancient measuring instruments. The T'ai Ho Tien is the largest wooden structure in China.

Behind it, beyond another courtyard, is the Chung Ho Tien (Hall of Complete Harmony), where the emperor paused to rest before going into the throne hall (the Hall of Supreme Harmony). Beyond the Chung Ho Tien is the last hall, the Pao Ho Tien (Hall of Preserving Harmony), after which comes the Nei T'ing (Inner Court). The Inner Court was used as the emperor's personal apartment. It contains three large halls, the Ch'ien Ch'ing Kung (Palace of Heavenly Purity), the Chiao T'ai Tien (Palace of Heavenly and Earthly Intercourse), and the K'un Ning Kung (Palace of Earthly Tranquillity).

The Ch'ien Ch'ing Kung is divided into three parts. The central part was used for family feasts and family audiences, audiences for foreign envoys, and funeral services; the eastern section was used for mourning rites and the west section for business of state. The other two palaces, one behind the other, were Imperial family residences. The three throne halls in the Outer Court and the three main halls in the Inner Court lie along the central axis. On either side are smaller palaces, with their own courtyards and auxiliary buildings. Behind the buildings, before the north gate of the Imperial Palaces is reached, lies the Imperial Garden. Each palace, its courtyard and side halls, forms an architectural whole.

The Museum of Chinese History and the Revolution, located on the eastern side of T'ien An Men Square, is a new museum completed in 1960. There are more than 8,000 antiquities on display, of which the greater part have been excavated only during recent years. These are arranged to give a comprehensive survey of the progress of human achievement in China, beginning with the appearance of the prehistoric Peking man some 500,000 years ago, then continuing through the last 6,000 years of Chinese history. The exhibition has three main sections, devoted to primitive society, slave society, and feudal society.

The Museum of the Chinese Revolution occupies the left wing of the museum building on the eastern side of T'ien An Men Square. Its aim is to trace the history of China since the middle of the 19th century, laying particular stress on the revolutionary movement and the part played by the Communist Party.

The Peking Planetarium, the first of its kind in China, is located outside one of the city's western gates. Completed in 1957, it is an educational centre for the dissemination of general knowledge in astronomy and natural science by means of exhibitions, forums, films, projector demonstrations, and telescopic observations of the heavens. The planetarium proper, the "Theatre of Heavens," is situated on the south side of the building and has a seating capacity of 600. Behind the main building stand an observatory and meteorological station.

The Peking Library

The Peking Library, with a collection of 7,000,000 volumes, is the largest public library in China and is located on the west bank of Pei Hai. The library has inherited books and archives from the Imperial Wen Yüan Ko library, a famous collection that has existed for more than 500 years and that, in turn, included books and manuscripts from the Imperial Library of the Southern Sung dynasty, established some 700 years ago. It also includes other collections from Imperial libraries of the Manchu dynasty, Imperial colleges, and private owners. Among them are rare copies of ancient manuscripts and books of five dynastic periods from the Sung to the Ch'ing, including 140,000 manuscript volumes on 18,000 different subjects, 8,700 copies of Buddhist sutras going back to the 6th century, old maps, diagrams, and 25,000 rubbings from ancient inscriptions on metal and stone; it also possesses the *Yung-lo ta-tien* ("Yung-lo Encyclopedia") of the Ming dynasty and a copy of the *Ssu-ku ch'üan-shu* (from the Imperial Library of Ch'ien-lung), dating from the Manchu dynasty.

The media. Peking is the chief publishing centre for newspapers, periodicals, and books in China. Almost all publishing enterprises are owned by the government. New China News Agency in Peking is the chief provider of news releases in English. There are almost 250 periodicals with national circulations published in Peking. Several foreign-language magazines, including *People's China, China Pictorial, China Reconstructs, Chinese Literature,* and *Women of China,* are also published in the capital. More than 20 national newspapers are published there. "People's Daily" (*Jen-min jih-pao*), the official organ of the Central Committee of the Chinese Communist Party, is the most influential paper in the country and reflects the ideology and policies of the party in both foreign and domestic affairs. *Kuang-ming jih-pao,* jointly published by the various minor democratic parties, the All-China Federation of Industry and Commerce, and nonparty members of the Chinese People's Political Consultative Conferences, gives special attention to culture, education, science, politics, law, and the life of the national minorities. *Ta-kung pao* emphasizes news and commentaries on commerce, finance, and international affairs. "Worker's Daily" is the official organ of the All-China Federation of Trade Unions. "China Youth News," the official organ of the Central Committee of the Communist Youth League of China, is a political and educational media for teen-agers. "Chinese Children" is an official paper for the Chinese Young Pioneers, published also by the Central Committee of the Communist Youth League of China.

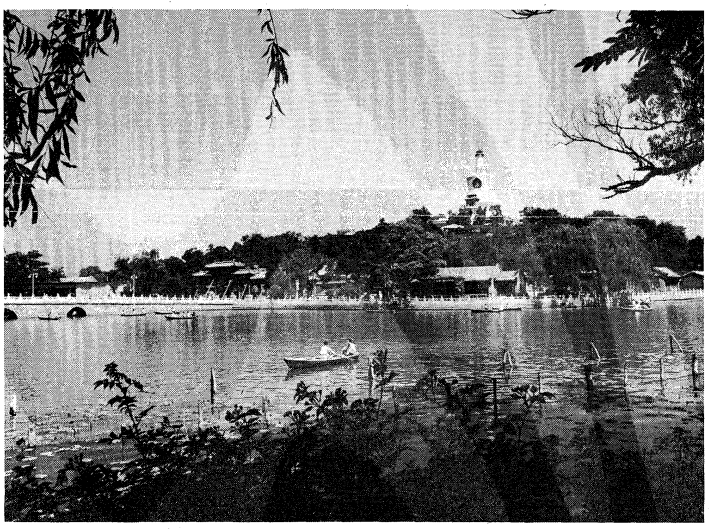
There are more than 40 publishing houses in Peking. The largest is the People's Publishing House; others deal in specialized fields, such as literature, fine arts, science, and national minorities. The Foreign Language Press is responsible for introducing China and the Chinese people to the world through books, pamphlets, pictorials, and translations of literary works; most are in English.

The most important radio station in China, the Central Chinese Broadcasting Station, is also located in Peking. Using more than a dozen different frequencies and broadcasting three sets of programs simultaneously, the central station is on the air for more than 47 hours a day. Three sets of programs are coordinated and supplement each other; the first gives news and news commentaries, while the second and third broadcast different literary or artistic items. Programs reach the city's population not only through radios but also through loudspeakers and radio-listening centres that are installed in almost every public gathering place, including railroad stations, public dining halls, playgrounds, and parks.

Television services

The first television station in Peking was established in 1959 by the Peking Broadcasting System. The city's television programming was still on a rather limited scale in the early 1970s, as the number of sets was not very large. Most television sets were for public use and are found in parks with benches provided for viewers, as well as in railroad stations, hotels, and other public places. Daily television programs include those devoted to popular science, sports, opera and theater, and the entertainment of children. The Peking Television College, offering preparatory courses in mathematics, physics, chemistry, and other subjects, was instituted in 1960 under the joint auspices of the city department of education, the Peking Broadcasting System, and three universities in the area. Students of the television college, numbering several thousands, are scattered in more than 800 institutions and organizations throughout the city; most of them work in factories, mines, and research organizations or are teachers in primary and secondary schools. In every district of the city the college also set up an advisory centre where students may go for additional tutoring.

Recreation. As the residence of the Imperial families through several dynastic periods, Peking is well-known for its numerous parks and playgrounds; few cities in China have as large a proportion of land within the city walls allocated for recreational uses. Among the most popular of Peking's parks are Chung Shan Park, Pei Hai Park, Coal Hill Park (Mei Shan Park), the Summer Palace, and the Peking Zoological Gardens.



Chung Shan Park adjoins the west wall of T'ien An Men; it is the most centrally located park in Peking and encloses the former Altar of Earth and Harvests, where the emperors made offerings to the gods of Earth and agriculture. The Altar of Earth and Harvests consists of a square terrace in the centre of the park, to the north of which is the 550-year-old Hall of Worship, now the Sun Yat-sen Memorial Hall, which is used for public meetings. The Hall of Worship is the oldest wooden structure in Peking; its simple form, masterly design, and sturdy woodwork bear the characteristic marks of early Ming architecture.

The Water Pavilion, built out over a lotus pond on three sides to provide a gathering place for scholars and poets, is also located in the park. Scattered among the park's pools, goldfish enclosures, rocky hills, weeping willows, pines, cypresses, bamboos, and flowers are pavilions, kiosks, and towers, which are typical of Chinese garden landscape.

Pei Hai Park

Pei Hai Park lies to the northwest of the Forbidden City. It covers some 176 acres, half of which is water. It contains the most northerly of the three lakes that lie roughly north and south within the Imperial City. Pleasure grounds, lakes, and buildings have existed on this site for 800 years. As the lakes were deepened and dredged, the excavated earth was used to build hillocks and islands of great beauty. In 1651, a Manchu emperor built the White Pagoda, the most striking landmark in the park, on the top of a hill. Many of the buildings in the park are used for serious pursuits, as well as recreation. They include an Institute of Research on the History of Chinese Classical Literature and a Natural History Museum, as well as a branch of the National Library. The lake in Pei Hai Park is crowded with rowboats in summer and freezes over to become a natural skating rink in winter.

Paolo Koch—Rapho Guillumette

Pei Hai Park in central Peking. In the background is the White Pagoda, which dates from the Yüan dynasty.

Coal Hill Park, also known as Mei Shan Park, is a man-made hill, more than a mile in circumference, located north of the Forbidden City. The hill, from the top of which a spectacular panorama of Peking can be seen, has five ridges, with a pavilion on each. The hill was the scene of a historical tragedy when, in 1644, at the end of the Ming dynasty, the defeated Ming emperor hanged himself on a locust tree on its east slope; the tree is still standing and may be seen there to this day, located amid ancient pines and cypresses. In the northern part of Coal Hill Park is Peking Children's Palace, with recreational, athletic, and educational facilities.

The Summer Palace

The Summer Palace, lying close to the Western Hills, is about six miles northwest of Hsi Chih Men, the nearest city gate. It is the largest park on the outskirts of Peking and is famous for its artificial landscaping, which provides an inimitable blend of woods, water, hills, and architecture. The Summer Palace covers more than 800 acres, four-fifths of which consists of lake, the remainder being man-made hillocks. More than 100 buildings—halls, towers, pavilions, bridges, and pagodas—lie scattered throughout the park; a marble boat, two stories high and some 80 feet long, located at the northwest corner of the lake, is one of its attractions. Connecting the buildings and courts along the shore of the lake are a series of richly painted covered promenades.

Peking Zoological Gardens is located on the western outskirts of the city, covering an area of 175 acres. The zoo was established toward the end of the 19th century and was named the Garden of Ten Thousand Animals. It is the largest zoo in the country with more than 3,000 animals from all parts of China and the world residing in captivity there.

Peking Workers' Gymnasium, which seats 15,000, is the largest and most complete athletic facility in China. Higher than a conventional eight-story building, it presents a facade of wide, gleaming windows set in light-green walls. Spectators may enter through gates on three of its sides, the north, east, and west sides; the south side is rimmed with practice rooms. The facility is used for basketball, volleyball, badminton, table tennis, gymnastics, fencing, weight lifting, as well as other sports. It is also used for large concerts and mass acrobatic performances.

For outdoor sports, the park located on the bank of the Shih Ch'a Hai (Lake of Ten Monasteries) is the largest open field in Peking. The park includes four indoor and outdoor swimming pools, a sunbathing ground, and an artificial lake for rowing.

The Peking Workers' Stadium, where soccer games and field and track events are held, is a large compound located to the east of the Imperial City, just outside the wall.

BIBLIOGRAPHY. HIKOTARO ANDO, *Peking* (1968), is the best illustrated recent description of the city by a foreigner. *Nagel's Encyclopaedia-Guide to China* (1968) includes a lengthy section on historical features and various localities of the metropolitan area. HU CHIA, *Peking, Today and Yesterday* (1956) and *Peking: A Tourist Guide* (1960), published by the official press in Peking, provide useful readings for visitors. The historical development of the city is covered both by NIGEL CAMERON and BRIAN BRAKE in *Peking: A Tale of Three Cities* (1965); and by E. BRETSCHNEIDER in *Die Pekinger Ebene und das benachbarte Gebirgsland* (1876; Eng. trans., *Archaeological and Historical Researches on Peking and Its Environs*, 1876). LIN YU-TANG, *Imperial Peking* (1961), deals with the cultural aspects of the city, with emphasis on arts and daily life in historical times. For a detailed account of architectural features of the walled city, see OSVALD SIREN, *The Walls and Gates of Peking* (1924) and *The Imperial Palaces of Peking* (1926). FRANK DORN, *The Forbidden City* (1970), vividly associates the details of the Imperial palaces with historical events. A number of important works on scenic and architectural aspects of the city were completed in the 1930s; among them are L.C. ARLINGTON and WILLIAM LEWISOHN, *In Search of Old Peking* (1935); and JULIET BREDON, *Peking: A Historical and Intimate Description of Its Chief Places of Interest*, 2nd ed. (1931). An account of living experience in the city in the 1930s is found in GEORGE N. KATES, *The Years That Were Fat* (1952). For a geographical analysis of the strategic location of the city, see SEN-DOU CHANG, "Peking: The Growing Metropolis of Communist China," *Geogrl. Rev.*, 55:313–327 (1965); GUSTAV STRATIL-SAUER, "Zur Stadtgeographie von Peking," *Petermanns geogr. Mitt.*, 103:180–189 (1959); and SIR REGINALD JOHNSON, "Peking," *Geogrl. Mag.*, 1:185–197 (1935). The urban growth and municipal development of the city in the past two decades are described in various articles that appeared in *China Reconstructs*, a monthly periodical published in Peking. *Carte Touristique de Pekin* (1957) is a coloured map of the city for Western visitors, and includes streets, scenic spots, bus lines, tramways, and the layout of the palaces and important parks.

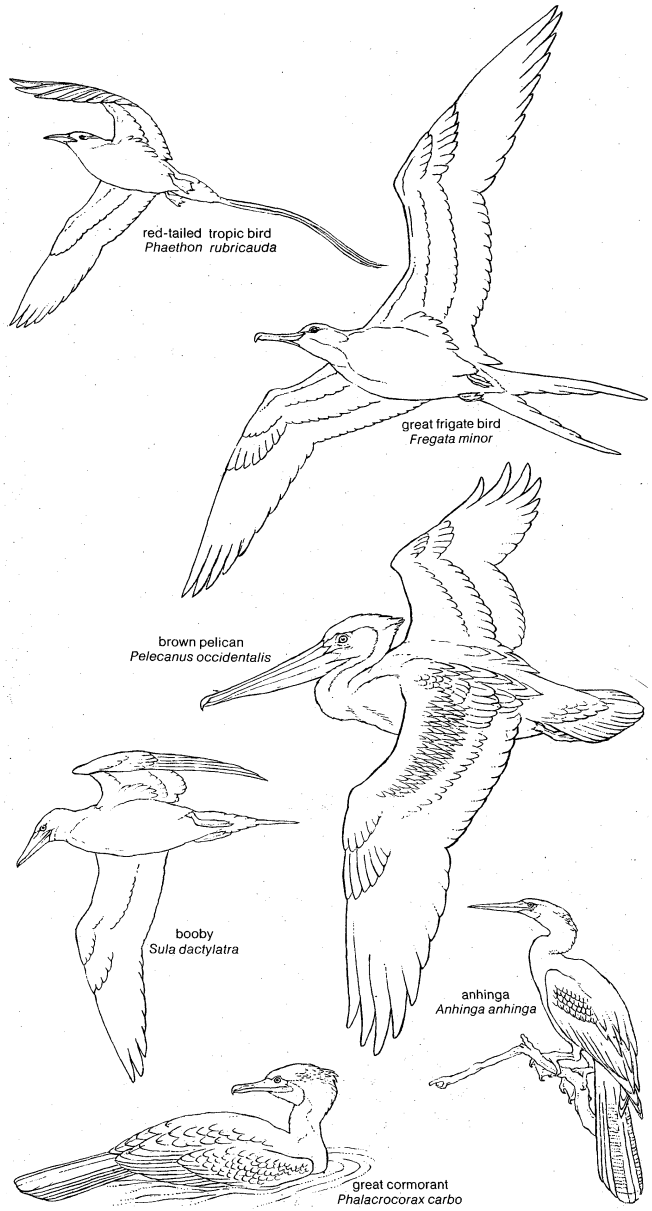
(S.-d.C.)

Pelecaniformes

The order Pelecaniformes comprises a number of diverse groups of aquatic birds that share the common characteristic of webbing between all four toes. There are three main groups (suborders): Phaethontes, the tropic birds; Fregatae, the frigate birds; and Pelecani, the pelicans, boobies (including the gannet), cormorants, and anhingas (or darters). All are relatively large birds: they range in length from about 40 centimetres or 16 inches (excluding the elongated central tail feathers) in the white-tailed tropic bird (*Phaethon lepturus*) to 1.8 metres (6 feet) in the Dalmatian pelican (*Pelecanus crispus*).

GENERAL FEATURES

In terms of their way of life, the pelecaniform birds fall into four adaptive groups: frigate birds—long-winged masters of piracy and aerial pursuit of surface-living marine prey; tropic birds and boobies—wide-ranging flyers that capture prey underwater by plunging from a height; pelicans—large, large-billed, long-necked, buoyant birds that fish mostly by reaching down while swimming at the surface; cormorants and anhingas—heavy-bodied, long-necked, underwater swimmers, respectively pursuing and lying in wait for their prey below the surface. The anhingas are largely confined to freshwater; pelicans and cormorants occur in both freshwater and marine habitats; and the other groups are entirely marine.



Production of guano as fertilizer

Importance to man. Most pelecaniform birds are of rather little significance to man, but the guano (excrement) of cormorants, boobies, and pelicans is an important fertilizer. Exploitation of old accumulations of guano reached its peak in the mid-19th century, and since then only the current production of guano has been available in most areas, but even this provides a substantial resource where the bird populations are large. There were an estimated 18,000,000 guano birds on the coast of Peru early in the 1960s. Of these, about 15,000,000 were guanay cormorants (*Phalacrocorax bougainvillii*), and the remainder were Peruvian boobies (*Sula variegata*) and brown pelicans (*Pelecanus occidentalis*). The harvest of guano at that time amounted to about 180,000 tons per year. The guano birds in the area feed largely on the Peruvian anchovy, and now that this fish is directly exploited on a large scale there is some competition between the birds and the fishing industry. In Southwest Africa artificial platforms have been constructed in coastal lagoons and on an offshore reef, greatly facilitating the collection of guano.

Pelicans, feeding on fish from inland and coastal waters, are among the animals whose diet tends to ensure that they will accumulate residues of insecticides (especially DDT) in their bodies. It recently has been found that among the physiological effects of these substances on birds are changes in calcium metabolism that result in their laying eggs with abnormally thin shells, or no shells at all, with the result that these eggs usually break before hatching. Effects of this kind have entirely prevented the successful reproduction of brown pelicans on the California coast during recent years, and some populations elsewhere are also showing adverse effects.

Distribution and abundance. Pelecaniform birds occur all over the world except in parts of the interior of North America, Africa, Asia, and Australia, in the high Arctic, and in most of Antarctica. Two groups, the tropic birds and frigate birds, are essentially confined to the tropics; the boobies, pelicans, and anhingas are widespread in the tropics but also penetrate far into the temperate zones; and cormorants breed from the Equator to the Arctic Circle and the Antarctic Peninsula.

The tropic birds are the most pelagic (free-flying over open ocean) of the pelecaniforms and can be seen even in the most unproductive central parts of tropical seas. Some boobies and frigate birds are found far out at sea, but most of them return to land to roost at night. Pelicans, cormorants, and anhingas do not venture far from land but may commute some distance between roosting or breeding places and their feeding grounds.

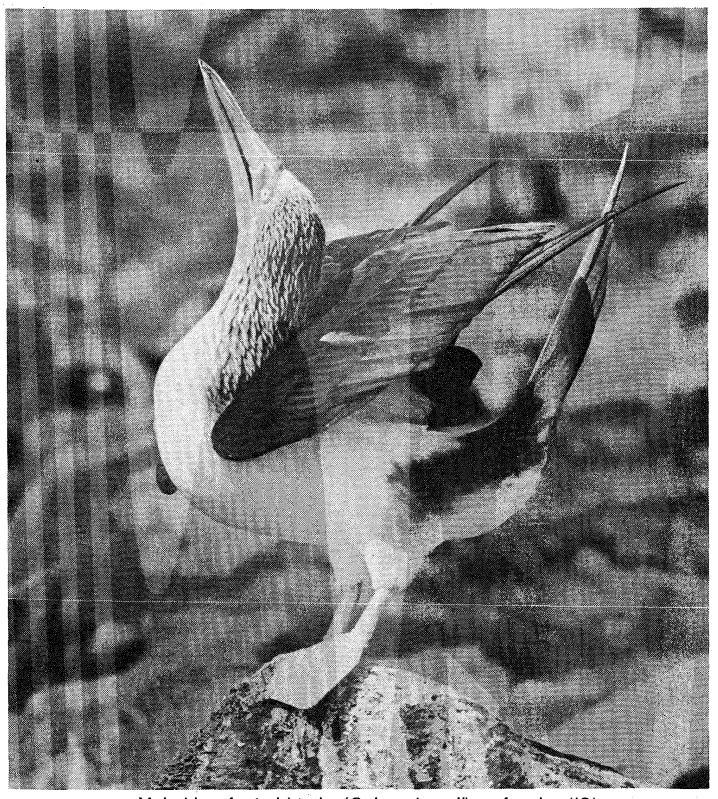
Representative Pelecaniformes.
Drawing by R. Keane

NATURAL HISTORY

Breeding grounds

Reproduction. The breeding of pelecaniform birds is essentially restricted to places free of mammalian predators. Tropic birds, boobies, and frigate birds typically breed on oceanic islands or on small islets and stacks off continental coasts. When man has introduced predators (such as cats) to isolated islands, pelecaniforms and other marine birds have often been eliminated from their traditional breeding grounds. On Ascension Island and St. Helena in the South Atlantic, for example, tropic birds, frigate birds, and boobies, which used to breed in large numbers on the main islands, have either been exterminated or driven to nesting on small offshore islets. Pelicans and cormorants are not normally found on islands far from continental land but breed on islands in lakes or offshore, or in other protected sites such as trees standing in water or cliffs. Anhingas breed in trees or bushes close to the sheltered waters where they feed.

Pelecaniform breeding, whether on the ground or in trees, is typically colonial, apparently because of the scarcity of safe places. If they are to breed at all, all the birds of an area must crowd into the available space. In practice, most colonies have a fairly definite upper limit of density determined by the distance that an incubating



bird can reach out to repel intruders. Nests of the gannet (*Morus bassanus*) have an average density of about one per square metre; those of the guanay cormorant average about 3.5 per square metre.

In some species, colonial breeding has become obligatory, and single pairs or small groups do not breed successfully. Other species breed colonially only where there is a shortage of space for nesting. The masked booby (*Sula dactylatra*), for example, breeds in dense colonies on islets off Ascension Island but in dispersed patterns on Christmas Island (Pacific). Breeding in a number of species is normally dispersed; the red-footed cormorant (*Phalacrocorax gaimardi*) of South America, for instance, often nests on cliffs where only scattered sites are available. Similarly, tropic birds nest in holes or crevices in cliffs or under the shelter of rocks or bushes. The sites are thus normally well dispersed, and in some places there is intense competition for them.

Pair formation displays

Courtship behaviour. During courtship (except in tropic birds) the male typically selects a nest site and then displays from this site to passing females. In the male advertising display of boobies ("Sky-pointing") and of cormorants and anhingas ("Wing-waving"), the head and tail are raised and the wings partially raised. The boobies have species-specific positions of the wings and tail; the cormorants and anhingas wave either their wing tips or their whole wings, to a varying degree. In many species a particular call is associated with the display. In the "Rattling" display of frigate birds, the male leans back on his tail, extends his wings along the ground, and with his bill pointing vertically throbs his inflated scarlet throat (gular) sac, vibrates his wings, and claps his bill.

Eric Hosking

Male blue-footed booby (*Sula nebouxii*) performing "Sky-pointing," a display effected in pair formation.

In most pelecaniforms, when a female has finally joined a male at the nest site, he may go and fetch nest material, which is then added to the nest structure by the female, alone or with the assistance of the male. There is no courtship feeding in the pelecaniforms, but in tropic birds there are a few records of one adult feeding the other during incubation. Copulation normally occurs on the nest site, without any special precopulatory or postcopulatory displays. The pair-bond, once established, is reinforced by such activities as joint nest building and defense, and preening of one bird by the other. Certain displays functioning in individual recognition are performed in the air or on the ground when one of a pair returns to the nest and also occur during the "handling" of nest material, which continues during incubation. The boobies have a "Head-wagging" recognition display; the cormorants and anhingas have a comparable "Kink-throat" display; similarly, the frigate birds use a "Rattling" display.

In tropic birds, which do not normally have nest sites in the open, courtship display is aerial. Birds fly around in a group, calling, then two individuals may leave the group and fly together, the upper bird depressing his tail (especially the long central feathers) during gliding or hovering; the flights often end with one or both birds flying into a nest cavity. Tropic birds do not collect nest material but probably sometimes enlarge nest cavities with their bills or feet.

In all or nearly all pelecaniform families, mating frequently occurs with the same partner in successive years, and in many populations the same nest site may be occupied repeatedly. Since most species nest colonially, fighting over nest sites is common. It is particularly intense in the gannet and in populations of tropic birds when nest sites are in short supply.

Breeding seasons. Outside the tropics, egg laying by pelicans, boobies, and cormorants occurs typically in the spring, and the laying period extends over one to three months. In the tropics there is greater diversity in both the timing and extent of the laying period. Although many tropical populations have distinct laying periods at the same season in each year, a number of those in relatively seasonless environments have been known to lay in every month of the year. The blue-footed booby (*Sula nebouxii*) in the Galápagos, for example, is known to breed at intervals of less than a year. In other populations, laying is synchronized but occurs at nonannual intervals; *e.g.*, the brown booby (*S. leucogaster*) on Ascension Island has laying periods roughly every eight months. For the cormorants (*Phalacrocorax carbo* and *P. africanus*) of Lake Victoria, conditions are favourable for breeding during about eight months in each year, but the scarcity of islands free of predators forces the birds to occupy the few safe colonies in relays.

Nests, eggs, and young. Most pelecaniforms build substantial but untidy nests of twigs, grass, algae, or feathers; in many species guano accumulates on and around the nest as breeding progresses. Many cormorants and pelicans habitually build their nests on the ground, but most species that normally breed where trees or bushes are available build their nests in them. Certain cormorants and boobies sometimes nest on cliff ledges, and tropic birds and most boobies lay their eggs on the open ground in insignificant depressions.

Clutch size

There is much variation in clutch size. In general, species living in the unproductive tropical seas lay only a single egg. Those living in seasonally productive areas at higher latitudes, or in areas where surface waters are enriched by the upwelling of nutrient laden water from deeper layers, lay larger clutches and raise several young at a time. Tropic birds and frigate birds all have clutches of one egg, but pelicans generally lay one to three eggs, cormorants two to five, and anhingas three to five. The boobies show a more complex picture. The gannet of the temperate zones and the tropical red-footed booby (*Sula sula*) have clutches of one egg, but the other typical boobies of the tropics—the masked and brown boobies —normally lay two eggs. These two-egg species, however, normally raise only one chick, the older nestling apparently pushing the younger out of the nest soon after hatching. The second egg in these ground-nesting species seems to function as an insurance against infertility, loss, or breakage of the first, risks that may be lower in the tree-nesting, red-footed booby. The single-egg clutch of the gannet has not been satisfactorily explained, since pairs have been able to raise two chicks when an extra has been provided experimentally.

Except in the tropic birds, the eggs of pelecaniforms are small in relation to body size. In the tropic birds they are

9–13 percent of the adult weight, in the frigate birds, 6 percent, in the boobies, 3–5 percent, and in the pelicans and cormorants, 2–3 percent. In species with clutches of more than one, eggs are laid at intervals as short as 24 hours, or as long as five to six days in the case of the masked booby. In all of the groups, both parents participate roughly equally in incubation and feeding of the young. The lengths of the incubation shifts vary extensively, both within and between species. In some species (*e.g.*, many cormorants) shifts last only a few hours, but in tropic birds and some boobies shifts of three or more days are not uncommon; in the great frigate bird (*Fregata minor*), on the Galápagos, shifts last 10–15 days.

Incubation generally starts with the laying of the first egg (though not in some cormorants). First and last young may hatch several days apart and often differ substantially in size during the nestling period. The incubation period is just under four weeks in anhingas, four to four and a half weeks in cormorants, about four and a half weeks in pelicans, six weeks in tropic birds, and six to eight weeks in frigate birds.

Growth of young birds

The young, which are helpless and essentially naked at hatching, are brooded continuously for several days, until their down grows. The tropic birds are exceptional in that they have thick down at hatching and are sometimes left alone by their parents even on the day of hatching. The rate of development of the young varies dramatically and is correlated with the characteristics of the environments in which the birds live. The fledging period in the pelagic tropical masked booby is double that of cormorants of comparable body size living in the cool, productive waters off the coast of North America (17 weeks versus less than 8 weeks). Brown pelicans in North America fledge in less time (9 weeks) than white-tailed tropic birds weighing only one-tenth as much (10 weeks) and in less than half the time needed by tropical frigate birds weighing about one-third as much (more than 20 weeks).

The young of all pelecaniforms are fed on regurgitated food that they obtain by inserting their heads into the mouths of their parents. In frigate birds and tropical boobies, the parents continue to feed their young for a long period after they can fly, apparently because the young take a long time to become sufficiently skillful in hunting to survive in tropical areas where food is generally scarce. The most extreme case is that of the great frigate bird, in which the young can fly at about five months of age but sometimes are fed for more than a year after this. In the tropic birds and the gannet, however, the young are not fed by the parents after fledging; they leave their birthplace either by flying straight out to sea or by fluttering down to the water and swimming out to sea.

Molt. In the pelecaniforms, as in most birds, replacement of the feathers (molt) occurs mainly in the intervals between breeding. In a few species molt progresses concurrently with breeding activities, but normally, a complete molt commences when breeding is over. In the anhingas the primary flight feathers of the wing are shed simultaneously, but in the other groups molt is gradual. The primary and secondary feathers typically are replaced by means of two or three molt waves that start several feathers apart and move outward in parallel until all feathers have been shed. In most, if not all, pelecaniforms, feathers of the head and neck, and some on the body, are replaced a second time shortly before the next breeding season. Special feathers (crests, neck plumes, white patches) acquired at this time are shed around the time of egg laying in some species; in pelicans some head feathers are replaced yet again during incubation.

In many of the pelecaniforms the colours of the soft parts (especially the bare skin on the face) change as the birds become sexually active. In some pelicans a horny triangular plate grows on the upper mandible towards the tip before the breeding season and is shed after laying.

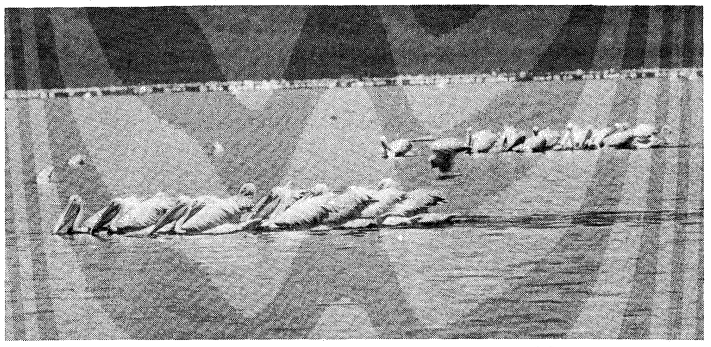
Ecology. *Survival and mortality.* Full-grown pelecaniform birds have few natural enemies, and although some are taken by marine predators they are generally long-lived. Nestlings, recently fledged young, and sometimes even adult birds suffer heavy mortality when food shortages occur. In many tropical areas where food is generally scarce, irregular fluctuations in the supply lead to drastic variations in breeding success. Mortality from starvation also occurs among birds of richer seas, most dramatically along the west coast of South America in years when oceanographic changes cut off the normally abundant food supply of the huge bird populations. Even under average conditions, young pelecaniforms in their first year after fledging experience much higher mortality than adults. In the European shag (*Phalacrocorax aristotelis*) more than half the young die during this period, although among adults annual mortality is only about 15 percent in males and 20 percent in females. In the British population of the gannet, about 80 percent of the fledglings die before reaching breeding age (about five years), most during their first year. Adults die at an average rate of less than 6 percent per year and have a mean expectation of life exceeding 16 years. Age records for individual banded birds include a great frigate bird that was recently found breeding at an age of more than 30 years and a masked booby breeding at about 23 years. Negative evidence suggests, however, that few individuals of these species survive much longer than the two examples.

Causes of death

Population movements. Members of the pelecaniform populations breeding at high latitudes generally move to lower latitudes in winter but do not perform transequatorial migrations. Adequate analyses of banding results have been carried out on only a few species. Great cormorants (*Phalacrocorax carbo*) from Britain do not show a well-defined migration but disperse random distances from the colonies. In all populations of gannets, juveniles move further than adults. A number of juvenile gannets from New Zealand have been found in eastern Australia only a week after leaving their natal colonies on their first flight, having made journeys exceeding 1,600 miles, at average speeds of more than 230 miles per day. Gannets that survive to breeding age usually return to the same cluster of nests where they were hatched. In a similar way, juvenile lesser frigate birds (*Fregata ariel*) from colonies in the central equatorial Pacific disperse on a broad front, many moving over 4,000 miles from their natal island. Their pattern of dispersal may be related to that of the prevailing winds in the area.

Feeding ecology. The various groups of pelecaniform birds are specialized for different ways of life and in particular for different feeding methods. Tropic birds and boobies, though they differ in many ways, are both adapted for catching prey underwater by plunging from the air. They are powerful flyers and buoyant swimmers, but, although their feet have large webs, their legs are not streamlined and they are not specialized for fast swimming. The feet are probably used underwater more for steering than for propulsion, and the birds depend mainly on the impetus of the dive to enable them to approach their prey at high speed.

Tropic birds are adept at hovering while locating prey, and probably obtain most of their food near the surface. Many boobies often dive from greater heights and probably go deeper than tropic birds; the gannet sometimes dives from more than 100 feet. Blue-footed boobies, when hunting in groups, tend to dive almost simultaneously. A disyllabic whistle is often heard from such groups as they start to dive and may be a signal given by the initiator. It has been suggested that the simultaneous plunging of several birds may confuse the fish in a school and so increase each bird's chance of catching one. Red-footed boobies, and perhaps also other boobies, catch flying fish (family Exocoetidae) in the air as well as in the water. These fish, with squid of the family Ommastrephidae, are staple foods of the tropical boobies and the tropic birds. Boobies of upwelling zones and the gannet feed almost entirely on fish.



Frigate birds are among the most aerial of all sea birds. Their best known feeding habit involves piracy, in which they harry other sea birds until they disgorge their prey, after which the frigate birds catch the food in the air or pick it from the surface. They also catch prey for themselves, however, pursuing flying fish in the air and

snatching fish (and probably squid) from the surface without alighting.

Feeding by pelicans

Pelicans generally catch their prey while swimming, thrusting their long bills and long necks below the surface to scoop up fish in their distensible throat pouches. When fishing in shallow water, pelicans often cooperate to form a kind of living net. They form a crescent facing the shore, or even a circle, and then close in, splashing, paddling hard. Each bird keeps station until the fish panic and can be captured as they try to escape between the birds. Pelicans have also been observed herding and capturing ducklings in a similar way. The brown pelican, unlike the other species, often forages some distance offshore and habitually fishes by plunging from the air.

Leonard Lee Rue III—Bruce Coleman, Inc.

Flocks of white pelicans (*Pelecanus onocrotalus*) fishing cooperatively on Lake Nakuru, Kenya.

Cormorants and anhingas are adapted for underwater swimming. The cormorants pursue free-swimming or bottom-living fish, and some species also eat mollusks and other invertebrate animals. When feeding on schooling fish, cormorants often engage in mass fishing activities in which a flock advances in a long line stretching at right angles to the direction of movement, apparently with the fish fleeing ahead of them. The birds swim forward while above the surface and also while pursuing prey underwater, and laggards fly forward and land just ahead of the line. Anhingas do not pursue their prey but lie in wait underwater and then stab passing fish. Most of the fish that they eat are slow swimming and laterally flattened.

The physiological adaptations for diving have been little studied in cormorants and anhingas. It is known, however, that for cormorants feeding on the bottom the mean length of the dives is directly related to water depth. Dives of most species usually last less than half a minute, although dives as long as one minute are not uncommon. The time spent resting after a dive averages between one-half and one-third of the duration of the dive, but if dives are very long the length of the rest periods approaches that of the dives. Anhingas often stay under water for as long as two minutes, and a dive of nearly seven minutes has been recorded in a captive bird.

FORM AND FUNCTION

Distinguishing characteristics. Few generalizations can be made about the gross morphology of the pelecaniforms, since their external form reflects the diversity of their adaptations. In the larger and more aerial species, the skeleton is extensively pneumatized: nearly all the bones contain air sacs that are connected with the respiratory system. In the frigate birds, pelicans, and boobies, the major limb bones are no more than thin-walled hollow tubes with some internal struts. Pneumatization is least developed in anhingas, which need to have a high specific gravity to remain underwater while motionless.

Cushioning by air sacs

Those pelecaniforms that plunge into the water from a height (boobies, tropic birds, and the brown pelican) have a system of air sacs under the skin, connected with the lungs, that form a spongy mattress that presumably protects the bird as it strikes the water, although its presence also in species of pelicans that do not plunge suggests that the buoyancy it confers may be advantageous in itself.

The reduction of the external nostrils in most pelecaniforms is probably also connected with diving and swimming underwater. The closure, complete in boobies and in adult cormorants and anhingas, is only partial in frigate birds and pelicans; the nostrils are developed normally in tropic birds. The reduction of the nostrils in the aerial Fregatae as well as in the highly aquatic Pelecani suggests (as does the structure of the foot) that the Fregatae originated from a more aquatic stock. In the birds with nonfunctional nostrils, air enters the mouth cavity directly from the outside and then reaches the lungs in the normal way via the glottis—*i.e.*, the muscular opening to the windpipe—at the base of the tongue. In boobies and cormorants entry of air to the mouth when the bill is closed is by means of secondary external nostrils. These are slitlike openings at the angle of the mouth on each side where a horny flap (jugal operculum) at the base of the upper mandible overlaps the lower mandible.

Tropic birds, pelicans, and boobies have water-repellent plumage and are very buoyant. They swim high in the water and can reach significant depths only by acquiring momentum during aerial dives; their return to the surface is rapid. Frigate birds have wettable plumage, cannot swim or dive, and quickly become waterlogged if they alight on the water. In cormorants and anhingas the large contour feathers are wettable and trap little air when the birds are swimming underwater; this keeps buoyancy low in these birds and enables them to submerge from the surface without benefit of an aerial dive. The compressible but dense body plumage remains dry near the skin, at least in many species. The hind limbs of anhingas, which are not specialized for fast swimming, are relatively efficient for climbing and perching. Anhingas do not normally take flight from the water but climb out and dry their wings in a characteristic spread-wing posture that is also commonly used by cormorants. Once dry, anhingas show highly manoeuvrable flight and can also soar well, in contrast to the cormorants, which have a higher wing loading. Many species of pelecaniforms habitually spread their wings in "sun-bathing" postures, even when dry. The function of this behaviour is not well understood.

Physiological adaptations. Most pelecaniform birds nest in exposed situations, and special adaptations are necessary to prevent overheating of adults and young, particularly in tropical areas. The masked booby on the Galápagos, for example, stands with its back to the sun, thus shading its feet and naked throat pouch and permitting loss of heat by convection and conduction; it elevates its scapular (shoulder) feathers and droops its wings allowing maximum exposure of shaded feather areas, and it exhibits sustained fluttering of the throat pouch. Throat fluttering, which permits evaporative cooling with minimum expenditure of energy, is used under heat stress by all the pelecaniforms except the tropic birds, which do not have a naked throat pouch. The rate of throat fluttering remains roughly constant under increasing heat stress but becomes continuous instead of intermittent, and there are increases in its amplitude and in the throat area involved. All species make use of panting to increase evaporative cooling. Under heat stress the rate of breathing increases with increasing body temperature, and when it reaches a maximum the amplitude of breathing increases.

Although even the newly hatched young of certain species are capable of throat fluttering, they cannot regulate their temperature when left in the sun, until they have acquired down, and in some species not until they are several weeks old. Young tropic birds provide an exception: they have dense down at hatching and are sometimes left alone for long periods within a few days of hatching; small chicks are capable of regulating their body temperature by panting, even in the sun, but most nests are in the shade.

Salt excretion

Evaporative cooling requires much water, which is obtained from the food and probably also by drinking seawater. The resulting high intake of salt necessitates special adaptations for elimination of the excess. Marine birds have highly developed salt excretory glands, the lateral nasal glands, which function when the amount of salt taken into the body is more than the kidneys can deal

with. The glands secrete a concentrated solution of sodium chloride, which flows through ducts to the nasal cavity. In most sea birds, including the tropic birds, it then flows out through the nostrils and may drip or be shaken off the tip of the bill. In boobies and cormorants, in which the nostrils are closed, the solution trickles from the internal nares in the roof of the mouth and out at the end of the bill. In some species of cormorants that occur in both marine and freshwater habitats, the salt gland is relatively larger in individuals from marine habitats. Presumably these individuals tend to eat food with a higher salt content or drink seawater for cooling.

CLASSIFICATION

Distinguishing taxonomic features. The classification of the order Pelecaniformes is based mainly on morphological features. Recent attempts have been made to clarify relationships by analysis of egg-white proteins, and by comparative analysis of social behaviour. The parasitic feather lice (Mallophaga) found on members of the different groups also provide clues to relationships.

The six modern families of pelecaniform birds are readily distinguished, although the relationships among them are not firmly established. The families are internally homogeneous, and in each of them the modern species are often placed in single genera; the Phaethontidae, Fregatidae, Pelecanidae, and Anhingidae are usually treated in this way. The relationships of many fossil groups—indicated below by a dagger (†)—are quite uncertain.

Annotated classification.

ORDER PELECANIFORMES

Aquatic birds characterized by totipalmate feet (webs connecting all 4 toes); the 1st toe (hallux) not pointing backward as in most birds, but turned inward and joined by a web to the 2nd toe.

Suborder Phaethontes

Family Phaethontidae (tropic birds)

Medium sized (16–19 in. or 40–48 cm long). Plumage satiny white with black markings; central 2 tail feathers much elongated in adult. Sexes similar. Bill laterally compressed, slightly decurved, and with undivided horny sheath (rhamphotheca). Nostrils open in slits; nasal glands each with 2 ducts. No naked gular (throat) pouch. Neck short, 14–15 cervical vertebrae. Pelvic girdle reduced, legs short, set far back. No nest building behaviour. Single egg heavily marked with brown and black. Chick hatched covered with grey down. 1 fossil genus, *Prophaeton* (lower Eocene of England); 1 extant genus, *Phaethon*; 3 living species, worldwide in tropical oceans.

Suborder Fregatae

Family Fregatidae (frigate birds)

Large sized (31–34 in. or 79–86 cm long), light bodied. Plumage blackish, juveniles and some adults with white underparts; juveniles with white heads, sometimes tinged with orange. Wings very long and pointed, tail deeply forked. Sexes differ in size (female larger) and in coloration of plumage and soft parts. Bill long, slender, strongly hooked at tip; horny sheath divided by deep grooves. Nostrils almost closed; nasal glands each with a single duct. Small gular pouch, highly distensible and brilliant red in courting male. Neck short, with 14–15 cervical vertebrae. Furculum (wishbone) fused with coracoids and with sternum (breastbone). Pelvic girdle and leg muscles reduced; legs very short. Feet small, with webbing only between bases of toes. One white, thin-shelled egg. Young naked at birth, soon acquire thick white down. No fossil record. One extant genus, *Fregata*; 5 living species, worldwide in tropical oceans.

Suborder Pelecani (pelicans, boobies, cormorants, anhingas)

Horny sheath of bill divided by deep grooves (largely suppressed in anhingas). Naked gular pouch; facial skin and pouch colorful, especially in breeding season. Nasal glands each with a single duct. Neck long, with 17–20 cervical (neck) vertebrae; 8th and 9th have articulations permitting sharp S-bend, especially in anhingas. Pelvic girdle not reduced, legs strong. Feet large, fully webbed. Eggs thick shelled, with chalky white outer layer. Young naked at hatching.

Family Pelecanidae (pelicans)

Very large (50–72 in. or 127–180 cm long). Plumage white, brown, or grey; some species crested. Wings long and broad, tail short. Sexes similar. Bill long, hooked at tip, with enormous gular pouch suspended from highly distensible rami (lateral elements) of lower mandible. Nostrils almost closed. Furculum fused with sternum. Down of nestlings white. 10 fossil species in the genera *Pelecanus* (the earliest from lower Miocene of France) and *Liptornis* (middle Miocene). One extant genus, *Pelecanus*; 7 living species, seacoasts and freshwater lakes of southern Africa, central and eastern Eurasia, Australia, and North America; north and west coasts of South America.

Family Sulidae (boobies)

Large (26–40 in. or 66–102 cm long). Plumage of most species white with black on wings; some brown and white; juveniles largely grey or grey-brown. Wings long and narrow, tail rather long, wedge shaped. Sexes generally differ in voice, sometimes in colour of bare skin. Bill stout, conical, slightly decurved near the tip and finely serrated on cutting edges. Nostrils closed. Down of nestlings white. 18 fossil species, in the genera *Sula* (the earliest *S. ronzoni*, lower Oligocene of France), *Microsula*, *Morus*, *Palaeosula* and *Miosula*. Two extant genera, *Sula* with 6 living species, *Morus* with 1 species (sometimes considered 3 species, forming a superspecies); widespread but irregular distribution, on seacoasts and oceanic islands.

Family Phalacrocoracidae (cormorants)

Medium to large (19–40 in. or 48–102 cm long). Plumage usually blackish; some with white underparts, and a few largely grey; some species have ornamental crests or patches of white when breeding. Wings broad, tail long and stiff. Sexes similar, but females up to 30 percent lighter in weight. Bill slender, sharply hooked at tip. Nostrils closed in adults. Bony occipital style projecting upward from back of skull. Down of nestlings dark. 24 fossil species in the genera *Graculavus* (the earliest, upper Paleocene of North America), *Actiornis*, *Miocarbo*, and *Phalacrocorax*. About 28 living species (and one recently extinct), all currently included in the genus *Phalacrocorax;* certain Old World species have sometimes been placed in a separate genus *Halietor*, and the Galápagos flightless cormorant (*Phalacrocorax harrisi*) in the genus *Nannopterum*.

Family Anhingidae (anhingas or darters)

Large (34–36 in. or 86–91 cm long). Plumage mainly black and brown with pale markings on back and wings; breeding male has light-coloured plumes on head and neck. Tail very long and stiff. In some forms the sexes differ in colour. Bill long, straight, slender, sharply pointed; cutting edges serrated towards tip. Nostrils closed in adults. Occipital style smaller than in cormorants. Head small, neck long and slender. Legs short but strong. Pyloric lobe of stomach with mat of hairlike processes. Down of nestlings brown. Five fossil species, in the genera *Protoplotus* (the earliest from the Eocene of Sumatra), and *Anhinga*. One extant genus, *Anhinga*; living forms have been treated as 1, 2, or 4 species and are here considered as 4 species comprising a single superspecies.

†*Family Elopterygidae*

Fossil. Marine birds probably related to the Pelecani, perhaps especially to the cormorants. Genera *Elopteryx* (Upper Cretaceous, Maastrichtian, of Romania); *Argillornis* and *Eostega* (Eocene of Europe).

†*Family Pelagornithidae*

Fossil. Marine birds probably related to the Pelecani, perhaps especially to boobies, but not adequately known. Genus *Pelagornis* (middle Miocene of France).

†**Suborder Odontopteryges**

Fossil. Very large marine birds, with long wings and short legs. Bill long and high, with sharply pointed, toothlike projections on margins of upper and lower mandibles, continuous with bony structure of jaws (and thus not true teeth). Upper and lower mandibles with longitudinal grooves, suggesting that their horny sheaths were divided.

†*Family Odontopterygidae*

Fossil. "Teeth" slant forward. Nostrils closed or nearly so. About half the size of the pseudodontorns (see below). Genus *Odontopteryx* (lower Eocene of England).

†*Family Pseudodontornithidae*

Fossil. "Teeth" vertical—not slanted forward. Wingspread about 4.5 metres. Genera *Pseudodontornis* (Miocene); and *Osteodontornis* (upper Miocene of California), one of the best preserved of early marine birds.

†*Family Cyphornithidae*

Fossil. Based on fragmentary material, and of uncertain relationships, but may be members of this suborder. Lower Miocene of North America. Genera *Cyphornis*, even larger than

the pseudodontorns; *Palaeochenoides*, rather larger than pelicans, may be synonymous with *Pseudodontornis* (and would take priority over it); *Tympanonesiotes*, smaller than the preceding form but may be related to it.

†Suborder Cladornithes

Fossil. Relationship to pelecaniforms doubtful. One family, with 1 genus, *Cladornis* (lower Oligocene of Patagonia); known only from a poorly preserved tarsometatarsus.

Critical appraisal. The tropic birds (Phaethontes) differ in many ways from the other members of the order Pelecaniformes and may well be wrongly placed in this order. They are united to the others primarily by the totipalmate condition, but the first toe in Phaethontes is distinctly more elevated on the tarsometatarsus than in the other groups. Some of the resemblances of the Phaethontes to the Laridae (gulls and terns) in the order Charadriiformes may not result from evolutionary convergence but may indicate that the Phaethontes arose from forms more closely related to the basal stock of the Laridae than to that of the Pelecaniformes.

The frigate birds (Fregatae) are generally treated as a distinct suborder, on the basis of a number of morphological characters that they share with members of the order Procellariiformes but not with the Pelecani. Pending further evidence from protein structure, this distinction seems worth maintaining.

There is little doubt that the suborder Pelecani is made up of closely related groups. The pelicans are sometimes placed in a separate superfamily, but it is more useful to emphasize the similarities among the modern groups by keeping them together. The anhingas have sometimes been treated as a subfamily of the Phalacrocoracidae, but their morphological and ecological differences from cormorants perhaps justify separation at the family level.

The Odontopteryges show a number of similarities to the Procellariiformes as well as to the Pelecaniformes and also show differences from both. The suggestion that they deserve to rank as a separate order Odontopterygiformes will be strengthened if it can be proved (as is now suspected) that *Osteodontornis* lacked or had a much reduced first toe, since this is an essential element of the totipalmate foot of pelecaniforms.

Available evidence suggests that the stocks leading to the Procellariiformes, Odontopteryges, typical pelecaniform birds (Fregatae plus Pelecani), Phaethontes, and Laridae, diverged during the Cretaceous Period, probably at least 70,000,000 years ago.

(N.P.As.)

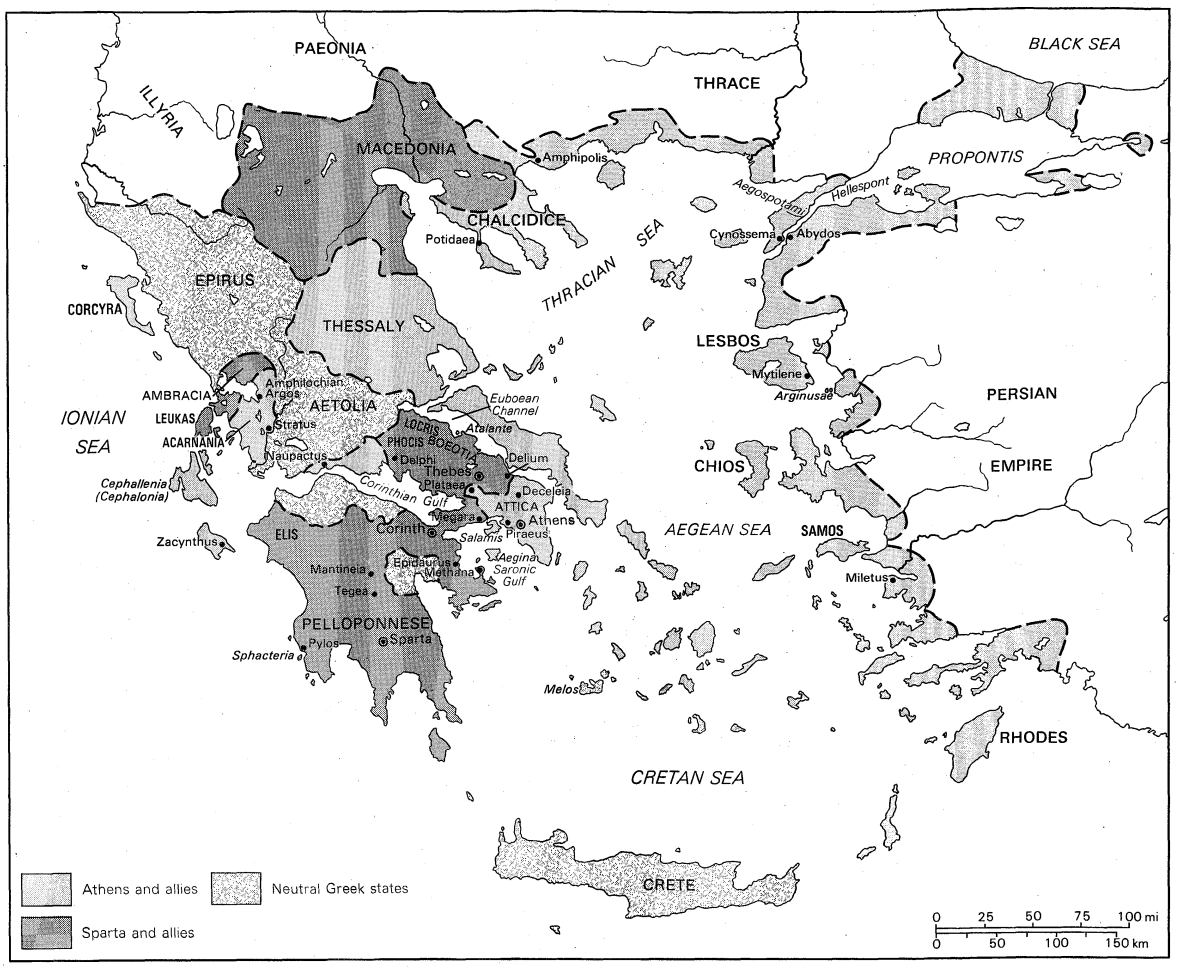
Peloponnesian War

The Great Peloponnesian War (431–404 BC), between Sparta and Athens, was one of the great watersheds in the history of the Ancient Greeks, and the subject of one of the greatest historical works of all time, the *Peloponnesian War* of Thucydides of Athens.

Thirty Years' Treaty

The antecedents of the war. The Thirty Years' Treaty of 445 brought a truce between the two leading blocs of power in Greece: Athens and its empire, which comprised most of the islands and maritime states on the northern and eastern coasts of the Aegean basin, along with the Greek states of the Propontis and Black seas; and Sparta and its allies, among whom were most of the leading land powers in the Peloponnese and central Greece, and Corinth, the leading sea power in the western seas extending to Sicily. The peace lasted as long as neither bloc trespassed on the other's sphere of influence; they were about equal in strength, and the outside powers were neutral. But in 433 Athens made a defensive alliance with a recalcitrant colony of Corinth, Corcyra, which held a strategic position in the western seas and possessed a fleet of 120 triremes (galleys with three banks of oars). This alliance infringed the principle but not the letter of the Thirty Years' Treaty and resulted in a clash between Athenian and Corinthian ships when Corinth and its allies attacked Corcyra. In the ensuing winter Athens not only banned one of these allies, Megara, from access to the eastern seas, which had been guaranteed under the Thirty Years' Treaty, but also ordered one of its own allies, Potidaea, which was a colony of Corinth, to break off relations with its founder city and dismantle its seaward walls. These were no idle threats because the fleet of Athens dominated the Aegean basin. Nevertheless, Potidaea refused. "Volunteers" from Corinth and its Peloponnesian allies reached Potidaea and enabled it to beat off an Athenian attack.

Corinth, Megara, and other states now maintained that Athens had committed aggression and had thus infringed the terms of the Thirty Years' Treaty. They complained, therefore, to Sparta. The Spartans' local interests were not involved. Yet their position at the head of the Spartan alliance was endangered by Athens' moves against two of its members, Corinth and Megara. The executive authorities at Sparta had already made a secret agreement to help Potidaea, but this fact was not known to the Spartan citizens when they met in the assembly to decide their attitude. A large majority found Athens guilty of aggression. The allies of Sparta, meeting in a formal congress, confirmed Sparta's verdict. The two components of the Spartan alliance, or, as it is commonly called, the Peloponnesian League, declared themselves ready to go to war if the Athenians proved unwilling to withdraw their ban on Megara and their order to Potidaea.



Peloponnesian League

The decision lay with Athens. The people were swayed by their leading statesman, Pericles, who had himself proposed the alliance with Corcyra and the ban on Megara. He warned the assembly against yielding to any demands made by the Peloponnesians. The majority accepted his advice, and the demands of Sparta were rejected. A diplomatic deadlock ensued. The Athenians offered to accept arbitration on the points under dispute. The Spartans refused arbitration. In spring 431 an ally of Sparta, Thebes, made a treacherous attack on an ally of Athens, Plataea. The Thirty Years' Treaty was flagrantly broken, and both blocs of power went to war. As Thucydides observed, the fundamental cause of the war was the interaction of two forces: the growing power of Athens and the growing apprehension of Sparta.

The first part of the war (the "Archidamian War," 431–421 BC). The armies of Sparta and its allies were far stronger than those of Athens. But they could be deployed for only a few months each year, because the Spartans had to keep their serfs, the helots, under control, and the allied soldiers had to maintain their farms. The Spartans hoped to force a decisive battle on land. Otherwise there was little hope of success, for Sparta and its allies had relatively small fleets and no financial resources for building large numbers of warships. On the other hand, the fleet of Athens, even without the squadrons of Lesbos, Chios, and Corcyra, was unrivaled; and the Athenians had large financial reserves and access to shipbuilding materials. Their infantry, though outmatched by the combined forces of their enemies, included a striking force of 13,000 men, free to operate at any time and capable of damaging their neighbours individually, and a reserve force of 16,000 men, able to hold the massive walls that circled Athens and the Piraeus and linked the city with its port.

The opening campaigns

Sparta's lines of communication with its allies beyond the isthmus—Boeotia, Phocis, and Locris—ran through the narrow corridor of northern Megaris, which separates Attica from the Corinthian Gulf. This corridor was

Greece at the beginning of the Peloponnesian War.
Adapted from W. Shepherd, *Historical Atlas*; Barnes & Noble Books, New York

threatened from the east by Athens and from the west by Athens' ally Plataea. In their desire to control the corridor, the Thebans attacked Plataea in March 431. The attack failed. Athens evacuated the noncombatants from Plataea and sent troops to reinforce the garrison. In May the Spartan king, Archidamus, led the allied armies slowly into Attica and ravaged part of the plain north of Athens, hoping to provoke an engagement. But on the orders of Pericles the Athenian population and the Athenian army were concentrated behind the walls of the city. Although the troops wanted to attack, Pericles held them back. He had no intention of offering battle then or later to the superior army of the enemy. He proposed to conserve his forces for a war of attrition during which the Athenian fleet would guard the empire and Athens' supplies and wear down the enemy by seaborne raids. In June, therefore, before the Spartans left Attica, a fleet of 150 triremes set off from the Piraeus. It raided the coasts of the Peloponnese and closed the mouth of the Corinthian Gulf by winning over Cephallenia (Cephalonia), an island off the entrance to the gulf, as a base. Meanwhile, a fleet of 30 triremes ravaged the coast of Locris and garrisoned the island of Atalante in the Euboean Channel, through which convoys passed to an Athenian army blockading Potidaea. Another force expelled the people from Aegina, and Athenians occupied the island, controlling the entry to the Saronic Gulf. Thus the net of naval blockade was closing round the enemies of Athens and its own sea lanes were secure.

The policy of Pericles was a wise one in the opinion of Thucydides. It safeguarded the city, the fleet, and the empire—the sources from which Athens drew its financial and naval strength. Even if it meant the loss of property in Attica, which was relatively unimportant, it involved no risks for the Athenian army; and Pericles was confident that he could maintain the morale of the people. In 431 and subsequent years the army ravaged the Megarid. In March 430 Pericles proclaimed his faith in Athens when he delivered a funeral speech in honour of the Athenian dead. But shortly afterward, when the Peloponnesian army was ravaging Attica for the second time, an unexpected blow fell on the crowded city of Athens—a terrible plague that within three years killed one-third of its best troops and maimed many others, apart from its toll among the civilian population. Pericles himself was one of the casualties. The power and the morale of the Athenians were seriously undermined; but they fought on with grim determination in Chalcidice, capturing Potidaea and instigating an extensive raid on Chalcidice and Macedonia by their ally, the Thracian king Sitalces, in 429.

Plague at Athens

While the plague raged at Athens, the initiative lay with the Spartans. They tried to oust the Athenians from their bases in the western area—Zacynthus, Cephallenia, Acarnania and Amphilochian Argos, Corcyra and, in the Gulf of Corinth, Naupactus—and thus to regain contact with Italy and Sicily, where they had allies and sources of supply. In 430, attacks on Zacynthus and Amphilochian Argos failed. In 429 a large army of Peloponnesians, Ambraciots, and light-armed levies from the tribes of Epirus invaded Acarnania but suffered defeat at Stratus. A Peloponnesian fleet of 47 warships and smaller troop-carrying vessels, which had intended to join the attack on Acarnania, was intercepted as it sailed out of the Corinthian Gulf by an Athenian squadron of 20 warships based at Naupactus. When the Peloponnesian warships formed a circle, facing outward to protect the smaller vessels at the centre, the Athenian commander Phormion ordered his warships to row round the outside of the circle, which contracted and fell into confusion. Phormion then attacked and gained a remarkable victory. The Peloponnesian fleet then threatened Naupactus. But Phormion won another victory, and reinforcements from Athens soon

reached Naupactus. Later in the year the Peloponnesians set out to raid the Piraeus by sea; but their courage deserted them, and they raided the island of Salamis instead. The other objective of Sparta in 429 was Plataea. When diplomacy failed, the Spartans built a double wall round the town and imposed a blockade that was destined to last into 427.

Mytilene revolt

In 428 the Peloponnesians made no further move in the western area, but an important opportunity arose for intervention in Aegean waters. Lesbos, one of the two allies of Athens that had a fleet, was planning to revolt and allied itself in August with the Spartans, who undertook to invade Attica that autumn and to send help overseas to Lesbos. But the Athenians moved first, blockading the leader of the revolt, the city of Mytilene, with a squadron of 40 ships and ravaging the east coast of the Peloponnese with an army transported on 100 ships. The Peloponnesians failed to invade Attica or to send help to Mytilene. During the winter Mytilene was hard pressed by the Athenians. The oligarchs in the town who had organized the revolt found themselves threatened by the democratic party, and they surrendered to the Athenian commander on condition that the Athenian people should make a final settlement. A week later a Peloponnesian squadron of 42 ships crossed the Aegean Sea, learned of the surrender, and sailed ignominiously home. The only success that Sparta gained during the years of the plague was the capture in 427 of Plataea, from which half the garrison had made a brilliant escape at night. The remainder surrendered, entrusting their fate to Spartan courts.

The strain of war lowered the standard of humanity on both sides. The Athenians, incited by a violent orator, Cleon, ordered the execution of all adult males at Mytilene and the enslavement of the rest. Next day the assembly repented. The order was countermanded just in time, but even so a thousand ringleaders were executed. The Spartans condemned and executed the captured garrison of Plataea, and the town was demolished by the Thebans. In Corcyra a terrible civil war, fanned by the intervention of a Peloponnesian squadron and later of an Athenian squadron, caused much loss of life and degenerated into guerrilla warfare, which lasted until 425. Supplies were now short in the Peloponnese. At Athens financial reserves were running low; and bitter animosity developed between the extreme democrats, led by Cleon, and the moderate party with which Thucydides and Aristophanes sympathized.

Athenian offensives

In 427–424 the Athenians abandoned the cautious strategy of Pericles and engaged in a series of offensives. An attack on Melos failed (426). A squadron of 20 ships started operations in 427 against Syracuse in Sicily, where Athens had allies, and gained control of the Strait of Messina; 40 more ships were sent in 425, but the Sicilian states made peace among themselves in 424 and so ended Athenian intervention. An enterprising general, Demosthenes, tried to extend Athens' power in western Greece by attacking Leukas and invading Aetolia, where he suffered defeat. In 426 the Spartans retaliated. Campaigning along the northern coast of the Corinthian Gulf and then joining the Ambraciots in an attack on Amphilochian Argos, they hoped to reduce Acarnania and control the northwestern mainland. But Demosthenes came up with 20 Athenian ships, took command of the Acarnanians and Amphilochians, and inflicted a double defeat on Sparta and Ambracia. His success was so great that the Acarnanians were alarmed and made a separate alliance with Ambracia. From this Athens derived no advantage.

In 425, when the reinforcements were sailing to Sicily, Demosthenes fortified Pylos, a rocky promontory on the west coast of Messenia, and stayed there with a small force. A Peloponnesian fleet of 60 ships, which had been operating at Corcyra, hastened south to Pylos and landed 420 Spartans on an island, Sphacteria, hoping to blockade the promontory. The Athenian fleet returned suddenly, defeated the Peloponnesian fleet by surprise, and isolated the Spartans on Sphacteria. Sparta then negotiated an armistice at Pylos, during which the Athenians were given possession of the Peloponnesian fleet as a guarantee of good faith. Sparta offered peace and alliance to Athens. Cleon persuaded the assembly to reject the offer in the hope of winning some decisive victory, and later in the year he was sent out to take command with Demosthenes at Pylos. There the Athenians, alleging a technical breach of the armistice, had refused to return the Peloponnesian ships but failed to land on Sphacteria. Cleon and Demosthenes, encouraged by a fire that burned the woods on the island, made a landing, fought the Spartans to a standstill, and obtained the surrender of 120 Spartiates.

Stripped of its fleet, shaken in morale, and threatened by helot risings in Messenia, Sparta was now at its lowest ebb. Athens tried to press home its advantage. During the voyage to Sicily the fleet from Pylos connived at a massacre of oligarchs at Corcyra. Nicias led successful raids by sea on the coasts of Corinth and Epidaurus and occupied Methana. In 424 he captured and garrisoned Cythera as a base for raiding Laconia. Demosthenes and Hippocrates came within an ace of capturing Megara and thus cutting the Peloponnese off from Boeotia. In the summer a triple attack was launched on Boeotia; but a failure in the timing and the slowness of the main force under Hippocrates at Delium enabled a Boeotian army of 7,000 hoplites (heavy-armed infantry) and 1,000 cavalry to force a battle, in which Hippocrates and 1,000 Athenian hoplites were killed. This disaster brought the Athenian offensive to an end.

The Battle of Delium

Meanwhile the Spartans broke out of the net in which the Athenians sought to enclose them. An able Spartan officer, Brasidas, having saved Megara from capture by Demosthenes and Hippocrates, led an army of Peloponnesian troops and freed helots into Chalcidice, an area neglected by Athens since the fall of Potidaea. There he raised city after city in revolt against Athens and in December 424 captured Amphipolis, Athens' chief base in the northwest Aegean. Athens tried to stop the landslide by concluding a year's armistice with Sparta; but it proved ineffective in Chalcidice, where Brasidas continued to detach states from the Athenian empire. Afraid of more widespread revolt, the Athenians sent an army under Cleon's command to recapture Amphipolis in 422. It was decisively defeated; Cleon was killed, but so was Brasidas. Nicias, Cleon's rival, now persuaded the assembly to accept the overtures for peace that Sparta had been making since 425. A treaty of peace was accepted in 421 by Athens and Sparta but not by four of Sparta's leading allies (Boeotia, Corinth, Elis, and Megara). Soon afterward Athens and Sparta entered into a defensive alliance, not of good will but of convenience.

The ineffective peace, 421–415 BC. These years gave the Athenians an opportunity to seduce Sparta's allies and isolate Sparta by diplomacy. They failed to use it because they were split internally by the rival policies of appeasement, led by Nicias, and of aggression, led by Alcibiades. The other states now distrusted both Athens and Sparta, but a breakaway group of Argos, Corinth, Elis, and Mantineia was too weak to withstand either great power. In the atmosphere of general mistrust the terms of the so-called Peace of Nicias were never implemented. Sparta managed to make an alliance with Boeotia, and Athens won over Argos, Elis, and Mantineia but not Corinth in 420. Sparta took military action in 418. The Spartan army of 6,000 hoplites and the levies of Boeotia, Megara, Corinth, Tegea, and lesser allies outmaneuvered the forces of Argos (numbering 6,000 hoplites), Elis, Mantineia, and some lesser states and imposed an armistice on Argos. Sparta's allies had gone home when Argos received 1,000 hoplites and 300 cavalry from its ally Athens and reopened hostilities. At Mantineia the army of Sparta, aided by Tegea alone, inflicted a decisive defeat on Argos, Mantineia, and Athens and rapidly re-established the Spartan alliance as it had been in 431. The feeble intervention of Athens in the Peloponnese with a mere 1,000 hoplites had lost the chance of diplomatic or military success on land. Meanwhile in the north, Amphipolis and Chalcidice remained independent and hostile. The war party at Athens now favoured adventure at sea. In 416 Athens attacked Melos, which refused to renounce neutrality and accept Athens' rule. When Melos capitulated, Athens massacred the adult males, enslaved the rest, and gave the island to 500

Athenian settlers. In 415 the Athenians sent out a great armada to conquer Sicily. These acts showed that their methods were unscrupulous and their ambitions were unlimited. They heralded the end of the Peace of Nicias.

The second part of the war, 415–404 BC. This was decided at Syracuse and at sea. On this element the Athenians began with complete supremacy. In all they committed 200 warships to the gamble in Sicily and left their home fleet dangerously weak. The expeditionary force in Sicily was commanded by three incompatible generals: Alcibiades, Lamachus, and Nicias. Alcibiades was soon recalled on a charge of sacrilege; he escaped and transferred his services to Sparta. Lamachus was killed in action. Nicias was soon affected by illness. In 414 the first attempt was made to surround and blockade Syracuse by land (for Athens held command at sea); it failed, mainly because a Spartan, Gylippus, with nearly 3,000 troops slipped through the Athenian lines and enabled the Syracusans to defeat the Athenian land forces, which had had only a small margin of superiority. Nicias then concentrated his army in defense of the naval base by the great harbour and advised Athens to recall the expedition. He was told to await reinforcements.

In July 413, when Nicias had lost his naval base and been defeated at sea, Demosthenes arrived with a large force. It was essential to establish military superiority at once. Demosthenes therefore launched a night attack, suffered a severe defeat, and wished to sail home. Nicias now refused to go. A month later Nicias agreed to sail; but after an eclipse of the moon on Aug. 27, 413, Nicias accepted his soothsayers' advice to stay "thrice nine days." While he stayed, the fate of the expedition was decided in the Great Harbour; the morale of the Athenian navy was broken by a single defeat, and the whole force attempted to escape overland. It suffered complete destruction. Mismanagement, indecision, and panic thus cost Athens more than 200 warships with crews totalling about 35,000 men, a fine army including 4,000 Athenians, and much material and treasure.

Athens' defeat at Syracuse

The Spartans and their allies declared war in 414. On the advice of Alcibiades, they established a fortified post at Deceleia in northern Attica that denied the Athenians the use of Attica and made them import all foodstuffs by sea at great expense. The Athenian disaster in Sicily gave Sparta hope of winning at sea. With Alcibiades' help the Spartans entered into alliance with Darius II of Persia, who could provide bases and money; they were joined by Chios, Miletus, and other states that revolted from Athens; and a small Peloponnesian fleet established itself at Miletus. The Athenians showed great energy; they built ships quickly, secured Samos as their main base, and covered their chief line of supply through the Hellespont. In 411 Abydos in the Hellespont revolted with the help of a Spartan force and Persia. At this stage the Persian king adopted a waiting game on the advice of Alcibiades, who suggested that he let the Greeks wear one another down and use his wealth to end the war at his pleasure. Alcibiades engineered his own recall to the Athenian fleet at Samos. He began by promoting an oligarchic revolution, which developed partly from the hypothesis that as an oligarchic leader he could obtain aid from Persia. Oligarchy at Samos was short-lived, but the succeeding democratic leaders appointed Alcibiades general of the fleet. Meanwhile at Athens an oligarchy seized power, ruled despotically, and negotiated with Sparta for terms of peace. It was overthrown by a popular rising, and a moderate government known as "the Five Thousand" took its place and cooperated with the democratic fleet at Samos. The slowness of Sparta and the deliberate inaction of Persia gave Athens the chance to ride out the storms of disaster in Sicily and of revolution at home. Late in 411 the Athenians won their first victory against the Peloponnesian navy at Cynossema in the Hellespont. Two more victories followed. They put the main enemy fleet out of action for three years and merged the two governments at Samos and Athens in a restored democracy.

The democratic leaders, especially Cleophon, pushed the war to a finish by rejecting the terms that Sparta repeatedly offered and by attacking those who advocated negotiation as oligarchs. Neither side had the money to outdo the other. Alcibiades came home in triumph in 407; but Persia chose to subsidize the Spartan admiral, Lysander, who equipped 90 ships and defeated an Athenian fleet. Alcibiades was held responsible by the Athenians; he fled into exile in 406. By tremendous efforts the Athenians survived further defeats at sea, manned 150 ships, and won a battle at Arginusae in which about 20,000 Greek lives were lost. The Persian policy of attrition was now coming to an end. In 405 the Persian prince Cyrus enabled Lysander to man 200 ships. He entered the Hellespont, drew the Athenian fleet of 180 ships after him, and caught them ashore in a sudden attack at Aegospotami. Only eight ships escaped. The Athenian navy was no more. The relentless advance of Lysander to the Piraeus and the blockade imposed from Deceleia starved the Athenians into final submission but only after Cleophon had been executed and the way had been prepared for an oligarchic government. In April 404 Lysander's troops began to demolish the walls of the Piraeus. Athens was to be stripped bare of empire, fleet, and fortifications, so that it should never try again to enslave the Greek states.

The fall of Athens

The Spartans owed their victory to the tenacity of their government, their excellent infantry, and their power of leadership, but also to the fighting quality of the Syracusans and to the gold of Persia, for which Sparta promised to sacrifice the liberty of the Greeks in Asia. The Athenians owed their failure to instability in government and temperament, mistaken policy, incompetent generalship, and declining morale. Although the principle of national independence was strikingly vindicated by the outcome, the general strength of the Greek states was fatally weakened; and Athens, the most progressive and civilized state, was reduced to impotence.

Penn, William

The 17th-century English Quaker William Penn, a religious leader, social philosopher, and colonial proprietor, was one of history's greatest advocates of religious toleration. In the American Commonwealth of Pennsylvania, which he founded, he sought to embody his political and religious principles.

Early life and education. He was born in London, October 14, 1644. His father, Adm. Sir William Penn, was forging a successful career in the navy at the time of his son's birth and could serve only as a distant model during the child's first dozen years because he was almost always at sea. Young William's mother, Margaret (*née* Jasper) van der Schuren Penn, was a childless widow when the elder Penn married her in 1644. In addition to William, the firstborn, their children included Margaret, born in 1652, and Richard, in 1656. The Penns lived in London until, shortly after William's serious bout with smallpox

at the age of three, they moved into the Essex countryside near the village of Chigwell, the seat of a renowned grammar school. From his sixth to his 12th year, young Penn pored over Greek and Latin eight to ten hours a day, laying the foundations of his classical education. The strong sense of the past that was thus engendered may have contributed to the feeling of security in his young life.

This stable world was shaken by Admiral Penn's naval defeat in the West Indies in 1655 and brief imprisonment in the Tower of London as punishment. This caused the family to move back to London and then, because of continuing political uncertainty, to Ireland the following year. It was while he was thus uprooted in early adolescence, William Penn later recalled, that "the Lord first appeared unto me . . . about the 12th Year of my Age, Anno 1656," a divine encounter probably fostered by the Puritan influence of Chigwell. In Ireland he heard Thomas Loe, a Quaker itinerant, preach to his family at the Admiral's invitation, an experience that apparently intensified his religious feelings.

Early religious experience

Four years were spent in Ireland, with tutors tending to Penn's education. He was now in closer association than ever with his land-bound father. At the restoration of the Stuart dynasty in 1660, the Admiral was knighted and named a commissioner of the navy. William, who was academically well prepared, the same year entered Oxford, where he demonstrated his piety by rejecting the Anglican formalism of the university. He was fined for refusing to attend chapel and dismissed in his second year. Admiral Penn was outraged by this conduct. Determined to thwart his son's religiosity, he sent the 18-year-old on a grand tour of the Continent and to the Protestant college at Saumur, in France, to complete his studies. The Admiral's purpose was to prepare the young man for high public office, but William devoted most of two years to the study of theology at Saumur. Summoned back to England, he entered Lincoln's Inn and spent a year reading law before his studies were cut short in early 1666 by the London plague.

His limited legal knowledge was put to use in managing the family estate in Ireland. Barely 21, he accepted his father's decision that he follow this worldly course, but then he crossed paths again with Thomas Loe. At a meeting in Cork, Penn heard Loe preach on the text "There is a Faith that overcomes the World, and there is a Faith that is overcome by the World." He committed himself from that moment to the Quakers, religious radicals who were reviled by respectable society and subject to official persecution.

Quaker leadership and political activism. Bent on converting a reluctant world to righteousness, the first Quakers would stop at nothing to preach the Truth. Penn joined the sect in this spirit and was imprisoned four times for publicly stating his beliefs in word and print. He published 42 books and pamphlets in the seven years immediately following his conversion, including the famous *No Cross No Crown* in 1669, a defense of his beliefs written in the Tower of London. Penn's willingness to withstand the harshness of his confinements, when he might have used his father's position to obtain release, as well as his missionary efforts on the Continent, convinced other Quakers of his commitment. He was on the way to a position of leadership at a time when the nature of the movement was changing.

In reaction to official persecution, George Fox, the founder of the Society of Friends, was imposing discipline on his people to control the excesses of radical Quakers and, thus, to give the government less provocation. Penn's contribution to the transformation of the society was a tireless advocacy of liberty of conscience, the fundamental principle of his social thought and action. This liberty could be realized only through an official policy of tolerating dissent; but to seek toleration was to admit, implicitly, that there might be many truths. Both Fox and Penn were accommodating "a Faith that overcomes the World" to the necessity of social survival.

Advocacy of religious liberty and toleration

Penn's move from zeal to moderation reflected not only a pragmatic temperament but also a change in his personal life. Though his academic training was extensive, Penn's theorizing was almost always a response to particular problems. His views on toleration were expressed not in a philosophical treatise but in a number of timely tracts. An example is "The People's Ancient and Just Liberties Asserted, in the Trial of William Penn and William Meade" (1670), a vindication of the independence of the jury, which Penn defended in a court case that stands as a landmark in English legal history. In his own life, the death of Admiral Penn in 1670, of his brother Richard in 1673, and of four of his eight children in infancy after his marriage to Gulielma Springett in 1672 were sorrowful and sobering experiences. Penn reached middle age more mellow than millenarian, content to work within the system. Inevitably, this led to political action.

Again the Quaker leader turned to his pen, and he began lobbying as well. He not only presented his case to men of influence but also prevailed upon fellow Quakers to compile a record of persecutions (institutionalized in the Meeting for Sufferings) and lay petitions before Parliament. His entrance into politics coincided with the emergence of the Whigs, whose advocacy of legislative power and religious toleration was naturally appealing to him. His *England's Great Interest in the Choice of this New Parliament* (1679) was one of the first clear statements of Whig policy. Among his personal acquaintances, however, were Tory leaders, the King (Charles II), and his brother, the Duke of York (later James II).

Founding and governorship of Pennsylvania. Within the Society of Friends there was resentment to the worldly militance Penn represented; older Quakers stymied his strategy. Nor did Penn's foray into politics serve him well when the Whigs faded before a Tory resurgence. Frustrated in England, Penn turned toward America as a means of institutionalizing his political and religious principles. Friends had been preaching across the Atlantic since 1655. By 1674 two Quakers had come into possession of West New Jersey, only to engage in a conflict over ownership that Penn was asked to mediate. Convinced of the virtue of single proprietorship, he applied to the crown for a grant of land in the New World, drew upon his connections with men of rank, and received Pennsylvania through a charter that named him the supreme governor.

Penn did not lay full claim to this privilege. Torn between the advice of Whigs and liberal Quakers, who advocated a vigorous popular legislature to offset executive power, and the need to lure politically conservative financial backing, he drew a frame of government that limited republicanism. Power was concentrated in the governor and his council, but he also guaranteed liberty of conscience and promised that the freemen could alter the system if they so chose. The response to this gesture was a political fray in Pennsylvania that was wilder than Penn

Problems of colonial government and independence

could have imagined—the consequence of the Quakers' quest for legislative power.

The turbulence in Pennsylvania caught the attention of English officials, who were already suspicious of such Quaker peculiarities as pacifism and the refusal to take oaths. As proprietor, Penn divided his energies between the demands of provincial Quakers and the threats of the home government. Because the latter were more crucial to the autonomy of his colony, he was forced to spend most of his time in England, living in Pennsylvania less than four years.

Penn's first visit (1682–84) was cut short by a boundary controversy with Maryland, which he settled advantageously after a hasty return to London. Simultaneously, James II took the throne and began to accelerate the absolutist policies of his older brother. Penn was personally sympathetic to James, persuaded by his professions favouring toleration and fearful that Pennsylvania's independence would be sacrificed to the Dominion of New England. Penn thus became implicated in a reign abruptly terminated by revolution. Ironically, the establishment of parliamentary ascendancy and religious toleration by statute in 1689 was coincident with Penn's alienation from the government. Pennsylvania was briefly brought under royal rule (1692–94), primarily because Quakers would not cooperate in the colonial war effort.

By the mid-1690s, when Penn emerged from hiding and began rebuilding his political alliances, he found both the King and Parliament intent on strengthening the crown's colonial policy and, concomitantly, undermining the autonomy of the chartered and proprietary colonies. Penn, who led the fight against passage of the Navigation Act of 1696 that embodied the new imperial designs, emerged as spokesman for the continued independence of these colonies. His own was commercially and strategically the most important and, therefore, the most visible and open to attack.

The provincial Quakers, who were indifferent to Penn's situation, continued to hammer away at executive power, even after he granted the Pennsylvania assembly pre-eminence in the Charter of Privileges, the climax of his second visit (1699–1701) to the colony. Discouraged by this lack of gratitude, shocked by the discovery that his personal steward had defrauded him of thousands of pounds, and disappointed by the un-Quakerly behaviour of his eldest son, William Penn, Jr., he initiated negotiations in 1702 to sell the "holy experiment" (while simultaneously defending it). On the verge of concluding an agreement of sale in 1712, Penn suffered a crippling stroke, lingering on pathetically until his death six years later, on July 30, 1718. The province, in trusteeship because of his indebtedness, passed to Hannah Callowhill Penn, whom Penn had married in 1696, two years after the death of his first wife. In the 18th century, Pennsylvania was distinguished by its unicameral legislature and its cultural diversity, late testimony to Penn's principles of republicanism and toleration.

Pennsylvania

One of the original 13 American colonies, the Commonwealth of Pennsylvania, as it styles itself, is the third most populous state in the nation. Since its founding in 1681, its geographical position has made it the Keystone State, integrating first the older colonies of the Northeast and the South and later the East and the developing territories and states of the Middle West. The role remains in evidence, with the state polarized by two great metropolitan areas: Philadelphia lies athwart the vast population belt stretching along the seaboard from Maine to Virginia, and Pittsburgh is the beginning of the booming industrial belt reaching westward across the Great Lakes plains to Chicago and Milwaukee. Its capital, Harrisburg, nestles in the foothills of the Appalachian Mountains.

An overview of the state

The nearly 11,800,000 Pennsylvanians counted in the 1970 census can look back over almost 300 years during which their state has played a pivotal role in the nation's history. An oasis of religious liberty as a colony, it played host in Philadelphia first to the meetings that led to the Revolution and to the formation of the new American government and then, from 1790 to 1800, to the government itself. Gettysburg saw one of the most crucial battles of the Civil War, and Titusville the world's first oil well. While Philadelphia's commercial and financial institutions long were providing the backbone of the nation's economy, the state's enormous coal beds were feeding the mills of Pittsburgh, Bethlehem, and other cities, which were to become major suppliers of iron and steel to American industry in peace and war. While Philadelphia was enjoying a dominant role in America's intellectual and artistic life until well into the 19th century, the great ethnic mix of Pennsylvanians was evolving one of the richest and most diversified folk cultures in the nation.

The 45,333 square miles (117,412 square kilometres) of Pennsylvania are bounded on the north by Lake Erie and New York; on the east by New York and New Jersey; on the south by Delaware, Maryland, and West Virginia; and on the west by the Panhandle of West Virginia and by Ohio. Although it is classified as a Middle Atlantic state, it does not touch the Atlantic Ocean at any point. Water, nonetheless, has been nearly as crucial in the state's growth as has the wealth of its earth. The boundary with New Jersey is formed by the Delaware River, on which Philadelphia is the major element in the Pennsylvania–New Jersey–Delaware harbour complex known as Ameriport, the world's third busiest shipping centre. In the northwest, a small panhandle bumps out to separate Ohio and New York, to form a 40-mile waterfront on Lake Erie and to give the state access to the iron-ore barges and other commerce of the Great Lakes. Located at the point where the Allegheny and Monongahela rivers meet to form the Ohio River, Pittsburgh has become one of the nation's busiest inland river ports. (For information on related topics, see the articles UNITED STATES; UNITED STATES, HISTORY OF THE; CIVIL WAR, U.S.; PHILADELPHIA; NORTH AMERICA; and APPALACHIAN MOUNTAINS.)

THE HISTORY OF PENNSYLVANIA

Swedes were the first European settlers in the area that was to become Pennsylvania. Travelling up the Delaware from a settlement at the present site of Wilmington, Delaware, Gov. Johan Printz of the colony of New Sweden established his capital on Tinicum Island in 1643, within the boundaries of modern Pennsylvania. Other Europeans, principally the Dutch, established trading posts within Pennsylvania as early as 1647, although the Swedes remained at Tinicum until 1655. In that year, rivalry and fighting between the Dutch and the Swedes led Peter Stuyvesant, governor of New Netherland, to seize New Sweden. Dutch control of the region ended in 1664, when the English seized all of New Netherland in the name of the Duke of York.

Swedish and Dutch settlements

The Quaker colony. In March 1681 King Charles II of England signed a charter giving the region to William Penn in payment of a debt of £16,000 owed by him to Penn's father, Adm. Sir William Penn. The charter, officially proclaimed on April 2, 1681, named the territory for Admiral Penn and included also the term *sylvania* ("woodlands"), as the younger Penn requested.

William Penn intended that the colony should provide a haven of religious tolerance for his fellow Quakers. While still in England, he drew up the first of his "frames of government" and dispatched his cousin, William Markham, to establish claim to the land and also to establish the boundaries of what became the city of Philadelphia. Penn arrived in 1682 and called a General Assembly to discuss the first Frame of Government and to adopt the Great Law, which guaranteed freedom of conscience in the colony. Under Penn's influence, fair treat-

ment was accorded the Indians, who responded with friendship in return. When Penn returned to England in 1684, the new Quaker province had a firmly established government based on religious tolerance and government by popular will.

Colonial growth. The next century was a period of great expansion and of turmoil for Pennsylvania. Its interior included land claimed by the French, and as time went on the Indians became increasingly hostile to the expansion of settlements to the west and north. Much of the fighting of the French and Indian War (1754–63) took place in Pennsylvania. Here the young George Washington began his trip into the Ohio Valley to warn the French to leave; later, it was in Pennsylvania that the English general Edward Braddock suffered defeat at the hands of the French and their Indian allies.

Site of battles and Revolutionary ferment

For many Pennsylvanians, the period following these conflicts marked growing dissatisfaction with British rule. Official limitations on westward expansion, especially as established by proclamation in 1763, were imposed to pacify the Indians, but Pennsylvanians nonetheless pressed westward over the Alleghenies. Outposts such as Ft. Pitt (Fort Duquesne under the French and now Pittsburgh) became settlements vital to the growing flow of trade from the opening lands to the west.

By the eve of the American Revolution, Pennsylvania had become a keystone state geographically and a centre of military, economic, and political activity. The first (1774) and second (1775–83) continental congresses met in Philadelphia, the Declaration of Independence was signed there, and after the war the city became the capital of the short-lived confederation and of the fledgling United States government.

Early years as a state. In 1790 a new state constitution replaced the unicameral legislature of the Revolutionary period with a bicameral one and a fairly strong governor. In the next 70 years, farm equipment was mechanized, roads were improved and extended, canals were built, and railroads spanned the state, all combining with the economic strength of thrifty Philadelphians to make Pennsylvania a major commercial power. Beginning in 1820, important mining companies were formed to exploit Pennsylvania's deposits of hard and soft coal, and in 1859 Edwin L. Drake drilled the nation's first successful oil well at Titusville. During this same period the state became a leading producer of textiles, ships, lumber, tobacco, and, most important, iron and steel.

The Civil War and its effects

The Pennsylvania Emancipation Act of 1781 had pledged the gradual abolition of slavery in the state. Once the Civil War broke out, Pennsylvania became once again a centre of military and political activity. The southern boundary of Pennsylvania, ratified in 1769, was the Mason and Dixon Line. It became the dividing line between the slave and the free states during the Civil War. At Gettysburg the Union Army won one of the most decisive victories of the war against a Confederate force led by Gen. Robert E. Lee.

Emergence of the modern state. With the end of the Civil War came a period of great economic, industrial, and population expansion in Pennsylvania. Until well into the 20th century, Pennsylvania was the second most populous state in the nation. In 1873 the state passed its fourth constitution; with amendments, the document has survived to the present day. In 1898 construction of a new, modern, state capitol building (replacing the earlier structure burned down the previous year) was begun at Harrisburg, which had functioned as the capital since 1812. The new building was completed in 1908.

In the 20th century, Pennsylvania has retained its position as one of the nation's wealthiest and most powerful states. Its mineral wealth was more fully exploited as the nation's industry became increasingly dependent first on coal and then on petroleum. In both world wars, Pennsylvania's heavy industries were major suppliers of iron and steel, arms, and machinery.

THE NATURAL AND HUMAN LANDSCAPE

The natural environment. *Topography and river systems.* The mountains and rivers dominating Pennsylvania's natural landscape have had a major influence in determining its use by man. The man-made boundaries that made it nearly rectangular in shape are totally decimated by the Allegheny section of the Appalachian Mountain system. Running across the state from southwest to northeast, it leaves only a triangle of Piedmont and Coastal Plain in the southeast, with Philadelphia and environs at its extreme point. The Allegheny Front and Mountains form an up-and-down diagonal spine across the centre of the state, while northward and westward a rugged plateau region falls almost at lakefront into the Lake Erie Lowland.

Surface features

In the eastern part of the state the Delaware is fed mainly by the Lehigh and Schuylkill. The Susquehanna, draining the largest section of the state, is a wide, shallow stream that meanders finally into Maryland and Chesapeake Bay. The Ohio system in the west has several tributaries within the state during its 980-mile course by way of the Mississippi into the Gulf of Mexico. Minor systems lead into Lake Erie in the northwest and the Potomac from the southwest.

Physiographic regions. From southeast to northwest, Pennsylvania takes in parts of seven physiographic regions. Inland from the fertile Coastal Plains around Philadelphia, the Piedmont is an area of rich limestone soils and prosperous farms that are the mainstay of the state's agriculture. The Reading Prong, part of the New England Upland, is a small tongue of a ridge in the northeast. In the south central region, the northernmost finger of the Blue Ridge extends into the state, its topography having played a large part in the Battle of Gettysburg.

The Appalachian Ridge and Valley region, running southwestward across the state to the west of the Piedmont, comprises a series of parallel ridges and valleys, including the long and wide Lehigh, Lebanon, and Cumberland valleys, which were important in America's early westward movement. From this rises the geologically newer Appalachian Plateau, whose rough-and-tumble aspect of small valleys and broken, ragged ridge lines covers more than one-half of the state, from the southwestern and western borders to the Delaware in the northeast and on into New York. Plateaus up to 2,000 feet high cover northern Pennsylvania, including Mt. Davis, at 3,213 feet (979 metres) the state's highest point. The home of the major coal-mining operations, its landscape is dotted with mines and mining towns. The sandstone soils of the mountains and plateaus are poor agriculturally. In the northwestern bump lie the Lake Erie Lowlands, a flat area of gravelly but fertile soils that once lay at lake or ocean bottom and now is a producer of grapes, wine, and potatoes.

Climate. The climate is far less variable across the state than is the landscape. Pennsylvania has a continental climate characterized by wide fluctuations in seasonal temperatures, with prevailing winds from the west. The frost-free period is longest in the southwest, the Ohio Valley, and the Erie Lowlands. Higher areas have from three to five months a year without frost. Coupled with some 42 inches (1,067 millimetres) of rain annually, this provides adequately for the cultivation of temperate-zone crops and vegetation. In the north, average temperature ranges from about 22° F (−6° C) in January to about 68° F (20° C) in July. In the southeast and western portions of the state, averages are several degrees higher.

Vegetation and animal life. Pennsylvania marks the transition zone between the northern and southern forests of North America. Over one-half of the state remains wooded, although only small areas are virgin forest. Hickory, locust, maple, cherry, beech, black walnut, elm, chestnut, poplar, ash, sycamore, willow, linden, white and yellow pine, and other conifers are all common in various parts of the state. The southeast has some trees common to the Mississippi Valley.

Pennsylvania's abundant wildlife makes it a leading state for hunting. Unprotected predatory species include red and gray foxes, wildcats, and weasels. Most large animals gradually have been eliminated by man. Species once common—*e.g.*, the black bear and the Canada lynx—are now rare, although skunks and racoons, pheasants and other game birds, and, in some areas, deer are still

found in abundance. Over 150 species of fish, including trout, bass, chub, pickerel, and white carp, are found in the streams.

Human imprints. The Pennsylvania landscape under human settlement is as varied as its physical geography. Although nearly all the land is forested or under cultivation, Pennsylvania is considered an urban, industrial state. Urban areas, however, comprise widely separated enclaves.

Rural and urban Pennsylvania

The rural areas of Pennsylvania, especially the farmlands, lie mostly in the southeastern counties. In the southwest and in the Susquehanna River Valley, pasturelands dot the landscape. Generally, several small villages, each consisting of a general store, a church, a gas station, and a few houses, are located within a short distance of a larger town that serves the surrounding farms. In the mining regions, the town structure is often completely dependent on the mines. Company towns in which almost everything—including the stores and the homes of the miners—is owned by the company can still be found. With such total dependence on a single company, a town may become a ghost town if a company discontinues mining operations.

For the most part, the urban centres developed along with specific industries. Reading is known as a textile and hosiery town, Hershey as a chocolate town, Pittsburgh and Bethlehem as steel producers, Erie as a Great Lakes port, and the Wilkes-Barre and Scranton areas as centres of the coal industry. In each case, the city extends its influence into the surrounding areas as a supplier of goods and as the determiner of artistic and cultural life.

THE PEOPLE OF PENNSYLVANIA

Four major Indian groups with tribal settlements occupied Pennsylvania at the time of European incursion. These included the Delaware, or Lenni Lenape, in the Delaware River Basin; the Susquehanna along the Susquehanna in Pennsylvania and Maryland; the Shawnee along the Susquehanna and near the present site of Easton; and various segments of the Five Nations of the Iroquois. With their bitter and bloody struggle to retain their land, the Indians were a very powerful force in the early history of Pennsylvania, but all were gradually pushed north or west as European settlers prospered. Fewer than 2,500 remain today in scattered locations.

The early Europeans. Although the Swedes and Dutch arrived in Pennsylvania first, the English Quakers were by far the most important early group that settled along the Delaware River. With a secure hold on the region, the Quakers quickly turned the Delaware counties—especially Penn's three original counties, Philadelphia, Chester, and Bucks—into a thriving commercial region.

Beginnings of ethnic diversification

Penn's policies of toleration and his experiments in democratic forms of government encouraged other groups to settle in Pennsylvania in large blocs. Germans from the Rhineland settled in numbers in the inland counties of Lancaster, Lehigh, Berks, and Northhampton. By the time of the Revolution, the Pennsylvania Dutch, as they had become known, constituted fully one-third of the colony's population. They turned their land into one of the richest and most productive farming areas in the world and made their customs, cooking, and artwork famous.

Small subgroups of the German community are important components of Pennsylvania's population in their own right. Largely religious, they include the Amish, the Mennonites, the Moravians, the Schwenkfelders, and the Dunkers. The Amish have attracted special attention because of their old-fashioned dress and educational methods and preference for living apart and farming without modern machinery.

The third major ethnic group to settle in Pennsylvania were the Scots-Irish. Pressing west past the areas of English and German settlement, this group settled along the western frontier during the middle of the 18th century. Along with the true Scots, with whom they intermingled, the Scots-Irish comprised about one-fourth of the entire population of the colony at the outbreak of the Revolution. In addition to the three main groups listed above, there were small numbers of French Protestants, or Huguenots, Welsh, Cornish, and Irish, and, of course, the Dutch and the Swedes. Through the early years of the 20th century, immigration to Pennsylvania continued to be largely German and Irish.

Later immigration. Until the 1860s, there was open land on the western frontier of the state. During this period the religious character of the commonwealth changed: the Quakers and the Pennsylvania Dutch lost numerical strength to predominantly Roman Catholic immigrants, and Presbyterianism and Methodism gained footholds in the west. In the 20th century, the most important European immigrants to enter the state have been of southern and eastern European origin, particularly Italians and Slavic peoples who provided manpower for the state's burgeoning industry and manufacturing. During and after World War II, in response to the needs of the economy, black Americans from the rural south began to settle in Pennsylvania in increasing numbers. For the most part, the newly arrived black Americans, like the Italians and Slavs, have tended to settle in urban, industrial areas.

Although Pennsylvania is a melting pot of many ethnic groups, the Quakers and the Pennsylvania Dutch continue to play roles in the culture and tradition of the state out of proportion to their actual numbers.

Contemporary demography. The census of 1970 recorded a 4.2 percent population increase in the preceding decade, a figure well below the national average of 13.3. Estimates for 1985 are well over 13,000,000, although the state will probably follow the national trend out of the cities into surrounding suburban areas. The greatest population density is found in Philadelphia and Allegheny counties, the latter including Pittsburgh. In 1790, when the first federal census was taken, 89.8 percent of the population was classified as rural. The turning point came in 1900, when for the first time the urban population, at 54.7 percent, outstripped the rural. In 1970, the urban figure was 71.5.

THE STATE'S ECONOMY

An economic overview

With fertile farmland, 16,000,000 acres of forest reserves, seemingly inexhaustible supplies of coal, many navigable waterways, and an economically strategic location on the Eastern Seaboard, Pennsylvania has always been one of the most prosperous states in the nation. As the exploitation of its primary wealth—soils, minerals, and forests—proceeded in the 18th and 19th centuries, Pennsylvania held a place second only to New York in wealth and population.

Pennsylvania still produces more steel than any other state, and its manufacturing industries are as diversified as those of any state in the Union. In the 20th century, however, the changing nature of modern industry, the use of fuels other than coal, and the growth of the rest of the country have left the Keystone State in third place in wealth (as measured in terms of gross personal income) and population. It is surpassed in manufacturing employment only by New York and in value added by manufacturing only by New York, California, Ohio, and Illinois. Technological changes have left their mark on the economy, and pockets of poverty and unemployment remain.

Sources of state income. *Mineral production and processing.* Nearly $1,000,000,000 worth of products come from Pennsylvania's mines, quarries, and wells each year. The largest share is from coal, in the production of which Pennsylvania ranks second only to West Virginia. Nearly 80 percent of the soft-coal resources remain. Oil is a minor resource in the west, but oil piped from Louisiana, Oklahoma, and Texas and brought by tanker from Venezuela and the Middle East is processed in the huge refineries lining the Delaware. The state ranks thirteenth nationally, however, in production of natural gas. Small deposits of iron ore have been discovered, along with limestone, silver and gold, copper, cobalt, and zinc. Salt beds recently were discovered in the west.

The steel industry. Pennsylvania's first ironworks, for the production of wrought iron, was built in Berks County in 1716. The eastern region long was the centre of pro-

duction, especially after large-scale exploitation of its anthracite fields began. The Pittsburgh area became increasingly important as bituminous coal and coke replaced anthracite and as the Great Lakes became the route for barges from the rich iron-ore beds around Lake Superior. Only in recent years has the complex of mills at the southern tip of Lake Michigan, in northwestern Indiana and northeastern Illinois, begun to exceed the Pittsburgh area in total steel production.

Manufacturing. Pennsylvania has always been known for the variety of its manufactures. In 1969 its industrial plants, with some 1,500,000 workers, produced more than $40,000,000,000 worth of goods. In addition to steel, Pennsylvania leads the nation in the production of flat glass, clay refractories, truck trailers, nonferrous-metal castings, and inorganic pigments. On the basis of the value of the manufactured products and the number of employees, the leading industries are metal and metal products and textiles. Other major industries include chemicals and allied products, leather and rubber goods, lumber and its remanufacture, and tobacco and its products. Industry is unevenly distributed, its greatest concentration being in Philadelphia, Allegheny, and Montgomery counties.

Retailing. The retail-sales industry is also important. John Wanamaker opened the nation's first department store in Philadelphia in the 1870s. Frank Woolworth opened his first successful five-and-ten-cent store in Lancaster in the same period. Other famous Pennsylvanians in the history of retailing are R.H. Kress, S.S. Kresge, C.G. Murphy, Newberry, and W.T. Grant, all of whom founded chains bearing their names.

Agriculture. Pennsylvania still has a sizable farm population. About one-third of the state is under cultivation in some 75,000 farms. The greatest farm acreage remains in Lancaster, York, and Berks counties in the southeast, which have the state's richest soils. Dairy products account for almost 50 percent of agricultural income, with milk the main product, followed by eggs and dairy cattle. Pennsylvania is also the leading American producer of mushrooms, cigar-leaf tobacco, sausage, scrapple, pretzels, potato chips, plantation-grown Christmas trees, state-graded apples, and quality-graded eggs. It is the second-largest national producer of ice cream and frozen dairy products and ranks among the top five states in the production of milk, eggs, sour cherries, apples, grapes, and maple syrup.

Major farm products and crops

Economic management. In 1956 the Pennsylvania Industrial Development Authority was set up to assist in the redevelopment of areas plagued by chronic unemployment. The greater part of the available funds is lent to "growth" industries. Two development corporations, the Pennsylvania Development Credit Corporation and the Southeastern Pennsylvania Economic Development Corporation, provide funds for equipment or working capital to business in the Philadelphia area.

Pennsylvania's Department of Forests and Waters is engaged in the protection and restoration of over 1,500,000 acres of forests under its control. The soil- and water-conservation division in the Department of Agriculture plays an advisory role for farmers and city dwellers. Soil-conservation districts have been established in 64 of the 67 counties.

Transportation. Pennsylvania's three major ports—Philadelphia, Pittsburgh, and Erie—are supplemented by others along the Delaware, the Susquehanna, and the channellized Inland Waterway System, which includes the Allegheny and Monongahela as well as the Ohio. Two-thirds of Philadelphia's imports are petroleum, but it has facilities for handling ores, coal, molasses, and general cargo as well. Part of Erie's facilities have been converted to the building of ore carriers for Great Lakes service.

Pennsylvania's highway system, the fourth largest in the nation, includes the Pennsylvania Turnpike, a four-lane toll road joining New Jersey and Ohio that was a model for the nation in modern superhighway construction. It is paralleled to the north by Interstate 80, also a superhighway spanning the state.

More than 8,000 miles of rail lines link the state's industrial communities. The Penn Central is the nation's largest railroad, and other lines are vital economic links throughout the Middle Atlantic region. Numerous smaller lines serve smaller areas. Philadelphia and Pittsburgh have major commercial airports, though 14 other cities are served by scheduled flights.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. *The state level.* Under the constitution of 1873, the executive branch of state government comprises the governor and lieutenant governor, the attorney general, the auditor general, and the members of the Cabinet. The governor is elected for a four-year term and can succeed himself for one additional term. Other elected officials include the auditor general, the state treasurer, and the secretary of internal affairs. The governor appoints the attorney general and the superintendent of public instruction, subject to Senate approval. Among the main powers of the governor are his rights to return bills for reconsideration and to veto portions of appropriation bills. The General Assembly is made up of a Senate and a House of Representatives. Senators are elected for four-year terms and representatives for two-year terms.

Functions of the executive, legislature, and judiciary

A unified judicial system comprises the Supreme Court, Superior Court, Commonwealth Court, and courts of common pleas, community courts, municipal and traffic courts in Philadelphia, and justices of the peace and such other courts as may be established by the General Assembly. The seven justices of the Supreme Court and judges of the Superior Court are elected for 10-year terms; justices of the peace and of the municipal and traffic courts of Philadelphia for six-year terms.

Local government. Under the constitution, local government is provided for by the General Assembly, which classifies cities, counties, boroughs, school districts, townships, and special authorities by population. All Assembly provisions must be uniform throughout each class, and no legislation may be directed toward one locality. As the only first-class city, however, Philadelphia becomes the target of legislation aimed at this class. It, with Pittsburgh and Scranton, second-class cities, has a strong-mayor government. Smaller cities have several governmental forms, while boroughs have elected councils and weak mayors.

Pennsylvania has two classes of townships and four classes of school districts. Local authorities are special units that were set up in 1933 to circumvent constitutional restrictions preventing local units from incurring debt. The cities, boroughs, and townships, as all-purpose governmental units, carry out all usual public service. A constitutional amendment in 1968 allowed all local governments to opt for home rule.

Political life. Between the Civil War and the 1920s, state government was, with a few breaks, in the hands of a succession of Republican administrations that made the statehouse a seat of "boss rule." A similar dynasty persisted in Philadelphia until the late 1940s. Pennsylvanians still tend toward the Republican Party in state elections, although the Democratic majorities in the cities exercise considerable influence in Harrisburg and, as in 1970, may carry the state. Pennsylvania generally exhibits the characteristic American pattern of rural conservatism and urban liberalism, although locally such labels may bear no necessary relation to particular parties.

The social milieu. The social and economic divisions in Pennsylvania are wide, from the affluence of Philadelphia's suburban Main Line and Pittsburgh's Oakland section to the black and Puerto Rican ghettos ringing the central city, from the lush and prosperous farms of Lancaster County to the pathetic ghost towns of Appalachia. Philadelphia and other large cities face all the grave problems of contemporary cities: the blighting of human life and the physical environment, inadequate finances, social instability and racial hostility, and a struggling educational system. The day of the isolated farm or mining community is over, but unemployment in mining regions is chronic. The federal Appalachian Regional Commission, established in 1965, is attempting to encourage economic redevelopment throughout the 12 states involved.

Statistically, however, Pennsylvanians live well, with a work force of nearly 5,000,000 and unemployment generally below the national average. Incomes and costs of living vary widely both from city to city and also from city to rural areas. Income in Pittsburgh is generally the highest, due largely to the high percentage of union employment, whereas the unemployed or unemployable of the mining regions and the city slums may live well below the poverty line.

Education. Consolidation of public-school districts in recent decades has reduced their number, the eventual goal to be fewer than 500. Districts provide physical facilities, teachers, and textbooks and levy taxes and issue bonds. The state Department of Education oversees statewide standards for teacher certification, curricula, and approximately half-cost subsidies to districts.

Institutions of higher learning

Pennsylvania is the home of more than 125 colleges and universities in addition to a state system of two-year community colleges. Pennsylvania State University, in University Park, is the publicly supported land-grant institution; it has 21 branch campuses throughout the state. The University of Pennsylvania, in Philadelphia, was originally a charity school at its founding in 1740 but was transformed by Benjamin Franklin and others into an academy. In 1765 it opened the first medical school in North America. Today, among its most notable divisions are the Wharton School of Finance and Commerce and the University Museum, a leading sponsor of archaeological expeditions and research throughout the world. Though privately endowed, it receives considerable state aid.

State aid is given also to Temple University (1884), in Philadelphia, whose programs are geared heavily to the urban setting, and to the University of Pittsburgh (1787). Philadelphia is still a major centre of medical education, while in Pittsburgh the Carnegie–Mellon University, formed in 1967 by the merger of the Carnegie Institute of Technology (1900) and the Mellon Institute (1913), makes that city a centre of scientific studies. Other schools with major reputations include Bryn Mawr College, for women (1880); Haverford College (1833) and Swarthmore College (1864), both Quaker schools; and Villanova University (1842), a Roman Catholic institution—all in the Philadelphia vicinity. Dating from the 18th century are Dickinson College (1773), in Carlisle; Franklin and Marshall College (1787), in Lancaster; and Washington and Jefferson College (1787), in Washington.

Health and welfare. More than one-half of Pennsylvania's budget is allotted to education, welfare, and highways. Hospitals and centres throughout the state deal with problems of chronic illness, old age, mental retardation, and the like, and local governments are assisted in welfare payments in a broad range of categories. Urban-renewal programs also receive state and federal funding.

CULTURAL LIFE AND INSTITUTIONS

In colonial times, Philadelphia was the focus of the nation's intellectual, cultural, and political life. As Pennsylvania grew and prospered, Pittsburgh and other, smaller cities also became centres of the arts.

The arts. Two of the nation's major symphony orchestras are located in Pennsylvania. The Philadelphia Orchestra, under conductors such as Leopold Stokowski and Eugene Ormandy, has become world famous, as has the Pittsburgh Symphony Orchestra, under such conductors as Victor Herbert, Fritz Reiner, and William Steinberg. Philadelphia's Academy of Music provides a home and concert hall for its orchestra, and the world-famous Curtis Institute of Music, founded in 1924, is one of the world's leading conservatories. In addition, many community orchestras perform throughout the state. Noted all over the world is the religious music of the Moravians. At their cultural centre, Bethlehem, the Bach Choir's Bach Festival attracts music lovers every May from many states.

Philadelphia is the home of one of the world's finest art museums, the Philadelphia Museum of Art, and of the Rodin Museum. The Pennsylvania Academy of the Fine Arts offers a base for teaching and study as well as for display. The Carnegie Institute's museum and library in Pittsburgh also houses many famous paintings. Among famous artists whose homes were in Pennsylvania are Charles Willson Peale and his two sons, Raphaelle and Rembrandt, Benjamin West, Mary Cassatt, Thomas Eakins, and the Wyeths, N.C. and his son Andrew. The Calder family of Philadelphia is famous in sculpture. Alexander Milne Calder's giant statue of William Penn stands atop City Hall, and his grandson, Alexander Calder, gained renown for his free-form mobile sculptures.

The visual arts: painting and sculpture

Philadelphia long vied with New York as the theatrical capital of the young nation, though today it is basically a tryout town for shows on their way to Broadway. Summer theatres have proliferated across the state, especially in the many resort areas. Temple and Carnegie–Mellon universities offer major programs in theatre. The Pennsylvania Ballet offers entertainment both within and outside the state. Among well-known writers of the 20th century with Pennsylvania origins are Pearl S. Buck, Rachel Carson, James Michener, Christopher Morley, John O'Hara, Mary Roberts Rinehart, and John Updike.

Museums. In addition to its art museums, Pennsylvania enjoys many other museums, both general and specialized. The Franklin Institute in Philadelphia is a museum of applied science. The William Penn Memorial Museum and Archives Building in Harrisburg, the Pennsylvania Farm Museum of Landis Valley near Lancaster, the Annie S. Kemerer Museum in Bethlehem, and the Mercer Museum of the Bucks County Historical Society (crafts and craftsmen's tools) in Doylestown house fine collections. There are also small museums in Allentown, Reading, Scranton, and Greensburg and historical society museums in Lancaster, York, Reading, Wilkes-Barre, and West Chester, to mention a few. The Pennsylvania Historical Commission, established in 1913 and known since 1945 as the Pennsylvania Historical and Museum Commission, is active in conservation of the state's historical heritage; the Philadelphia Historical Commission oversees that city's many historic shrines.

Folk culture. Pennsylvania has retained strong elements of folk culture among its diverse ethnic groups. The "plain people"—the Amish, Mennonites, and other small sects—have kept their old customs and dress and often resist the use of machinery. In Lancaster County, where the Amish still farm with horses and oxen, their wagons are a familiar sight on the country roads. The folk art and the cooking of the Pennsylvania Dutch are famous, and their brightly painted hex signs adorn their large barns. At Czestochowa, in Bucks County, the largest Polish church in America is evidence of the area's Polish population.

Communications. Public figures such as Benjamin Franklin were responsible for the emergence of newspapers, magazines, and libraries in the colony. Later, the Lippincott and the Curtis publishing families became giants in the publishing world, the Lippincotts as book publishers and the Curtis family as publishers, until very recently, of such magazines as *The Saturday Evening Post*, *Ladies Home Journal*, and *Country Gentleman*. The *Farm Journal*, a Philadelphia publication, is one of the nation's largest farm magazines. Several other major publishers are also headquartered here. In the 1970s a new magazine, *Philadelphia*, was increasing in popularity.

Historic eminence in publishing

Founded in 1870, Philadelphia's *Evening Bulletin* is one of the nation's leading evening newspapers, with its pervasive slogan that, in Philadelphia, "nearly everybody reads the *Bulletin*." The state has also pioneered in the publication of many foreign-language newspapers and in black newspapers.

All of Pennsylvania's cities and larger towns have newspapers, either daily or weekly. The major cities have their own television stations, and most local communities have their own radio stations. Station KDKA, the first commercial broadcasting station in the world, opened in Pittsburgh in 1920.

In the age of television and rapid transportation, the various cultural elements in Pennsylvania see the same movies and television programs, read the same newspapers, and share in a wider national culture.

PROSPECTS

From the ghost towns of Appalachia to the skyscrapers of Philadelphia's centre city, Pennsylvania is a land of sharp contrasts. The traditional and old contrasts sharply with the new; the pastoral countryside adjoins the industrial towns; the old families spread out in suburban comfort, while the newest of the newcomers struggle in the black ghettos.

Today, Pennsylvania has its share of financial, political, and social problems. Political struggles between the state and city governments are not uncommon. And the urgent need of the cities, particularly Philadelphia, for slum clearance, urban renewal, and crime control is reflected in their demands upon the state.

BIBLIOGRAPHY. The best current source material about Pennsylvania may be found in the many publications issued by the state in Harrisburg; these are available at little or no charge. The *Pennsylvania Manual* (biennial) has outlines of the history of the state, its government, and its economic development. This manual, a direct offspring of THOMAS JEFFERSON, *A Manual of Parliamentary Practice* (1801), provides invaluable and voluminous reference material. The *Pennsylvania Statistical Abstract* (annual) is also rich in detail, with graphs and maps to illustrate the statistical tables; as is E. WILLARD MILLER, *An Economic Atlas of Pennsylvania* (1964). For the history of Pennsylvania, one of the most interesting and detailed one-volume studies is SYLVESTER K. STEVENS, *Pennsylvania: Birthplace of a Nation* (1964). Other works of Stevens include *Pennsylvania: The Keystone State*, 2 vol. (1956); *Pennsylvania: Titan of Industry*, 3 vol. (1948), with more detailed economic history; *Portrait of Pennsylvania* (1970), a small volume of photographs with a lively text; and a paperback, *Pennsylvania History in Outline* (1968). A more detailed work on Pennsylvania's geography is RAYMOND E. and MARION MURPHY, *Pennsylvania: A Regional Geography* (1937). Pennsylvania's rivers are featured in three volumes of the "Rivers of America" series: RICHARD E. BANTA, *The Ohio* (1949); FREDERICK WAY, *The Allegheny* (1942); and RICHARD P. BISSELL, *The Monongahela* (1952). Newer books describing travel in Pennsylvania include JAMES and M. CAWLEY, *Along the Old York Road* (1965); GOTTLIEB MITTELBERGER, *Journey to Pennsylvania* (1960); and ERWIN L. PETERSON, *Penn's Woods West* (1958). On Pennsylvania's agriculture, the PENNSYLVANIA HISTORICAL AND MUSEUM COMMISSION has published *Pennsylvania Agriculture and Country Life, 1648–1840* (1950). On government, an authoritative small handbook is *A Citizen's Guide to Local Government*, published by the commonwealth in 1967. On the people of Pennsylvania there are many interesting studies, among them: SOLON J. and ELIZABETH H. BUCK, *The Planting of Civilization in Western Pennsylvania* (1939); JOHN A. HOSTETTLER, *Amish Society* (1963); FREDRIC KLEES, *The Pennsylvania Dutch* (1950); WILLIAM I. SCHREIBER, *Our Amish Neighbors* (1962); the studies of Quakers and Quakerism by FREDERICK B. TOLLES, including *Quakers and the Atlantic Culture* (1960); and PAUL A.W. WALLACE, *Indians in Pennsylvania* (1961).

(C.L.T.)

Pentecostal Churches

Pentecostal churches, a group of Protestant churches originating in the United States in the 19th century and subsequently spreading throughout the world, teach that all Christians should seek a postconversion religious experience called the baptism with the Holy Spirit. They believe that this experience corresponds to the first outpouring or descent of the Holy Spirit upon the 12 disciples of Christ assembled in Jerusalem on the day of Pentecost (seventh Sunday after Easter, or the Resurrection of Christ), as recorded in Acts 1:12–2:4, and that this experience is accompanied by the same sign: the ability to speak in a language entirely unknown and foreign to the speaker, or to "speak in tongues." Pentecostals also hold that a Spirit-baptized believer may receive at least one of the other supernatural gifts that were known to have been in existence in the early church—the ability to prophesy, to heal, or to interpret what is said when someone speaks in unknown tongues. Beyond these unique distinctions, Pentecostal churches reflect those patterns of faith and practice that are characteristic of the Fundamentalist–Holiness branches of Protestantism that also originated in 19th-century America, with their emphases of biblical literalism, conversion, and moral rigour (see also FUNDAMENTALIST AND EVANGELICAL CHURCHES; HOLINESS CHURCHES).

The significance of baptism with the Holy Spirit

Nature and significance. During the early years of the 20th century, many observers prophesied the rapid demise of the Pentecostal movement. On the contrary, however, it has burgeoned and has become one of the fastest growing religious movements in the Western Hemisphere. Though no one knows exactly how many Pentecostals there are in the world, some authorities within the movement estimate that the total membership is between 8,000,000 and 12,000,000.

Despite a common belief in certain doctrines, such as baptism of the Spirit, speaking in tongues, and healing, Pentecostals have not united in a singular denomination. The taproots of this charismatic (spiritually inspired) movement reach back into too many differing personalities, cultures, and religious heritages to allow a normative Pentecostalism to become established. Consequently, it consists of scores of groups, differing in size, church government, ordinances, modes of worship, and a veritable spate of things most other churches consider to be adiaphoristic (nonessential or peripheral to matters of faith): eating pork, wearing jewelry, using tobacco, the grounds for remarriage and divorce, taking medicines, and other such matters. Despite the tendency of Pentecostals to differ and to polarize into groups that, on the one hand, favour ardour, spontaneity, legalism, or hierarchical control and, on the other, to favour order, ritual, tolerance, or independence, the movement as a whole has grown phenomenally.

The sources of Pentecostalism's appeal. *Social appeals.* The initial success of the Pentecostal movement during the early decades of the 20th century, as well as its widespread appeal since then, had its roots in the post-Civil War period. That period was a time of mounting indifference to the claims of the biblical faith. Denominations that had been noted for their revivalistic fervour suddenly changed; they became subdued. Emotional modes of religious expression—enthusiastic congregational singing, spontaneous testimonies, prayer in unison, and extemporaneous sermons on simple biblical themes by lay preachers—gave way to ordered, formal worship services that were conducted by "reverends" who had been trained in homiletics (preaching skills) and influenced by higher biblical criticism. Chautauqua lecture centres (religious, general education, and entertainment programs that originated in Chautauqua, New York) and elegantly appointed sanctuaries replaced camp meeting sites and crude, frame tabernacles.

Changes in American Protestantism in the post-Civil War Period

As the large popular denominations—Methodist, Baptist, Disciples of Christ—that had once been known as the poor man's churches became transformed into churches of the upper middle class, people of limited means began to feel more and more out of place. They yearned to return to a "heart religion" that would satisfy not only their craving for religious certainty but also their emotional, psychological, and physical needs. The newly emerging Holiness and Pentecostal movements fulfilled these needs for many—churchgoers and unchurched alike.

Psychological appeals. Pentecostals radiated a certain assurance. The tentativeness that characterized so much of the belief within the larger historic denominations was absent in Pentecostal churches. Pastors and parishioners of Pentecostal churches had an intense faith in God. They believed in the reality of the supernatural because they had been filled with the Holy Spirit. Because of various charismatic experiences, Pentecostals possessed a certainty of faith, an assurance of salvation, and an ability to live joyously and triumphantly.

Moreover, in an era of industrial expansion with its attendant evils—*i.e.*, urban loneliness and increasing alienation—Pentecostal churches continued to minister to all levels of society, especially to the economically and culturally neglected and socially isolated. To the disinherited, Pentecostalism appears to have had a perennial appeal. According to many observers, Pentecostal churches have been able to provide more opportunity for personal fellowship than is usually found in the traditional church-

es, because their congregations are generally small. A visitor is called "brother" or "sister" and is welcomed warmly.

Worship experiences in storefront churches

Many rural-to-urban migrants found it possible to worship personally and meaningfully in a Pentecostal tabernacle or storefront mission. They had many opportunities for emotional release, which undoubtedly fulfilled a genuine psychological function. Although otherwise inhibited, people who experienced the Spirit's "moving" during a worship service felt very free to participate in it. They could accompany the exuberant gospel songs by rhythmically clapping their hands or tapping their feet; they could respond to the preacher's sermon whenever so moved by shouting "Amens" and "Hallelujahs"; and they also could speak with other tongues or could admonish listeners by prophesying. According to some psychologists, all of these actions had therapeutic effects on the participants.

Faith healing. Another probable source of Pentecostalism's appeal is the emphasis placed on the doctrine of healing. From the very beginning of the Pentecostal revival, its evangelists—Mrs. Mary B. Woodworth-Etter, Charles Price, Aimee Semple McPherson, and, more recently, Oral Roberts—have taught that deliverance from sickness was provided for in Christ's atonement and is, therefore, the privilege of all who have the requisite faith. This effort to minister to the physical needs of people most likely has been responsible for winning many followers to Pentecostalism.

Origins of Pentecostalism. *Speaking in tongues.* Glossolalia, the phenomenon of speaking in tongues, in the apostolic church is known primarily from the writings of St. Luke and St. Paul. After an initial outburst of speaking in tongues, in Jerusalem on the day of Pentecost, the phenomenon appeared later at Caesarea, Ephesus, and Corinth, a city in which prophets, healers, and speakers in tongues were very active. Other post-apostolic instances of glossolalia have been recorded throughout the history of the Christian church: among the Montanists (heretical followers of the 2nd-century Phrygian prophet Montanus), among radical Anabaptists (extreme left-wing Protestants in 16th-century Germany), and among the Camisards (a radical Protestant peasant group from southern France) and Jansenists (a Catholic reform movement) in 17th- and 18th-century France. The gift of tongues was also prolific among the Shakers, a celibate communal religious sect in the mid-18th century United States. During the 19th century, an outburst of glossolalia and some instances of healing occurred, notably in the Scottish preacher Edward Irving's church in London's Regent Square, among the Mormons, and among various groups of Holiness people in the mountains of Tennessee and North Carolina.

20th-century Pentecostal origins. The roots of the modern Pentecostal movements go back to a small religious school called Bethel Bible College in Topeka, Kansas. The director of the institution, Charles Fox Parham, one of many ministers who had been influenced by the Holiness movement, believed that what he saw as a complacent, prosperity-ridden, and coldly formalistic church of the era needed to be revived and that such a revival could only be achieved by another outpouring of the Holy Spirit. He therefore instructed his students, many of whom already held ministerial credentials with Methodist, Friends, or Holiness churches, to pray, fast, study the Scriptures, and await an endowment of Pentecostal blessing and power that would be very much like the events recounted in the book of Acts.

Influence of Charles Fox Parham

On January 1, 1901, a student, Agnes N. Ozman, was the first of Parham's many students to experience a Spirit baptism, and she began speaking in an unknown tongue. Henceforth, most Pentecostals usually declared that glossolalia was the "initial evidence" that one had been truly Spirit baptized.

That recurrence of Pentecost in Topeka also had some prophetic overtones, for those who had been Spirit filled were familiar with the prophecies of the Old Testament Book of Joel ("in those days, I will pour out my spirit"). They had experienced what they saw as a supernatural outpouring of the so-called Latter Rain; they therefore believed that they must be living in the last days. Imbued with this sense of urgency, Parham and his students set out to evangelize the U.S. Southwest before the end came. Their efforts were so successful that by 1905, according to Parham, approximately 25,000 persons in Texas alone had embraced Pentecostal faith and practice. The embryonic charismatic movement was at first significant only regionally: in the tri-state region of Kansas, Missouri, and Texas, and in Alabama and western Florida. The national and international expansion occurred as a consequence of what is recorded as the Azusa Street revival of 1906.

The Apostolic Faith Gospel Mission at 312 Azusa Street in the industrial section of Los Angeles was unpretentious. Its leader, William Seymour, a one-eyed Negro former Holiness preacher, had been exposed to Pentecostal teaching at a Bible school that Charles Parham had established in Houston, Texas. Under his guidance, the old frame building, which formerly had housed a Methodist congregation, became a Pentecostal mecca (or pilgrimage centre). From April 1906 onward, rich and poor, blacks and whites, native Americans and those from abroad, and seekers and skeptics flocked to the Azusa Street Mission to receive spiritual help.

Spiritually energized and convinced that they had been charismatically endowed, scores of men and women spread out to tell of their experiences, extolling the reality and purposiveness of speaking in tongues. Soon storefront missions, modest tabernacles located in sparsely populated rural areas, and upper-story lofts in squalid urban neighbourhoods housing lively groups of Pentecostal believers sprang up in many parts of the world. These congregations represented the effects of a novel revival that was known variously as the Latter Rain, Apostolic Faith, or Pentecostal movement.

Initial unification of Pentecostal Christians

At first, the ultimate in organizational development among Pentecostal Christians was an amorphous sort of "spiritual union." Little if any thought was given to forming a separate "Pentecostal" branch of the Christian Church. Despite the fact that scores of members of the historic Protestant churches embraced the teachings and practices of tongue speaking, healing, and prophesying, they initially had no intention of withdrawing from their own churches to form another denomination. They merely wanted to be agents of reform and revival, helping to rid their churches of formalism in worship, modernism in belief, and worldliness in practice and striving to transform them into vibrant, spirit-filled communities similar to those described in the New Testament book of Acts. They fully expected the "showers of blessing," the prophetically promised Latter Rain of which they had received a few droplets, to fall copiously upon their respective denominations, which would make them wholly Pentecostal.

But the triumphant conquest of the Protestant religious world by Pentecostal ideas during those early years never materialized. In fact, the embryonic movement became the object of rather widespread opposition. Pastors who endorsed Pentecostal practices were relieved of their pulpits by their churches; missionaries who were sympathetic toward the charismatic movement were notified by their mission boards that their financial support was being stopped; and parishioners who practiced speaking in tongues found their names being stricken from membership rolls. Resolutions were passed and anathemas (rigorous ecclesiastical denouncements) were pronounced against those exhibiting Pentecostal practices. Those who desired to retain their charismatic religious way of life found it increasingly difficult to do so within the institutional framework of conventional Protestantism, with the result that many holding such views withdrew from their churches to form new and distinctly Pentecostal groups.

At the outset, most Pentecostals shunned anything that reminded them of the religious bodies from which they had separated. They were particularly wary of the multiplication of, or the concentration of, power in administrative bureaus. They were unwilling to subject themselves to external ecclesiastical control or to be bound by

common practices in matters of faith or polity. The result of such fears was a heterogeneity that was totally ineffectual. What became viewed as false doctrines spread unchecked; self-styled evangelists preyed on congregations that found it difficult to discriminate between sincere and insincere preachers; and financial accounts and records went unaudited. Leading Pentecostals, recognizing that the problems created by unbridled individualism and autonomy far surpassed the evils of organization and bureaucracy, attempted to establish a denomination that was unmistakably charismatic. A unitive Pentecostal movement, however, never developed. Divisions occurred as groups of Pentecostals tended to gravitate toward gifted leaders in their locales or because some demanded universal obedience to their unique tenets of faith or practice. Instead of a singular movement, a variety of Pentecostal groups evolved. They differed—often radically—in matters of belief, liturgy, and organization. Some favoured ardour, spontaneity, legalism, and independency; others preferred order, ritual, tolerance, and hierarchical control.

It was imperative, then, that Pentecostals organize, and they did, although not into one massive body. Most interpreters of Pentecostalism have overlooked this fact, namely, that Pentecostalism is not a singular movement, that normative Pentecostalism is virtually nonexistent, and that, therefore, it consists of a variety of groups that differ—often radically—on many matters of faith and practice.

Varieties of American Pentecostalism. *Churches of God.* In 1896, before either the appearance of Pentecostal phenomena at Topeka, Kansas, or the massive outburst at Los Angeles, at least 100 North Carolinians had received the baptism of the Holy Spirit and had spoken in tongues. They were members of an organization called the Christian Union, the name of which was later changed to the Holiness Church (1902) and, finally, to Church of God (1907). Doctrinally, that denomination is similar to the other groups that emerged from the Holiness movement in its emphasis upon sanctification and personal holiness. Moreover, it is perhaps the only large Pentecostal body that observes foot washing as an ordinance.

Holiness Church origins

The Church of God is administered by a General Assembly, the highest governing body. Composed of ministers and laymen from all recognized churches, it meets biennially to deal with matters of polity or doctrine and to select its chief administrators: four overseers, a general secretary-treasurer, and a director of world missions. Those six executives, who are elected to four-year terms, together with a council of 12 elders, who are elected every two years, constitute the Supreme Council. This is the denomination's highest administrative body and is responsible for handling policy matters in the periods between General Assemblies.

Since its origin, the Church of God (Cleveland, Tennessee), so designated to distinguish it from the many other groups bearing the same name, has experienced a number of schisms. Most of them occurred after A.J. Tomlinson, general overseer from 1909 to 1923, was impeached and removed from office. Tomlinson withdrew but remained in Cleveland and founded a Church of God bearing his name. After his death in 1943, the Tomlinson Church of God split into the Church of God of Prophecy (headed by one son, Milton) and the Church of God, World Headquarters (under the leadership of another son, Homer).

Despite this fragmentation, the Church of God (Cleveland, Tennessee) has experienced substantial growth. It has erected a multi-million-dollar printing plant and a world-headquarters office in Cleveland, Tennessee, and has developed Lee College into a four-year institution of higher learning. In 1951 it effected an amalgamation with the Full Gospel Church in South Africa, thus increasing its membership by 30,000 and its number of churches by nearly 200. Thus, in little more than half a century, the Church of God (Cleveland, Tennessee) has grown from the five-church denomination of 150 members that convened at Union Grove, Tenneseee, in 1907 to a rather respectable size: 2,917 ordained ministers, 3,933 churches, and an inclusive membership of 257,995.

Assemblies of God. With 11,677 ministers, 8,619 churches, and 625,027 members, the Assemblies of God is probably the largest Pentecostal denomination in the United States. Until its formation at Hot Springs, Arkansas, in 1914, Pentecostals in America were governed either by a small association with a dynamic leader at its head, such as Charles Fox Parham or Florence Lewis Crawford of the Apostolic Faith, or they were governed by bodies such as the Church of God and the Pentecostal Holiness Church, which were largely regional. No national organization existed to serve the thousands of Pentecostals who were either not from the South or, if they were, were not from the Holiness groups within American Protestantism. Some Pentecostal leaders were aware of this—especially Eudorus Bell, Howard A. Goss, Arch P. Collins, and Daniel C. Opperman—and they provided the impetus for establishing a denomination that would fuse the heterogeneous Pentecostal assemblies, missions, and tabernacles that were scattered throughout the United States. They called a "General Council of Pentecostal saints" to convene at Hot Springs (April 2–12, 1941). About 120 pastors and evangelists from 20 states and several foreign countries responded. Their primary task was to establish an acceptable system of organization and to formulate a doctrinal statement to which the delegates, coming from such diverse religious traditions, could subscribe. They adopted a simple kind of polity, a curious admixture of Congregational and Presbyterian elements. The Council elected an Executive Presbytery to serve as the central administrative group; this organ was empowered to execute the mandates given it by the General Council and to act for the council in all matters that affected its interest when it was not in session.

Establishment of the Assemblies of God

Except for a pronouncement that "the Holy inspired Scriptures are the all-sufficient rule for faith and practice . . . and we shall not add to or take from them," that first General Council postponed action on the matter of a definitive doctrinal statement. Subsequently, however, a *Statement of Fundamental Truths* was adopted. The document demonstrated that the Assemblies of God are Trinitarian (believing in God as Father, Son, and Holy Spirit) and Arminian (accepting the doctrines of grace and free will as espoused by the 16th–17th-century Dutch theologian Arminius). They also subscribed to two ordinances (Baptism by total immersion in water and the Lord's Supper), held a view of sanctification (becoming holy) that may be described as "progressive," or gradual, rather than "instantaneous" in regard to moral purity, and, finally, were strongly pre-millennial (believing in the doctrine of Christ's Second Advent before the 1,000-year reign of Christ and his saints).

From the outset, the Assemblies of God has been intensely missions-conscious. Its members contribute millions of dollars annually toward the support of more than 800 missionaries who serve in about 70 countries. In addition, the denomination conducts a diversified program of home missions among foreign language groups in America's urban centres, on Indian reservations, in prisons, and among the deaf and the blind.

Its printing plant, the Gospel Publishing House, located in Springfield, Missouri, prints more than ten tons of religious literature each day. It operates two fully accredited colleges of arts and science—Southern California College (Costa Mesa) and Evangel College (Springfield, Missouri)—and a number of regionally located Bible institutes.

Church of God in Christ. Of the several Pentecostal groups that have been established by gifted personalities, the largest probably is the Church of God in Christ. This large Pentecostal denomination, the membership of which is principally within the black community, is largely the result of the dynamic leadership of one individual, Charles H. Mason. At the turn of the 20th century, Bishop Mason was pastor of the Church of God in Christ in Memphis, Tennessee, and he was associated with the Holiness movement. When news of the outpouring of Pentecostal blessing at the Apostolic Faith Gospel Mission

Influence of Charles H. Mason

reached him, he decided to go to Los Angeles. During his five-week stay, he received Spirit baptism and spoke in tongues. He returned to his congregation and began to preach the need for a charismatic experience. Tensions developed, and a non-Pentecostal faction withdrew. Mason proceeded to convene a General Assembly and to declare that the Church of God in Christ was henceforth Pentecostal. At that first Assembly, which met in Memphis, Tennessee, *c.* 1907, Mason was elected general overseer of about 12 churches located principally in Tennessee, Arkansas, Mississippi, and Oklahoma.

For decades, Mason almost single-handedly supervised the activities of a denomination that in the early 1970s claims more than 4,000 churches and a worldwide membership in excess of 2,000,000. In 1933, however, after his administrative responsibilities had apparently become too burdensome for him, Mason, who had the titles "Chief Apostle," "Bishop," and "Elder," relinquished some of his authority to four assistant bishops and later to state overseers. This form of church government, with its adherence to Episcopal authority, is not characteristic of most contemporary Pentecostal groups, which combine elements of Congregational and Presbyterian polity. In doctrinal matters, however, there is little difference between the Church of God in Christ and other charismatic groups, especially the Churches of God and the Pentecostal Holiness Church, that stress perfectionism.

Pentecostal Holiness Church, Inc. At the turn of the 20th century, a number of churches that had been affiliated with the Holiness movement were converted to Pentecostal beliefs and practices and withdrew from their parent bodies. Gradually, three such groups—The Fire-Baptized Holiness Church, the Pentecostal Holiness Church, and the Tabernacle Pentecostal Church—consolidated and formed the Pentecostal Holiness Church, Inc. Unlike most other Pentecostal churches, this denomination permits candidates for Baptism to "have the right of choice between the various modes as practised by the several evangelical denominations." It even permits the Baptism of infants. In matters of polity, it is decidedly less democratic than other Pentecostal bodies. Reflecting its Methodist Episcopal heritage, the denomination is divided into conferences: general, annual, district, and missionary. The General Board of Education oversees the operations of three church-related institutions of higher learning: Emmanuel College, a fully accredited academy and junior college in Franklin Springs, Georgia, close to the denominational headquarters; Holmes Theological Seminary in Greenville, South Carolina; and Southwestern Pentecostal Holiness College in Oklahoma City, Oklahoma, which Oral Roberts, a well-known faith healer and evangelist, helped to establish. Although the expansion of the church has not been spectacular, it has been consistently steady. In 1916 it reported having 192 churches and 8,096 members; by the 1970s it had grown to 1,355 churches and 66,790 members.

Pentecostal Church of God of America, Inc. When the General Council of the Assemblies of God was formed in 1914, many ministers could not understand how a local church could affiliate with a national organization and not lose its sovereignty. Many of them, therefore, refused to unite with the Assemblies of God. When a subsequent General Council adopted a *Statement of Fundamental Truths,* this merely confirmed the suspicions of these independents, who regarded such an action as a regression to the conventional ecclesiasticism from which many Pentecostals had just recently emerged. Consequently, they united to form the Pentecostal Church of God of America, Inc., which demonstrated its independence by establishing rather liberal policies on ordination, church membership, and the issue of divorce and remarriage of the clergy. Though not very active in the area of foreign missions, the Pentecostal Church of God has conducted an extensive ministry among the American Indians. Headquarters for the church, which had 975 churches and 115,000 members by the 1970s, are in Joplin, Missouri, where new facilities were constructed in 1950.

United Pentecostal Church, Inc. During the second decade of the 20th century, the Pentecostal movement was convulsed by a doctrinal controversy that originated on the West Coast of the United States and swept through the heartland of America. The "New Issue," "Oneness," or "Jesus Only" churches, as they were variously called, contended that true Baptism must be "in the name of Jesus" only, rather than in employing the traditional Trinitarian formula. Furthermore, the proponents of this view denied that there were three Persons in the Godhead, asserting instead that there were three manifestations of one Person, namely, Jesus. This teaching, for a time, threatened to decimate the newly organized Assemblies of God, because many of its leaders submitted themselves to rebaptism in "Jesus' name." After the fourth General Council in St. Louis, Missouri, in 1916, when the Assemblies of God articulated a position that was staunchly Trinitarian, the "unitarian" faction withdrew to form the Pentecostal Assemblies of the World, Inc., locating their headquarters in Indianapolis, Indiana, where G.T. Haywood, a black evangelist, had a strong "Jesus Only" congregation. Originally, all unitarian Pentecostals were united in this one interracial body. In 1924, however, the white members asserted that integration hindered their evangelistic efforts and withdrew to form what became the Pentecostal Church, Inc. In 1945 it united with another body of unitarian Pentecostals, the Pentecostal Assemblies of Jesus Christ, to form the United Pentecostal Church, Inc., the largest body of "Jesus Only" Pentecostals. In 1968 it numbered 2,500 churches and reported having 225,000 members. Besides espousing a somewhat unorthodox doctrinal position, the United Pentecostal Church, Inc., takes a more rigorous stand than most other Pentecostal groups concerning such practices as the use of cosmetics, wearing revealing clothing, watching television, or listening to radios. These practices are considered to be worldly and not in accord with the way of life of the believer who is filled with the Spirit.

The rise of the "Jesus Only" movement

International Church of the Foursquare Gospel. Aimee Semple McPherson, a popular and colourful American revivalist preacher, was conducting a revival campaign in Oakland, California, in 1921. According to her own testimony, she saw a vision of four living creatures reminiscent of the one recorded in the Old Testament Book of Ezekiel (1:5–10). To "Sister" Aimee the faces of these four creatures—a lion, a man, an ox, and an eagle—symbolized perfection, and she equated a perfect, foursquare, full gospel with one that would stress four themes: salvation, Holy Spirit baptism, healing, and the Second Coming of Christ. These four themes became the hallmark of her preaching, and, in a short time, hundreds flocked to her meetings; in two years she was able to dedicate Angelus Temple in Los Angeles as the "mother church" of the Foursquare Gospel Association. From 1923 onward, her organization, which initially centred on her and her multi-million-dollar sanctuary (Angelus Temple), grew to national and international importance.

The rise of Aimee Semple McPherson

Students who graduated from her Evangelistic and Missionary Training Institute had launched into the work of establishing home and foreign missions. Branch churches sprang up in the environs of Los Angeles; by 1925, 32 had been established in southern California, and 50 more were appealing to Angelus Temple for permission to affiliate. By 1970 the Foursquare Church had become one of the largest Pentecostal denominations: 1,796 churches and an inclusive membership of 186,782.

The episcopal character of its church government bears the stamp of the founder, around whom everything centred during her lifetime. Aimee Semple McPherson was president of the church and the ruling power and voice of the organization. She held the power of veto; she appointed all officers; she hired all personnel and set their salaries. Her son and successor, Rolf K. McPherson, carries on this tradition. Doctrinally, however, the church is similar to the Assemblies of God, on the ministerial rolls of which Mrs. McPherson's name appeared for several years during her early evangelistic career.

Regional, ethnic, small, and cultic varieties of Pentecostalism. The forenamed Pentecostal denominations have expanded, nationally and internationally, and rep-

resent the majority of Pentecostals in the United States. There are, however, about 24 other groups—many rather obscure—that have had an impact only upon certain sections of the United States, that are racially or ethnically oriented, that have never become numerically impressive, or that remain on the outer fringes because of a preoccupation with individual practices.

Most of the racially or ethnically oriented Pentecostal groups are in general agreement in matters of faith and practice. Perhaps the two most widely known are the United House of Prayer for All People, the handiwork of Bishop Charles Emmanuel "Sweet Daddy" Grace, and the Church of God with Signs Following, the so-called "Mother Church of snake-handling" in the South. They are, to be sure, by no means representative of the Pentecostal movement.

Pentecostalism outside the United States. Though the phenomenal growth of U.S. Pentecostalism during the last 50 years is well documented, the expansion of Pentecostalism in other parts of the world has been equally remarkable, though less well known. In Mexico, the 146,000 Pentecostals constitute the largest segment of Evangelical Protestantism. The growth of Pentecostalism in Latin America, especially Argentina, Brazil, and Chile, has been quite impressive. The memberships of the Congregação Cristã and Assembléias de Deus do Brasil, the two largest Brazilian Pentecostal bodies, are in excess of 4,000,000. Chile probably is the most Pentecostal of all the South American countries: two-thirds of its Protestant inhabitants are Pentecostal.

Latin American and European Pentecostalism

In Sweden as well as Norway, the Filadelfia Pentecostal Churches are numerically second only to the state church (Lutheran). Most astonishing, perhaps, is the growth of Pentecostalism in the Soviet Union. Despite the fact that the movement has no official recognition and is frequently the object of scurrilous attacks both in the Soviet press as well as in government circles, the Pentecostal movement apparently has experienced significant growth in the two decades following World War II. According to a British Pentecostal leader, J. Nelson Parr, there were, in the early 1960s, approximately 250,000 Pentecostal believers in the U.S.S.R., especially in the Ukraine and in Siberia. Because many Pentecostals have been intransigent, refusing to affiliate with the All-Union Council of Evangelical Christians and Baptists, which is approved by Soviet authorities, and are hostile toward the Orthodox Church or toward religious groups that are politically docile, they have often been vilified by Soviet authorities for engaging in activities that are characterized as "hostile to humanity."

As the Pentecostal movement has grown, it has experienced change. Though continuing to minister to those on the social periphery, Pentecostal churches are no longer meeting only the needs of the dispossessed or disinherited. Allegiance to the storefront, second-floor mission, or frame tabernacle on the wrong side of the tracks has given way to interest in more permanent structures. Pentecostals in Grand Falls, Newfoundland, have constructed an ultramodern building that cost $1,000,000; the Apostolic Church in England recently erected the largest church building in Wales.

Recent developments. Also, Pentecostals were once militantly anti-intellectual. Many of them held the view that those who were filled with the Spirit needed no one to instruct them. Since 1950, however, nearly a score of Bible colleges and colleges of arts and science have been established by various Pentecostal denominations. Pentecostal services have changed as well. The lack of any order of worship and the emotional and charismatic outbursts that were allowed free course have largely disappeared. The spontaneous outbursts of glossolalia that frequently punctuated the services of worship have become controlled by the minister.

In the early days of the movement, Pentecostals were sometimes charged with being aloof, critical, or suspicious of non-Pentecostals. This possibly was a reaction to the vilification that was directed at them by many of the established denominations. Whatever the reason, the attitude persisted until the 1950s, after which the suspicion and criticism of others subsided and was replaced by a probing self-criticism.

A growing number of Pentecostals have been aroused to concern themselves with social problems. Unlike many of their predecessors, they have not been as prone to ignore the various social, economic, and political problems that concern their contemporaries. Some, for the first time, have recognized an obligation to attempt to relate the principles of the gospel to these problems. As a result of this concern, some have become involved in political activities; others have become counsellors to prison inmates; still others have been working with drug addicts, neighbourhood gangs, prostitutes, and other persons overpowered by urban problems.

Transformation of Pentecostalism

A large segment of the Pentecostal movement has undergone a transformation. While this has been going on and the larger groups have been gaining adherents and becoming increasingly successful, some others, remembering the simplicity of the early days, have become uncomfortable and have started to withdraw and form new factions. Such new factions—as the early Pentecostals before them—advocate little or no organization, stress "leadings of the Spirit" in place of a fixed order of worship and a structured organization, and prefer isolation to compromise. At the end of World War II, a veritable spate of these independent Pentecostal groups appeared: the New Order of the Latter Rain, the World Church, Wings of Healing, and the Full Gospel Fellowship of Ministers and Churches, International.

Teachings, organization, and practice. *Teachings.* In matters of doctrines, Pentecostals can be described as Evangelicals whose theology is akin to Fundamentalism. Almost universally, they believe in the infallibility of the Bible, the Trinity, the virgin birth and complete deity of Christ, the atoning sacrifice of his death for the sins of the world, the Resurrection, and the return of Christ in bodily form to earth. In other matters of faith and practice, they resemble revivalistic and Holiness movements that flourished during the late 19th century. They believe that one must pray unceasingly, expressing godly sorrow for his sins until he feels an inward assurance of salvation. They also declare that a person can attain holiness if he abandons his own efforts to achieve perfection and permits the Holy Spirit to live within him the Christ life.

But the teaching unique to Pentecostalism, setting it apart from other types of Protestant Christianity, is the belief that a baptism in the Holy Spirit, accompanied by speaking in tongues, should be the normative religious experience of all Christians. Pentecostals base their belief in a Spirit baptism and glossolalia on instances recorded in Acts. To them, speaking in tongues is a supernatural utterance in a language never learned by the speaker, not understood by him, and, furthermore, rarely comprehended by the listener. Pentecostals value the purposiveness of the tongue-speaking experience. They believe that tongues often strengthen the individual Christian in his witness; that, when accompanied by interpretation, glossolalia edifies the church; and that this activity is a vehicle of the loftiest kind of spiritual praise. What is frequently overlooked, however, is that, for most aware Pentecostals, glossolalia is not intended to be the culminating event in a catalog of religious experiences but rather the commencement of a new life in the Spirit that is distinguished by certain charismatic gifts, such as the ability to speak wisely or prophetically, the power to heal or work miracles, and the ability to discern error or control demons.

Pentecostal normative experiences

Worship. Pentecostal worship presents a variegated pattern. In the United States, for example, some churches are still presided over by lay preachers who encourage demonstrative meetings, in which opportunities for handclapping, crying, shouting, and the exercise of the charismata (spiritual powers) abound. On the other hand, in churches served by trained ministers—trained either in college, seminary, or Bible institute—worship is more orderly; disrupting manifestations of emotionalism have largely disappeared; ardour has been counterbalanced by a growing respect for order; and a sort of modified liturgical tradition has emerged. Even in the more sedate

churches, however, Pentecostal worship is still joyful, emotional, and sometimes unpredictable: strong men weep, and quiet women shout "Hallelujahs."

The ordinary Pentecostal worship service may include many, if not all, of the following elements: (1) spirited singing of gospel hymns by the entire congregation, often accompanied by a choir and orchestra; (2) extemporaneous prayers, generally by one person but frequently by the entire gathering; (3) personal testimonies by church members who will witness publicly to some spiritual triumph or answered prayer, who will confess to some act of sin, or who will request the prayers of fellow believers for a particular physical, spiritual, or material need; (4) biblical, evangelistic preaching that concentrates on one or more of the following topics—salvation, Spirit baptism, divine healing, or the Second Coming; and (5) the altar service, during which time those who wish to be "saved, sanctified, filled with the Holy Spirit, or healed" are invited to go forward to the altar, where they are prayed for by the minister and many of the members.

Pentecostal ordinances

Like most Protestants, Pentecostals practice two ordinances: Baptism, generally of adults and by immersion; and Communion (the Lord's Supper). A few groups, such as the Churches of God, advocate another—foot washing, explaining that, because Jesus instructed his disciples to wash another's feet and because the early church practiced this rite, it, too, ought to be continued as a Pentecostal ordinance.

Organization. During the early years of the Pentecostal revival, many of its adherents were anti-denominational, aloof toward established denominations, and fragmented among themselves over a variety of issues.

In the 1940s, however, changes began to occur. Pentecostals decided to abandon their isolationism. They joined the National Association of Evangelicals (1943); they united to form national as well as international fellowships: *i.e.*, the Pentecostal Fellowship of North America (1948) and the Pentecostal World Conference (1947). Pentecostal groups from Latin America have applied for and have been admitted to membership in the World Council of Churches.

Recent estimate of Pentecostalism by other Christian Churches. Through organizations such as the Full Gospel Businessmen's Fellowship International, the efforts of Pentecostal ecumenists and the impact of the salvation-healing revivals, conducted by outstanding television personalities such as Oral Roberts, the charismatic movement has affected not only Protestants of nearly every denomination but many Roman Catholics as well. This has forced many critics who had earlier rejected Pentecostalism as a suspect religious movement to revise their appraisals of it.

Pentecostals are frequently lauded for their dynamic missionary concern, for re-emphasizing the central place that ought to be accorded the Person and work of the Holy Spirit in the Christian Church, for helping nominal Christians and casual churchgoers become vital believers and zealous witnesses after experiencing their personal Pentecost, and for ministering to the heterogeneous needs of the dispossessed—*i.e.*, the economically disinherited, the educationally deprived, the geographically uprooted, the physically afflicted, and the psychologically insecure.

Other estimates of Pentecostalism have been less positive. The movement has been criticized for channelling too much of its resources and services into evangelistic missionary enterprises and for remaining indifferent to the manifold social problems that afflict contemporary society.

Pepin the Short

Pepin III, called Pepin the Short, was the founder of the Frankish Carolingian dynasty of medieval Europe and the father of Charlemagne. He was the first king of the Franks to be anointed by the pope upon accession to the throne.

Rise of the mayors of the palace

For years the Merovingian kings had been unable to prevent power from slipping from their hands into those of the counts and other magnates. The kings were gradually eclipsed by the mayors of the palace, whose status developed from that of officer of the household to regent or viceroy. Among the mayors, a rich family descended from Pepin of Landen (Pepin I) held a position of especial importance. When Charles Martel, the scion of that family, died in 741, he left two sons: the elder, Carloman, mayor of Austrasia, Alamannia, and Thuringia, and Pepin III, mayor of Neustria, Burgundy, and Provence. No king had ruled over all the Franks since 737, but to maintain the fiction of Merovingian sovereignty, the two mayors gave the crown to Childeric III in 743.

Charles had had a third son, however—Grifo, who had been born to him by a Bavarian woman of high rank, probably his mistress. In 741, when his two brothers were declared mayors of the Franks, Grifo rebelled. He led a number of revolts in subsequent years and was several times imprisoned. In 753 he was killed amid the Alpine passes on his way to join the Lombards, at this time enemies of the Franks as well as of the papacy.

Numerous other rebellions broke out. In 742 men of the Aquitaine and Alamannia were in revolt; in 743 Odilo, duke of Bavaria, led his men into battle; in 744 the Saxons rebelled; in 745 Aquitaine, and in 746 Alamannia, both for the second time.

In 747, when Carloman decided to enter monastic life at Rome, a step he had been considering for years, Pepin became sole ruler of the Franks. But Pepin was ambitious to govern his people as king, not merely as mayor. Like his father, he had courage and resolution; unlike his father, he had a strong desire to unite the papacy with the Frankish realm. In 750 he sent two envoys to Pope Zacharias with a letter asking: "Is it wise to have kings who hold no power of control?" The Pope answered: "It is better to have a king able to govern. By apostolic authority I bid that you be crowned King of the Franks." Childeric III was deposed and sent to a monastery, and Pepin was anointed as king at Soissons in November 751 by Archbishop Boniface and other prelates.

Pepin and Pope Stephen II

The Pope was in need of aid. Aistulf, king of the Lombards, had seized Ravenna with its lands, known as the exarchate. Before long, Lombard troops marched south, surrounded Rome, and prepared to lay siege to its walls.

This was the state of things when in 752 Zacharias died and Stephen II became pope. In November 753 Pope Stephen made his way over the stormy mountain passes to Frankish territory. He remained in France until the summer of 754, staying at the abbey of Saint-Denis, Paris. There he himself anointed Pepin and his sons, Charles and Carloman, as king and heirs of the crown.

The Pope returned to Italy accompanied by Pepin and his army. A fierce battle was fought in the Alps against Aistulf and the Lombards. The Lombard king fled back to his capital, Pavia; Pepin and his men plundered the land around Pavia until Aistulf promised to restore to papal possession Ravenna and all the Roman properties claimed by the Pope.

Aistulf broke his word. Again and again Pope Stephen wrote to Pepin of his difficulties. In 756 the Frankish king once more entered Italy. Aistulf was once more constrained to make promises, but the same year he died—of a fall from his horse—and in April 757 a new king, Desiderius, became ruler of the Lombards. That year Stephen II also died, and Paul I was elected pope. He, too, constantly wrote to Pepin asking for help.

But the King of the Franks had other concerns. He had to put down revolts in Saxony in 748 and 753 and a rising in Bavaria in 749. He was continually marching against rebellious Aquitaine. In 768 Pepin died at Saint-Denis, on his way back from one of his Aquitainian expeditions.

Pepin is remembered not only as the first of the Carolingians but also as a strong supporter of the Roman Church. The papal claims to territory in Italy originated with Pepin's campaigns against Aistulf and the latter's pledge to return the Roman territories. His letters also show him calling for archbishoprics in Frankish territory, promoting synods of clergy and layfolk, and as deeply interested in theology.

(E.S.D.)

Pepys, Samuel

English man of letters and naval administrator whose celebrated diary gives a valuable, entertaining, and intimate picture of the social life of his day, Samuel Pepys was born on February 23, 1633, in Salisbury Court near St. Bride's Church, London. He was the son of a working tailor who had come to London from Huntingdonshire, in which county, and in Cambridgeshire, his family had lived for centuries as monastic reeves, rent collectors, farmers, and, more recently, small gentry. His mother, Margaret Kite, was the sister of a Whitechapel butcher. But, though of humble parentage, Pepys rose to be one of the most important men of his day, becoming England's earliest secretary of the admiralty and serving in his time as member of Parliament, president of the Royal Society (in which office he placed his imprimatur on the title page of England's greatest scientific work, Sir Isaac Newton's *Philosophiae Naturalis Principia Mathematica*), master of Trinity House and of the Clothworkers' Company, and a baron of the Cinque Ports. He was the trusted confidant both of Charles II, from whom he took down in shorthand the account of his escape after the Battle of Worcester, and of James II, whose will he witnessed before the royal flight in 1688. The friends of his old age included Sir Christopher Wren, Sir Isaac Newton, John Evelyn, Sir Godfrey Kneller, John Dryden, and almost every great scholar of the age.

Early career. Samuel Pepys (pronounced peeps) was sent, after early schooling at Huntingdon, to St. Paul's School, London. In 1650 he was entered at Trinity Hall, Cambridge, but instead went as a sizar to Magdalene College, obtaining a scholarship on the foundation. In March 1653 he took his B.A. degree and in 1660 that of

Pepys, oil painting by John Hayls, 1666. In the National Portrait Gallery, London.
By courtesy of the National Portrait Gallery, London

M.A. Little is known of his university career save that he was once admonished for being "scandalously overserved with drink." In later years he became a great benefactor of his college, to which he left his famous library of books and manuscripts. He was also once offered—but refused—the provostship of King's College, Cambridge. Education and marriage

In December 1655 he married a penniless beauty of 15, Elizabeth Marchant de Saint-Michel, daughter of a French Huguenot refugee. At this time he was employed as factotum in the Whitehall lodgings of his cousin Adm. Edward Montagu, later 1st earl of Sandwich, who was high in the lord protector Cromwell's favour. In his diary Pepys recalls this humble beginning, when his young wife "used to make coal fires and wash my foul clothes with her own hand for me, poor wretch! in our little room at Lord Sandwich's; for which I ought forever to love and admire her, and do." While there, on March 26, 1658, he underwent a serious abdominal operation, thereafter always celebrating the anniversary of his escape by a dinner—"This being my solemn feast for my cutting of the stone."

In 1659 Pepys accompanied Montagu on a voyage to the Sound. About the same time he was appointed to a clerkship of £50 per annum in the office of George Downing, one of the tellers of the Exchequer, after whom Downing Street was later named. It was while working in Downing's office and living in a small house in Axe Yard that on January 1, 1660, he began his diary. A few months later he sailed, as his cousin's secretary, with the fleet that brought back Charles II from exile. Appointed, through Montagu's interest at court, clerk of the acts of the navy at a salary of £350 per annum and given an official residence in the navy office in Seething Lane, he became in the next few years a justice of the peace, a commissioner for and, later, treasurer of, Tangier, and surveyor of naval victualling. When he entered upon his functions, he was ignorant of almost everything that belonged to them. His chief use of his position was to enjoy his newfound importance and the convivial companionship of his colleagues Admirals Sir William Batten and Sir William Penn. But early in 1662 there came a change. The colleagues whose bacchanalian habits and social position had made them so attractive began to prove irksome, and their insistence on their superior experience and status galled Pepys's pride. In his isolation, he sought for ways by which he could show himself their equal. He had not far to look, for his fellow officers were anything but attentive to business. "So to the office," Pepys wrote, "where I do begin to be exact in my duty there and exacting my privileges and shall continue to do so." He had found his vocation.

Naval administration. It was not in Pepys's nature to do things by halves. Having resolved to do his duty, he set out to equip himself for its performance. In the summer of 1662, he occupied his leisure moments by learning the

multiplication table, listening to lectures on shipbuilding, and studying the prices of naval stores: "into Thames Street, beyond the Bridge, and there enquired among the shops the price of tar and oil, and do find great content in it, and hope to save the King money by this practise." At the same time, he began his habit of making careful entries of all contracts and memoranda in large vellum books—beautifully ruled by Mrs. Pepys and her maids—and of keeping copies of his official letters.

The qualities of industry and devotion to duty that Pepys brought to the service of the Royal Navy became realized during the Second Dutch War of 1665–67—years in which he remained at his post throughout the Plague and saved the navy office in the Great Fire of London. Before trouble with his eyesight caused him to discontinue his diary in 1669—an event followed by the death of his wife—these qualities had won him the trust of the King and his brother James, the duke of York, the lord high admiral. In 1673, in the middle of the Third Dutch War, when York's unpopular conversion to Catholicism forced him to resign his office, Pepys was appointed secretary to the new commission of admiralty and, as such, administrative head of the navy. In order to represent it in Parliament—before whom he had conducted a masterly defense of his office some years before—he became member first for Castle Rising and, later, for Harwich. For the next six years he was engaged in stamping out the corruption that had paralyzed the activities of the navy. His greatest achievement was carrying through Parliament a program that, by laying down 30 new ships of the line, restored the balance of sea power, upset by the gigantic building programs of France and the Netherlands. In his work both at the Admiralty and in Parliament, Pepys's unbending passion for efficiency and honesty (combined with a certain childlike insistence on his own virtue and capacity for being always in the right) made for him powerful and bitter enemies. One of these was Lord Shaftesbury, who in 1678 endeavoured to strike at the succession and at the Catholic successor, the Duke of York, by implicating Pepys in the mysterious murder of the London magistrate Sir Edmund Berry Godfrey, the crime on which the full credulity of the populace in the Popish Plot depended. When Pepys produced an unanswerable alibi, his enemies endeavoured to fasten Godfrey's murder on him indirectly by accusing his confidential clerk, Samuel Atkins. Despite the third-degree methods employed against him, Pepys also proved an alibi for Atkins, who would otherwise almost certainly have perished. Six months later, his enemies brought into England a picturesque scoundrel and blackmailer called John Scott, who had begun his life of crime in what today is Long Island, New York, and whom Pepys had endeavoured to have arrested at the time of Godfrey's death on account of his mysterious activities disguised as a Jesuit. Pepys was flung into the Tower on an absurd charge of treason brought against him by Scott and supported by the Exclusionists in Parliament, as also on a minor and equally unjust charge of popery, brought against him by a dismissed butler whom he had caught in bed with his favourite maid. Had not Charles II almost immediately dissolved Parliament and prevented a new one from meeting for a further year and a half, Pepys would have paid the penalty for his loyalty, efficiency, and incorruptibility with his life. He employed his respite with such energy that by the time Parliament met again he had completely blasted the reputation of his accuser by collecting circumstantial details of his infamies from almost every country.

Member of Parliament

In 1683, when the King felt strong enough to ignore his opponents, Pepys was taken back into the public service. He had accompanied the Duke of York in the previous year on a voyage to Scotland, and he now sailed as adviser to the Earl of Dartmouth to evacuate the English garrison of Tangier—a voyage that he described in a further journal.

Return to the Admiralty

On his return, in the spring of 1684, he was recalled by Charles II to his old post. Entitled secretary of the affairs of the admiralty of England and remunerated by a salary of £500 per annum, he combined the modern offices of first lord and secretary of the admiralty, both administering the service and answering for it in Parliament. For the next four and a half years, including the whole of James II's reign, Pepys was one of the greatest men in England, controlling the largest spending department of state. With his habitual courage and industry, he set himself to rebuild the naval edifice that the inefficiency and corruption of his enemies had shattered, securing in 1686 the appointment of a special commission "for the Recovery of the Navy." When, at the beginning of 1689, after James II had been driven from the country, Pepys retired, he had created a navy strong enough to maintain a long ascendancy in the world's seas. Hitherto there had been brief spells when the emergence of a naval genius like Sir Francis Drake and Robert Blake had given England a temporary advantage over its maritime neighbours, but for long periods the English "sovereignty of the seas" had been an idle boast. When Pepys became associated with the navy in 1660, the line of battle had consisted of 30 battleships of a total burden of approximately 25,000 tons and carrying 1,730 guns. When he laid down his office, he left a battle line of 59 ships of a total burden of 66,000 tons and carrying 4,492 guns. Not only had he doubled the navy's fighting strength; he had given it what it had never possessed before and what it never again lost—a great administrative tradition of order, discipline, and service. He had made the scabbard of the sword that the great 18th-century admirals used.

Last years

"To your praises," declared the orator of Oxford University, "the whole ocean bears witness; truly, sir, you have encompassed Britain with wooden walls." Pepys's last 14 years, despite attempts by his political adversaries to molest him, were spent in honorable retirement in his riverside house in York Buildings, amassing and arranging the library that he ultimately left to Magdalene College, Cambridge, corresponding with scholars and artists, and collecting material for a history of the navy that he never lived to complete, though he published a prelude to it in 1690, describing his recent work at the Admiralty, entitled *Memoires relating to the State of the Royal Navy of England for ten years determined December 1688*. He died on May 26, 1703, at the Clapham home of his former servant and lifelong friend William Hewer. His fellow diarist John Evelyn wrote of him: "He was universally belov'd, hospitable, generous, learned in many things, skilled in music, a very greate cherisher of learned men of whom he had the conversation."

The diary. The diary by which Pepys is chiefly known was kept between his 27th and 36th years. Written in Thomas Shelton's system of shorthand, or tachygraphy, with the names in longhand, it extends to 1,250,000 words, filling six quarto volumes in the Pepys Library. It is far more than an ordinary record of its writer's thoughts and actions; it is a supreme work of art, revealing on every page the capacity for selecting the small, as well as the large, essential that conveys the sense of life; and it is probably, after the Bible and James Boswell's *Life of Samuel Johnson*, the best bedside book in the English language. One can open it on any page and lose oneself in the life of Charles II's London, and of this vigorous, curious, hardworking, pleasure-loving man. Pepys wanted to find out about everything because he found everything interesting. He never seemed to have a dull moment; he could not, indeed, understand dullness. One of the more comical entries in his diary refers to a country cousin, named Stankes, who came to stay with him in London. Pepys had been looking forward to showing him the sights of the town—

> But Lord! what a stir Stankes makes, with his being crowded in the streets, and wearied in walking in London, and would not be wooed by my wife and Ashwell to go to a play, nor to White Hall, or to see the lions, though he was carried in a coach. I never could have thought there had been upon earth a man so little curious in the world as he is.

Pepys's style

Pepys possessed the journalist's gift of summing up a scene or person in a few brilliant, arresting words. He makes us see what he sees in a flash; his Aunt James, "a poor, religious, well-meaning, good soul, talking of nothing but God Almighty, and that with so much innocence that mightily pleased me"; and his sister Pall, "a pretty,

good-bodied woman and not over thick, as I thought she would have been, but full of freckles and not handsome in the face." He could describe with wonderful vividness a great scene: as, for example, the day Gen. George Monck's soldiers unexpectedly marched into a sullen City and proclaimed there should be a free Parliament—"And Bow bells and all the bells in all the churches as we went home were a-ringing; it was past imagination, both the greatness and suddenness of it." He described, too, the Restoration and coronation; the horrors of the Plague; and the Fire of London, writing down his account—so strong was the artist in him—even as his home and its treasures were being threatened with destruction:

> We saw the fire as only one entire arch of fire from this to the other side of the bridge, and in a bow up the hill for an arch of above a mile long: it made me weep to see it. The churches, houses, and all on fire and flaming at once; and a horrid noise the flames made, and the cracking of houses at their ruine.

Above all, Pepys possessed the artist's gift of being able to select the vital moment. He makes his readers share the very life of his time: "I staid up till the bell-man came by with his bell just under my window as I was writing of this very line, and cried, 'Past one of the clock, and a cold, and frosty, windy morning.' " He tells of the guttering candle, "which makes me write thus slobberingly"; of his new watch—"But Lord! to see how much of my old folly and childishness hangs on me still that I cannot forebear carrying my watch in my hand in the coach all the afternoon and seeing what o'clock it is one hundred times"; of being awakened in the night—

> About 3 o'clock this morning I waked with the noise of the rain, having never in my life heard a more violent shower; and then the cat was locked in the chamber and kept a great mewing and leapt upon the bed, which made me I could not sleep a great while.

Pepys excluded nothing from his journal that seemed to him essential, however much it told against himself. He not only recorded his major infidelities and weaknesses; he put down all those little meannesses of thought and conduct of which all men are guilty but few admit, even to themselves. He is frank about his vanity—as, for example, in his account of the day he went to church for the first time in his new perriwig: "I found that my coming in a perriwig did not prove so strange to the world as I was afeared it would, for I thought that all the church would presently have cast their eyes upon me, but I found no such thing"; about his meannesses over money, his jealousies, and his injustices—"Home and found all well, only myself somewhat vexed at my wife's neglect in leaving her scarfe, waistcoat and night dressings in the coach today; though I confess she did give them to me to look after." For he possessed in a unique degree the quality of complete honesty. He is both Everyman and the recording angel; his diary paints not only his own infirmities but the frailty of all mankind.

BIBLIOGRAPHY

Diary: After the successful publication of John Evelyn's diary in 1818, Pepys's diary was transcribed—with great accuracy—by JOHN SMITH, later rector of Baldock, Hertfordshire, at the instance of the master and fellows of Magdalene College, Cambridge. About a quarter of it, ed. by the 3RD LORD BRAYBROOKE, was published as *Memoirs of Samuel Pepys, Esq., F.R.S.*, 2 vol. (1825). Many fuller editions followed, until the whole diary, with the exception of about 50 short passages omitted on grounds of decency, ed. by H.B. WHEATLEY, appeared in 10 vol. (1893–99, reprinted 1968). The St. Olave edition, 18 vol., was published in 1903. Later editions and selections include *Everybody's Pepys*, abridged and ed. by O.F. MORSHEAD (1926 and 1960); and *The Diary*, selections ed. by JOHN WARRINGTON, Everyman's Library, 3 vol. (1953). The definitive ed. (the first in which the entire diary is printed) in a new and complete transcription is currently being issued under the editorship of ROBERT LATHAM and WILLIAM MATTHEWS, *The Diary of Samuel Pepys*, to comprise 11 vol.: 9 vol. of text, 1 vol. of commentary, and an index volume (1970–).

Correspondence: The Life, Journals and Correspondence of Samuel Pepys, ed. by JOHN SMITH, 2 vol. (1841); *Private Correspondence and Miscellaneous Papers of Samuel Pepys, 1679–1703*, 2 vol. (1926), *Further Correspondence of Samuel Pepys, 1662–1679* (1929), and *Samuel Pepys's Naval Minutes* (1926), all ed. by J.R. TANNER; *The Tangier Papers of Samuel Pepys*, ed. by EDWIN CHAPPELL (1935); *The Letters of Samuel Pepys and His Family Circle*, ed. by H.T. HEATH (1955).

Pepys's Library: A Descriptive Catalogue of the Naval Manuscripts in the Pepysian Library at Magdalene College, Cambridge, ed. by J.R. TANNER, 4 vol. (1903–23); *Bibliotheca Pepysiana: A Descriptive Catalogue of the Library of Samuel Pepys*, 4 vol. (1914–40); S. GASELEE, *The Spanish Books in the Library of Samuel Pepys* (1921).

BRIDGE, *Samuel Pepys: Lover of Musique* (1903); PERCY LUBBOCK, *Samuel Pepys* (1909); E.H. MOORHOUSE, *Samuel Pepys* (1909); J.R. TANNER, *Samuel Pepys and the Royal Navy* (1920, reprinted 1971), *Mr. Pepys: An Introduction to the Diary Together with a Sketch of His Later Life* (1925, reprinted 1971); EDWIN CHAPPELL, *Samuel Pepys As a Naval Administrator* (1933); SIR ARTHUR BRYANT, *Samuel Pepys: The Man in the Making* (1933; 2nd ed., 1947), *The Years of Peril* (1935; 2nd ed., 1948), and *The Saviour of the Navy* (1938; 2nd ed., 1949)—new ed., *Samuel Pepys*, 3 vol. (1967); RUDOLF KIRK, *Mr. Pepys upon the State of Christ-Hospital* (1935); CECIL EMDEN, *Pepys Himself* (1963); RICHARD BARBER, *Samuel Pepys, Esquire* (1970).

(Ar.Br.)

Perception

Perception, or perceiving, refers to the process whereby sensory stimulation is translated into organized experience. That experience, or percept, is the joint product of the stimulation and of the process itself. Relations found between various types of stimulation (*e.g.*, light waves and sound waves) and their associated percepts suggest inferences that can be made about the properties of the perceptual process; theories of perceiving then can be developed on the basis of these inferences. Because the perceptual process is not itself public or directly observable (except to the perceiver himself, whose percepts are given directly in experience), the validity of perceptual theories can be checked only indirectly. That is, predictions derived from theory are compared with appropriate empirical data, quite often through experimental research.

Historical background

Historically, systematic thought about perceiving was the province of philosophy. Indeed, perceiving remains of interest to philosophers, and many issues about the process that were originally raised by philosophers are still of current concern. As a scientific enterprise, however, the investigation of perception has especially developed as part of the larger discipline of psychology.

Philosophical interest in perception stems largely from questions about the sources and validity of what is called human knowledge (see EPISTEMOLOGY). Epistemologists ask whether a real, physical world exists independently of man's experience, and if so, how man can come to learn its properties and how the truth or accuracy of that experience can be determined. They also ask whether there are innate ideas or whether all experience originates through contact with the physical world, mediated by the sense organs. For the most part, psychology bypasses such questions in favour of problems that can be handled by its special methods. The remnants of such philosophical questions, however, do remain; researchers are still concerned, for example, with the relative contributions of innate and learned factors to the perceptual process.

Such fundamental philosophical assertions as the existence of a physical world, however, are taken for granted among most scientific students of perceiving. Typically, researchers in perception simply accept the apparent physical world particularly as it is described in those branches of physics concerned with electromagnetic energy, optics, and mechanics. The problems they consider are those relating to the process whereby percepts are formed from the interaction of what is called physical energy (for example, light) with the perceiving organism. Of further interest is the degree of correspondence between percepts and the physical objects to which they ordinarily relate. How accurately, for example, does the visually perceived size of an object match its physical size as measured (*e.g.*, with a yardstick)?

Questions of the latter sort imply that perceptual experi-

ences typically have external referents and that they are meaningfully organized, most often as objects. Meaningful objects, such as trees, faces, books, tables, and dogs, are normally seen rather than separately perceived as the dots, lines, colours, and other elements of which they are composed. In the language of Gestalt psychologists, immediate human experience is of organized wholes (*Gestalten*), not of collections of elements.

A major goal of Gestalt theory in the 20th century was to specify the brain processes that might account for the organization of perception. Gestalt theorists, chief among them the German-U.S. psychologist and philosopher, the founder of Gestalt theory, Max Wertheimer and the German-U.S. psychologists Kurt Koffka and Wolfgang Köhler, rejected the earlier assumption that perceptual organization was the product of learned relationships (associations), the constituent elements of which were called simple sensations. Although Gestaltists agreed that simple sensations logically could be understood to comprise organized percepts, they argued that percepts themselves were basic to experience. One does not perceive so many discrete dots (as simple sensations), for example; the percept is that of a dotted line.

The role of brain function

Without denying that learning can play some role in perception, many theorists took the position that perceptual organization reflects innate properties of the brain itself. Indeed, perception and brain functions were held by Gestaltists to be formally identical (or isomorphic), so much so that to study perception is to study the brain. Much contemporary research in perception is directed toward inferring specific features of brain function from such behaviour as the reports (introspections) people give of their sensory experiences. More and more such inferences are gratifyingly being matched with physiological observations of the brain itself.

Many investigators relied heavily on introspective reports, treating them as though they were objective descriptions of public events. Serious doubts were raised in the 1920s about this use of introspection by the U.S. psychologist John B. Watson and others, who argued that it yielded only subjective accounts and that percepts are inevitably private experiences and lack the objectivity commonly required of scientific disciplines. In response to objections about subjectivism, there arose an approach known as behaviourism that restricts its data to objective descriptions or measurements of the overt behaviour of organisms other than the experimenter himself. Verbal reports are not excluded from consideration as long as they are treated strictly as public (objective) behaviour and are not interpreted as literal, reliable descriptions of the speaker's private (subjective, introspective) experience. The behaviouristic approach does not rule out the scientific investigation of perception; instead, it modestly relegates perceptual events to the status of inferences. Percepts of others manifestly cannot be observed, though their properties can be inferred from observable behaviour (verbal and nonverbal).

One legacy of behaviourism in contemporary research on perception is a heavy reliance on very simple responses (often nonverbal), such as the pressing of a button or a lever. One advantage of this Spartan approach is that it can be applied to organisms other than man and to human infants (who also cannot give verbal reports). This restriction does not, however, cut off the researcher from the rich supply of hypotheses about perception that derive from his own introspections. Behaviourism does not proscribe sources of hypotheses; it simply specifies that only objective data are to be used in testing those hypotheses.

Behaviouristic methods for studying perception are apt to call minimally on the complex, subjective, so-called higher mental processes that seem characteristic of adult human beings; they thus tend to dehumanize perceptual theory and research. Thus, when attention is limited to objective stimuli and responses, parallels can readily be drawn between perceiving (by living organisms) and information processing (by such devices as electronic computers). Indeed, it is from this information-processing approach that some of the more intriguing theoretical contributions (*e.g.*, abstract models of perception) are currently being made. It is expected that such practical applications as the development of artificial "eyes" for the blind may emerge from these man–machine analogies. Computer-based machines that can discriminate among visual patterns already have been constructed, such as those that "read" the code numbers on bank checks.

CLASSICAL PROBLEMS

Sensing and perceiving. Many philosophers and psychologists have commonly accepted as fundamental a distinction made on rational grounds between sensing and perceiving (or between sensations and percepts). To demonstrate empirically that sensing and perceiving are indeed different, however, is quite another matter. It is often said, for example, that sensations are simple and that percepts are complex. Yet, only if there is offered some agreed upon (a priori) basis for separating experiences into two categories—sensations and percepts—can experimental procedures demonstrate that the items in one category are "simpler" than those in the other. Clearly, the arbitrary basis for the initial categorization itself cannot be subjected to empirical test. (See also SENSORY RECEPTION, HUMAN.)

Problems of verification aside, the simplicity–complexity distinction derives from the assumption that percepts are constructed of simple elements that have been joined through association. Presumably, the trained introspectionist can dissociate the constituent elements of a percept from one another, and in so doing, experience them as simple, raw sensations. Efforts to approach the experience of simple sensations might also be made by presenting very simple, brief, isolated stimuli; *e.g.*, flashes of light.

Perceptual learning

Another commonly offered basis for distinction is the notion that perceiving is subject to the influence of learning while sensing is not. It might be said that the sensations generated by a particular stimulus will be essentially the same from one time to the next (barring fatigue or other temporary changes in sensitivity), while the resulting percepts may vary considerably, depending on what has been learned between one occasion and the next (see LEARNING, PERCEPTUAL).

Some psychologists have characterized percepts as typically related to external objects and sensations as more nearly subjective, personal, internally localized experiences. Thus, a spontaneous pain in the finger would be called a sensation; however, if the salient feature of experience is that of a painfully sharp, pointed object, such as a pin located "out there," it would be called a percept.

The above definitional criteria all relate to properties of experience; that is, they are psychological. An alternative way of distinguishing between sensing and perceiving that has become widely accepted is physiological–anatomical rather than psychological. In this case, sensations are identified with neural events occurring immediately beyond the sense organ, whereas percepts are identified with activity farther "upstream" in the nervous system, at the level of the brain. This assignment of anatomical locations to sensory and to perceptual processes seems consistent with psychological criteria. That is, the complexity and variability of percepts (both a product of learning) are attributed to the potential for physiological modification inherent in the vastly complex neural circuitry of the brain.

Temporal (time) relations. Clearly, many subjective processes (such as problem solving) take time to run their courses. This is true even for such relatively simple activities as perceptual discriminations in the size of different objects. It is not readily apparent, however, whether percepts themselves—which, for example, might enter as elements in problem solving—take time to form. To the naïve observer, percepts probably do seem essentially instantaneous: the moment a square is shown, a square seems to be seen. Yet, experimental evidence suggests that percepts, even of simple geometric forms, follow a measurable, developmental time course. In some instances the temporal development of percepts is relatively long (on

the order of seconds), and in some it is quite brief (on the order of thousandths of a second).

Pictures that are incomplete or ambiguous provide good examples of relatively long-term temporal development of percepts. Look at Figure 1 and continue looking until

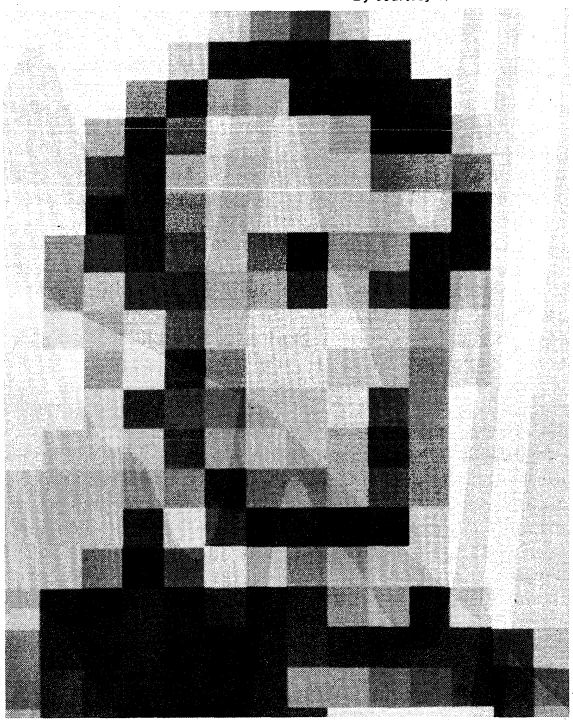

Figure 1: An ambiguous picture. Increasing viewing distance permits more precise perception (see text).

you see something more than a pattern of black, gray, and white patches. Abruptly, you probably will perceive a familiar face that, on subsequent viewing, will reappear to you without difficulty. How long it takes for such a percept to develop will vary considerably from one person to another, perhaps revealing fundamental differences among individuals in their speed of perceptual processing. It might be instructive to show Figure 1 to several people, and with the aid of a stopwatch, measure the time it takes each of them to achieve the desired percept, both initially and then on some later occasion. (Figure 1 commonly is seen by most people as the face of Abraham Lincoln.)

A somewhat different way in which percepts may change with time is illustrated in the article ILLUSIONS AND HALLUCINATIONS. On initial viewing of this type of drawing, one will probably immediately see a meaningful picture. After continued gazing at the drawing, the initial percept may abruptly be replaced by another. Thereafter, the two percepts should alternate with the passage of time. Stimuli of this sort (which can yield more than one percept) raise such questions as, for example, what determines the initial percept; why do some people first see a vase whereas others see two profiles; why does the initial percept give way to the alternate; what determines the rate of fluctuation from one percept to the other; do differences from one person to another in the rate of fluctuation of ambiguous figures indicate fundamental differences in perceptual activity? Tentative answers to such questions continue to be proposed.

Instances of slowly developing percepts require relatively simple procedures to uncover. Those percepts with a very rapid time course may be studied with the aid of instruments known as tachistoscopes that permit the durations of visual stimuli to be precisely controlled. Sophisticated electronic tachistoscopes flash reliably for periods as brief as one millisecond (one-thousandth of a second). Such precision permits study of the short-term development (microgenesis) of such percepts as those of simple geometric figures. Thus, it has been found that perception of a small black disk is disrupted (masked) by the rapidly successive tachistoscopic presentation of a second stimulus: a black ring that fits snugly around the disk. Indeed, as far as experimental subjects can tell, the disk target simply does not appear, though when flashed without being followed by the ring, it is readily detectable. Other target and mask stimuli also have been successfully employed.

Backward masking, or metacontrast

It has been theorized that it takes time for any percept to develop; that one's experience of a figure such as a disk develops from the figure's centre outward; that one's percept of the disk becomes stable only when the outer contour is appreciated; and that the ring functions in backward masking (metacontrast) because in the course of its own emergence as a percept the inner contour of the ring "absorbs" the perceptually developing contour of the disk. (Unless the viewer becomes aware of its contour, the disk theoretically cannot be perceived.) This interpretation is consistent with evidence of an optimal time interval between disk and ring onsets (about 30 to 50 milliseconds) for the best masking effect. Thus, masking is most evident at the moment developing awareness of disk contour is held to coincide in space and time with the initial perceptual growth of the ring's inner contour. If the ring is presented too soon or too late, theoretically, the contour absorption on which masking presumably depends is ineffective.

While such theories are controversial, masking experiments in general do clearly indicate that in human beings there is a brief period (100 to 200 milliseconds at most) during which a percept is highly vulnerable to disruption. Whatever its exact mechanism, the phenomenon of masking manifestly demonstrates that percepts do not emerge instantaneously and full-blown at the moment of sensory stimulation. Thus, assuming that percepts are synthesized from simpler elements, relatively complex percepts would be expected to take longest to develop and, hence, to be most vulnerable to masking. Yet empirical studies show just the opposite, indicating that the more complex the visual target, the more difficult it is to mask.

Perceiving as synthesizing. The organization apparent in percepts has been attributed by some to learning, as being built up through arbitrary associations of elements that have repeatedly occurred together in the person's experience. Other theorists (particularly Gestaltists) stress the view that perceptual organization is physiologically inborn, being inherent in innate aspects of brain functioning rather than depending on a synthesizing process of learning to combine simpler elements into more complex, integrated wholes. One way of resolving such theoretical disputes would be to deprive people from birth of all visual sensory experience and, hence, of all opportunity for visual perceptual learning. Then at the time normal sensory function was restored, they would need to be tested to determine what perceptual functions, if any, were intact. Such a strategy was proposed in a letter to the British philosopher John Locke by a fellow philosopher William Molyneux in 1690. Molyneux's suggestion waited until the 20th century to be taken seriously, after surgical methods had been found to restore the sight of people born blind because of cataract (clouded lens within the eye).

The use of cataract surgery to study perception

After removal of their cataracts, such newly sighted people are found to be normally sensitive to changes in intensity of illumination and to colour. Though they are able initially to tell when a figure is present, they cannot at first discriminate one simple shape from another, nor can they readily remember the shape of a just-exposed object. This deficiency extends to such socially important visual stimuli as people's faces. Only after a long and painstaking period of experience—perhaps of several months duration—do such seemingly primitive visual performances as discriminating a square from a triangle come easily. Until then, the person must count corners, for example, to achieve accurate discrimination.

Findings derived from cataract surgery have provided a rich source of hypotheses for further research, including posited neurophysiological mechanisms (*e.g.*, assemblies of brain cells) that might serve as the medium for the

structural changes presumed to accompany perceptual learning. This situation led to experimental attempts to show how, through repeated stimulation, the perceptual system could progress from performance of only very primitive functions to the highly complex operations (such as form identification and discrimination) that are characteristic of the mature organism.

A host of experiments using laboratory animals as subjects (*e.g.*, pigeons, rats, cats, dogs, monkeys, and chimpanzees) have been conducted to determine, under rigorous experimental control, the extent to which learning early in life contributes to later perceptual functioning. By analogy with humans born with cataract, such animals were deprived of visual experience from as close to birth (or hatching) as possible; *e.g.*, chimpanzees were reared in darkness. In another type of experiment, animals were reared in environments that provided more than the normal amount and variety of stimulation or were exposed to specific stimuli they might not ordinarily encounter. These research strategies are said to provide impoverished or enriched environments. Experiments of both sorts have consistently provided verification of the general hypothesis that early perceptual experience plays an important role in later perceptual (as well as intellectual and emotional) development, even producing changes in brain weight and biochemistry. This research also offers a strong scientific rationale for efforts to enrich the environments of so-called disadvantaged or culturally deprived children.

Studies of human infants indicate that their early perceptual experiences are not the "blooming, buzzing confusion" postulated by the U.S. psychologist William James late in the 19th and early in the 20th century. Rather, even infants one or two days old are capable of refined visual discriminations. Recording of the infants' visual fixations as their eyes move indicates them to have reliable preference for one paired stimulus over another, giving evidence of visual discrimination. Research employing this technique shows that preferences among various visual patterns or shapes generally are related to the complexity and novelty of the stimuli, for infants and for older human subjects as well. Evidence of this sort seems out of keeping with the findings of cataract surgery, which suggest that figural discrimination is not innate for the visually naïve. It may be, however, that adults who were blind with cataracts at birth suffer more than mere lack of normal visual experience; they are not quite comparable to visually naïve, but otherwise intact, infants. It may be that visual experience is necessary, not to generate pattern perception but to maintain it; that is, the infant's built-in (innate) perceptual abilities may somehow deteriorate through disuse.

The visual cliff technique

Similar research has dealt with visual depth perception in laboratory animals and human babies. One technique (the visual cliff) depends on the evident reluctance of young animals to step off the edge of what seems to be a steep cliff. The so-called visual cliff apparatus in one of its versions consists of a narrow platform on which the subject is placed and two wide platforms on either side of it. Although both flanking platforms are equally and only slightly lower than the central platform, the subject sees visual patterns designed so that one looks much deeper than the other. Typically, the subject explores the central platform and then investigates the flanks, finally stepping down onto the shallow-appearing side. By this response, the subject indicates sensitivity to visual depth cues. To discover if prior visual experience is necessary for the typical avoidance of the flanking platform that looks deepest requires subjects able to locomote well from the start (*e.g.*, chicks) or those deprived of visual experience (*e.g.*, rats) until their locomotor ability has developed. Research with the visual cliff clearly demonstrates the presence of depth perception in visually naïve subjects.

In summary, there is evidence among cataract sufferers of the necessity of early visual experience in human visual pattern discrimination; laboratory animals reared in impoverished or enriched environments demonstrate the importance (if not necessity) of early visual stimulation for perceptual development; human infants and other visually naïve animals behave as if they are innately capable of pattern and depth perception (*i.e.*, without the need for learning). These data together suggest that some basic visual functions, including pattern perception, are built in but that visual experience serves to maintain and elaborate them.

Structuralism

In a theory called structuralism, that everyday perceptual experience is structured or synthesized from "sensations," psychologists such as the English-U.S. introspectionistic psychologist Edward Bradford Titchener even devised a formal method of introspection for experimentally analyzing (or taking apart) percepts in an effort to reveal their constituent elements. The procedure required that the introspecting experimental subjects learn to avoid reporting on their experiences as they naïvely seemed. To establish this way of treating experience required careful training. One consequence of this training is that the observer's introspective reports may be contaminated by his expectations and hence may, in all honesty, reflect little more than his theoretical biases.

But the problem remains interesting: If percepts are indeed syntheses of simpler elements, can those elements be made to appear in experience? If so, what will they turn out to be? Can this problem be investigated without recourse to the structuralist's method of introspection and reliance on the reports of strongly biassed observers?

Evidence that percepts have constituent elements emerged serendipitously from research on stabilized retinal images. The image cast on the retina of the eye by a fixed object normally is continually moving because the perceiver himself is always in motion. Even when dampened by physical restraint, some residual movement will be left, attributable largely to high-frequency tremors (nystagmus) of the eyeballs. If the perceiver functioned as if he were a camera, the normal instability of the retinal image would produce a blurred percept and a concomitant impairment of visual acuity.

It is not feasible to eliminate eye movements, but it is possible to stabilize or fix the location of the retinal image by coupling the source of the image to the eyeball itself. An optical lever system can be so adjusted that when the eye moves the image source moves with it, and potential motion in the retinal image is eliminated. As expected, visual acuity is slightly enhanced when the retinal image is kept motionless. A remarkable, unexpected finding, however, was that such stabilized images rapidly seem to disappear, the perceiver losing awareness of them. It would seem that some movement in retinal image is needed to maintain perception over extended periods of time.

The optical lever system

One limitation of the optical lever system is that it permits the use of only very simple targets, such as straight, vertical lines. With a different device (in effect, a miniature projector attached to the eyeball), stabilized images of complex patterns may be presented. Complex patterns are found to produce percepts that are relatively slow to deteriorate; furthermore, they do not disappear in toto. The manner of the fragmentation is perhaps revealing of the way in which complex percepts are synthesized. Speaking metaphorically, observing how percepts "come apart" under retinal stabilization may be very much like discovering the structure of a rock by striking it with a powerful hammer blow.

Indeed, under retinal stabilization, single lines seem to disappear and reappear in a unitary (altogether) fashion. In a figure comprised of several lines (say, a square), percepts of parallel lines are likely to disappear and reappear together; proximity also affects the joint perceptual fate of pairs of lines. Retinally stabilized segments of such geometric figures as circles and triangles can seem to disappear and reappear without implicating the entire figure. In the disappearance of percepts of triangles, lines rather than angles are the functional units. (This finding is embarrassing to earlier theorizing about the crucial role of angles in the development of the neural network underlying the percept of a triangle.)

Clearly, with stabilized images, the constituent perceptual elements of complex geometric forms are lines, straight or curved; and lines with the same orientation are likely to have similar perceptual fates, as though forming

a higher-order component of complex patterns than do individual lines. These conclusions are remarkably similar to those drawn from studies of the effect of visual stimuli on the electrical activity of single neurons in the cerebral cortex. A finding of major theoretical significance is the failure of percepts of circles, squares, and triangles to act as units. Such percepts are treated in classical Gestalt theory, however, as though they are basic and unitary and not readily decomposable.

PRIMARY TENDENCIES IN PERCEPTUAL ORGANIZATION

Gestalt principles. Gestalt theory was meant to have general applicability; its main tenets, however, were induced almost exclusively from observations on visual perception. Whatever their ultimate theoretical significance, these observations have been raised to the level of general principles. It is conventional to refer to them as Gestalt principles of perceptual organization.

The overriding theme of the theory is that stimulation is perceived in organized or configurational terms (*Gestalt* in German means "configuration"). Patterns take precedence over elements and have properties that are not inherent in the elements themselves. One does not merely perceive dots; he perceives a dotted line. This notion is captured in a phrase often used to characterize Gestalt theory: "The whole is more than the sum of its parts."

The notion of "good" configurations

Of the many principles of organization that have been enunciated by various Gestalt theorists, the most general is referred to as *Prägnanz*. In effect, according to the principle of *Prägnanz*, the particular perceptual configuration achieved, out of a myriad of potential configurations, will be as good as prevailing conditions permit. What constitutes a "good" configuration, or a poor one, is unfortunately not clearly specified, though several properties of good configurations can be listed, chief among them being simplicity, stability, regularity, symmetry, continuity, and unity. What happens when these properties of figures come into conflict is not specified, but should be possible to determine empirically.

The principle of closure often operates in the service of *Prägnanz*; for example, a circular figure with small gaps in it will be seen as a complete or closed circle. Similarly, if a portion of the image of a figure falls on the blind spot of the retina, a complete figure often will still be perceived. Some distortions from good configuration may be so large as to preclude closure; in those cases, the figures may be a source of tension for the observer.

Prägnanz may also be achieved through good continuation; this principle describes a tendency for smooth continuity of contour to be dominant over discrete, irregular, abruptly changing contours. Thus, a figure composed of the overlapping outlines of an ellipse and a rectangle will probably be seen as such rather than as three figures, each with irregular, noncontinuous borders.

Closure and good continuation represent two of the factors that are held to determine what percepts will emerge from a complex stimulus. Implicit in them (and in the general principle of *Prägnanz*) is the assumption that whenever possible some figure will be perceived; more specifically, that the visual field will be articulated into figures and patterns of figures. It is understood that such emerging patterns are not *in* the stimulus. Although they are *permitted by* the stimulus, they are created by the perceptual system; that is, by the perceiver himself.

In the illustrations in Figure 2, in the panel on the left, the vertical distance between elements is less than the horizontal distance. By virtue of this differential proximity, the elements become perceptually organized into columns. In the right-hand panel, similarity, another principle of organization, is operative. Here, by virtue of similarity in brightness, the visual field tends to be perceptually articulated into alternating sets of black and gray rows.

It is not at all obvious why organization by similarity should occur; physical stimulation allows but does not demand it. Clearly in that case the articulation of the visual field into columns reflects a tendency in the perceptual system itself. Organization by proximity may not seem to reveal anything more than a close correspondence between perception and stimulation. (Though as

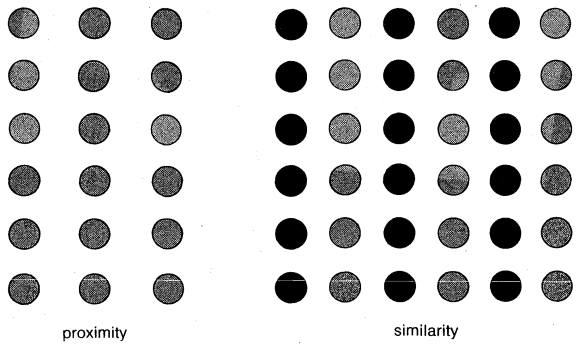

Figure 2: *Examples of Gestalt principles of organization.* (Left) Horizontal distance between dots is greater than vertical distance. (Right) equal distance between horizontal and vertical.

argued by the Gestalt theorist Kurt Koffka, it is not an adequate explanation to say that "things look as they do because they are what they are.") Yet, when a proximity pattern like the one shown in Figure 2 was briefly presented and subjects were asked (under guise of another task) to reproduce what they saw, many people failed to indicate a differentiated percept of columns. Instead, they reproduced a homogeneous matrix of elements. After repeated exposures, some of those subjects began to draw proximity-based columns of elements. Organization according to the principle of proximity seems to be neither universal nor, for those who achieve it, immediate.

Proximity patterns

In the latter experiment, people who failed to obtain the differentiated percept of columns scored significantly lower on a test of verbal intelligence than did those who succeeded at some point in the experiment. Perhaps the Gestalt principles of organization apply to perceivers (such as Gestalt theorists) whose intellectual development has reached a high degree of maturity. When organized percepts are easy to come by, gradations in intelligence do not seem to matter; when some barrier to organization is imposed (as by brief stimulus exposure), however, then the effect on perception of such differences among individuals may show up.

If people see a pattern of columns in the left panel of Figure 2 because that is how the stimulus is constructed, then why do some people not see it that way? Both achieving and failing to achieve an organized percept must be explained. Surely, part of the explanation must lie in the nature of the perceptual process itself. Thus, the experimental results indicate that perceptual organization is not universal and immediate; rather, they support the major tenet of Gestalt theory that things look as they do because of the organization imposed by the perceptual process (*i.e.*, by the perceiver).

One Gestalt principle, that of common fate, depends on movement and is quite striking when observed. According to the principle of common fate, stimulus elements are likely to be perceived as a unit if they move together. An illustration of this principle is provided by a well-camouflaged object, such as a military vehicle; when stationary, the elements of the vehicle are integrated, through proximity, similarity, and so on, into patterns of background elements, and the object is difficult to detect. But it is easy to see it once it starts moving; with all of its elements moving in unison, the vehicle is readily perceived as a unitary figure, clearly segregated from its background.

Gestalt views of movement

Movement is also at the heart of a set of observations of considerable significance in the historical development of Gestalt theory. These observations concern circumstances in which people perceive movement in the absence of actual physical motion of the stimulus. One familiar instance of this class of events is referred to as the phi phenomenon. In simplest form, the phi phenomenon can be demonstrated by successively turning two adjacent lights on and off. Given appropriate temporal and spatial relations between the two lights, an observer will perceive the first light as if it were moving from its location to that of the second light. The phi phenomenon is basic to the eye-catching displays used on theatre mar-

quees and to cinematic and television presentations. The motion-picture screen, for example, presents a series of briefly flashed, still images; the movement people see is a creation of their own perceptual systems (see also PERCEPTION OF MOVEMENT).

It is the lack of one-to-one correspondence between stimulation and perception, as dramatically illustrated in the phi phenomenon, that underscores the Gestaltists' dissatisfaction with stimulus-bound models of perception and their insistence on the priority of patterns and relations. What people perceive is determined not only by what is present at the point under direct observation but also by what is occurring in the total stimulus context or display.

Context effects. One of the simplest instances of relational (or context) effects in perception is that of brightness contrast. Thus, the apparent brightness of a stimulus depends not only on its own luminance but also on that of the surrounding stimulation. The same gray square looks whiter against a dark background and blacker when placed in a bright surround. Similarly, a white or gray patch will take on an apparent hue that is complementary to the colour of the surround (*e.g.*, the patch will seem tinged with yellow when it is placed against a blue background).

Analogous context effects

Analogous context effects are evident in many commonplace experiences. A man of average height seems to be a runt when he is on a basketball court with much taller players; yet the same man looms like a giant when refereeing a game played by little boys. It is known that a typical winter's day seems delightfully balmy when temperatures rise after a week of subfreezing weather.

To the Gestaltist, contrast effects dramatize the relational nature of perception. They also play a significant role in a more recently developed adaptation-level theory, which also provides a general perceptual model. At the core of the model is the notion that the manner in which a stimulus is perceived depends not only on its own physical characteristics but also on those of surrounding stimuli and of stimuli previously experienced by the observer. In other words, the perceiver is said to be perceptually adapted to past sensory stimuli; his adaptation level forms a kind of zero point against which any new stimulus is perceived. An example is provided by the almost overwhelming silence one experiences when the sound of an air conditioner (to which he has adapted) suddenly ceases.

Gestalt theorists also attached significance to the observer's history of stimulation; indeed, some of them interpreted so-called figural aftereffects within a Gestaltist model of brain functioning. Figural aftereffects refer to changes in the perceived shape or location of a figure following its inspection; for example, a curved line will appear to get straighter after prolonged inspection. Or the distance between two parallel lines seems to change as an aftereffect of previous inspection.

In a typical experiment one looks at a point adjacent to a dark vertical bar (the inspection figure) on a screen. Following this inspection period, the dark bar is replaced by two identical pairs of vertical lines, one pair on either side of the region where the bar had been, the second pair alongside in a region not previously exposed to the inspection figure. The subject again fixates the same point. A figural aftereffect shows up as a greater apparent distance between the pair of lines surrounding the region of the inspection figure even though the other pair is actually identical. This distortion is not simply a generalized contrast effect because it occurs only in the small area along the borders of the inspection figure; that is, the effect is localized and restricted.

Localized satiation in the brain

It thus has been speculated that visual exposure to a figure induces in the brain a condition of localized satiation. The passage of electrical activity is assumed to be impeded in satiated areas of the brain. Moreover, it is postulated that the perceived distance between two borders of a figure is directly related to the time it takes for electrical currents to pass between them. Thus, it is held that one effect of satiation is to increase the apparent distance between the borders of a figure that straddles a satiated region. Whatever the merits of such physiological speculations, they have stimulated a vast amount of research on figural aftereffects. Good evidence for similar effects in other senses, such as touch, also has been obtained. Clearly, perception can be influenced not only by the context of current background but also by the residues (aftereffects) of previous stimulation.

Concurrent visual stimulation may modify one's acuity in detecting auditory stimuli. Similar interactions are claimed to occur for other combinations of senses. Some dentists report success in using audioanalgesia, in which stimulation with sound waves is said to reduce the experience of pain in the mouth. The high specificity of some of the reported sensory interactions seems to preclude an explanation that concurrent stimulation works by changing the subject's general level of alertness. However these intersensory effects might be mediated, they do suggest that the brain does not function as a collection of entirely independent sensory channels. As a physical system, the brain follows physical principles; thus overlapping and spreading or waning fields of neural excitation in the brain have been theorized to underlie such phenomena as closure and audioanalgesia. Köhler referred to these models of neural analogues of perceptual phenomena as physical Gestalten; unfortunately, there is little direct physiological evidence for them.

An alternative to field effects in brain functioning is the assumption that local stimulation gives rise, in one-to-one fashion, to a mosaic of local responses. Implicit in the mosaic hypothesis is a kind of telephone switchboard model of the brain as a machine in which the electrical activity is strictly confined to separate pathways of neurons that are well insulated (isolated) from one another. The Gestaltists rejected this model because in its early formulations it did not explain intersensory and intrasensory perceptual phenomena. A more sophisticated machine model, however, provides for fieldlike effects through the operation of complex networks of neural elements. It is held that electrical activity remains confined to discrete pathways, but that these pathways do not simply travel straight through the system; that they also interconnect, with both excitatory and inhibitory consequences. Supporting evidence comes from records of the electrical activity in single neurons in the cat brain; when the cat's eye is probed by a small spot of light, a specific area on the retina can be found that serves to excite a given brain neuron.

Further mapping of the cat retina often uncovers inhibitory areas adjacent to the one that is excitatory; that is, when light strikes those retinal areas the activity in the brain neuron being monitored is depressed. The excitatory and inhibitory areas thus comprise the brain neuron's retinal receptive field. Analogous inhibitory effects have also been found in research on the eye of the crab, *Limulus*. Such context effects as brightness contrast could be based on these simple inhibitory mechanisms. It remains to be seen, however, just how many perceptual phenomena that fit Gestalt field theory also can be handled by sophisticated variants of the machine or mosaic model.

Perceptual constancies. Even though the retinal image of a receding automobile shrinks in size, the normal, experienced person perceives the size of the object to remain constant. Indeed, one of the most impressive features of perceiving is the tendency of objects to appear stable in the face of their continually changing stimulus features. Though a dinner plate itself does not change, its image on the retina undergoes considerable changes in shape and size as the perceiver and plate move. What is noteworthy is stability in perception despite gross instability in stimulation. Such matches between the object as it is perceived and the object as it is understood to actually exist (regardless of transformations in the energy of stimulation) are called perceptual constancies.

Dimensions of visual experience that exhibit constancy include size, shape, brightness, and colour. Perceptual constancy tends to prevail for these dimensions as long as the observer has appropriate contextual cues; for example, perception of size constancy depends on cues that allow one a valid assessment of his distance from the

object. With distance accurately perceived, the apparent size of an object tends to remain remarkably stable, especially for highly familiar objects that have a standard size. Thus, people's heads all tend to look the same size regardless of distance; similarly, an object identified as a lump of coal tends to look black even when intensely illuminated.

Loss of perceptual constancy

The experience of constancy may break down under extreme conditions. If distance is sufficiently great, for example, the perceived size of objects will decrease; thus, viewed from an airplane in flight, there seem to be "toy" houses, cars, and people below. To the extent that they prevail, the constancies lend the perceiver's experience and behaviour relative stability. Imagine an alternative, kaleidoscopic perceptual world in which everything seems to change, solid objects apparently swelling, shrinking, and warping with every movement. Breakdown in perceptual constancy seems to complicate the course of some psychiatric disorders in which the perceptual boundary between the sufferer and the external world is weakened. Normal constancies also can be intentionally overcome, as in paintings of flabby watches and distorted people that apparently depict the unique perceptual world of the artist.

INDIVIDUAL DIFFERENCES IN PERCEIVING

Theoretical assertions about perceiving are often made as though they apply indiscriminately to all organisms, or at least to all people. Perhaps perceptual principles of such great generality eventually will be uncovered. In the meantime it is evident that there are clear differences in perceptual functioning among individuals, among classes of individuals, and within the same individual from one occasion to another.

Age. That perceptual functioning should change with the perceiver's age is expected on the grounds that psychological development stems from maturation and learning. Indeed, empirical evidence for age-related changes in perceiving is substantial. There are, for example, reliable data that perceptual constancies are enhanced with the person's increasing age, improvement leveling off at about age ten. Similarly, there is a great deal of evidence for both decreased and increased susceptibility to various optical illusions with increasing age (see ILLUSIONS AND HALLUCINATIONS). Those illusions that become less pronounced with increasing age probably depend on the subject's changes in scanning and on his increased ability to segregate parts of a pattern from one another; illusions that become more pronounced probably reflect the operation of expectancies that develop through experience. Anatomical and physiological changes in the eye itself also may account for some age-related perceptual changes.

Optical illusions among older persons

Sex. It is difficult to assess the degree to which differences related to the sex of the perceiver are biologically based or are the cultural product of traditional differences in sex role. Biological sex and sex role thus far have been hopelessly confounded in experiments with human subjects.

Sex differences in perceiving, whatever their basis, can be illustrated in research on differences in the style with which people perceive. This stylistic difference emerges in extremes of response to context. If a person perceives the world as highly differentiated, he tends to resist contextual influences and is said to be field independent; the person who perceives in an extremely diffuse style, the field-dependent individual, tends to be highly susceptible to contextual effects. Thus, field-independent people are superior in locating a simple visual figure (*e.g.*, a triangle) embedded in a complex pattern; similarly, field-independent subjects can better adjust a rod in a tilted frame to the true vertical when no other visual cues to verticality are present.

Both age and sex are found to be implicated in these differences in perceptual style. Specifically, field dependence declines with increasing age, as does the closely related susceptibility to optical illusions. In North American studies, female subjects tend to be more field dependent than are males, especially after puberty. Perhaps these results are distinctive of cultures in which females are at least implicity trained to be passive and perceptually diffuse, and in which males are encouraged to assume an active, perceptually articulated stance. This hypothesis has received some support in studies of the parent–child interactions characteristic of the early years of the two types of subject.

Culture. Beyond sex differences in perceiving that seem to be culturally imposed, there is evidence for more general cultural influences on perception. The burden of much research is to show that the type of physical environment people construct for themselves or choose to inhabit can influence their style of perceiving. There are African groups (*e.g.*, Zulu and Bushmen), for example, whose environments are virtually lacking in rectangular forms, by contrast with the carpentered, right-angled world of people in Western cultures. People in these African groups also fail to make use in their art work of two-dimensional representations of three-dimensional objects. Such differences in visual environments show up in tests of susceptibility to illusions. Zulu and Bushmen subjects are relatively resistant to those visual illusions that depend for their effectiveness on the subjects' treating the lines comprising the pictures as borders of three-dimensional, rectangular objects. Analogous effects with different classes of illusion have been shown for other peoples who live in a perceptually unique environment.

Expectancies, motives, and conflicts. The inherent ambiguity of much sensory stimulation is coupled with a strong tendency of people to impose order and meaning on their experience. It may thus be predicted that a person's perceptions may be influenced by such factors as his expectancies, needs, values, and conflicts. The cross-cultural differences between, say, Europeans and Zulus in susceptibility to illusions probably arise from differences in expectancies. The same can be said for the ease with which one becomes aware of Lincoln's face in Figure 1 once it has been perceived or even after simply being told what the picture is supposed to be.

Psychoanalytic theory explicitly calls for motivational influences on such functions as memory, thinking, and perceiving (see MOTIVATION). In particular, the theory is concerned with unconscious motives and conflicts and with unconscious defenses (such as repression) used to control them. According to the psychoanalytic hypothesis, there should be wide perceptual variation among individuals in response to stimuli that have motivational significance. At any rate, a host of experiments have been designed to show that perceiving is indeed subject to unconscious influences.

Studies using obscenities

In some studies, for example, it seemed that so-called obscene words flashed on a screen had to be exposed longer than apparently neutral (control) words before their meaning could be perceived. In the other studies, children of poor families have been found to overestimate the size of coins as compared with the judgments of children of richer families. One major problem with such research lies in finding or creating appropriate experimental and control stimuli. Considering differences in the use of language, for example, it is most unlikely that what once were widely called obscene words would currently evoke the conflicts and defenses of more than a few subjects.

Assuming suitable stimuli can be found, an even more serious problem arises around the interpretation of the subjects' behaviour; for example, do people really find it more difficult to recognize obscene words or are they simply reluctant to admit recognition? Problems of this sort have plagued researchers, and unambiguously interpretable experiments in this field are most difficult to produce. The hypothesis of such individual influences as motivation on perception remains appealing and viable, but unproved.

BIBLIOGRAPHY. For a clear presentation of Gestalt theory and its case against structuralism and behaviourism, see W. KOHLER, *Gestalt Psychology* (1959). A comprehensive historical overview is available in E.G. BORING, *Sensation and Perception in the History of Experimental Psychology* (1942). tion along with material on illusions, context effects, and related phenomena are provided in W.N. DEMBER, *The Psychology of Perception* (1960); J.J. GIBSON, *The Perception of the Visual World* (1950); and J.E. HOCHBERG, *Perception* (1964). Implications of research on early experience for perceptual and intellectual development are spelled out in J.M. HUNT, *Intelligence and Experience* (1961). Two excellent collections of technical articles on perception, covering a wide range of topics, have been compiled and edited by R.N. HABER: *Contemporary Theory and Research in Visual Perception* (1968), and *Information-Processing Approaches to Visual Perception* (1969). For a scholarly discussion of depth perception and a lucid description of an elegant series of experiments, see B. JULESZ, *Foundations of Cyclopean Perception* (1971). The potential contributions of neurophysiological research to an understanding of perception are suggested in N. WEISSTEIN, "What the Frog's Eye Tells the Human Brain: Single Cell Analyzers in the Human Visual System," *Psychol. Bull.* 72:157–176 (1969).

(W.N.D.)

Perception of Movement

Most animals (including people) move in search of food that itself often moves; they move to avoid predators and to mate. Animals must perceive their own movements to balance themselves and to move effectively; without such perceptual functions the chances for survival would be sharply reduced.

VISUAL CUES

The eye is by far the most effective organ for sensing movement. Some animals are especially sensitive to visual stimuli that move in specific ways. For instance, electrical patterns from the eye of a frog show that some elements in the organ respond only when the stimulus is about the size of a fly moving in the insect's range of speed. Generally the eyes of lower animals seem to respond selectively to what is of importance to survival. In these animals the eye's retina does much of the visual processing. This is an economical arrangement since the animal tends to respond only to essential stimuli, the brain having little to do but relay signals to the motor system. It is an inflexible mechanism, however; higher animals process visual information in more elaborate ways, the brain being more heavily involved. Thus, some cells in the visual area of the cat's brain respond only to moving stimuli, sets of movement-detector cells functioning specifically for each direction across the field of view. Features of human visual experience also suggest that movement detectors exist in the human brain.

Eye and brain

Each retina in most higher animals has a central (foveal) zone for detailed colour and pattern vision and a surrounding peripheral zone that effectively is sensitive only to the grosser features of the outer visual field. The peripheral retina is especially sensitive to movement (often a signal of danger), which induces a reflex turning of the eyes to project the image on the fovea and permit the moving object to be recognized.

Visual stability. Mechanisms have evolved that yield stable, clear visual input despite swaying and other blurring factors. In a reflex mechanism called optokinetic nystagmus, the eyes pursue a moving scene to keep the image stationary on the retina. When they can move no farther, they snap back and pursue the scene again in a to-and-fro alternation of slow pursuit and quick return. These eye movements are readily observed in people who are looking at a moving pattern of stripes or turning their heads, this response being inhibited only when something stationary is visually fixated.

Similar nystagmic movements are triggered by impulses arising in the inner ear when the head moves. These persist even when the eyes are closed and may be felt by pressing the eyelids lightly as one rotates the whole body.

Nystagmus; saccades

In a related stabilizing activity the eyes scan in quick jerks (saccades) with short fixations; *e.g.*, in reading. Normally the eyes cannot move steadily over a stationary scene but make a series of stationary images (like still photographs); visual function tends to be suppressed when there is saccadic blurring. Yet the eyes can follow a steadily moving object smoothly.

When one looks from one point to another, movements of the retinal image are the same as those produced by a moving scene on a stationary eye. It might be thought that the sensory structures found in the eye muscles would provide the cues for judging whether it is the eye or the scene that has moved. Yet we see the scene as stationary only when we move our eyes voluntarily and not when they are moved passively by the finger. This suggests that motor-nerve signals inform us whether our eyes are moving, rather than the sensory structures in the eye muscles. When the eye is moved by pushing it with the finger there is no normal motor discharge to inform the brain, and changes in retinal image are perceived as movement of the scene. Indeed, people with paralyzed eye muscles experience the scene as moving when they try to move their eyes. When the motor discharge thus generated is not accompanied by the expected image motion, the person falsely perceives the scene and the eye to be moving together.

Relative visual movement. A visual field containing familiar objects provides a stable framework against which relative motion may be judged. People often report that an isolated point of light in a dark room is moving when it is not; the experience is known as autokinetic movement. It was observed in 1799 by Alexander von Humboldt while he was watching a star through a telescope, and he attributed it to movement of the star itself. Not until about 60 years later was the effect shown to be subjective, apparently arising from instability in the sense of eye position without a visual frame of reference.

Autokinesis; induced movement

Similarly, if a small object is presented in a frame with nothing else in view, movement usually is attributed to the object even when only the frame moves. This induced movement effect reflects our tendency to use the larger surround as a stable frame of reference. Recall the illusion that your train is moving when it is really the moving train alongside that, seen through the window, is falsely accepted as the frame of reference.

People cannot perceive very slow movement; below a minimum speed (about that of the minute hand on a watch) movements become imperceptible and can only be inferred (as in remembering the previous position of the hour hand). At high speeds, one perceives a blurred streak rather than a definite object in motion.

Movement aftereffect. When a parade is interrupted after some minutes, the pavement may seem to move in the opposite direction to the marchers who have passed. Phenomena similar to this movement aftereffect occur in other senses. For instance, after disembarking, a sailor feels the land to be rolling like a ship as the result of kinesthetic and vestibular aftereffects. The visual movement aftereffect probably arises when movement detectors in the brain that respond to the original direction of motion become fatigued, leaving predominant those detectors that respond to contrary movement.

Apparent movement. Motion-picture film is a strip of discrete, still pictures but produces the visual impression of continuous movement. Stationary light bulbs coming on one after the other over the theatre entrance also produce an impression of steady movement. In part, such effects of apparent movement (called the visual phi phenomenon) depend on persistence of vision: visual response outlasts a stimulus by a fraction of a second. When the interval between successive flashes of a stationary light is less than this visual-persistence time, the flicker will appear to fuse into a continuous light. The flicker frequency at which this occurs is called the perceiver's flicker-fusion frequency (or critical flicker frequency) and represents the temporal resolving power of his visual system at the time. Another process on which apparent movement depends is a tendency (called visual closure or phi) to fill in the spaces between adjacent visual objects. This means that the movement detectors of the visual system are triggered as effectively by a closely spaced pair of lights alternately going on and off as by a single light moving back and forth. It would seem that two aspects of visual function (flicker fusion and phi) make the motion-picture industry possible.

Flicker fusion; phi

Stroboscopic effect. When a rotating electric fan is illuminated by a flashing light source (called a strobo-

scope) so that a flash arrives whenever a fan blade passes a fixed position, the blades will seem to stand still. This is a useful way of observing fast-moving objects such as machinery or insect wings. If the flashes occur less frequently, the object will seem to move slowly in its actual direction; when the flashes arrive more frequently, the object will seem to move backward, as stagecoach wheels may do in the cinema.

Visual movement in depth. An object moving directly away from an observer provides fewer visual cues of movement than it would by moving across the field of view. However, changes in retinal-image size are produced that give a clue to its movement. Thus a stationary, but shrinking, luminous object in the dark is seen as if it were receding. Other clues to movement in depth are changes in the convergence angle of the two eyes, in the focussing mechanism, and in the haziness and brightness of the object.

NONVISUAL CUES TO MOVEMENT

Auditory. Sound waves travel well in water, and fish rely heavily on acoustic cues to detect moving objects. Land animals, although typically more visually oriented, also make some use of such cues, including changes in intensity (loudness) and small differences in the time at which the wave reaches each ear. Some animals (*e.g.*, rabbit, horse) have mobile external ears that track moving sound sources. Bats vocalize high-frequency waves, detecting objects by sonic reflection (similar to sonar).

Kinesthetic. Kinesthesis here refers to experiences that arise during movement from sense organs in the membranes lining the joints and from the sense of effort in voluntary movement; receptors in muscles seem to have little role in the perception of bodily movements. Depending on speed of motion and the joint involved, blindfolded people can detect a passive joint movement as small as a quarter of a degree. People vary widely in the accuracy with which they can actively produce movement of a given extent; this ability also varies with direction of movement and the opposing friction, mass, and springiness.

Phantom limb

Kinesthetic perception may persist for a limb that has been amputated, giving rise to a hallucinatory experience known as the phantom limb. The patient may experience vividly the "movement" of the absent part; a recent amputee may attempt to stand on his missing leg or to grasp with his missing hand.

Vestibular system. Vestibular structures, enclosed in a fluid-filled cavity in the region of each inner ear, include the utricle, a small sac containing minute sensitive hairs associated with tiny sandlike granules called otoliths. The utricle functions as a linear accelerometer. When the head tilts relative to gravity or is accelerated, the relatively dense otoliths deflect the hair cells and nerve impulses are transmitted to the brain. At constant velocity the otoliths become stable, stimulation ceases, and a person must rely on other cues (*e.g.*, by observing the passing scene) to detect his motion.

Equilibrium

Vestibular structures for each ear also include three fluid-filled semicircular canals, each in a different plane. Each canal has a swelling (ampulla) that contains the cupula, a cluster of sensitive hairs embedded in a jellylike mound. As the head moves in the plane of a given canal, motions of the fluid deflect the cupula to produce nerve impulses. These travel through the brainstem to other brain and spinal centres that mediate equilibrium or balance and that generate nystagmic eye movements.

Taken together, the semicircular canals serve as a rotary accelerometer. If a person is rotated at constant velocity and then is suddenly stopped, the cupula is redeflected to give a feeling of rotation in the opposite direction; this also gives rise to dizziness and postrotational nystagmus. Dancers and skaters learn to overcome such effects by concentrating on some fixed, visible object; with their eyes closed they are as likely to fall as anyone.

Overstimulation of the vestibular system (*e.g.*, on a ship or airplane) may induce motion sickness. A person with vestibular function totally destroyed is not subject to motion sickness; but if the vestibular mechanism is impaired only on one side, each movement of the head can be nauseating. Such a patient takes a long time to compensate for this imbalance.

In outer space there is no gravitation to mediate feelings of up or down, although these still may arise from visual cues. The utricles and vestibular canals still respond to movements of the head, however, and serve orientation within the spacecraft.

Perciformes

The order Perciformes, the perchlike fishes, is the largest group of fishes in the world today, comprising over 6,000 species that have been classified into about 150 families. Perciform fishes occur in abundance in both marine and freshwater areas of the world, ranging from shallow freshwater ponds to depths of over 2,300 metres (7,500 feet) in the oceans. Most perciforms are marine fishes, generally found along coastal areas of tropical and temperate regions of the world. The order includes many of the world's most important food and game fishes, such as tunas, mackerels, bonitos, and skipjacks (family Scombridae), billfishes and marlins (Istiophoridae), swordfish (Xiphiidae), sea basses (Serranidae), and carangids (Carangidae), a large family that includes pompanos, jacks, cavallas, and scads. The freshwater food and sport fishes of the perciform order include the sunfishes (Centrarchidae) and the perches and walleyes (Percidae). Many perciforms are popular aquarium fishes.

GENERAL FEATURES

Size range. Perciform fishes comprise a wide variety of sizes, ranging from the tiny freshwater goby *Pandaka pygmaea* (Gobiidae) of the Philippines, which is fully grown at about 1.2 centimetres (less than one-half inch) in length, to the black marlin (*Makaira indica*), swordfish (*Xiphias gladius*), and the bluefin tuna (*Thunnus thynnus*), which attain lengths of about 3.3 metres (11 feet). The bluefin tuna and the Indo-Pacific black marlin have been known to exceed 680 kilograms (1,500 pounds) in body weight. Generally, most percoid fishes fall within the range of 30 to 250 centimetres in length.

Distribution. Perciform fishes occur worldwide and are clearly a highly successful group. Coral reefs of tropical seas abound with colourful perciforms, such as wrasses, butterfly fishes, gobies, damselfishes, blennies, and cardinal fishes. The perciform order comprises a large part of the fauna of the Indo-West Pacific region, which is probably the world's richest in the variety of its fish fauna. Of the Antarctic fish fauna, approximately 75 percent belong to the Perciformes. These include the icefishes (Chaenichthyidae), known for their "bloodless" appearance, which results from the lack or near lack of red blood cells and blood pigments. Freshwater perciforms include the cichlids (Cichlidae), which occur naturally in India, Africa, South America, and parts of southern North America; these fishes also have been introduced elsewhere. The perch and sunfish families are found in North America and Europe, and the European perch (*Perca fluviatilis*) occurring well north in Siberia.

IMPORTANCE TO MAN

Use as food. Since early times, the rivers and oceans have provided man with food; fishing was one of man's earliest means for securing food. Archaeological findings among shell mounds of Scotland include the sea bream (Sparidae) as part of the diet of early man. The Nile perches (Latidae) have been found as mummies in ancient tombs in Egypt. The goatfishes (Mullidae) appear in ancient Roman archives as one of the most highly

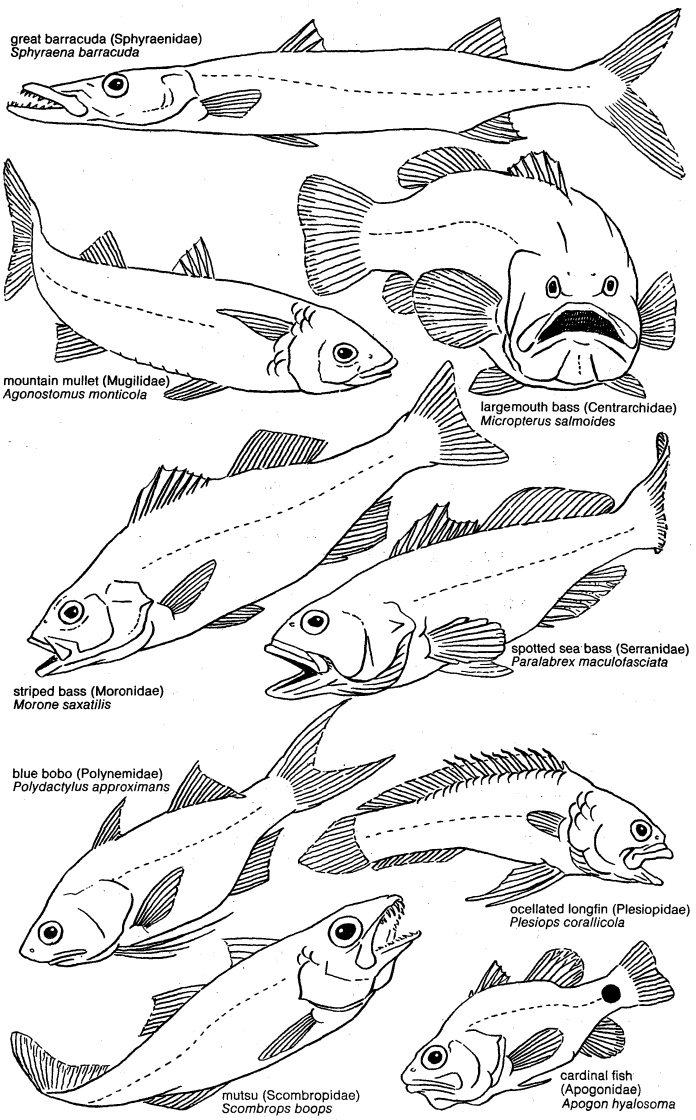

Figure 1: Representative perciforms of the families Sphyraenidae, Mugilidae, Polynemidae, Scombropidae, Apogonidae, Moronidae, Serranidae, Plesiopidae, and Centrarchidae.
Drawing by G. Christman

valued food fishes, and in Japan the goatfish holds a good market and is eaten raw as *sashimi* or as dried fish cakes known as *kamaboko*. In Japanese art through the ages, the fish god is shown with the "king of sea fish" under one arm; this highly valued food fish is the porgy *Chrysophrys major* (Sparidae). A Japanese New Year's dinner usually includes *buriko*, the eggs of the sandfish *Arctoscopus japonicus* (Trichodontidae).

The perciform fishes play an important part in commercial fisheries all over the world. The fishery statistics of the Food and Agricultural Organization of the United Nations show that the catch for tunas, bonitos, billfishes, and various tuna-like fishes exceeds 1,500,000 metric tons; a similar catch was recorded for chub mackerel (Scombridae) alone during 1970. Catches for sea breams and grunts (Pomadasyidae) exceed 100,000 metric tons, and the catches for freshwater perciforms were around 4,000 metric tons for cichlids and 2,000 metric tons for the yellow perch, *Perca flavescens*. Other important food fishes include groupers (Serranidae), snappers (Lutjanidae), carangids, and dolphins (Coryphaenidae). Isinglass, which is used in the production of jellies and also in the process of clarification of wine and beer, is obtained from fishes that include the drums (Sciaenidae) and the threadfins (Polynemidae). The skin of the wolffishes (Anarhichadidae) provides a leather of fair quality. The guanin present in the skin of the Japanese cutlass fish (*Trichiurus*; Trichiuridae), is used in the manufacture of artificial pearls in Japan.

Breeding and cultivation of perciforms has been successful in many parts of the world. The African mouthbreeder (*Tilapia macrocephala*, Cichlidae) has been successfully introduced in many areas and is valued for its rapid rate of reproduction and growth, providing a source of low cost protein.

Aquarium fishes. Colourful and interesting perciforms are kept for aesthetic reasons by aquarists, augmenting an industry partially supported by fishes of other orders. Popular aquarium fishes of the perciform order include cichlids, butterfly fishes (Chaetodontidae), angelfishes (Pomacanthidae), labyrinth fishes (suborder Anabantoidei) such as the Siamese fighting fish (*Betta splendens*) and the kissing gourami (*Helostoma temmincki*), and various gobies (Gobiidae), blennies, and blenny-like fishes of the suborder Blennioidei.

The freshwater angelfish *Pterophyllum scalare* and the discus (*Symphysodon discus*) are among the most popular aquarium fishes for breeding because of their remarkable means of feeding their young on the mucous secretions of their bodies.

Poisonous perciforms

Tropical food poisoning, or ciguatera, has been attributed to some perciforms that are otherwise considered to be excellent food fishes. Among these are certain carangids, snappers, barracudas (Sphyraenidae), surgeonfishes (Acanthuridae), groupers, and porgies. A species completely edible in one area may be poisonous in an area just a few hundred miles away. This curious phenomenon has not yet been fully explained, although it has been suggested that the source of poisoning may be a toxic form of blue-green alga passed up the food chain and thus present in the food of toxic species.

Danger to man. A few of the perciforms are known to be harmful to man. Swimmers have been attacked by the barracuda (*Sphyraena*), which is a voracious fish reaching nearly two metres (six feet) in length. Perciforms possessing venom glands are also considered dangerous fishes. The dorsal spine of the weever fishes (Trachinidae) has a grooved structure containing a venom gland; in addition, there is also a stinger located on the opercular (gill cover) structure. Both the stinger and the dorsal spine can be extremely painful if stepped on in shallow waters. Similar venom-bearing structures are found in the dragonets (Callionymidae) and surgeonfishes. The venomous spines in the surgeonfish are located on either side of the caudal peduncle (the narrow stalk just in front of the tail). Especially well armed are the electric stargazers (*Astroscopus*, Uranoscopidae), which are capable of discharging up to 50 volts of electricity from the modified muscle tissue just posterior to the eyes; in addition, they possess a venom spine just above the pectoral fins. The venom from uranoscopids has been known to cause death in man.

NATURAL HISTORY

Life history. Many perciforms live out their whole lives in small areas, but others, especially open-ocean (pelagic) species, perform extensive migrations, about which much remains to be learned. Some marine serranids, however, are anadromous (*i.e.*, entering fresh or brackish water to spawn); some freshwater perciforms, such as certain species of gobies, enter the sea to spawn (catadromous). Tuna (Scombridae) may travel across the entire Pacific Ocean from the California coast to Japan, or the reverse. Spawning in perciforms generally takes place in shallow coastal areas or in rivers and ponds among rocks, seaweeds, and aquatic plants. *Paraclinus marmoratus*, a clinid blenny, is known to lay eggs at times in the lumen (cavity) of a living sponge.

Breeding behaviour among perciform fishes is diverse. Pairing of male and female is common, although a single female may pair with more than one male, as among certain serranids, perches, and cichlids. The sexes are usually distinct, but hermaphroditism (presence of functional male and female organs in a single individual) normally occurs among certain sea basses and porgies.

The young of the black sea bass (*Centropristis striatus*) are mostly females with normal egg-laying functions; after five years, however, some of these females transform into functional males. About 11 species of sparids have been found to display hermaphroditism at one time or throughout their lifetime.

Differences in appearance between sexes

Characteristic differences usually exist, especially during the breeding season, between sexes regarding colour, size, markings, or structure. The male is generally smaller in size (some exceptions are found in sunfishes, gobies, and blennies) and has brighter coloration of the fins and body. Black, white, green, red, blue, and silver are colours characteristic of the brightly coloured males of damselfishes (Pomacentridae), wrasses (Labridae), labyrinth fishes, and cichlids. Structural differences between the sexes vary from easily observed characteristics, such as the presence of a longer dorsal fin in the male dragonets, to less obvious characteristics, such as larger canines in the dentition of male blennies (Blenniidae) and gobies. Bands, blotches, and tinged markings may also be characteristic of the brighter coloured males, as in some wrasses. During the spawning season, males of certain species of cichlids, parrotfishes (Scaridae), sparids, and wrasses develop a swelling on the forehead that may persist throughout life. These characteristics presumably enhance the male in its breeding and courtship activities.

Drawing by G. Christman

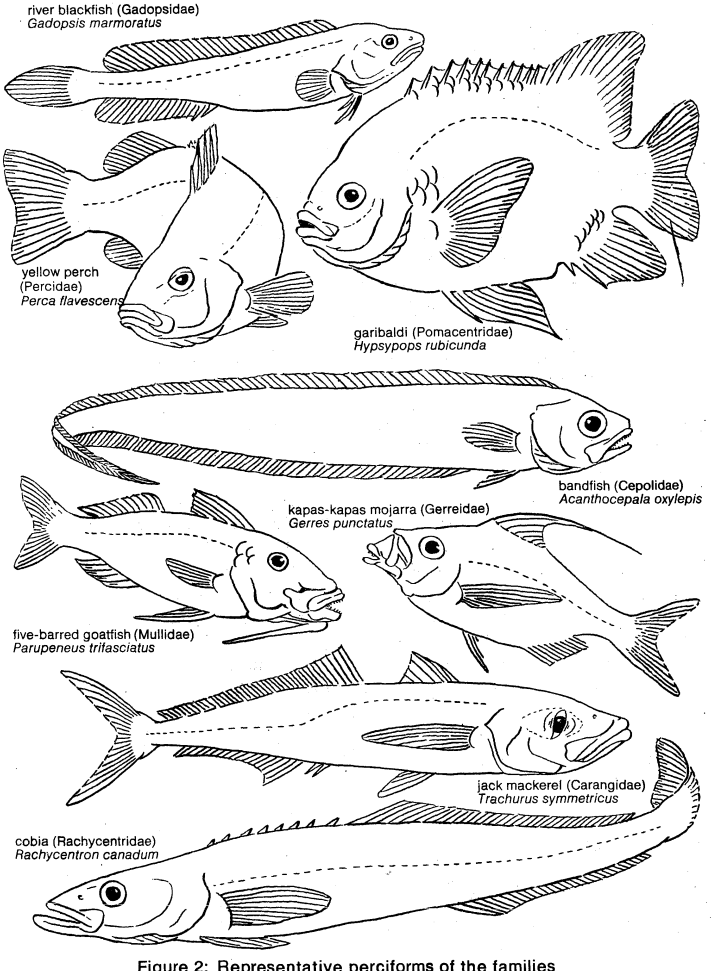

Figure 2: Representative perciforms of the families Pomacentridae, Percidae, Cepolidae, Mullidae, Gerreidae, Carangidae, Rachycentridae, and Gadopsidae.

Little is known of the courtship activities in most marine perciforms. The male dragonet, with extended fins and gill covers, performs a display of colours while swimming repeatedly around the female. A similar courtship activity is also carried out by the fighting fishes (*Betta*).

Fertilization is usually external, although internal fertilization, in which the eggs are fertilized within the body of the female, is well known in such groups as surfperches (Embiotocidae); and the male in such cases generally possesses an intromittent organ, which functions in the transfer of sperm to the female. Internal fertilization also occurs among some of the gobies, clinid blennies (Clinidae), apogonids, and eelpouts. Perciforms that undergo internal fertilization mostly are viviparous; *i.e.*, they give birth to live young. The number of young in viviparous perciforms varies from three to 50 in the surfperches. The larger viviparous forms, however, have been found to produce a greater number of young.

Most perciform fishes are oviparous—*i.e.*, they lay eggs that are fertilized externally. The number of eggs laid varies from a few hundred to more than 3,000,000 in a 32-pound (15 kilogram) yellowtail (*Seriola dorsalis*, Carangidae). Often, the eggs are released to float freely, but many species have evolved elaborate nest-building behaviour. Nest construction frequently consists merely of clearing away of a small area under rocks, which may be on the open bottom or even inside empty animal shells. The sunfishes and darters (Percidae) use their fins or body to dig a circular depression for use as a nest. Wrasses construct a nest out of stones, shells, and seaweed. Males generally undertake the task of building the nest, but in many cases both male and female share the labour.

Nest-building behaviour

Most labyrinth fishes build bubble nests, the procedure being similar among members of the family. The male Siamese fighting fish takes a bubble of air into his mouth, coats it with a mucous secretion, then blows the coated bubble to the surface; this process is repeated until a bubble nest is formed. After pairing, the female allows the fertilized eggs to drop to the bottom, where the male picks them up in his mouth and blows them into the bubble nest. Many marine perciforms produce pelagic eggs; *i.e.*, that float on or near the surface of the open sea. Almost all of the freshwater perciforms produce demersal eggs (*i.e.*, that sink to the bottom). A certain amount of adhesiveness in the demersal eggs keeps the eggs together in clusters; the elongated shape of the clusters of perch eggs help in securing the clusters to aquatic plants and rock bottoms. Not all eggs become attached to aquatic plants and other objects; the mature male humphead (Kurtidae) possesses a hooked structure on his forehead, to which the cluster of eggs is attached as soon as the female produces them. Oral incubation, in which the eggs are held in the mouth of one of the parents, is found in certain species of cardinal fishes (Apogonidae), jawfishes (Opisthognathidae), labyrinth fishes, and cichlids. The male, female, or both may incubate the eggs orally until they hatch, after which the young may be mouthbreeders. Similarly, guarding of the nest sites may be undertaken by the male, female, or both parents; however, males of some sunfishes, darters (*Etheostoma*), and the Siamese fighting fish defend their nest against intruders. In addition to guarding the nest, certain perciforms also aerate the eggs by directing a flow of water into the nest with fanning movements of the fins.

Although there is no evidence of parental care in perciforms that produce pelagic eggs, a strong protective behaviour is shown by most perciforms that build nests or carry their eggs around with them. The male dwarf cichlid may help in the care of the young, but it is the female that looks after the eggs, removing dead eggs from the clutch. In certain other cichlids (*Apistogramma species*, for example) the female may help free the young from the eggs by gently chewing off the egg shells. The young of many cichlids follow their mother around and quickly enter her mouth should danger threaten. The discus and the freshwater angelfishes of the cichlid family feed their young on mucous secretions of their own bodies. The male Betta guards the young until they can swim away freely on their own.

Behaviour. *Territorial activity.* Territorial behaviour is found in many perciforms, especially during the breeding season, when the male, and in some cases the female, displays territorial behaviour in guarding the nest of eggs or the young; such fishes include certain cichlids, sunfishes, and darters. The young tigerfish (Theraponidae) protects a restricted area around a small hole dug by using its body; such territorial behaviour disappears when the ti-

gerfish grows beyond a length of about nine centimetres (3.5 inches). An intruder approaching the burrow of a jawfish is usually greeted by a threatening pose of flared gill covers and erected fins. Gobies and blennies are also known for their marked territorial display; peck order may be present among gobies holding territories, with the highest degree of competition between male gobies of the same size. The characteristic threats of gobies and blennies include flaring gill covers, gaping jaws, puffing of throats, head raising, and shaking of bodies. When threat displays fail to settle a territorial dispute, male gobies fight, biting and chasing each other.

Threat displays of gobies and blennies

Sound production. The significance of sound production among perciform fishes is not well known, but most acoustic activity seems to be related to feeding and spawning periods. The level of sound production in croakers (Sciaenidae) increases considerably in the spawning season during the hours of late evening. There is also a difference in level between day and night; this may result from their feeding time. Damselfishes produce clicking sounds during feeding time, grinding the pharyngeal teeth. Another type of sound produced during feeding can be heard when parrotfishes feed on plant material covering reefs, biting on coral with their powerful platelike teeth. Grunts produce sounds by grinding their upper and lower pharyngeal teeth; the sounds are in turn amplified by the air (swim) bladder. Croakers, however, produce sounds by vibrating muscles of the abdomen that are attached to the sides of the air bladder, amplifying the vibrations of other muscles. The tigerfishes, or grunters (Theraponidae), have a similar system for sound production.

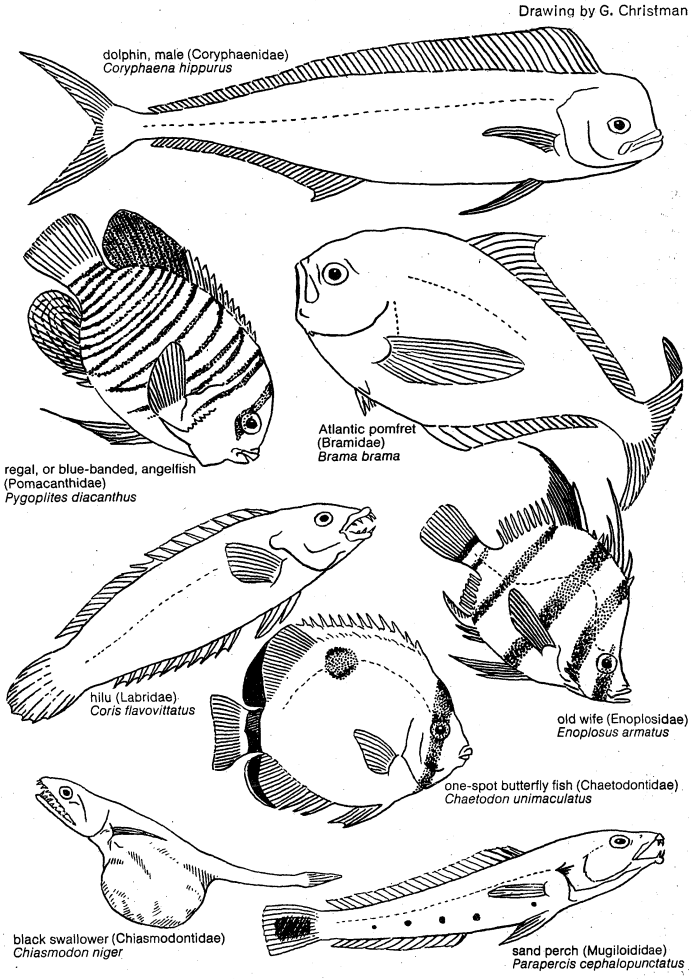

Figure 3: Representative perciforms of the families Coryphaenidae, Bramidae, Pomacanthidae, Enoplosidae, Chaetodontidae, Labridae, Mugiloididae, and Chiasmodontidae.

Feeding behaviour. Perciforms include both predator and prey species and are thus of great importance within the ecological food chains. The diverse adaptations for feeding are partly responsible for the success of this abundant order. Many of the colourful perciforms that occur around coral reefs are herbivorous fishes, the food of which consists mainly of plankton, algae on corals, and other reef vegetation; such fishes include parrotfishes, damselfishes, butterfly fishes, rabbitfishes and surgeonfishes. Among freshwater perciforms, certain species of *Tilapia* depend on aquatic plants for food. Most freshwater perciforms, however, are carnivorous, taking mosquitoes, insect larvae, and small insects. The larger predatory perciforms, in both freshwater and saltwater, feed on smaller fishes and even on birds and small mammals. They occupy a higher position within the food chain; examples include barracudas, groupers, tunas, and billfishes. The dolphins (*Coryphaena*) use their speed to catch fast prey such as flying fishes (Exocoetidae). The bluefish (*Pomatomus saltatrix*, Pomatomidae) is known for its voracious feeding behaviour; it feeds on open-water schooling fishes and, for unknown reasons, will continue to kill food fishes after its hunger is satiated.

Feeding behaviour of archer fishes

An interesting means of securing food is seen in archer fish (*Toxotes*, Toxotidae). The structure of the mouth in the archer fish is modified to form a groove along the roof of the mouth, against which the tongue fits to form a tube. The fish is able to direct a drop of water with remarkable accuracy at insects clinging to vegetation above the water surface. Thus bombarded, the insects fall into the water where they are quickly seized. Similar but less powerful squirting behaviour is also found in the butterfly fish. Another interesting type of feeding behaviour is seen in an African cichlid, which practices lepidophagy, the eating of scales plucked from other fishes.

Some predators lie in wait for their prey instead of pursuing it. An outgrowth of the mouth of the stargazer (*uranoscopus scaber*) acts as a lure for prey. Groupers are also known to lie in wait for prey among rocks.

Adaptations of the mouth and jaw structure are seen in many of the perciforms. The piscivorous nandids (Nandidae) and the leaf fishes (Polycentridae) have large protrusible mouths capable of taking prey two-thirds their size, and the deeply cleft mouth of the swallowers (Chiasmodontidae) permits them to pass prey larger than themselves into their highly distensible stomachs.

Interspecific relationships. Mutual relationships among species are found in many perciform fishes. The cleaner fishes of the wrasse genus *Labroides* (Labridae) are well-known for their role in the removal of parasites from larger carnivorous fishes. The larger fishes recognize the cleaner fish and will not devour it. They allow free passage into their cavernous mouths and gill chambers, in which the cleaner fish feeds upon leftovers and parasites. Each *Labroides* maintains a "cleaning station," which is visited regularly by larger fishes such as groupers, eels, jacks, and snappers. A relationship of a protective nature exists in the butterfishes (Stromateidae), the young of which are often found among the tentacles of jellyfishes; the fishes are immune to the stings of the jellyfishes. Fry of horse mackerel and tuna (Scombridae) have been also found among the tentacles of jellyfishes. A similar relationship is seen in the clown anemone fish (*Amphiprion percula*), which is found among the tentacles of sea anemones. The mucous substances secreted by the anemone fish protect it from the stinging cells of the sea anemone. Some anemone fishes seek out only one type of sea anemone; others do not show any species preference. The sleepers of the genus *Vireosa* (Eleotridae) are usually found close to rock oysters and clams, into which they quickly disappear when danger threatens. A similar relationship exists between certain sea cucumbers (sac-shaped echinoderms of the class Holothuroidea) and cucumber fishes (Carapidae). These fishes are found among starfishes, clams, and sea urchins, as well as sea cucumbers. Some are host specific and may even parasitize the host, as in the Florida cucumber fish (*Carapus bermudensis*), which seeks out a specific sea cucumber of the genus *Actinopyga*, within which the cucumber fish makes it home. At times *Cara-*

pus also feeds on the internal organs of the sea cucumber; this does not really harm the host because it regenerates the lost parts.

The blind goby, *Typhlogobius californiensis,* depends entirely upon holes dug by the ghost shrimp (*Callianassa*) for a home, and is unable to live without its help. Other gobies are known to share holes with burrowing worms, pea crabs, and snapping shrimps.

Imitative resemblance among perciforms

Certain perciform fishes depend upon imitative resemblance for survival. Immature tripletails (Lobotidae) will turn on their sides and float on the surface of the water, resembling dead leaves; similar behaviour is found in the leaf fish *Monocirrhus polycanthus* (Nandidae). Some wrasses (Labridae) resemble green algae because of their body coloration, a mixture of white, green, and brown. A remarkable mimic is seen in the case of the sabre-toothed blenny (*Aspidonotus taeniatus*), which mimics the cleaner fish *Labroides.* By resembling a cleaner fish, the blenny is able to approach other fishes and surprise them by rushing in to bite off a piece of fin (see MIMICRY). Similar mimicry also occurs in an East Indies species of blenny that mimics a wrasse, apparently for food and protection.

FORM AND FUNCTION

The nature and diversity of the perciforms make a general definition of the group difficult; the most common characters are found in the large families of sea basses, mackerels, perches, sunfishes and others. Perciform fishes usually have spines present on their dorsal, anal, and pelvic fins. The dorsal fin is usually divided into two parts, with the first part supported by one or more spiny rays; these are believed to have evolved for defense purposes. The pelvic fins are usually present, directly below or a little ahead of the pectoral fins, and they are supported by one spine and five or fewer soft rays. This position of the pelvic fins gives the perciforms an advantage in manoeuvring over short distances. The pelvic fins are lacking in some perciforms; in others, such as gobies, they are united to form a cuplike sucker; and, in the gouramis, the pelvic fin may be drawn out into long filaments.

Drawing by G. Christman

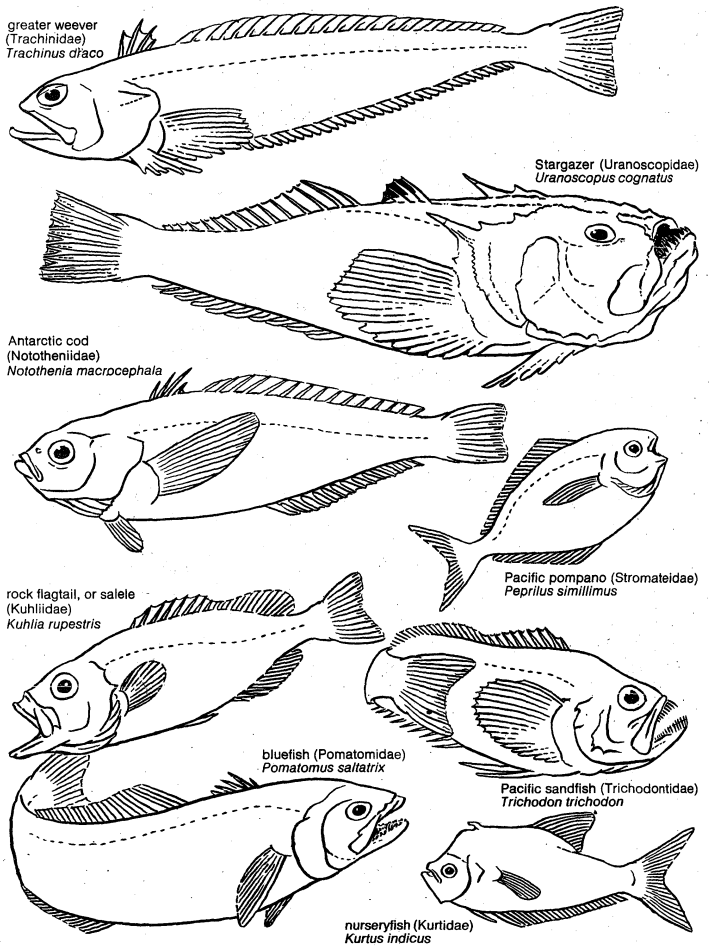

Figure 4: Representative perciforms of the families Kuhliidae, Pomatomidae, Trichodontidae, Trachinidae, Uranoscopidae, Notothenidae, Stromateidae, and Kurtidae.

A diversity of mouth and jaw structure occurs in the perciforms; most of it is brought about by the various types of feeding behaviour. Perciforms usually have protrusible jaws; and in the leaf fishes and swallowers, the jaws are easily distensible. The protrusible jaw may have thick lips, as in the wrasses, or may possess fleshy projections, as in certain species of African cichlids. Weever fishes (*Trachinus*) and stargazers (*Uranoscopus*) possess jaws that are directed upward; the jaws help when capturing prey as they lie buried in the sand. The upper jaws are greatly prolonged in the swordfishes and billfishes; the significance of this feature is rather uncertain. Many of the perciform species that inhabit coral reefs have modifications of the snout and jaws; the butterfly fishes have a straight tubelike mouth for reaching food among coral crevices.

Other structures of the perciforms have also undergone modification according to the various types of feeding behaviour. Most of the piscivores possess numerous short, fine, and pointed teeth; *e.g.,* the perches and sea basses. Barracudas have long piercing canine teeth for holding and stabbing prey, and certain gobies and blennies characteristically have long, curved canines in the lower jaw only. Perciforms that are either herbivorous or consumers of small invertebrates in addition to vegetation possess incisors, which are chisel-like teeth, as in certain sea breams; incisors may become fused into a beaklike structure, as in the parrotfishes. Enlarged pharyngeal (throat) teeth are present in some perciforms and are used for grinding and crushing food such as clams and snails. Tooth structure has undergone various modifications in many of the African cichlids. Herbivorous cichlids possess chisel-like teeth to feed on plants and algae; the piscivorous ones have strong, pointed teeth. Cichlids that feed on the eggs and young of other species possess a highly distensible mouth with reduced teeth embedded in the gums. (M.W.L.)

CLASSIFICATION

Annotated classification. The classification presented here is mainly that of British ichthyologist P.H. Greenwood and colleagues, published in 1966; it in turn is fundamentally that established by the British ichthyologist Carl C. Tate Regan in 1929. Certain changes have been incorporated, based mostly on characters from the nervous system.

All of the features distinguishing the order Perciformes are found in the fishes of the most generalized group, the suborder Percoidei, which contains the sea basses, sunfishes, perches, and fishes of many other families. As the subordinal name implies, the fishes composing it are "percoid," or perchlike in appearance. The fishes in the other suborders have presumably evolved from a percoid-like ancestor, but some have changed so much as to hardly resemble a percoid fish externally.

ORDER PERCIFORMES

Swim bladder not connected by an open duct to the throat; dorsal, anal, and pelvic fins usually with spines; dorsal fin usually with the first or anterior part supported by spiny rays and the rest by soft (articulated) rays, the spinous- and soft-rayed portions often separated from each other so as to constitute two distinct dorsal fins, or there may be a notch in the profile of the dorsal fin that indicates the two joined portions. A fin is considered long- or short-based on the basis of the length of its attachment to the body. Pelvic fins with 1 spine and 5 or fewer soft rays, or pelvic fins absent; pelvic fins thoracic in position (*i.e.,* placed ventrally below the base of the pectoral fins), pelvic fins sometimes ahead of pectoral fins (that is, jugular in position), or, occasionally, pelvic fins posterior to pectoral fins; pelvic girdle usually directly attached to base of pectoral girdle; caudal fin with not more than 17 principal (branched) rays supporting it; skull lacking orbitosphenoid bone; shoulder girdle lacking meso-

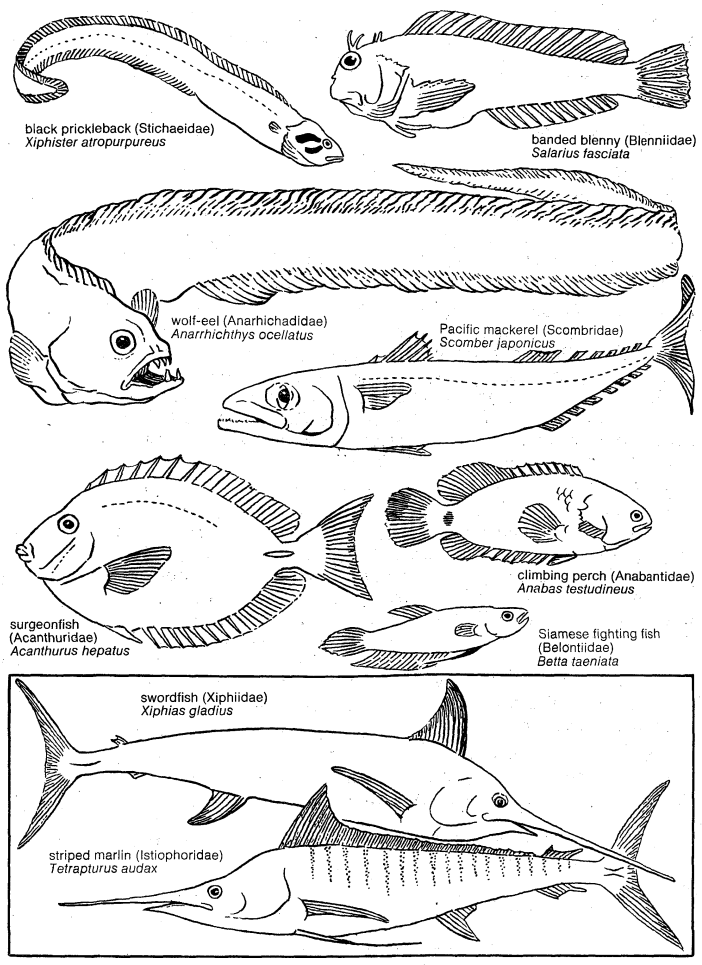

Figure 5: Representative perciforms of the families Blenniidae, Stichaeidae, Anarhichadidae, Acanthuridae, Scombridae, Xiphiidae, Istiophoridae, Anabantidae, and Belontiidae.
Drawing by G. Christman

coracoid bone; jaws typically protrusible; premaxillary bone of upper jaw excluding the maxilla from the gape of the mouth. Scales usually rough-edged (ctenoid), provided with small teeth (ctenii) along their posterior edge, sometimes round and smooth (cycloid). About 6,000 species, marine and freshwater; most species along shorelines in tropics and temperate zones, and in freshwater, the number of species dropping off drastically in higher latitudes. Fossil remains from the Upper Cretaceous Period (more than 75,000,000 years ago).

Suborder Mugiloidei

Spiny-rayed dorsal fin rather widely separated from soft-rayed dorsal; pelvic fins of 1 spine and 5 rays, not thoracic but located more posteriorly on the abdomen; scaled lateral line with nerve pattern resembling that of some lower nonperciform fishes; taste nerves of trunk like many percoids; olfactory bulbs far forward, unlike other perciforms.

Family Mugilidae (mullets). Lower Oligocene to present; cigar-shaped, roundish body, short snout; large cycloid scales; usually numerous small movable teeth; muscular gizzard-like stomach in many species. Moderately large schooling fishes, 30 to 90 cm (1 to 3 ft) long. Less than 100 species; tropical and temperate waters, some in brackish water and freshwater.

Suborder Sphyraenoidei

Two dorsal fins, both short-based and widely separated from each other; pelvic fins some distance posterior to pectorals; pattern of trunk lateral line nerves in a rudimentary percoid pattern resembling pre-percoid patterns found in atheriniform fishes; pattern of taste nerves on trunk resembles that in atheriniform fishes; large teeth set in deep sockets.

Family Sphyraenidae (barracudas). Eocene to present; large, elongated, pikelike, with long, pointed jaws and big teeth; piscivorous; probably not over 120 cm (4 ft) long; all warm seas; about 20 species; fine game fishes.

Suborder Polynemoidei

Pelvic fins thoracic; pectorals low on side of body, divided into an upper normal part and an unusual lower part, consisting of a number of fin rays grown out into long sensory filaments, reaching to anal fin and far beyond in some species.

Family Polynemidae (threadfins). Upper Miocene to present; resembling mullets in body shape and widely separated two dorsal fins but like anchovies (see CLUPEIFORMES) in ventral mouth with projecting snout, rather deeply cleft mouth, and adipose eyelids; in most warm seas, often abundant at river mouths and over sandy bottoms; about 24 species, most 30–69 cm (12–24 in.) long, but 1 giant species reaches 180 cm (6 ft).

Suborder Percoidei

The largest suborder in both numbers of families and of species; fishes typically of a perch or bass appearance; jaws protrusible; dorsal fin usually conspicuously spinous, often with the spinous and soft portions separated or nearly so or with a notch between the 2; anal fin with 2 or more spines at anterior end, occasionally with 1 spine, sometimes with more than 3 spines; pelvic with 1 spine and usually 5 soft rays; body often somewhat deep rather than elongated; territorial, bottom-oriented, investigative shorefishes with great close-quarters swimming manoeuvrability, swimming backward and forward short distances with much use of pectoral fins; great variety in adaptive design and operation of jaws; generalized predators of fishes and crustaceans in all warm seas near shores, especially in tropics; in freshwater. Almost 4,000 species, some of large size; about 90 families.

Superfamily Percoidea (basses, perches, sunfishes, cichlids, damselfishes, and many others)

About 60 families grouped together because they show no great morphological specialization away from the general bass, grouper, or perch kind of fish taken as a model. Most inhabit shores of tropical and temperate seas or lakes. Two aspects most obviously contributing to the success of this group are the adaptability of the protractile mouth and the detailed variety of specializations for swimming manoeuvrability in restricted areas.

Family Scombropidae. Pliocene to present; rare, deep water marine (down to 600–800 m, or 2,000–2,600 ft); this and the next several families retain some features that may have been those of the most generalized ancestors of present-day percoids such as: 2 dorsal fins separate, anal fin with 2 spines, primitive pattern of taste nerves on the body and remains of a special system of lateral line nerves on the head. About 7 genera and 20 species.

Family Acropomatidae. Rare, deepwater marine species rather similar to scombropids; anus located anteriorly from normal position at front of anal fin. Light organs present; midwater depths of 300–500 m (1,000–1,650 ft); 2 species; Indo-Pacific.

Family Apogonidae (cardinal fishes). Eocene to present; 2 well-separated dorsal fins; 2 spines in anal fins; midsection of body often short, with head, eyes, and caudal peduncle proportionately larger; mouth large. Males orally incubate eggs. Mostly marine species, often reddish; live around coral reefs in tropics and subtropics; nocturnal; a few species from deep oceanic midwaters 1,000–1,200 m (3,300–4,000 ft); most with special lateral line system of nerves and free organs well developed on head (among the few percoids with the system). About 200 species.

Family Moronidae (temperate basses). Eocene to present. Two dorsal fins connected at their bases. Most species slim-looking basses; well-known food and game fishes such as striped bass and white basses of the genus *Morone*. Some species anadromous. Weight to 50 kg (about 110 lb) in striped bass. About 12 species, marine and freshwaters of North America, Europe, Africa, Australia, and the Orient.

Families Pomadasyidae and Banjosidae (grunts). Eocene to present. Spinous and soft dorsal fins continuous, often notched. Resemble snappers (Lutjanidae), but teeth weaker, canines absent; sound produced by grinding pharyngeal teeth together and amplified by adjacent swim bladder. Second anal spine often much enlarged; about 75 species, tropical and subtropical shorefishes, many entering estuaries; good food and game fishes.

Family Centropomidae (snooks or robalos). Eocene to present. Elongated, basslike fishes; head long and sloping; sizable mouth, projecting lower jaw; two separate short-based dorsal fins; short-based anal fin. Oceans and estuaries of Pacific and Atlantic coasts of tropical Americas; about 8 species, 45–150 cm (about 1½ to 5 ft); good food and game species.

Family Dinolestiidae. One species, resembling, but not related to, the barracudas (Sphyraenidae, above). Marine; Australia and Tasmania; length to 50 cm (20 in.).

Family Latidae (Nile perches). Eocene to present. Closely similar to Centropomidae. Piscivorous; freshwaters of Africa; at river mouths and along coasts in Southeast Asia and northern Australia; up to about 180 cm (6 ft) long and 140 kg (300 lb); excellent food fishes.

Family Percichthyidae (perch trouts). Eocene to present. Dull-coloured, small, perchlike freshwater and marine fishes of Chile and Argentina. Dorsal fin deeply notched. About 9 species.

Family Ambassidae (glass perches). Small fishes similar in body form to Apogonidae; body short, rather deep. Spinous and soft-rayed parts of dorsal fin nearly separated by deep notch. Good predators on mosquitoes; large schools in sea around river mouths and in freshwater; Indo-Pacific; about 24 species.

Drawing by G. Christman

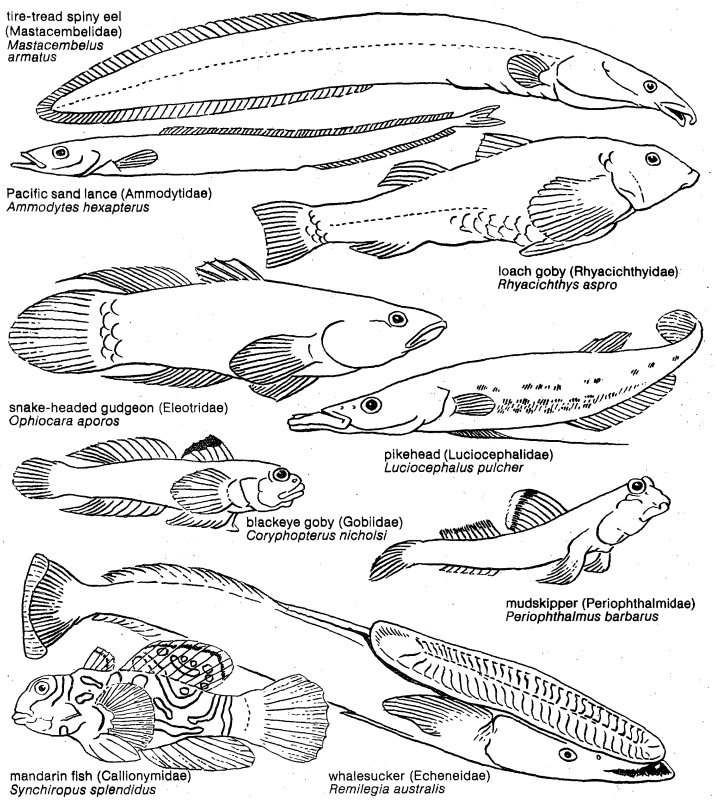

Figure 6: Representative perciforms of the families Luciocephalidae, Mastacembelidae, Echeneidae, Ammodytidae, Eleotridae, Gobiidae, Periophthalmidae, Rhyacichthyidae, and Callionymidae.

Family Serranidae (sea basses, groupers, and many others). Paleocene to present. Structurally diverse; variously similar to many of the percoid families mentioned above in their general spiny-rayed, perchlike appearance. Dorsal fin continuous, but may be deeply notched; spinous portion of dorsal fin with longer base than soft dorsal portion; anal usually with 3 spines and short based; no scaly sheath along base of dorsal and anal fins; mouth large; pectorals broadly rounded; caudal fin usually truncate or rounded, sometimes moderately forked. About 400 species in tropical, subtropical and warm temperate seas; some in freshwater; good food and game fishes; weight to about 320 kg (700 lb).

Families Pseudochromidae, Grammidae, Plesiopidae, Pseudoplesiopidae, and Acanthoclinidae. Quite similar, small, darkly colourful, rather secretive coral-reef basslike fishes of tropical Indo-Pacific and Caribbean seas. An interesting specialization of numerous species is the presence of multiple horizontal, interrupted lateral lines on trunk: one along the back, one along the side, and one along the bottom of each side of the body. Dorsal and anal fins vary from few or no spines up to 24; long dorsal fin, sometimes deeply notched between spines with a little banner or flag of fin membrane extending up and out from the end of the spine. Together, about 40 species.

Families Glaucosomidae (pearl perches), *Lobotidae* (triple tails), *and Banjosidae.* Deep-bodied perchlike fishes, all found in eastern Pacific Ocean, except *Lobotes*, which also occurs elsewhere in tropical salt and freshwater; 5 or 6 species in Glaucosomidae; 1 in each of the other families.

Family Priacanthidae (big eyes or catalufas). Eocene to present. Deep-bodied, reddish, serranid-like dwellers of deeper offshore waters, toward the bottom. Jaws almost vertically hinged; carnivorous. Tropical Indo-Pacific and Atlantic; few species; 30–45 cm (12–18 in.) long.

Family Centrarchidae (sunfishes and basses). Eocene to present. Moderately deep-bodied; spinous and soft dorsal fins continuous, not separate as in Percidae; more than 3 anal spines. Freshwaters of North America; only 1 species, *Archoplites interruptus*, native west of the Rocky Mountains; various species widely introduced elsewhere; prefer quieter waters, such as ponds, lakes, swamps; excellent game fishes; size from 30 gm (1 oz) to about 10 kg (22 lb); 30 species.

Family Embiotocidae (surfperches). Miocene to present. Laterally compressed, ovate, smooth-scaled, fairly small, with small head. One long dorsal fin, depressible into a scaled sheath alongside the fin. Give birth to actively swimming young; 23 species from central Baja California, to Japan, absent from Aleutian chain; most species (20) occur in California; one freshwater species (*Hysterocarpus traski*) in central California; 12–30 cm (5–12 in.).

Families Nandidae and Polycentridae (near leaf fishes and leaf fishes). Small, mostly piscivorous fishes with large to huge protrusible mouths; consume prey up to ⅔ their own length. Bodies moderate to deep, laterally compressed; long spinous dorsal fin and 3 to 13 spines in anal fin; soft dorsal and anal short-based and colourless, used together with colourless pectoral fin in *Polycentrus* and *Monocirrhus* in swimming imperceptibly toward prey without any evident signs of fin or body movement. Six species in freshwaters (and brackish for *Nandus*) from India to Malaysia; for Polycentridae, West Africa, Central America and east coast of South America. Six species.

Family Cichlidae (cichlids). Eocene to present. Small freshwater (a few brackish water) percoids, resembling damselfishes (below) and North American sunfishes. One pair of nostrils instead of the 2 of most fishes; spinous dorsal fin long-based; anal fin short-based, 3-spined dorsal and anal fins often pointed at posterior ends; caudal fin usually rounded; first pelvic rays of males often elongated; lateral line interrupted. Native to Texas, Central America, South America, and West Indies; Africa; Palestine, India, and Sri Lanka (formerly Ceylon). Complicated courtship, nest-building and mouth-brooding (several genera). Over 700 species, many important aquarium fishes; almost 600 native to 3 big rift lakes in Africa (especially Tanganyika, Malawi, and Victoria); a few species up to 30 cm (12 in.); 1 up to 9 kg (20 lb; genus *Tilapia*).

Family Pristolepidae. A deep-bodied, laterally compressed, small-mouthed percoid, resembling a cichlid or pomacentrid but having a patch of blunt, molariform teeth on base of skull opposite similar teeth on rear floor of mouth. Long spinous dorsal fin; oval 3-spined; interrupted lateral line. One species only, of unsolved percoid relationship but evidently not allied to Nandidae as once thought. Freshwaters; Burma to Indo-China and Malaysia.

Family Pomacentridae (damselfishes and anemone fishes). Eocene to present. Abundant, conspicuous, active little fishes, often brightly coloured, of shores and coral reefs, mainly in tropical, a few in subtropical seas. Resemble cichlids in general appearance and, like cichlids, also have only 1 pair of nostrils. Lateral line continuous or interrupted; long spinous dorsal fin; anal with 2 spines, sometimes 3; soft dorsal and anal fins similar; caudal fin usually forked; all fins may have pointed filamentous ends; head scaled; scales large, ctenoid; bases of unpaired fins scaled; first ray of pelvic fin somewhat elongated; floor of mouth with one triangular, fused tooth plate in pharynx (pharyngeal plate). Territorial, pugnacious; about 250 species.

Family Percidae (perches, walleyes, darters). Eocene to present. Spinous and soft dorsal fins usually well separated; anal with 1 or 2 spines and short-based; scales ctenoid; bodies rather elongated. All freshwater, temperate species; perches and pike perches Holarctic with a few brackish-water species and a marine species of pike perch in parts of Black and Caspian seas; darters are native only to North America. Perches prefer quiet waters, darters running waters; pike perches occur in either and are semi-migratory. Many species build nests and show parental care; size up to about 90 cm (3 ft) and 25 lb for walleyes; darters from 2.5 to 7.5 cm (1 to 3 in.). About 125 species, of which about 100 are darters.

Family Sciaenidae (drums or croakers). Upper Cretaceous to present. Some species resemble cods, others resemble sea basses; most have lower jaw short or underslung, with upper

jaw and snout extending beyond lower jaw; often 1 or more barbels (fleshy filaments) at tip of lower jaw. Spinous and soft dorsal fins separate; soft dorsal fairly long based; anal fin small, with 2 spines (most percoids have 3 or more); lateral line continues out to posterior end of caudal fin (unusual for most percoids); air bladder often with intricate outpocketings and with muscles attached to it that operate to make resonating sounds in air bladder, hence name of drum; surface of head may be cavernous through expansion of lateral line canal system. Most species occur on slopes of continental shelf, a few around islands; most in tropics, a few in temperate waters; a few freshwater. About 160 species; size from about 100 gm to 100 kg (a few ounces to 225 lb); many important food fishes.

Family Odacidae (rock whitings). Teeth incompletely fused together making a parrot-like beak as in parrot fishes (Scaridae), but odacids are evidently not related to wrasses (Labridae), parrotfishes, or whitings (Sillaginidae), all of which they also resemble. Seven species; southern Australian and New Zealand seas.

Family Labracoglossidae. Resemble grunts (Pomadasyidae) to which they are allied. Five species. Easter Island to New Zealand, Australia, Japan.

Family Sillaginidae (whitings). Oligocene to present. Elongated fishes with long, conical snout, small mouth; moderately long dorsal and anal fins; anal with 2 weak spines. About 6 species of small marine fishes of shallow water; Indo-Pacific, often in estuaries and river mouths; dig in bottom with long snouts for food.

Family Branchiostegidae (tilefishes). Pliocene to present. Body elongated; large, oblique mouth with strong canines; body deep through chest region; eyes high on head at top of steep sloping forehead; single, rather long dorsal fin; fin spines weak. Moderate to large body size; about 20 species, most in shallow seas of tropics and temperate zone.

Family Lactariidae (milk trevally). Miocene to present. Moderately deep-bodied, laterally compressed; mouth large, oblique; eyes large; pectorals pointed; two dorsal fins separated; anal fin long-based. One or two species marine in Indo-Pacific.

Families Owstoniidae and Cepolidae (bandfishes). Eocene to present. Owstoniids are marine, deep-water fishes, basslike, but large mouth is oblique, eye large, and dorsal and anal fins long, continuous, and high; caudal fin with long rays; body tapers noticeably. Cepolids similar, but have a long tapering body and are shallow- and deep-water fishes. Cepolids occur from Europe through Mediterranean to India, China, Japan, and Philippines; owstoniids only in Far East; few species.

Family Mullidae (goatfishes). Miocene to present. Resemble minnows (Cyprinidae); have a long pair of chin barbels that usually lie flat against chin, except when in use as sense organs, probing the bottom for food. Spinous dorsal fin well separated from soft dorsal. Fifty to 60 species at reefs and shallow sandy or muddy bottoms near shore in tropics and warmer temperate seas.

Family Lutjanidae (snappers). Miocene to present. Resemble sea basses (Serranidae), but when mouth is closed jaw slips under bony cover over preorbital area (between eye and jaw); enlarged canine teeth in jaws; spinous dorsal fin longer than soft and joined to it; anal fin short-based; caudal fin usually truncate. About 250 species; marine and brackish water in all warm seas.

Families Nemipteridae, Scolopsidae, Lethrinidae, Pentapodidae. Resemble Lutjanidae; some with wider preorbital area under which upper jaw slips; others (Nemipteridae) with molar teeth in sides of jaws and incisors or canine-like teeth at front end of jaws. About 50 species collectively; marine, Atlantic and Indo-Pacific, especially around coral reefs; some species up to 90 cm (3 ft) long; good eating.

Family Sparidae (breams, porgies). Eocene to present; resembling fishes of families Nemipteridae and Lutjanidae; mouth small but with a powerful dentition of incisors or canines across the front of the jaws and molar-like teeth to the sides, the teeth enlarging toward the rear of the mouth; used in crushing crustaceans, mollusks, and small fishes. About 100 species in shallow seas of tropical, subtropical, and temperate zones; most species less than 30 cm (1 ft) long, a few up to 120 cm (4 ft); important food and game fishes.

Family Gerreidae (mojarras). Small perchlike fishes with compressed, rather deep, silvery bodies; they are set off from most other percoids by their highly protrusible mouths used in probing soft, sandy bottoms to catch food organisms; about 40–50 species, mostly tropical marine, a few in freshwater; abundant in American tropics and East Indian region. Resemble fishes of family Leiognathidae, but the similarity is thought to be the result of parallel evolution.

Family Pempheridae (sweepers). Perchlike fishes with compressed body and a very short-based dorsal fin but long-based, low anal fin; big eyes. About 20 species in tropics of Atlantic, Indian, and Pacific oceans.

Family Bathyclupeidae. Resemble sweepers but apparently not related; compressed body; prominent lower jaw; single short-based dorsal fin; anal fin long-based; eye large; mouth large. Few species; deep-sea midwaters, 400–500 m depth.

Family Leptobramidae (salmon trout). A slender carangid-like species with large mouth, rather long-based anal fin, and with a single dorsal fin placed behind the beginning of anal fin; resembles Pempheridae but apparently is not related to it; a single species reaching 43 cm (17 in.) and about 2 kg (4 lb); off coasts of western Australia and New Guinea.

Family Carangidae (jacks, scads, and pompanos). Eocene to present. Lateral line usually strongly arched anteriorly and the posterior part usually armed with enlarged, keeled, scutelike bony scales; second dorsal and anal fins elevated and falcate anteriorly and sometimes followed by short-based free finlets; soft-rayed portions of dorsal and anal fins preceded by separated or nearly separated free, short spines; swift-looking fishes with thin, streamlined bodies, very constricted caudal peduncle, deeply forked caudal fin, and long, sickle-shaped pectoral fins; eyes often covered with clear eyelids; worldwide in tropics and warm temperate areas; over 200 species; most are good food and game fishes.

Family Rachycentridae (cobias). Long and slender, somewhat resembling mackerels and shark suckers (remoras); may be related to shark suckers (family Echeneidae); soft portion of dorsal fin preceded by a row of short, separate dorsal spines. One species, worldwide in warm seas but absent in eastern Pacific; size up to 90 cm (3 ft) and over 70 kg (150 lb); pelagic in habit.

Family Coryphaenidae (dolphins). Sleek, fast-swimming fishes of tropic and temperate open seas; speeds up to 65 km (40 mi) per hour; dorsal and anal fins long-based and low; dorsal fin begins on head; deeply forked caudal fin; long, slender pelvic fins fitting into groove on belly; young males of one species change into adults with almost vertical forehead. Two species, 1 large, up to 150 cm (5 ft) and 25 kg (55 lb).

Family Formionidae (black pomfrets). Body deep, strongly compressed; dorsal and anal fins long-based and elevated at anterior end, both fins with spines rudimentary in adult fish; a few enlarged scutes at end of lateral line, a characteristic of fishes of jack family (Carangidae). One species, up to about 60 cm (2 ft); Indian Ocean to Australia and China.

Family Menidae (moonfishes). Eocene to present. Body strongly compressed, triangular, very deep behind head, with edge of chest razor-sharp; anal fin very long and low, reaching forward to pelvic fins; first ray of pelvic fin long and filamentous; mouth protrusible into an upward extended tube; one species, less than 30 cm (12 in.) long, in Indo-Pacific seas.

Family Leiognathidae (slip mouths). Oligocene to present. Small fishes; body greatly compressed, ovate; mouth small but highly protrusible into a tube pointing up or down; long dorsal and anal fins elevated anteriorly, folding down into scaly sheath lying alongside bases of the fins; exude large amounts of mucus after capture. About 25 species, mostly marine shallow-water shorefishes, some in estuaries of Indo-Pacific area.

Family Bramidae (pomfrets). Body deep, strongly compressed; head broadly rounded in profile; pectorals long and curved; long-based dorsal and anal fins, low, sloping back to narrow caudal peduncle and deeply forked caudal fin; mouth small, oblique; about 23 species of darkly coloured fishes in rather deep waters of open ocean; size up to 90 cm (3 ft). One species, *Pteraclis velifera*, with enormously high and long fanlike dorsal and anal fins.

Family Caristiidae (manefishes). Rare black pomfret-like fish from midwater depth of 1,000 m (3,300 ft) over much deeper bottoms; dorsal fin begins far forward over end of cranium, high and like a mane; pelvic fins very long; 1 or 2 oceanic species.

Family Monodactylidae (fingerfishes). Includes family Psettidae. Small, silvery, ovate, small-mouthed fishes of salt and brackish water, temporarily in freshwater. Pelvic fins minute; dorsal and anal fins long; anterior spines of dorsal fin short and detached. Five species, coasts of Africa to India and Southeast Asia.

Family Toxotidae (archer fishes). Lower Tertiary to present. Moderately deep-bodied percoids distinguished by nearly

straight line from dorsal fin to tip of jaws; jaws large, oblique; lower jaw prominent; jaws and roof of mouth adapted for expelling under force drops of water fired from surface of water at insects on overhanging tropical vegetation in mangrove swamps. Dorsal and anal fins set far back on body; dorsal fin with 4 enlarged spines at front; 5 species, with black saddle markings or spots on dorsal surface; marine and freshwaters of Indo-Pacific.

Family Ephippidae (spadefishes and batfishes). Includes Chaetodipteridae, Drepanidae and Platacidae. Eocene to present. Body deep, orbicular, greatly compressed laterally; long-based dorsal and anal fins, usually high, especially anteriorly in young; mouth quite small. About 15 species in tropics of world, few in temperate zone; size up to 40 cm (16 in.).

Family Pomacanthidae (angelfishes). Eocene to present. Body deep, laterally compressed; mouth quite small; strongly resemble Pomacentridae and Chaetodontidae (in which family they traditionally have been placed) but distinguished from these and other deep-bodied coral-reef fishes by a rather long, sharp spine projecting posteriorly from the lower part of cheek region (from the preopercle bone); profile of head from dorsal fin to tip of snout mainly convex, rarely straight, never concave as in butterfly fishes; young often differently coloured from adults; less than 100 species of conspicuous coral-reef and tropical fishes; mostly of small size, a few species up to about 45 cm (18 in.).

Family Scatophagidae (scats). Eocene to present; deep-bodied, laterally compressed; small mouth; 2 dorsal fins joined at base; bases of dorsal and anal fins scaled; about 4 species; coasts of Africa to Indo-Pacific, entering brackish and freshwater; scavengers, eating decaying plant and animal remains and fecal matter, including human; size up to 40 cm (16 in.).

Family Rhinoprenidae. One species, recently discovered, superficially similar to Scatophagidae, but really quite different. Long free filament at front of dorsal and anal fins and 1 on pectoral fin; posterior nostril of each side of head enlarged and confluent across snout. One species over muddy bottoms at river mouths in Gulf of Papua, New Guinea.

Family Enoplosidae (old wife). Eocene to present. Body laterally compressed; spinous and soft dorsal fins elevated anteriorly, as is anal fin; general appearance gives impression in side view of two separate bodies joined together at midpoint; pelvic fins large. One species in rocky areas of Australian coast; size up to 22 cm (9 in.).

Family Chaetodontidae (butterfly fishes). Oligocene to present. Body deep, disk-shaped; mouth small, jaws sometimes on end of small (or, occasionally, fairly long) beak; slope of forehead from dorsal fin to tip of snout is concave, never convex; spinous portion of dorsal and anal fins usually prominent; bases of dorsal and anal fins scaled. Body often marked with oblique dark bands and one or two eye-like spots. Over 100 species in tropics of world, all marine; typical of coral reefs.

Family Pentacerotidae (pelagic armorheads). Resemble Chaetodontidae but with higher dorsal fin and much larger dorsal, anal, and pelvic spines; dorsal fin usually strongly elevated; head rough with exposed bony plates; snout usually elongated bearing small mouth at its end; lips with "hairy" skin. Seven or 8 species, in deeper coastal waters from South Africa, Australia, and New Zealand to Japan; size up to about 50 cm (20 in.).

Superfamily Kuhlioidea

Classified together under this suborder are a number of percoid families that have in common the same pattern of main branches of a complex of taste nerves that occur on the body.

Family Kuhliidae (flagtails and aholeaholes). Typical percoids resembling North American freshwater sunfishes and basses; dorsal fin single, notch between soft and spinous portions; dorsal and anal fins folding into scaly sheaths along their bases; 6 species of tropical Indo-Pacific oceans, preferring brackish water and freshwater; size up to 45 cm (18 in.); good eating.

Families Scorpididae (sweeps and halfmoons), *Kyphosidae* (sea chubs), *Girellidae* (opaleyes), *Coracinidae* (galjoen fishes). All quite similar families recognized by combination of ovate body, small mouth, strong caudal fin that is usually weakly forked; and, especially, a spinous dorsal fin with low spines followed by a higher evenly curved or falcate soft dorsal fin; about 36 species, many partly herbivorous; tropical and warm temperate coasts in Atlantic, Pacific, Indian oceans; size usually not over 45 cm; some are good food and game fishes.

Family Oplegnathidae. Pliocene to present. Strongly resemble Scorpidae and Kyphosidae, but incisiform teeth of young become fused in adult to form a parrot-like beak to upper and lower jaws; these fishes are not related to true parrotfishes (Scaridae); several species of shorefishes mostly in tropics of Southern Hemisphere; size up to 60 cm (24 in.).

Family Theraponidae (grunters or tigerfishes). Typical percoids of small bass type; colours dull or silvery with horizontal dark stripes; dorsal fin deeply notched, spinous portion longer than soft portion; some species make grunting sounds. Less than 25 species, Indian and western Pacific oceans in freshwaters of Australia and New Guinea; small to medium size.

Family Arripidae (Australian salmon; ruffs). Not related to true salmons of Northern Hemisphere. Rather long, slender body; deeply forked tail; moderately long dorsal fin, a notch between the shorter spinous dorsal and longer soft dorsal fin. Two species; marine, young in brackish water; shallow waters off South Australia, New Zealand and adjacent islands; size up to 1 m; important food and game fishes.

Family Emmelichthyidae (bonnetmouths). Includes families Caesionidae, Erythricthyidae, Dipterygonotidae, Maenidae, Spicaridae, Centracanthidae, Merolepidae by some authors. About 25 species of 2 general body types: one with slender, elongated bodies with moderately protrusible upper jaws; the other deeper bodied and with enormously protrusible upper jaws. Some school in open waters at depths of 3–45 m (10-150 ft), others in deeper water.

Family Pomatomidae (bluefish). Resembles Australian salmon (family Arripidae), but spinous dorsal smaller and separate from soft dorsal; anal fin longer; body more robust; 1 or 2 small spines before anal fin. One species, widely distributed in tropical and subtropical seas; voracious feeder on other fishes; size up to 120 cm and 11 kg (4 ft and 25 lb); good game and food fish.

Family Nematistiidae (roosterfish or papagallo). Streamlined fish resembling jacks (Carangidae); dorsal fin remarkable for spinous portion consisting of greatly lengthened spines nearly separate from each other, the fin connected by fin membrane only at their bases, except the last ray, which is free at its base. Caudal fin deeply forked; pectoral fin long, falcate; mouth rather large. One species found only on west coast of Central America, from Gulf of California south to Panama; frequents sandy shores; size up to 35 kg (80 lb); great game fish.

Superfamily Labroidea

Family Labridae (wrasses). Paleocene to present. Various body forms, but commonly cigar-shaped, fairly slender; snout moderately long, sometimes lengthened; dorsal and anal fins long-based and low; caudal fin truncate; especially characteristic are the noticeable lips and outcurving sizable canine teeth at ends of upper and lower jaws, the large scales and the habit of swimming around the coral reefs by "rowing" with the pectoral fins. About 300 species, many beautifully coloured and marked, often with differences of colour and pattern between sexes; also differences between young and adults; size from 5 cm to nearly 2 m (2 in. to several ft), 10 kg (20 lb); marine shallow-water fishes of tropics and warm temperate zone.

Family Scaridae (parrot fishes). Eocene to present; resemble Labridae but with stouter bodies and with teeth fused to form a parrot-like beak to upper and lower jaws; large scales in regular rows; herbivorous; about 80 species, often brilliantly coloured; species separable by colour and pattern; sexes often differ in colour. Size up to 120 cm (4 ft) and 20 kg (45 lb); tropical marine fishes.

Superfamily Gadopsoidea

Family Gadopsidae (river cod). Slender, somewhat elongated, with longer based dorsal and anal fins than typical percoid. Characterized by very slender and fairly long pelvic fins located in front of pectoral fins; caudal fin rounded. One species, rivers of southern half of Australia; somewhat resembles Ophidiidae (order Paracanthopterygii) but apparently is a derivative of family Serranidae; size up to 60 cm (2 ft).

Superfamily Cirrhitoidea

Family Cirrhitidae (hawkfishes). Small colourful perchlike fishes having lower rays of pectoral fins unbranched, thickened, and separate from one another; small flag of skin projects from tip of each spine of dorsal fin; about 35 species; shallow coastal waters in warm seas.

Families Chironemidae, Haplodactylidae, Cheilodactylidae, and Latridae. Similar to Cirrhitidae; 25 to 30 marine species, mostly in shallow waters of Australia and New Zealand, some species off South America; size up to 60 cm (2 ft).

Superfamily Champsodontoidea

Family Champsodontidae. Small, elongated spiny-rayed fishes with a small spinous first dorsal fin and rather long, soft

dorsal and anal fins; pelvic fins rather large; eyes near top of head and close together; unusual is the large mouth, the jaw extending obliquely past the eyes; several species; carnivorous; deep waters of Indo-Pacific oceans.

Superfamily Trichodontoidea

Family Trichodontidae (sandfishes). Resemble codfishes, but eyes high on side of head; mouth large, oblique; lips fringed; pectoral fins with long base extending forward past pelvic fins. Two species; marine; North Pacific; to 25 cm.

Superfamily Trachinoidea

Family Opisthognathidae (jawfishes). Resemble Clinidae, but jaws large to huge, extending far past eye; dorsal fin long-based; spinous and soft portions continuous; anal fin long-based; body usually elongated, slender; eye almost at anterior tip of head; pelvic fins below pectorals. About 24 species, mostly small, in shallow tropical and temperate seas.

Family Bathymasteridae (ronquils). Resemble Opisthognathidae, but jaws not so large; no spines in dorsal or anal fins; pelvic fins slightly ahead of pectorals; about 8 species; bottom dwelling; coasts of North Pacific Ocean.

Family Mugiloididae. Includes Parapercidae and Pinguipedidae. Some resemble labrids in long dorsal and anal fins (sometimes with few spines), enlarged lips that appear to curl back, and enlarged canines at front of jaws. Body elongated, cylindrical; usually spotted and banded; eyes near top of head. Size from small up to 60–90 cm (2–3 ft); about 30 species; marine; bottom dwellers, coasts of South America, South Africa, Indo-Pacific to Japan; a few good food species.

Family Percophiidae. Includes Bembropidae and Hemerocoetidae, resemble flatheads (Platycephalidae; see SCORPAENIFORMES); body long, slender; head flattened; eyes on top of head, close together; separate spinous and soft dorsal fins; dorsal and anal fins long-based; jaws large. About 12 species; marine, from shallow to about 200 m; South America, Indo-Pacific to Japan.

Family Cheimarrichthyidae (torrent fish). Small, resembling a cottid or sculpin (family Cottidae; see SCORPAENIFORMS); eyes on top of head and close together; one species; freshwater streams of New Zealand; young in brackish water.

Family Trachinidae (weever fishes). Eocene to present. Body elongated, compressed, deep at head end, tapering to narrow, small caudal fin; a separate short-based spinous dorsal fin with black membrane and poison glands along grooves in each spine; anal and soft dorsal fin long-based; a long spine on gill cover with poison glands along grooves of spine; eye black in upper half, white in lower half; scales small, set in distinct oblique rows; 4 species, marine shallow water down to 90 m (300 ft); lie buried in sand with eyes and top of head showing; northern Europe, Mediterranean, Pacific coast of South America; venom very painful, even dangerous.

Family Trichonotidae (hairfins). Resemble Percophiidae and Mugiloididae, but body extremely elongated and dorsal fin unusually high; snout pointed; lips fringed; dive head first into sand. Several species; tropical and subtropical Indo-Pacific oceans.

Family Creediidae. Elongated little fishes resembling Percophiidae; 2 species known; coasts of Australia, Marshall and Mariana islands.

Family Limnichthyidae. Resemble Percophiidae; 5 species; New Zealand, Australia, Society, Marshall, Marianas, and Hawaiian Islands; sand burrowers.

Family Oxudercidae. A single species from coast of China at Macao; relationships still in doubt.

Superfamily Uranoscopoidea

Eocene to present. Three families; resembling toadfishes (Batrachoididae) and weever fishes (Trachinidae). Bodies rather elongated, with long dorsal and anal fins usually with few or no spinous rays; head broad, deep, flattish on top; eyes on top of head and somewhat erectile; mouth broad, oblique; lips fringed with toothlike dermal projections that interdigitate and strain water through sand when the fishes are buried to top of head and eyes; similar fringe of skin at upper end of gill slit; pectoral fins enlarged and fanlike; pelvic fins anterior to pectorals.

Family Leptoscopidae. Sand-burrowing fishes; no spines in dorsal and anal fins. Three species; marine; coasts of Australia and New Zealand; size up to 30 cm (12 in.).

Family Dactyloscopidae (sand stargazers). General features as described under superfamily; body elongated. Shape of pelvic fins is characteristic: each has 3 thickened segmented rays whose tips are free from the fin membrane, divergent and somewhat curled. Small fishes, mostly marine, up to about 10 cm (4 in.); burrow in sand with eyes and mouth protruding from surface of sandy bottom; 20 to 25 species in tropical America in Atlantic and Pacific oceans.

Family Uranoscopidae (stargazers). Head very broad and deep; posterior half of body tapering to a small truncate tail fin; eyes on top of head, projecting above surface of head; large posteriorly pointing spine on shoulder girdle above pectoral fin (in some species); dorsal fin moderately long and either with a short, nearly separate spinous portion or spines absent; anal fin moderately long and with few or no spines; large electric organs behind eyes of species of genus *Astroscopus;* about 25 species living buried on sandy bottoms usually in shallow shore areas; the only marine teleosts with electric organs; a few species at greater depths, to about 600 m (2,000 ft), Atlantic, Pacific, and Indian oceans; size up to about 9 kg (20 lb).

Superfamily Chiasmodontoidea

Family Chiasmodontidae (swallowers). Slender fishes with extremely deeply cleft mouth; large, backward-pointing teeth; dorsal fin long with spinous and soft dorsals separate; pelvic fins thoracic. Capable of swallowing and holding in their greatly distensible bellies fishes larger than themselves. About 12 species in open oceanic waters down to 500 m (1,600 ft); size up to 15 cm (6 in.); relationships in doubt.

Superfamily Notiotheniodea

Four families of codlike or sculpin-like percoids found mainly in the Antarctic, some in cold temperate Southern Hemisphere seas near Chile, Argentina, and New Zealand; superfamily includes about 75 percent of all Antarctic fishes.

Family Bovichthyidae. About 15 species in Subantarctic and south temperate seas, off Chile, Argentina, southern New Zealand, and Southern Australia; 1 species in rivers of South Australia and Tasmania.

Family Notothenidae (Antarctic cods). Miocene to present; about 50 species, most in Subantarctic waters; some species near Antarctic continent; a few in cold temperate zone, one species in rivers of southern South America. Mainly bottom dwellers of littoral zone, some deep-water species resemble true cods (Cottidae) and have a barbel on lower jaw; 2 species, large, up to 150 cm (5 ft).

Family Bathydraconidae (Antarctic dragon fishes). About 15 species; true Antarctic fishes, occurring on coasts of Antarctic continent; body greatly elongated; usually a spatulate, pikelike snout; no first dorsal fin; live on coasts of Antarctic continent to depths of 500–700 m; a few down to 2,500 m. Size up to about 50 cm, but usually much smaller.

Family Chaenichthyidae (white-blooded or icefishes). Famous white-blooded fishes of Antarctic; lack red blood cells and hemoglobin. Mostly large, up to 60 cm (2 ft) long, with scaleless body and two or three lateral lines each side; head large, snout long, spatulate, pike-like; teeth large; jaws nonprotractile. About 17 species, all in Antarctic except one in Subantarctic; mainly bottom dwellers feeding on crustaceans and small fish; most at 100 to 200 m (330–660 ft), some to 700 m (2,300 ft).

Suborder Stromateoidei

Five percoid-like families with an unusual and characteristic feature, a toothed saccular outgrowth in the gullet directly behind last gill arch. One family, the Amarsipidae, lacks the toothed saccular outgrowth in the gullet. Stromateoids may be related to fishes of superfamily Kuhlioidea.

Family Stromateidae (butterfishes). *Centrolopidae* (medusafishes), *Nomeidae* (flotsam fishes), *Ariommidae*, *Tetragonuridae* (squaretails). Eocene to present; slender to ovate, deep-bodied fishes; dorsal fin continuous or spinous portion set off from soft portion by deep notch; in the most generalized species, which resemble Kyphosidae, the soft dorsal is preceded by about 6 low, stoutish spines; other species resemble Carangidae. Eyes often with adipose (fatty) tissue around them; pelvic fins absent in some species, especially in ovate species; skeleton often weakly calcified; scaly sheath along bases of dorsal and anal fins. Young often found under jellyfishes or flotsam; adults live in deeper layers of ocean over continental shelves or are pelagic; a few species close to shore, in bays, even entering estuaries; 78 recognized species, many rarely seen; some feed largely on jellyfishes; others on crustaceans, tunicates, and small fishes; many are important commercially, especially in the Orient; family includes good-tasting species, such as butterfishes and pompanos. Tropics to temperate zone; never near oceanic islands; size 10–120 cm.

Suborder Icosteoidei

Family Icosteidae (ragfish). A single species of rare deep-sea fish of North Pacific Ocean; body highly flexible in water,

limp as a rag out of water; little is known of its anatomy. Resembles Stromateidae; presumably derived from a percoid-like ancestor; no spines in fins; pelvics and scales present in young, both absent in adult; body elongated, much compressed; up to 220 cm (7 ft).

Suborder Blennioidei

Fairly large suborder composed of 2 groups, the tropical blennies, some of which are percoid-like, and the northern blennies. The northern blennies are eel-like fishes, but the appearance of their faces and the aspects of their fins generally resemble those in the tropical blennies.

Superfamily Blennioidea (tropical blennies)

All soft, articulated fin rays in the dorsal, anal, and pelvic fins unbranched; pelvic fins, which are seldom reduced, of 1 spine and 4 or fewer rays and located in front of the pectoral fins; there are the usual 2 nostrils on each side of the head. Exact 1-to-1 ratio between the vertebrae and the dorsal rays and posterior anal rays; only 1 lateral line. About 620 species.

Family Clinidae (clinids). Eocene to present. Percoid-like fishes, some moderately elongated, rather flat-sided, usually with somewhat pointed snouts and fleshy lips; dorsal and anal fins rather high and long-based, with fin membranes conspicuously supported by thin, riblike fin rays; caudal fin fanlike, not large; pelvic fins ahead of pectorals, slender; 1 spine and usually 2 or 3 rays; pelvics in some species appear usable in walking movements; cirri (bushy tentacles of skin) often present above eyes, on anterior nostrils, and just behind head on each side. Body scaled; scales cycloid; first 3 rays of dorsal fin often higher and more or less separate from rest of dorsal. A few species "four eyed" (*i.e.*, with eye divided so as to see out of water). Most inhabit tide pools, kelp, rock crevices; some species down to 30 m (100 ft); size up to 30 cm (12 in.), most are smaller; about 180 species.

Family Tripterygiidae (threefin blennies). Pliocene to present. Much like clinids but dorsal fin divided into 3 distinct parts, the first 2 of spines only; small bottom fishes of reef and rocks. About 100 species mostly in warm seas.

Family Blenniidae (combtooth blennies). Eocene to present. Resemble clinids in fins and body shape but differ in being scaleless, in having a steep forehead and only a single row of teeth in both jaws, the teeth being close-set, long, comblike. Sometimes a pair of large to enormous curved "canines" further back in jaws; some species hop about out of water in intertidal zone; fins without pungent spines; eyes large and at top of forehead; pelvic fins with 2 rays. About 300 species, in tropical, subtropical, and warm temperate seas; of small size.

Family Chaenopsidae (pike blennies). Pliocene to present. Body very elongated; jaws long; long gill area; dorsal and anal fins long, confluent with caudal fin; no scales or lateral line; 6 species in tropical and subtropical marine shore areas of Central America and Caribbean; small fishes living in worm tubes and burrows.

Family Pholidichthyidae (engineer fish). Very elongated eel-like fish; reclusive, living under excavations; move sand and gravel in mouths; known previously only by young stage; adult recently discovered by L. Dempster. One species; marine; in tropics, Indonesia and Philippines; size up to 30 cm (12 in.); poorly known; relationships in doubt.

Family Notograptidae. Eel-shaped; dorsal and anal fins long-based and high, both confluent with caudal fin; pelvics 1-rayed, filamentous, placed before pectorals; body scaled, mouth large. Two small species; marine; western Australia.

Superfamily Stichaeoidea (northern blennies)

Eel-like fishes; single pair of nostrils; dorsal and anal fins long-based and often joined to caudal fin; pelvic fins usually present, placed a little before pectoral fins, of 1 spine and usually fewer than 4 rays; bottom fishes usually of littoral zone, some supralittoral; a few in deep water (down to 450 m, or 1,500 ft).

Family Stichaeidae (pricklebacks). Includes families Chirolophidae, Lumpenidae, Xiphiodontidae, Cebedichthydae. Eel-like; body usually scaled; dorsal fin with spines only or some soft rays at rear of fin; pectorals reduced; pelvics present or absent; some species with 3 or 4 lateral lines but most species lacking lateral line. About 54 species, most in North Pacific, some in Atlantic; often among seaweeds when tide is out; also in deeper water (to 200 m); most feed on invertebrates, a few on seaweed; most species small, a few up to 60 cm.

Family Pholidae (gunnels). Elongated; strongly compressed laterally; scaled; pelvics reduced to 1 spine and 1 ray, very small or absent; spines only in dorsal fin. About 8 species, most in North Pacific; also in North Atlantic; size small; intertidal zone or shallow water; feed on small bottom invertebrates.

Family Anarhichadidae (wolffishes). Big head and long tapering body, laterally compressed; massive dentition on jaws, roof of mouth, and throat for crushing mollusks, sea urchins, crustaceans; length to 2.3 m (7.5 ft). Nine species, in northern oceans; littoral zone of shore to 300 m (1,000 ft); good eating.

Family Ptilichthyidae (quillfish). Extremely elongated, body ending in a free, fleshy point; pelvic fins absent; dorsal and anal fins like vanes of a feather. One species, rare; North Pacific.

Family Congrogadidae. Includes Haliophidae. Resembles Stichaeidae but mouth and lips large; fins almost or entirely spineless; 3 lateral lines. About 8 species; rock-dwelling, in shallow coastal waters of Indo-Pacific from Africa to Japan.

Family Zaproridae (prowfish). A single species like a shorter, deeper bodied prickleback; pelvic fins absent; size up to 2.8 m (9 ft); deeper coastal waters to 350 m, California to Alaska.

Family Scytalinidae (graveldiver). Eel-like, with dorsal and anal fins soft-rayed and not beginning until middle of long straight body; body appears to flare out somewhat at these fins; pelvic fins lacking. One species; marine, California to Alaska; small, to 15 cm (6 in.); burrows quickly in sand or gravel in intertidal zone.

Suborder Acanthuroidei:

Modified perciod-like fishes characterized by peculiarities of bones suspending the jaws, which thereby are extended far forward as small nibbling mouths at end of more or less lengthened snout.

Family Acanthuridae (surgeonfishes). Includes Zanclidae. Percoid-like fishes characterized by one lancet-like, darkly coloured spine (like a surgeon's scalpel) or tubercles alongside the caudal peduncle (in front of base caudal fin); body deep, compressed; dorsal and anal fins long-based; scales small; eyes high on side of head; mouth small, low, sometimes extended into a beak; teeth close-set and lobate. About 75 species; many herbivorous; inhabit shallow tropical shores, a few in deeper water.

Family Siganidae (rabbitfishes). Resembling surgeonfishes but uniquely characterized by pelvic fins each having two stout spines, along the outer and inner edges, respectively; both spines grooved for carrying venom; no lancet-like spine or buckler on caudal peduncle; mouth small, rabbitlike, used for nibbling algae. About 18 marine species of small to moderate size; tropical Indo-Pacific, around coral reefs and rocky areas.

Suborder Scombroidei

Streamlined, mackerel-like or marlin-like fishes the interrelationships of which are in doubt; upper jaw not protrusible; maxillary bones of upper jaw more or less firmly attached to non-protractile premaxillaries that lie ahead of them.

Family Gemphylidae (snake mackerels). Eocene to present. Elongated, laterally compressed; mouth large, with large, cutting teeth; spinous part of dorsal fin longer than soft-rayed part, the latter often broken up into finlets posteriorly; pelvic fins usually not rudimentary. Sixteen species; tropical and temperate seas; down to 600 m (2,000 ft); length to 1 m (40 in.); some commercial value; good eating.

Family Trichiuridae (cutlass fishes). Paleocene to present. Elongated, bandlike body; large mouth with large fangs anteriorly. Scaleless; dorsal fin long, spinous anteriorly; anal fin long-based, spines short; caudal fin deeply forked on most species, absent in some (body ending in tapered point); pelvic fins reduced to scalelike spine and one small ray, or absent. Fifteen species in warm oceans; rather deep water offshore, to about 1,000 m (3,300 ft); piscivorous.

Family Scombridae (tunas and mackerels). Moderate to large, streamlined, swift-swimming, schooling fishes; body often thickly rounded, tapering to a narrow caudal peduncle bearing in some species 2 or 3 keels on its side; caudal fin widely forked or lunate (scimitar-shaped); distinguished from all fishes by series of separate finlets following spinous first dorsal and spinous anal fins; well-developed vascular system under skin of tunas is associated with sustained high-speed swimming and an elevated body temperature up to 9° C (5° F) above the surrounding water; make extensive migrations to spawning and feeding grounds; fins fit into grooves or depressions on body; about 40 species, open waters of tropics and warm seas of world; feed on fish, crustaceans, squids, and other abundant animal life; length 30 cm to 3.3 m, weight to 800 kg. Many species subjected to ever-increasing fishing exploitation and will be threatened with extinction.

Family Xiphiidae (swordfishes). Bones of upper jaw prolonged into a swordlike structure, flatter and sharp-edged, as compared with the round, shorter bill of marlins and billfish-

es; dorsal fin high and short-based, not extending beyond middle of body; caudal fin with high lobes; second dorsal fin small; pelvic fins absent; no teeth in jaws except in very young; no scales. Probably only 1 species, *Xiphias gladius*, worldwide in tropics and temperate seas; from surface to 400 m; size up to 3.6 m and 450 kg. Sword is lashed about inside schools of fishes; injured fishes are eaten. A major big-game fish; excellent eating and commercially important.

Family Istiophoridae (billfishes, marlins, sailfishes, and spearfishes). Bill round and shorter compared with sword of swordfish; dorsal fin long, extending almost the length of back of body and reaching striking height in the sailfish, *Istiophorus gladius*; pelvic fins present as thin filaments; body scaled; 2 small keels on each side of caudal peduncle; fine teeth on jaws. About 7 species; worldwide in warm seas; all are large species, the black marlin (*Makaira indica*), the largest, probably attains 900 kg (2,000 lb); record for rod and reel is 710 kg (1,560 lb); greatest game fishes in the ocean, and excellent food fishes, of considerable economic importance.

Family Luvaridae (louvars). One species; rare; resembles a dolphin (family Coryphaenidae) in its very high forehead and eye placed low almost on level with mouth; mouth small, toothless; body deep, laterally compressed; a fleshy keel on each side of caudal peduncle; pelagic in tropics and subtropics; length to 1.5 m (5 ft).

Suborder Anabantoidei

Small percoid-like fishes characterized by an accessory air-breathing chamber of labyrinthic structure on each side of head, above regular gill chamber; an unusual patch of teeth on roof of mouth, teeth which attach to floor of cranium; usually build foam nests. Freshwater fishes of Southeast Asia, India, and Africa; about 70 species in 5 families, 4 of which are closely related; the fifth, Badidae, is more generalized.

Family Badidae. Resembling Anabantidae externally but lacking accessory air-breathing chamber. Have special patch of teeth on roof of mouth and characteristic courtship behaviour of anabantids; 1 species, freshwaters of India and Southeast Asia; small, 5–8 cm (2–3 in.) long.

Family Anabantidae. Pleistocene to present; about 20 species, freshwaters of tropical Africa, Southeast Asia and Philippines; includes the "climbing perch"; size small.

Family Belontiidae (fighting fishes, some gouramies, and others). About 50 species of small freshwater fishes from tropical Africa, India, Burma, Sri Lanka, Southeast Asia, Malaya; includes Siamese fighting fish (*Betta splendens*), various species of gouramis, which have 1 ray of each pelvic fin extended into an elongated filament; paradise fishes and other popular aquarium fishes. Most of these species were formerly placed in family Anabantidae.

Family Helostamatidae (kissing gourami). Freshwater, Southeast Asia; popular aquarium fish; one species.

Family Osphronemidae (gourami). Pelvic fins each with 1 ray drawn out into a long filament; 1 species; freshwater in Sumatra, Java, Borneo, grows to about 9 kg (20 lb).

Suborder Luciocephaloidei

Family Luciocephalidae (pikehead). Pike-like in body form and long head; an accessory suprabranchial air-breathing chamber (but not labyrinthic); bony plate in throat region; peculiar jaws. One species, freshwater; Malay Archipelago and Peninsula.

Suborder Mastacembeloidei

Family Mastacembelidae (spiny eels). Eel-like; head elongated with fleshy, mobile proboscis projecting beyond lower jaw; soft dorsal fin preceded by series of erectile spines. About 50 species, freshwaters from tropical Africa to Southeast Asia up to China; up to 90 cm (3 ft), but most much smaller; some attractively coloured aquarium fishes.

Family Chaudhuriidae. One species in freshwaters of Burma; similar to spiny eels but small and without fleshy proboscis.

Suborder Kurtoidei

Family Kurtidae (nurseryfishes). Peculiar, small, percoid-like; males carry eggs, stuck under an anteriorly pointing hornlike process on top of back of head. Two species; brackish water and lower parts of streams; Indo-Malaysia and New Guinea.

Suborder Echeneioidei

Family Echeneidae (remoras). Oligocene to present; differ from percoids mainly in having a sucking disk on top of head, modified from the spinous first dorsal fin. About 10 species; warm marine seas; ride attached to large fish or other marine animals or ships; carnivorous; some are cleaner fish for other fishes; length 30 to 90 cm (1 to 3 ft).

Suborder Ammodytoidei

Families Ammodytidae and Hypoptychidae (sand lances). Eocene to present. Long slender percoid-like fishes with long, pointed head and projecting lower jaw; dorsal fin long-based, with soft rays only; pelvic fins thoracic or (usually) absent. About 18 species; most seas of the world, especially colder waters; sand burrowers; large schools near shores form an important food source for many other fishes; 20–40 cm (8–16 in.).

Suborder Gobioidei

Almost all with pelvic fins located beneath pectorals and joined together to form a vacuum cup or suction disk; some with pelvic fins close together but not in form of a suction cup; a few lack pelvics; all lack one particular bone of cranial roof. More than 800 species, most of small size, living as bottom dwellers, worldwide, in saltwater, freshwater, or brackish water, especially in tropics.

Family Eleotridae (sleepers). Pelvic fins close together or in contact anteriorly, but not united into a sucking cup; short-based spinous first dorsal fin and longer based soft-rayed second dorsal; all fins usually with rather long fin rays; no lateral line. Numerous species; along coasts and rivers in tropics and subtropics; most 10–30 cm (4–12 in.) long, one to 90 cm.

Family Gobiidae (gobies). Eocene to present. Pelvic fins united to form a suction cup; no lateral line; simple-looking but often colourful fishes with 2 dorsal fins; all fins rather conspicuously large compared with small, usually slender body; definite rows of naked lateral-line organs on head. More than 700 species; size from 1.2 cm (0.5 in., world's smallest vertebrates) to something under 30 cm (12 in.), with most less than 10 cm. Shallow coastal waters of tropics and temperate zones; usually resting on bottom or hidden; carnivorous.

Family Periophthalmidae (mud skippers). Elongated gobies with blunt head; eyes erectile, prominent, on top of head; pectoral fins with muscular base used to walk over mud and climb mangrove roots; about 6 species in estuaries and mud flats of Indian and Pacific oceans, to Japan.

Family Rhyacichthyidae (loach goby). Pelvic fins widely separated; head flattish, pointed; mouth ventral; 1 species living in torrential mountain streams of Indonesian Archipelago, up to Philippines; size up to 33 cm (13 in.).

Family Gobioidae. Elongated, eel-like gobies; dorsal fin very long, spinous part distinct from, but connected to, soft part; dorsal and anal fins confluent with caudal; eyes tiny to indistinct; mouth often obliquely upward; about 20 species, marine and brackish water of tropical America, Indian and Pacific oceans; about 8–30 cm (3–12 in.).

Family Trypauchenidae. Eel-like; scaled; dorsal and anal fins very long and confluent with caudal; pelvic fins united at base but not forming a cup or disk; eyes tiny. A blind cavity above gill cover opening to exterior by a pit. Burrowers in mud and gravel; about 12 species, along coasts and estuaries from Africa to Japan and Oceania.

Family Kraemeriidae. Rare little elongated fishes; pelvic fins separate; chin of lower jaw large, pointed, forming terminal end of head; eyes small, on top of head; 2 species, Indo-Pacific oceans.

Family Microdesmidae. Rare, small, eel-like; chin large, forming pointed end of snout; about 6 species; both coasts of tropical America, West Africa, tropical Pacific.

Suborder Callionymoidei

Family Callionymidae (dragonets). Eocene to present; resembling flatheads (Platycephalidae; see SCORPAENIFORMES); body flattened, broad, muscular; snout very short; mouth small; gill openings restricted, on top of head; eyes on top of head, close together; pelvics in front of pectorals; large spine pointing posteriorly at angle of preopercle on gill cover; bottom dwellers from tidepools down to 600 m (2,000 ft); burrow into sand; push along bottom using pelvic fins; about 40 species in tropical and temperate zones.

Family Draconettidae. Look like callionymids but are separated on differences in head skeleton; no preopercular spine; a few species; North Atlantic and North Pacific in deep water.

Critical appraisal. Classification of perciform fishes will be receiving much more study in the future. Expected changes include removal of some groups from the order, addition of some from other orders, and considerable realignment of many groups within the Perciformes. Evidence suggests removal of Gobioidei to a preperciform position, possibly as a distinct order. The snakeheads (order Channiformes) should likely be returned to the order Perciformes, associated with the anabantoid and luciocephaloid fishes. Particularly difficult problems

are the relationships and classifications of trachinoid, uranoscopoid, notothenioid, and stichaeoid fishes. Studies are presently being made on possible interrelationships between clusters within the 60 or more families of percoid fishes (suborder Percoidei). The placement and relationships of the atherinoid (sometimes called percesocine) fishes are still in dispute. The present classification follows that of Greenwood *et al.* in the removal of Atherinidae from perciform fishes (see ATHERINIFORMES) and in the removal of the ophidioid and zoarcid fishes (see PARACANTHOPTERYGII). Support for retaining the Atherinidae in order Perciformes and for other differences in the order Perciformes has been given by an American ichthyologist, W.A. Gosline, in a series of papers published between 1962 and 1971. Questions of relationships between carangid, rachycentrid, echeneid, and scombroid fishes are still unsettled. Many large and exciting problems thus remain. (W.C.F.)

BIBLIOGRAPHY. Recent books containing many excellent illustrations of perciform fishes and short accounts of the biology of each group are: JAMES E. BOEHLKE and CHARLES C.G. CHAPLIN, *Fishes of the Bahamas and Adjacent Tropical Waters* (1968), an excellent work in which each species is well illustrated, many beautifully in colour, with keys for identifying species and excellent summaries of the biology of each family; DAVID STARR JORDAN and BARTON WARREN EVERMANN, *The Fishes of North and Middle America*, 4 vol. (1896–1900, reprinted 1963); TOM C. MARSHALL, *Fishes of the Great Barrier Reef and Coastal Waters of Queensland* (1964), contains many large colour and black-and-white pictures of perciform fishes; IAN S.R. MUNRO, *The Fishes of New Guinea* (1967), 1,095 fishes illustrated by photographs, with 76 species in colour; JAMES L.B. SMITH, *The Sea Fishes of Southern Africa*, 4th ed. (1961), profusely illustrated with many colour plates; JAMES L.B. and MARGARET M. SMITH, *The Fishes of Seychelles* (1963), 880 species illustrated, many in colour; ALWYNE C. WHEELER, *The Fishes of the British Isles and North-West Europe* (1969); JOHN E. RANDALL, *Caribbean Reef Fishes* (1968), contains many fine photographs of perciforms and others.

Other books with information about perciform fishes are EARL S. HERALD, *Living Fishes of the World* (1961); NORMAN B. MARSHALL, *The Life of Fishes* (1966); and U. OKADA, *Fishes of Japan* (1955).

Percussion Instruments

Two distinct groups of musical instruments, namely, idiophones and membranophones, comprise the large classification known as percussion instruments, which after the string and wind sections forms the third section of the Western orchestra. Idiophones are instruments whose own substance vibrates to produce sound (as opposed to the strings of a guitar or the air column of a flute); examples include bells, clappers, and rattles. Membranophones emit sound by the vibration of a stretched membrane; the prime examples are drums. Although many idiophones and some membranophones are tunable and hence may be melody instruments, both groups serve typically to delineate or emphasize rhythm. The term percussion instruments goes back to the German composer and organologist Michael Praetorius, who in 1619 wrote of *percussa, klopfende Instrument* (German *klopfen*, "to beat") as any struck instrument, including struck chordophones (stringed instruments). The same combination, including pre-bow chordophones, constituted the *divisio rhythmica* in the 7th-century *Etymologiae* of Isidore, archbishop of Seville.

This article covers the principal types of idiophones and membranophones found in the major areas of the world and attempts to list, within the considerations imposed by space, some of their diverse functions. (For more detailed treatment of percussion instruments in the Western orchestra, see ORCHESTRATION AND INSTRUMENTATION.) It is divided into the following sections:

Idiophones
  In Europe
    Antiquity
    The Middle Ages
    Modern times
  In Asia
  In Africa and Afro-America
    Muslim Africa
    Black Africa
    Afro-America
  In America
  In the Pacific
Membranophones
  In Europe
    Antiquity
    The Middle Ages
    Modern times
  In Asia
  In Africa and Afro-America
  In America
  In the Pacific

Idiophones

The following classification of idiophones provides some idea of the diversity of this large group of disparate instruments. Concussion instruments, consisting of two similar components struck together, include clappers, concussion stones, castanets, and cymbals. Percussion idiophones, which are instruments struck by a nonsonorous striker, form a large subgroup including triangles and simple percussion sticks; percussion beams, such as the *semanterion;* percussion disks and plaques, single and in sets; xylophones, lithophones (sonorous stones), and metallophones (sets of tuned metal bars); percussion tubes, such as stamping tubes, slit drums, and tubular chimes; and percussion vessels varying from struck gourds and pots to gongs, kettle gongs, steel drums, bells, and musical cups.

Types of idiophones

Shaken idiophones, or rattles, include vessels filled with rattling material, such as pellet bells, gourd, basketry, and hollow-ring rattles; strung rattles, such as dancers' leg rattles or anklets; stick rattles, including the sistrum, originally a forked stick with crossbars on which rattling shells, etc., were strung; pendant rattles with suspended rattling objects; and sliding rattles.

Other categories include scraped idiophones, comprising scrapers and cog rattles; split idiophones made of split hollow cane, including the Southeast Asian "tuning fork" idiophones and the chopstick; plucked idiophones, or linguaphones (so named because of their plucked tongues), such as the Jew's harp, sansa, and music box; friction idiophones, including friction sticks, simple or combined, and musical glasses; and blown idiophones, such as the 19th-century *Äolsklavier* and *piano chanteur.*

IN EUROPE

Europe received most of its idiophones either directly or indirectly from the high cultures of the ancient East or from Egypt, a country regarded by the Greeks and Romans as forming part of Asia rather than of Africa.

Antiquity. European antiquity knew many idiophones. Dancers' clappers, held pairwise in the hands of maenads

(women participants in Dionysian rites) and other female dancers, often stressed the rhythm of accompanying *auloi* (the ancient Greek reed pipes). The time-beating foot clappers of chorus leaders, attached to the right foot like a sandal, were known in Greece as *kroupalon* and adopted by Rome as the *scabellum.* Other idiophones included bells, cymbals, the unidentified *ēcheion,* and an instrument simply called "the bronze" (*chalkos*), probably a metal percussion disk. When the cult of Isis spread to Greece and Rome, her sistrum followed, always in the hands of priest or—rarely—priestess.

Use of bronze

With the exception of clappers, all these instruments were of bronze; as such they were credited with the apotropaic powers (the special protective powers against evil) accorded this metal in the East. Not only among primitive Asian islanders but in Greece itself was it customary to "sound the *chalkos* at eclipses of the moon," for example, "because it has power to purify and to drive off pollutions" (a scholiast, writing on Theocritus). According to the Roman poet Ovid, the annual visit of ghosts of the dead to their former homes was terminated by requests to depart emphasized by the clanging of a bronze plate. Thin, bronze percussion disks have been excavated at Volci, Etruria, and at Pompeii, affixed to metal handles; one from Pompeii is even garnished with pellet bells. Bells of bronze do not emit the clear, ringing tone associated with modern ones of bell metal; those of antiquity were small and made a clanging rather than ringing sound. They warded off evil spirits, averted the evil eye, served as sentinels' and watchmen's signal instruments, or were attached to the handle of a Greek warrior's shield in order to terrify the enemy by their clamour. Anklets adorned with small bells were frequently worn by jesters, dancers, and courtesans, particularly in Hellenistic times. In Rome, *tintinnabulae* ("bells") served as signal instruments or were suspended from the necks of herd animals—again to ward off evil.

Cymbals were sounded in religious rites, also at secular dances; deeply cupped, they may be seen on Greek and Roman art objects played together with a frame drum. Forked cymbals known as *crotala* travelled from Egypt to Greece and Rome, and finger cymbals were introduced from the East, chiefly for dancers, a pair being attached to thumb and middle finger of each hand.

Among the oldest instruments of mankind, rattles originally combined the functions of prophylactic amulets and children's toys; both functions coexisted as late as Roman times when *crepundia* ("rattles") served both as charms against evil and as children's toys. A number of existing Roman pellet bells (often misnamed jingles) are notable for their exquisite workmanship.

The Middle Ages. Greek and Roman idiophones were passed on to postclassical Europe, their distribution undoubtedly aided by wandering *joculatores,* or minstrels. Whereas prior to the adoption of Christianity most were ritual instruments, their function in medieval times—with the notable exception of the bell—was strictly secular.

Clappers, castanets, cymbals, and gongs. Clappers called *tabulae,* made of bone, are mentioned by Amalarius of Metz (9th century AD) as being in the hands of church cantors during liturgical services; possibly they were similar to the flat clappers played by jongleurs in the late Middle Ages and by lepers who sounded them as a warning of their approach. A three-piece clapper was used for this purpose in Spain, the *tablillas de San Lázaro* (*lazarus* being a Late Latin synonym of leper).

Lepers' warning clappers

Dancers' castanets, hollow clappers in bivalve form, were played in Spain throughout the Middle Ages; they are illustrated from the 11th century on. Already in Roman times, dancers of Cádiz are known to have played metal castanets, but those of sonorous hardwoods have been preferred since. Forked cymbals are portrayed on ivory and in miniatures of the Carolingian period. Small, cup-shaped cymbals called *acetabulae,* made of brass or silver, are mentioned by Cassiodorus (died *c.* 580) and Isidore of Seville. Interestingly, the modern practice of striking a single cymbal with a stick was anticipated by Isidore and by Suidas (10th century). Nonetheless, larger cymbals continued to be played pairwise and—at least in the later Middle Ages—were found among the "loud" instruments that accompanied dancing and were played at seigneurial festivities. Gongs appear intermittently from the 15th century on, first in the soup-plate form associated in Asia with gong chimes.

Bells. Bells were still thought to possess apotropaic powers; with their adoption, the Christian Church took over the belief that ghosts and demons could be put to flight by the sound of metal, a power henceforth augmented by the protection afforded by association with the divine cult and, more specifically, by baptism. The rite of baptizing bells is first recorded in a capitulary (civil ordinance) of Charlemagne of 789. Exorcizing celebrants sounded handbells or wore bells on their garments. St. John Chrysostom (died 407) felt compelled to protest against the custom of attaching bells to the clothing or bracelets of children in order to preserve them against demons, yet small bells or pellet bells continued to adorn the vestments of priests, a practice inherited from the ancient Near East: 51 bells ornamented the cope of Lanfranc, 11th-century archbishop of Canterbury. The Roman Catholic Church still officially recognizes the power of bells to divert the spirits of the dead; the tolling of passing bells in England, already recorded by Bede (died 735), was intended to ward off evil spirits from dying persons. Church bells announced the time of day, summoned the faithful to worship, sounded alarms, fought off lightning, broadcast the news of peace or the birth of a princeling, and praised God. In secular life handbells were played in mixed instrumental ensembles, usually one bell in each of the player's hands.

Symbolic importance of bells

Tuned bells are strung together to form chimes. Early chimes are generally represented as clapperless, hemispheric bells—inverted resting bells, in fact—struck on the outside by a hammer; less frequently, they are shown as clapper bells sounded by pulling on long cords attached to the clapper. From the 13th century, chimes were connected to clockwork and struck mechanically. As bells grew larger and the compass of the chime was extended, it became known as a carillon. The distinction today is merely one of compass, any set exceeding 1½ or two octaves in compass being considered a carillon.

Other instruments. In secular life, pellet bells were suspended from ladies' belts or worn by jesters. Before the introduction of bells in the Greek Orthodox Church in the 11th century, the *semanterion,* a percussion beam sounded by a striker, summoned the congregation, and in the Roman Catholic Church it has been used as a substitute for bells during Easter Week. Triangles first appear in the 14th century; originally a number of loose, rattling rings were threaded on the lower portion, as though the ancient sistrum had projected itself through the centuries. Scraped idiophones, known in Europe since Paleolithic times, are encountered as scraped pots intermittently from the 12th century on; such noisemakers were played—to judge by a 14th-century miniature—with other percussive instruments for merrymaking. Few instruments are as suitable for personal music making as the Jew's harp; coming from the East, it passed through Rome, but there is no evidence of its presence in the West before the mid-14th century, although it is unlikely to have disappeared completely during the intervening centuries.

Noise-making and musical improvisation

Most of the above idiophones are nontonal; with the exception of bells and percussion beams, they form part of the *musica irregularis* decried by writers such as the German organologist Sebastian Virdung in 1511 and as such were restricted to popular entertainment or signalling. Written music of this period does not help to determine whether, or how, idiophones were played with voices or with other instruments.

Modern times. *Xylophones.* Additional idiophones came into use from the Renaissance on. The xylophone was introduced from Indonesia; curiously enough, its first appearance was as the name of an organ stop in 1506, when it was termed a new stop. Virdung and the blind organist Arnold Schlick were the first to write of it, both in 1511. It remained little exploited until the Flemish carillonneurs combined it with a keyboard and transformed it into a practice instrument in the first half of the

17th century. The older form remained a folk instrument, chiefly in and east of Germany. An Austrian violinist, Ignaz Schweigl (died 1803), wrote concert pieces for it during his last years, and Saint-Saëns revived it in his *Danse macabre* of 1874. Lately, Afro-American marimbas have been incorporated into Western rhythm bands. Lithophones, stone imitations of xylophones, enjoyed a certain vogue in the 19th century, of which short-lived curiosities, the English stonemason Richardson's "rock harmonicon," with its tuned basalt bars, is best known.

Gongs. Gongs were always considered alien instruments, as indeed they are: although the word gong was known in the 16th century, its use is not further recorded until the late 18th century. Since then, gongs of indefinite pitch have been included in orchestral scores for arresting effect. For generations both flat and bossed (knobbed) gongs also performed the lowly task of summoning the family to meals.

Cymbals and castanets. Cymbals were apparently forgotten during the Renaissance; they reappear in the German composer Nicolaus Adam Strungk's opera *Esther* (1680) to provide local colour and are reintroduced through "Turkish music" (imitating the Turkish Janissary bands) to opera from 1770 on; soon afterward they acquired a permanent position in the orchestra. As folk instruments they have been played for centuries in Provence in France, probably as a continuation of an older ritual tradition.

In 16th-century Spain the saraband was usually danced to castanets or to a guitar; castanets have remained dancers' instruments ever since, either clicked together rhythmically or in sustained rolls. Modern rhythm bands now include one or two single castanets or a pair attached to a long handle for ease in clicking (the traditional manner of playing in the hand is difficult to master).

Bells. Bells grew larger until the largest ever produced, the Tsar Kolokol (Emperor Bell; 1734) of Moscow, weighing 433,200 pounds, proved too cumbersome and heavy for hanging. The hemispherical form was abandoned early as chimes became larger, culminating in tower-borne carillons brought into existence by progress in casting methods and mechanization. Chime bells were connected to town clocks and then hung in separate bell towers. In carillons of the Low Countries and northern France the bells' external hammers were automatically released by iron pegs set in a large wooden barrel (later, a metal cylinder) revolved by weight and pulley, permitting whole tunes to be played. Chorales and other melodies preludized the announcements of time on the European continent, while in Britain "chimes," or short sequences, fulfilled the office of timekeeper. Furthermore, instead of automatically playing melodies, British tower bells are rung in "changes"—a series of mathematical permutations—on bells hung dead. The role of small bells has become negligible, although handbell ringing is still a hobby in England.

Metallophones. Metallophones reached northern Europe from Indonesia in the second half of the 17th century and, like the xylophones, were promptly adopted by carillonneurs. In both the Low Countries and the regions to which such instruments spread from there, steel was the metal employed for bars. Provided with a keyboard, one served as "carillon" in Handel's oratorio *Saul*; another, struck with a beater, served as *strumento d'acciaio* (literally, "steel instrument") in Mozart's *Die Zauberflöte* (*The Magic Flute*). The modern glockenspiel (from the German *Glockenspiel*, "bell chime") was originally a bell chime, as its name indicates. Its transformation into a metallophone was in response to the need for a portable instrument; for marching bands the bars were hung in a lyre-shaped frame and called bell lyre. Symphony and opera orchestras—and today rhythm bands as well—make use of a larger, horizontal glockenspiel to which resonators have been added since 1935. Graduated steel bars struck from a keyboard by piano hammers form the celesta, patented in 1886 by Auguste and Alphonse Mustel of Paris; this has been scored in both symphony and opera and is a favourite of light orchestras. Its descendant, the vibraharp (called vibraphone in England), has characteristic tubular metal resonators that sustain the tone while imparting vibrato. These last two instruments are successfully exploited for their special tone colour in 20th-century music. Late 18th-century experiments with graduated sets of tuning forks struck by hammers from a keyboard produced the 19th-century "tuning-fork pianos," the most noteworthy of which were different models of Victor Mustel of Paris (from 1865 on).

The celesta

Tubular bells. Tubular bells are European adaptations of Southeast Asian bamboo chimes. Bells have always been both expensive and cumbersome, and substitutes started appearing in the 19th century, first in the form of steel bars, then hollow bronze cylinders, and finally brass tubes struck with wooden mallets. For use in churches, tubular bells can be played directly from the manual of an organ and the tone picked up, amplified, and fed into a system of loudspeakers in the tower.

Rattles and scrapers. Pellet bells and other rattles today play a very minor role, the former chiefly as horse or mule bells. In the present century the gourd-shaped maraca rattle has been added to the complement of rhythm band idiophones. Scrapers have all but disappeared from Europe: Virdung illustrated the scraped pot, now defunct, but other forms survive, mostly as carnival noisemakers. More sophisticated were the giant cog rattles with diameters up to 6½ feet installed in or outside church towers in the Iberian Peninsula, substitutes since the 15th century for bells during Easter Week. Scraped gourds are now part of the professional percussionists's equipment.

Plucked instruments. Jew's harps were part of the regular stock-in-trade of instrument dealers in the 16th and 17th centuries, and in the mid-18th century the playing of multiple Jew's harps is mentioned. Several of these little instruments combined in a single frame were played by virtuosos in the late 18th and 19th centuries and enjoyed enormous popularity. Miniaturization of musical clocks in the latter part of the 18th century resulted in the creation of the music box, a linguaphone provided with a metal-comb mechanism made from about 1770 on, chiefly in Switzerland. In its heyday—1810 to 1910—it was an immensely popular household instrument with a repertory of opera arias, folk songs, popular tunes of the day, and waltzes (after the midcentury). In the late 19th century it was transformed into a free-reed wind instrument (aerophone) by the substitution of free reeds for the metal comb, but neither comb nor free reed could resist the impact of the phonograph, which rendered both forms obsolete.

Friction instruments. During the 18th century several friction idiophones were introduced, among them the nail violin of Johann Wilde (*c.* 1740) with its tuned nails bowed by a violin bow. More characteristic of the period were the friction-bar instruments arising as a result of the German acoustician Ernst Chladni's late 18th-century experiments, particularly those concerned with the transmission of vibrations by friction. Chladni's own instrument, the euphone of 1790, and the aiuton of Charles Claggett of about the same time were first in a series of models, some with piano keyboard and horizontal friction cylinder or cone acting on upright bars and others with bars stroked by the player's fingers or bowed by a continuous bow.

Experimental instruments

Musical glasses are considerably older: the tuned metal cups or bowls of the East were transformed in Europe into tuned glasses and are first seen in the *Musica theoretica* (1492) of the Italian musical theorist, Franchino Gafori. One hears of them intermittently thereafter until they come to the fore in the mid-18th century as concert instruments. The rims of glasses of graduated sizes containing enough water to tune them were rubbed by the player's moistened fingers. By the 1760s they had attracted the attention of the American scientist and philosopher Benjamin Franklin, who proceeded to convert them into a more efficient and, above all, a polyphonic (many-voiced) instrument, which he called armonica—now known as the glass harmonica. Its popularity was immediate. Mozart's *Adagio und Rondo* K. 617 was written for it, as was his *Adagio für Harmonika* K. 356, both per-

formed in 1791. Efforts to combine it with a keyboard were successful from 1784 on but enjoyed only a passing vogue. Among the last to write for it was the French composer Hector Berlioz in his *Fantasia on The Tempest* of 1830; a decade later it was replaced by the growing family of free reeds.

Changing use of various types. The foregoing reveals the trend in Western musical culture to make diminishing use of nontonal idiophones. Those that succeeded in gaining access to the orchestra are used sparingly, often only as special effects (gongs) or indications of local colour (castanets). This trend is reversed in popular music of the 20th century, in which idiophones, both traditional and alien, play a basic part. On the other hand, tonal idiophones have assumed increasing importance. Those inherited from the Middle Ages, such as xylophones and Jew's harps, were expanded to the limit of their potential; others were imported and modified to meet local requirements. The new idiophones that came into being—for example, the music box and the friction-bar idiophones—proved ephemeral. Influenced by the great popularity of the piano, keyboards were adapted to numerous 19th-century idiophones in an attempt to render hitherto monophonic (single-voiced) instruments polyphonic.

IN ASIA

Clappers and cymbals. Still preserved today are actual clappers from Sumer of about 3000 BC and ancient Egyptian clappers, some of which took the form of a pair of hands. Their use seems never to have died out in Egypt. Copts still ritually strike clappers of a type that has probably been in existence since the 3rd or even 4th millennium BC. Modern Vietnam also retains clappers—often artifacts of great beauty—in its religious observances. On the Indian subcontinent circular wooden clappers, one held in each hand, are played by beggars and fakirs in some regions and are used as rhythm instruments in others. In the Far East they have a role in the theatre, as signal instruments, at funerals, or, as in the Ryukyu Islands, accompanying traditional dances. Castanets probably originated in ancient Phoenicia; they appear in Egypt in the 24th dynasty (*c.* 730–709 BC) and are typical dancers' instruments.

Ritual, social, and musical uses of clappers

Cymbals are indigenous to Asia; ancient Assyria had a unique form, funnel-shaped with long necks serving as handles. Known in ancient Israel from *c.* 1100 BC on, cymbals were the only permanent idiophones of the Temple orchestra. Egypt did not have true metal cymbals until the 24th dynasty. Today they remain in ritual use in northern India, Japan, Tibet, and Vietnam. They appear in the 5th century AD in India, where they are now also played at secular festivities. In China they play a prominent part in the theatre. Turkey, in contrast, has traditionally connected cymbals with military usage. In some part of Southeast Asia their ancient metal-connected function of dispelling evil spirits still prevails.

Xylophones, lithophones, and metallophones. Xylophones reach their highest development in Southeast Asia. They vary in form from the most primitive log type to the highly developed orchestral instruments found in Indonesia. Trough xylophones were depicted in Java in the 14th century but are not restricted to Southeast Asia; those of Japan, for instance, are rhythm rather than melody instruments, and in Burma they are associated with royalty. Xylophones of the Indonesian gamelan, or percussion orchestra (and some mainland ensembles), have various complementary compasses.

Stone chimes (lithophones) of two types occur: oblong bars like xylophone keys resting horizontally, found in Vietnam only, and vertically suspended plaques. In China their generic name is *ch'ing*; there, single sculpted musical stones and also 16-stone chimes are suspended from ornate frames. Stones forming a chime are carved in a typical L-form and struck with a mallet on their larger portion. The L-shape is very ancient; a chime of this form dating from the late Shang era (*c.* 1401–*c.* 1123 BC) was excavated at An-yang, in northeast China. Both in China and Korea, where the oldest chime goes back to the 14th century, the lithophone is a Confucian ritual instrument. Single stones and chimes are still in use in rural Annam (Vietnam).

Use of chimes in Confucian ritual

Metallophones occur in the same two forms as lithophones, those in the horizontal position being the more common. Indonesia and Indochina have metallophones constructed like xylophones, of which they are indeed metal counterparts. But in China the *fang-hsiang* with its 16 bars is a metal imitation of the lithophone. Among important components of the gamelan is the *saron*, a trough metallophone depicted as early as *c.* 800 AD on the Borobuḍur *stūpa* (Buddhist monument), Java, and the frame metallophone *gender*, now usually supplied with tubular resonators, which has been known from the 12th century on. Introduced to China by a Turkic people in the 7th century, the horizontal type of metallophone reached Korea in the 12th century and is still occasionally played there. In Japan it is a Buddhist ritual instrument.

Slit-drums. The slit-drum is an instrument made by hollowing a log or wood block through a slit. Those of east Asia and Indonesia are of great antiquity and of a high degree of development. The Chinese *mu yü* (traditionally fish-shaped) is a Buddhist and Taoist ritual slit-drum. Its Korean and Japanese counterparts are likewise ritual time markers, while in Vietnam the slit-drum is both a temple and a watchmen's instrument. On Java slit-drums can be traced to the Hindu–Javanese period (1st–9th century AD). Small models are generally suspended vertically, whereas larger ones rest horizontally; some underscore dance rhythms; others are signal instruments.

Tubular chimes and gongs. Southeast Asia is the home of tubular chimes; resonant, tuned bamboo tubes are united to form a chime in rural Annam and Java. In western Java up to 16 tubes are strung in ladder formation and suspended from a house or a tree and played with padded beaters.

Western Asia is believed to be the home of the gong, which reached China in the 6th century, Java by the 8th. Originally, it seems to have afforded protection against evil spirits, and even today the Iban people of Borneo beat gongs during a storm. Chinese gongs are both bossed (knobbed) and flat, those of Indonesia are bossed, while those of India are flat. Chinese gongs serve a whole gamut of purposes: as signal instruments of the army, as rhythm makers to accompany a song and, in the case of the bossless *lo*, as a Buddhist ritual instrument. In Japan the employment of the gong varies from temple to theatre to folk festival.

Gong chimes in Indonesian orchestras

In Indonesia and eastern Asia tuned gongs are united to form gong chimes. The Chinese upright *yung lo* is a Buddhist and Confucian cult chime and was formerly also played at court. Better known are the horizontal gong chimes of Indonesia (called *bonang* in Java), outstanding components of Southeast Asian orchestras and known from the 10th or 11th century on. Individual gongs comprising a *bonang* are often referred to as "bonang kettles," from their sharply bossed and deeply rimmed form. Frames of Thai gong chimes arch upward at both ends to form an upright semicircle. Ancient kettle gongs, products of Bronze Age culture, are found only in China, Indochina, and Indonesia. They are hung so that the striking surface is vertical and are struck in the centre of this surface (the head). Kettle gongs were cult instruments connected with rainmaking; those of the Dong Son culture area of North Vietnam may be dated from the 5th to the 3rd centuries BC.

Bells. Bells of bronze dating from about 1000 BC have been excavated in India, from the 22nd dynasty (945–730) in Egypt, and from *c.* 700 in Assyria. An intimate connection existed in ancient India between bell sound and mystic experience, and today a handbell is still rung in temple ceremonies in India and other areas of Buddhist influence. The Chinese differentiate between clapper bells (*ling*) and clapperless ones (*chung*); their temple bells, like those of Japan, are always of the *chung* type. Temple bells usually assume the form of chimes in China; one from the 6th century has 13 bells, but more modern chimes consist of 16 bells hung in two rows of a

frame. In addition to metal bells of the high-culture domains, rural areas still use primitive wooden bells with single or multiple clappers.

Rattles, scrapers, and split idiophones. The sistrum in its earliest form, that of a U, is seen in Sumer in the mid-3rd millennium BC, and a little later, about 2100/2000, a rectangular form appears in Horoz tepe, Anatolia (modern Turkey). Egyptian sistrums are characterized by being closed at the top: the *sesheshet* was shaped like a temple, the *iba* like a closed horseshoe. Sacred to the Egyptian goddess Hathor, the *iba* was played only by women, and after Hathor's metamorphosis into Isis it remained sacred to Isis.

A sliding rattle called *angklung*, found only in Indonesia, consists of several tuned bamboo tubes with cut-back tongues, inserted into a frame; they slide back and forth when the frame is shaken. When the *angklung* is constructed as a chime, each player shakes his frame when it is his turn to sound it.

Scraped idiophones are Confucian ritual instruments in east Asia. The "tiger" of China is a vessel scraper of wood with a series of notches cut along its back; known as early as the Chou dynasty (*c.* 1122–221 BC), it is scraped with a split bamboo stick. Split idiophones (made of hollow cane split between nodes) are slapped against the player's wrist or thigh in south China and Southeast Asia, producing a fixed-pitch buzz.

Plucked and friction instruments. Jew's harps have idioglott tongues (cut from the same material as the frame) in Indonesia, while both idioglott and heteroglott (the tongue made separately and attached to the frame) forms occur in China and on the Indian subcontinent. In southwest Yunnan (in southern China), three separate idioglott, tuned Jew's harps may be united by young people for the purpose of exchanging messages; such instruments are of bamboo and have the older, clothespin form. More recent are those of metal having the outline of an onion. In the Philippines and some other areas Jew's harps are important adjuncts to courtship.

Musical cups

Musical cups, the forerunners of musical glasses, are depicted on the Borobuḍur *stūpa* of *c.* 800; the Indian *rastrarang* can be played either with small sticks by percussion or by rubbing wetted fingers along the rims—the cups do not contain water. But the *jaltarang*, also of India, makes use of water for fine tuning and for the playing of *gamaka*s (ornaments) by carefully bringing the sticks into contact with the surface of the water. Similar musical cups are played in Japan in Buddhist temples and in the music of the Kabuki theatre.

IN AFRICA AND AFRO-AMERICA

Muslim Africa. Idiophones of Muslim Africa are mainly those of the Near East or derivations thereof. Outsize hollow clappers shaped like a dumbbell sliced lengthwise are clicked by Moroccan singers, who hold a pair in each hand. A percussion bowl, an inverted bowl set afloat in a larger, water-filled bowl, is beaten with a single stick by the Saharan Tuareg as their substitute for the West African water gourd. Finger cymbals are worn pairwise on finger and thumb of each hand by dancers. Basically, however, the percussion of this area is executed by drums. Idiophones do not participate in art music.

Black Africa. In contrast, Black Africa has an almost bewildering variety of idiophones. Clappers, generally of wood, are played from coast to coast. Simple percussion sticks are known in East and West Africa.

Xylophones. Xylophones vary from the primitive pit xylophone, with few wooden bars placed over a pit or trench and isolated from the ground by bundles of grass or by wooden members, to the leg xylophone, with a couple of bars placed on the outstretched legs of a woman player, to the large instruments with independent framework and tuned keys graduated in size. African xylophones are usually provided with a gourd resonator suspended from each key, often containing a mirliton device that adds a characteristic buzzing quality to the tone. Ensemble playing of several xylophones, reported by 17th-century travellers, is still practiced. In some areas xylophones form small orchestras with several players to one larger instrument. Unmistakable similarities of form, playing technique, tuning, and even of the music performed confirm the African xylophone's Southeast Asian origin.

Xylophone ensembles

Slit-drums. Slit-drums occur in the Western "Bend" and Congo Basin. They may be cylindrical, boat-, wedge-, or crescent-shaped, and zoomorphic with dorsal slit. Possibly related to the drummed tube zither, a cylindrical slit-drum with from two to five slits is encountered in West Africa; the Kissi people of Guinea not only strike the slats formed by the multiple slits but the ends of the slit-drum as well.

Bells. Bells occur in a large variety: metal and wooden, single or double, clapperless and with single or multiple clappers, played as rhythm or signal instruments. The apotropaic qualities of metal bells are recognized in Africa also, where such bells may be associated with chieftainship. Double bells, usually of metal, share a common handle: if this is straight, a dumbbell form results, but if bent, the bells lie cheek by jowl. Those of a pair differ in length or in diameter and, consequently, always in pitch. Metal double bells are devoid of clappers and are often made of sheet iron soldered down the side, whereas double bells of wood often have multiple clappers.

Water gourds, rattles, and scrapers. Water gourds—half gourds floated open side down in a pan of water and struck rhythmically with small sticks—are played in West Africa; in Dahomey their chief use is at funeral rites.

Construction of rattles

Rattles are the instruments *par excellence* of dancers, although they can also be worn on the leg simply to provide walking rhythm. Strung and gourd rattles are common, with the latter often serving in religious cults or magic rites in the Congo Basin area. In West Africa a variety of rattle sounded by external percussion was developed: the surface of a gourd is covered by a network of dried fruit seeds threaded on a cord. Sistrum-like forked sticks strung with threaded pairs of calabash fragments have an important part in fertility and initiation rites among the Mali of West Africa. The ancient horseshoe and rectangular forms of sistrum are still played in Ethiopia in the Monophysite Christian Church.

Scrapers in both solid and vessel form are widespread; a notched calabash, the *quilando*, was described by Girolamo Merolla in 1692.

Plucked instruments. The African linguaphone is known to the West by the native name sansa (zanza) or the Bantu name *mbira* and in English additionally by the misnomers "kaffir piano" and "thumb piano"; it consists of a varying number of cane or metal tongues fitted to a wooden board or resonator so as to permit one end of the tongues to swing freely; their different lengths determine the pitch. Sansas show affinity of tuning with xylophones that cannot be considered accidental, and thus they may be considered as small, portable versions of the latter.

Afro-America. West African idiophones introduced into the Americas with the slave trade are still flourishing. Clappers originating among the Yoruba (a Nigerian people) are played in Cuba; the claves, or pair of cylindrical percussion sticks of Haiti and Cuba, are now standard equipment in Western rhythm bands. The xylophone may already have entered America in pre-Columbian times. Known chiefly as marimba, one of its African names, it has been accepted in Western musical culture. Bells frequently figure as voodoo cult instruments in Caribbean and Afro-Brazilian communities. In Cuba water gourds are played at funeral rites for Afro-Cubans.

Steel drums

Steel drums originated in Trinidad during World War II and have become vehicles for popular music in the U.S. since. Actually a single "drum" forms a chime, as one head of an ordinary oil drum is divided into sections of different sizes by punched grooves, each section then being tuned to its own pitch. Today only a greater or lesser rim, depending upon the range required, is left but originally the oil drum was left intact.

Rattles play an important part in African cults of the New World, both gourd rattles with internal and external percussion and a distinct variety consisting of two metal cones joined at their widest part. (The maraca gourd rattle is probably indigenous to South America.)

Scrapers are highly popular. The notched gourd with natural handle, called guiro, is another Afro-American instrument taken over by the West. Notched turtle carapaces are scraped in the Caribbean. The jawbone of a horse, mule, or donkey, with its teeth left in, is played in both North and South America and in the Caribbean; its use among coastal Negroes of Peru goes back to the 18th century. In the United States it is still encountered in Louisiana and the Carolinas.

Sansas in the Caribbean and in South America bear such names as *marimbula* (Cuba) and *marimbao* (Brazil), clearly indicating their origin.

IN AMERICA

A wide assortment of idiophones is available to American Indians, but many of these are restricted to nonmusical uses. Concussion sticks, for instance, serve as game calls in North America, while concussion stones are invariably ritual: they are clashed to make thunder. Small, conical bells of metal and multiclapper bells of wood were known in ancient Peru.

Slit-drums have been played in Central and South America since pre-Columbian times, but their occurrence in South America is now rare. Characteristic of the well-known *teponaztli* is the form of its slits, cut to form an H with tongues of different thicknesses, thus allowing it to emit two sounds. Formerly, Zapotec warriors of Ixtepeji, Mexico, went into battle carrying an idol and singing to the accompaniment of the *teponaztli*, while Indians of 16th-century Hispaniola danced to their slit-drums.

Strung rattles are worn as leggings to emphasize a dancer's movements, but when the strung material consists of a dead enemy's teeth, as among the Brazilian Mundurucú, the rattle becomes a source of magic strength to the wearer; elsewhere, strung deer or caribou hooves attract game during the hunt. Vessel rattles of gourd and pottery imitations of gourds have been in use since Aztec times. Cult instruments in prehistoric America, they are still used by medicine men during their incantations. Hollow, seed-filled staffs were ceremonial rattles of Aztec and Maya, and descendants of these instruments are still played in North America.

Scrapers are seen on the 8th- or 9th-century frescoes of the temple at Bonampak in Chivas State, Mexico, played in a procession. Today among the Pima Indians of Arizona, scrapers play an important part in rainmaking ceremonies. Elsewhere in North America they serve as time markers. Scraped sticks of animal or human bone or of antler, with a series of notches practiced along one side, were sounded at sacrificial or memorial ceremonies of the Aztec Empire. In modern times they have been played in North America by medicine men. Split idiophones were employed in western coastal areas of North America chiefly for ceremonial purposes; some tribes slapped them against their chests, others against their palms. Finally, a curious friction-instrument vessel of Central and South America, the rubbed tortoise carapace, is a ritual instrument and taboo to the noninitiated; the instrument is rubbed with the fingers, not scraped.

IN THE PACIFIC

The different cultures of this wide area where singing and dancing form so prominent a part of the musical life include a number of primitive idiophones, some of which are played with considerable sophistication. Concussion sticks are clashed by an Aboriginal Australian singer to lend emphasis. The Maori breathe words of a song onto a carved stick held between their teeth while tapping it with a second stick. In Hawaii concussion stones were held pairwise by dancers who clicked them together like castanets. In New Britain and Papua primitive log xylophones are played, consisting of two banana stems or other logs placed on the ground with a few keys placed across them.

Aboriginal concussion sticks

A percussion gourd of New Guinea has an hourglass form, open at both ends; when plunged in and out of water, it is said to emit the sounds "uh-ah-uh-ah". Split-bamboo percussion tubes, doubling as rattles, are indigenous to the same area, while the percussion board *o-le-polotu* of Samoan and Tongan chiefs accompanies solo songs. Slit-drums can be huge. Made from a tree trunk, living slit-drums in the New Hebrides are carved with the faces of ancestors, and in New Guinea roofed drum houses are built over large, horizontal slit-drums to protect them from the weather. The Maori, one of the relatively few peoples who have no membrane drums, use their slit-drums as signal instruments. Related to these is a percussion tube of Fiji, partly hollowed and tapering at the ends and struck with two sticks on the side opposite the slit.

Slit-drums

Idioglott Jew's harps of bamboo are the major tonal idiophones of the area; here the tongue is vibrated either by the player's finger or by jerking it with a cord. A friction vessel of New Ireland consists of a rounded and hollowed block of wood, its upper portion carved into three tongues of different lengths and hence emitting as many pitches. Already rare nowadays and taboo to women and children, it is played at death commemoration rites by a male performer who rubs well-oiled hands over the tongues.

Membranophones

Musical instruments in which the sound-producing medium is a vibrating membrane fall into four main groups: kettledrums and bowl-shaped drums; tubular drums—whether cylindrical, barrel, conical, double conical, hourglass, goblet, or shallow—and rattle drums, the membranes of which are set in motion by enclosed pellets or by knotted ends of a thong or cord; friction drums, with membranes caused to vibrate by friction; and mirlitons, musical auxiliaries with membranes set in motion by directing the vibrating air column of an instrument or voice against them.

Kettledrums and tubular drums occur in both tunable and nontunable forms; friction drums and mirlitons are not tunable. The membranes of the first two groups are either glued, nailed, lapped, or laced to the body, or shell; if they are glued or nailed, the pitch can be modified by exposure to heat. Lapped and laced heads are readily tunable by tightening the lacings or screws, and wooden wedges may be inserted between the shell and lacings to further increase the membrane's tension and thus raise the pitch. The membranes of such instruments and of friction drums are set in vibration by percussion, while those of mirlitons vibrate by impact of sound waves. In all groups the shell plays a subordinate acoustical part, acting as resonator only. The greater the diameter of a head, the deeper is its sound; and the greater its tension, the higher is the pitch. In Western culture the only drums tuned to a definite pitch are kettledrums (the orchestral timpani).

Kettledrums and tubular drums may be struck by the hands, with beaters, or both combined or by the knotted ends of a thong or cord. Beaters can be cylindrical, club-shaped, straight, curved, or angled, with or without knobs or padding, or may take the form of a switch or wire brush. Friction drums are sounded by rubbing the membrane with a piece of hide or by the more usual method of working an inserted friction stick or cord up and down or by rubbing the membrane with a player's wet fingers. Acoustically, they are subject to the same laws as other membranophones, but the speed of friction is an influencing factor. They occur in Africa, America, Europe, Asia (India and Japan), and Hawaii. Mirlitons are not true musical instruments but always voice modifiers, be it a human or an instrumental voice (as when affixed, *e.g.*, to African xylophone resonators); as such they have no pitch of their own.

Methods of striking drums

Primitive ground drums, consisting in their simplest form of an animal skin stretched over the opening of a pit, are still found in many parts of the world. A skin may also be held taut by several players, each beating it with a stick. These and similar ground drums are played by women in Africa and Australia, in North America usually by men. By their very nature ground drums are nonportable; when need arose for a smaller "drum," a skin was stretched over the opening of a gourd, clay pot, or other object. Among the Swazi of South Africa such skins are not attached but held taut. Whether the skin is attached

to or held taut over a pot, etc., such instruments are known as pot drums. They are found in Asia, Africa, and America—in Africa and America often in connection with exorcism.

IN EUROPE

Antiquity. Only a few kinds of drum, none indigenous, were known to antiquity. The frame drum came from the East at an early date. The barrel drum was possibly known in Hellenistic times, for it appears in the Greco-Indian culture of Kushan. A shallow drum is depicted on a Greco-Scythian metal *gorytus*, or bow and arrow case, of the 4th century BC, but there again no evidence exists of its having been known to Greece. Frame drums, traditionally women's instruments in the Near East, remained in the hands of female players and dancers in Greece, and the Eastern playing technique was maintained: held upright on edge in the palm of one hand, the drum was tapped with the fingers of the other.

The frame drum

Probably introduced into Greece in the 6th century BC with the cult of the great mother-goddess Cybele, the frame drum is depicted as being played by maenads and was also a cult instrument in rites of the Orphic religion. From Greece the frame drum passed into Rome, where it was also associated with Cybele. Romans also had double-headed drums and spread them as far north as the Isle of Wight, in Britain, where one is represented on a mosaic pavement as a dancing girl's instrument. In the late days of the Roman Empire, frame drums became instruments of street musicians and *joculatores*; the latter are sometimes portrayed throwing them up in the air and catching them again and are probably responsible for spreading them beyond the Italian Peninsula.

The Middle Ages. Frame drums were described by Isidore of Seville in the 7th century, but they seem to have played a negligible role in medieval Europe until reintroduced by the crusaders, after which they appear both in round and square form in the hands of both men and women. Jingles and pellet bells, frequently attached from the 14th century on, enliven the sound. French medieval poems place the instrument in the hands of female dancers, and in the 14th century Boccaccio writes of it as accompanying the voice.

Double-headed drums served as time beaters from the 6th century on. From the 7th century dates the first evidence of their being played with drumsticks, a technique adopted from Asia. Hourglass drums appear in southern Europe by the 10th century, only to die out in the late Middle Ages. The small cylinder drum known as the tabor was provided with a snare (material stretched across the head to produce a rattling sound) and struck with a stick right on the snare. Played together with the three-holed pipe, it formed a lively one-man ensemble, the companion of country dances throughout western Europe for centuries; it is still in use in some areas.

The naker

With the Crusades the small kettledrum called naker, always paired, entered Europe, reaching Russia in the 11th century and the West at the turn of the 12th and 13th century. A pair of nakers would be attached by a belt to the player's waist or suspended from the shoulder, each struck alternately as the heads sounded at different pitches. Not until the mid-15th century do the wide-diameter horse-borne kettledrums reach the West. Henceforth, they were to be paired with trumpets and associated with royalty and the cavalry, whereas the marching of infantry was regulated by plebeian fife and *Landsknecht*'s (lansquenet's) drum, a cylinder drum of considerable proportions slung to the player's left. As mercenary soldiers from the late 15th century on, Swiss drummers and fifers popularized such ensembles throughout western Europe. The shallow drum, presumably of Turkish derivation, is seen in the late 14th century. Its two heads were at first nailed in Oriental fashion, but by the mid-15th century the instrument was suitably Occidentalized by the use of laced heads.

The less common friction drum first appears in the late 12th-century sculpture of the archbishop's palace at Santiago de Compostela, in Spain, complete with friction rod. Although it undoubtedly continued in existence, it is not known to be either pictured or mentioned again until the 17th century.

Modern times. By the Renaissance, Europe had a variety of drums performing specialized functions: frame drums and small tabors accompanied dance and song; larger tabors served as time beaters in small mixed ensembles; great cylinder drums with fifes were placed at the disposal of foot troops; large kettledrums and trumpets were restricted to cavalry and ceremonial music. Frame drums remained popular in the south, particularly in Spain, as dancers' instruments; from Spain they travelled to Hispaniola by the mid-16th century.

Before the late 17th century, drums in the West served principally at court or other ceremonial functions and increasingly as military instruments, although smaller models filled social needs of everyday life. The 17th-century French composer Jean-Baptiste Lully appears to have been the first to admit drums and kettledrums to the opera and even, according to Titon du Tillet, 18th-century French writer and courtier, into church music. In the year of Lully's death (1687), Daniel Speer, a contemporary German musician, commented that echo effects could be obtained on kettledrums by playing softly close to the rim and striking hard at the centre; with such new techniques, modified drumstick heads, and the possibility of notating their music (hitherto prohibited by the rules of secrecy imposed upon guild members), kettledrums, henceforth called timpani, triumphantly entered orchestra, opera and church.

Admission of kettledrums to the orchestra

"Turkish" drums, descendants of the shallow drum, were admitted to the orchestra and military band in the 18th century. The composer Christoph Willibald Gluck was an early writer for this instrument in his opéra comique *Les Pélerins de la Mecque* (*The Pilgrims of Mecca*, 1764); also known as *La Rencontre imprévue*), and Mozart scored for it in his *Die Entführung aus dem Serail* (*The Abduction from the Seraglio*, 1782). Still called "Turkish" drum in 1823 by the French musicologist Guillaume-André Villoteau, a member of Napoleon's scientific mission to Egypt, it began to be known as the bass drum around this time. Another type sometimes called bass drum is the long drum, a military instrument of Turkish origin. Great, battle-scarred specimens of the 18th and 19th centuries in museums attest its continued use in Europe in its original form. The old *Landsknecht*'s side drum became too unwieldy and was cut down to the proportions of the modern side or snare drum. It may also have been the ancestor of the tenor drum, the original function of which was to play rolls and which was gradually eased out of military bands in most countries in the 19th century in favour of the far lighter side drum. The long drum continues in use as a folk instrument in the Balkans.

The northern frame drum, or tambourine, was given the status of a salon instrument by 18th-century French society, and, combined with harp or keyboard instrument, it could be heard at fashionable soirees. Although it is rarely written for, Weber uses one for local colour in his opera *Preciosa* (1820), Berlioz in his overture *Carnaval romain* (*Roman Carnival*, 1844).

Friction drums have maintained an existence to this day in various parts of Europe, where they are played at Christmas, during the carnival season, or to greet the New Year in less industrialized areas.

Mirlitons, with their ability of amplifying and colouring tone, have been known in Europe since the 16th century, possibly earlier, but did not gain popularity until the early 19th century. From 1883 on, a French toy maker named Bigot brought out a series of bigotphones shaped like orchestral instruments, and as late as 1910 gatherings of "bigotphonists" took place in Paris. Popular in mid-20th century was the tubular kazoo.

Changes in drumming technique

Drumming in the 20th century gained an important place outside its traditional preserves of orchestra and military band: rhythm bands and experimental music opened hitherto unexplored fields. The latter was preoccupied with rhythmic stress and also exploited drum tone for its own sake as a source of independent sound and tone colour. Playing techniques consequently became

freer, players striking either the membrane or the shell, using bare hands or a large range of beaters varying from stiff to flexible and hard to soft; wire "brushes" were frequently substituted for sticks in rhythm bands. The drum was treated as a solo instrument amid a group of its peers. On the popular level, rhythm may be stressed or punctuated, often by the clarity and opposing pitches of a pair of Afro-American drums (usually referred to as Latin-American drums).

IN ASIA

Unlike the drums of Western musical tradition, those found in ancient (and parts of modern) Asia are primarily cult and ceremonial instruments. Most, if not all, Western drums are their descendants, and west Central Asia may well be their common homeland. Babylonia already had a variety of forms: cylinder, hourglass, goblet, and bowl-shaped, all of terra-cotta and all beaten with bare hands. Assyrians also carried in procession a large, conical drum played in the same manner.

Babylonian drums

Temple drums were of considerable proportions: huge frame drums existed from the 3rd millennium on in Mesopotamia, and the waist-high *lilissu* had a goblet form—a bowl on a stand—and may have been the ancestor to the kettledrum. All these were played by men, but the smaller frame drums appearing in Sumeria in about 2000 BC are depicted in the hands of women. An early Sumerian text informs us that the king's granddaughter was appointed player of the *balag di* in the Temple of the Moon at Ur around 2400 BC. Ever since, frame drums have been predominantly women's instruments. The Bible says that in ancient Israel "Miriam, the prophetess, the sister of Aaron, took a timbrel in her hand; and all the women went out after her with timbrels and dancing." They are still played throughout the Near East, in some areas in art music ensembles, in others only in popular and folk music.

Wherever the Muslim presence has made itself felt, large and small kettledrums are encountered. In Turkey classical monophonic singing is accompanied solely by a small kettledrum, played either in the centre of the head or close to the rim, depending upon whether clear or muffled beats are desired.

Association of drums with thunder

Thunder drums. In many regions of the ancient and modern East drums were believed to create or imitate thunder. Sets of thunder drums are depicted on East Turkistan art objects from the 9th century to the 11th century. In China, Lei Kung, duke of Thunder, is traditionally surrounded by numerous drums on which he creates thunder, and in Japan thundering drums were even automated by attaching a number of them to the outer circumference of a wheel that, when revolved, caused them to rattle—an early application of the rattle-drum principle. As in Africa and America, cult drums of Asia have been associated with human sacrifice; thus the Chinese *Tso Chuan* ("The Commentary of Tso," one of the classics of Confucian literature) mentions the consecration of drums in the 7th and 6th centuries BC by smearing them with the blood of a sacrificial human, usually a war captive.

Rattle drums, either containing in their cavities objects that rattle when the drum is twirled by a handle or with attached cords having knotted ends that strike the heads, can be traced back to the Shang dynasty (*c.* 1766–*c.* 1122 BC) and are now in use from Tibet and India to Japan. Still a cult drum in some areas—it is an attribute of Śiva (Shiva), the third member of the Hindu trinity—in others the rattle drum has degenerated to a mere toy. On the giant *stūpa* of Borobuḍur, Java, an archetypal image of the known cosmos, are sculpted the musical instruments in use at the time of its erection (*c.* 800). These include cylinder, conical, hourglass, and pot drums—all Indian instruments. Yet, today's Indonesian orchestra, the gamelan, virtually ignores drums in favour of metallophones. Drumming is exclusively a man's business on some islands of the Malay archipelago, where drums are kept in the men's house, out of sight of women.

Drums played an important part in early court orchestras of China and Korea, judging by their surviving elements in *gagaku*, court orchestral music of Japan. Here, the leader beats time on a drum, either cylindrical or hourglass-shaped, having projecting heads, a characteristic feature of Japanese hooped drums. Larger barrel-shaped drums with nailed heads are suspended from elaborate frames. On the Indian subcontinent a variety of membranophones participate in art music ensembles or accompany dances, while small kettledrums are played pairwise in processions; large, single kettledrums are temple instruments or may be mounted on elephants' backs in outdoor ceremonies. Many smaller drums have laced and wedged heads, the skin being further tensed by an application of tuning paste. In Burma, Thailand, and south Nias Island a number of tuned barrel drums of varying sizes are suspended in a low circular pen to form drum chimes; such a chime may consist of from 16 to 24 drums, all played by a single musician with his fingers and palms, occasionally with a drumstick. These chimes form part of the theatre orchestra and are even played in processions.

Drum chimes

Mirlitons. In East and Southeast Asia a mirliton device is applied to many woodwinds in order to obtain a characteristic modification of tone quality. To this end an additional aperture is cut in the tube and covered with a thin membrane. A different application of this principle is encountered in India, where a pair of short, wooden mirliton "trumpets" are placed against the throat of a humming performer. During the 1950s a similar technique was employed by the United States recording industry for the obtaining of anthropomorphic effects.

IN AFRICA AND AFRO-AMERICA

Muslim Africa. Drumming tradition in the Muslim north centres on smaller, portable drums, such as frame, goblet, and small kettledrums. Frame drums are made in a number of forms: circular with single membrane, square, even diamond-shaped (ancient Egypt had circular, square, and rectangular ones). Islāmic cult admits no musical instruments, and the human voice is the preponderant instrument here, hence the frame drum's important role as vocal accompaniment. It also lends rhythm for dancing and is the basic percussion instrument of Muslim art-music ensembles. In Morocco groups of women may sing to the accompaniment of a frame drum supplied with jingles, a spike fiddle (one in which the handle traverses the body and emerges at the lower end to form a spike), small cymbals, and a pair of kettledrums, each playing her own instrument.

Black Africa. Black Africa makes perhaps wider use of its membranophones than does any other culture. Numerous variant forms of drums and lacings make classification difficult; indeed, a study of types remains to be established. Some drums are played as musical instruments, others transmit messages ("talking" drums), some are restricted to cult and funerals and others—partly desacralized—to royalty, while yet others participate in everyday life. Ethiopia admits drums to the church, while West African cult drums may not be seen by the uninitiated. Drums are beaten with bare hands or with rectangled or knobbed sticks. Footed drums (*i.e.*, with a base prolonged to form "feet") attain a height of ten feet in the Loango area of west Central Africa and must be tilted to bring the head within the performer's reach. The playing head of hourglass drums may be struck with one hand and with a stick alternately. Kettledrums are royal, ritual, or ceremonial, and unlike their North African counterparts they are of wood, often with sculpted shells. Their traditional pairing with trumpets reaches as far as south of the Congo.

"Talking" drums

That portion of West Africa known as "the Bend" is the area of "talking" drums, by means of which messages are conveyed for up to 20 miles, to be relayed by another drummer. Languages of this area are characterized by pronounced high and low pitch tones (tone languages), a quality exploited when two drums—a lower pitched, or male drum, and a higher pitched, or female one—transmit low and high tones respectively. Accent, number, and pitch of the syllables are transmittable. Among the Yoruba a "talking" drum set consists of four hourglass

drums and a kettledrum; the leather lacings of the former are gripped by its player, enabling him to change the pitch as he exerts more or less pressure on them; the chief drum of the set is capable of an octave range and, in addition to tones, produces also the typical Yoruba glides by manipulation of the lacings.

East African drum chimes, of Asian heritage, are tuned to specific pitches; these instruments attained royal status in Uganda, where the largest chime consists of 15 drums requiring six musicians to play them.

Friction drums of the lower Congo area were once exclusively cult instruments but are now becoming desacralized. Whereas in Central Africa they are played only by men, women of the South African Pedi play them at female initiation rites.

African mirlitons can be most imaginative: standard material is a spider's egg membrane, and this may be added to apertures pierced in the bottom of xylophone resonators or applied to one end of an independent cane tube that is inserted into a nostril, as among the Fan of Gabon.

Afro-America. West Africans reconstructed their native drums in the New World, preponderantly as cult instruments. Small sets of two or, more often, three drums of graded sizes form an integral part of Afro-American rituals and, in the Caribbean, also of voodoo dances. Only the skins of sacrificial animals may be used for membranes among Afro-Bahians in Brazil, who baptize their new drums, prefereably with "holy" water obtained from a Catholic church. Drums in Haiti are sacred objects and may even represent the deity itself: as such they receive libations. One type of bongo drum—there exist at least four of these—has been adopted by Western rhythm bands, as has the conga.

IN AMERICA

Pre-Columbian drums of Central America appear to have been played without sticks, regardless of their size, and to have been devoid of lacings, whether they were small pottery drums, such as those excavated in Costa Rica, or the large footed drums of Mexico. Slender pottery drums of the Guatemala highlands, open top and bottom, can be dated to the late classical period (*c.* 700–1000). Skeletons of wooden cylinder drums, very shallow, have been found in Peru. In shape but not in structure they are identical to the shallow drums played by North American Indians today.

The North American shallow drums are "medicine" (magic) and dance drums, having a heavy hide head struck by a hard beater and emitting a loud, staccato sound. Larger models are suspended and struck simultaneously by up to ten drummers seated in a surrounding circle. The "dream-dance" drum, a tub-shaped shallow drum, is elaborately decorated and has a bell suspended in its interior; it is credited with great medicine power.

Cylinder drums, made of a hollowed log of cottonwood, traditionally war and dance drums of tribes of the Southwestern United States, are now sold in tourist shops. Pottery drums, either potbellied, bowl-shaped, or footed, were formerly common among the eastern and southern tribes of the United States; the potbellied type remains in use among the Pueblo Indians of the Southwest.

American Indian frame drums are usually circular; square shapes are rare, but rectangular frame drums are found in California, Mexico, and Bolivia and octagonal ones among the Cherokee of the Southeastern United States. All were war drums, regardless of whether they had one or two membranes. By adding a rattling device, a frame drum is converted into a medicine drum. The Eskimo frame drum, a shaman's instrument, is distributed over Greenland, northern Siberia, North America, and among the Lapps of northern Scandinavia and differs from other frame drums in that it has a fixed handle and is struck on the hoop, not on the membrane. It may be circular, oval, or fan-shaped.

Eskimo shaman's drum

Friction drums are rare; in Venezuela one is formed from a small barrel over which a piece of leather is stretched, with central perforation to admit a friction stick.

IN THE PACIFIC

Two forms of drum are distributed over this huge area. Elongated hourglass drums, usually with wooden handles of a piece with the drum shell, often beautifully carved and ranging up to six feet in height, are commonly in the hands of dancers and singers and are said to symbolize the transition from earth to heaven. Among the Wapenamundu of New Guinea they lack handles and are war drums. Such hourglass drums are not found in Polynesia. The other form is a conical, footed drum made of a tree trunk, reaching great dimension. Those of Polynesia are sometimes eight feet high and have elaborately carved pedestals. They are usually made of breadfruit tree wood or hollowed coconut palm, with a single, sharkskin head. Throughout the area drums are beaten with bare hands.

Whirled friction drums are met with in Hawaii, where a large nut or a calabash is furnished with a friction cord and swung through the air.

Pericles

The greatest statesman of ancient Athens, Pericles brought Athenian democracy to its zenith, built the most magnificent of ancient Greek buildings, and came near to establishing Athens as the leader of all Greece.

Anderson—Alinari

Pericles, marble herm. In the Vatican Museum.

Knowledge of his life derives largely from two sources. The historian Thucydides admired him profoundly and refused to criticize him. His account suffers from the fact that, 40 years younger, he had no firsthand knowledge of Pericles' early career; it suffers also from his approach, which concentrates exclusively on Pericles' intellectual capacity and his war leadership, omitting biographical details, which Thucydides thought irrelevant to his theme. The gaps are partly filled by the Greek writer Plutarch, who, 500 years later, began writing the life of Pericles to illustrate a man of unchallengeable virtue and greatness at grips with the fickleness of the mob and

finished rather puzzled by the picture he found in his sources of Pericles' responsibility for a needless war. These sources are not all ascertainable, but they certainly preserve an invaluable amount of fact and contemporary gossip, which is sometimes nearly as useful.

Family background and education. Pericles was born (*c.* 495 BC) into the first generation able to use the new weapon of the popular vote against the old power of family politics. His father, Xanthippus, a typical member of this generation, almost certainly of an old family, began his political career by a dynastic marriage into the controversial family of the Alcmeonids. He soon left their political camp, probably on the question of relations with Persia, and took the then new path of legal prosecution as a political weapon. Perhaps outbid in his search for popular support, he was ostracized in 484 BC, though he returned in 480 to command the Athenian force at Mycale in 479, probably dying soon after. From him Pericles may have inherited a leaning toward the people, along with landed property at Cholargus, just north of Athens, which put him high, though not quite at the highest level, on the Athenian pyramid of wealth. His Alcmeonid mother, Agariste, provided him with relationships of sharply diminishing political value and her family curse, a religious defilement that was occasionally used against him by his enemies. A few days before Pericles' birth, according to the Greek historian Herodotus, Agariste dreamed she bore a lion. The symbolism, although ambiguous, is most likely to be unfavourable. That Pericles' skull was of unusual shape seems well attested, but one can hardly speculate about the possible psychological consequences.

Education by the Sophists

The only name associated with his early education is that of the musical theorist Damon, whose influence, it is said, was not just confined to music. The arrival of the Sophist philosophers in Athens occurred during his middle life, and he seems to have taken full advantage of the society of Zeno and particularly Anaxagoras, from whom he is said to have learned impassivity in the face of trouble and insult and skepticism about alleged divine phenomena.

The first known date in his life is 472 BC, when he paid for the production of the playwright Aeschylus' Persian trilogy. Nothing further is known until 463, when he unsuccessfully prosecuted Cimon, the leading general and statesman of the day, on a charge of having neglected a chance to conquer Macedonia; this implies that Pericles advocated an aggressive policy of expansion for Athens. Only rumour associates him directly with the political convulsion of the next two years, which drove Cimon into exile, swung Athens away from its alignment with Sparta, and decisively strengthened the democratic elements in the Athenian constitution; but he probably did support the democratic leader Ephialtes in this period, and his introduction of pay for juries, unfortunately undatable, is a logical consequence of Ephialtes' reforms.

Rise to democratic leadership. That Pericles immediately succeeded the assassinated Ephialtes as head of the democratic party in 461 is an ancient oversimplification; there were other men of considerable weight in Athens in the next 15 years. The outbreak of war among the Greek states in 459 put a premium on military talent, and Pericles' only recorded campaign in the next few years was a naval expedition in the Corinthian Gulf in 454, in which Athens defeated Achaea but failed to win more important objectives. Politically he is credited with some kind of rapprochement with Cimon, who is said to have been recalled and allowed to resume the war with Persia, much preferred to fighting other Greeks, but the date of Cimon's recall is uncertain, and the rumours are hard to disentangle.

Legislation on Athenian citizenship

In 451 or 450 Pericles carried a law confining Athenian citizenship to those of Athenian parentage on both sides. No source provides any background to this proposal; it is not even clear whether it was retrospective. A correct assessment is vital for understanding Pericles, but explanations vary considerably; some argue that Pericles was merely forging a low-level political weapon for use against Cimon, who had a foreign mother. The upper classes certainly had no prejudice against foreign marriages; the lower classes may well have had more, and, on the whole, it is possible to view Pericles here as championing exclusivist tendencies against immigrants who might break down the fabric of Athenian society. One hundred years later, an orator argued for firm distinctions of status on the ground that the law provided even the poorest Athenian girl with a dowry in the form of her citizenship. The law also may have passed because of a general wish to restrict access to the benefits of office and public distributions, but there was never any disposition on the part of Athenians to restrict economic opportunities for foreigners—who served in the fleet, worked on public buildings, and had freedom of trade and investment, with the crucial, but normal, exception of land and houses. To speak of this legislation as a move forward creating a "master race" is thus partly misleading, but the demagogic nature of the law seems clear.

Cimon died after 451, during his last campaign against Persia. The policy of war with Persia was abandoned and a formal peace probably made. The Persian War, begun as an ill-considered gesture in 499, could be considered ultimately successful. The city of Athens, however, was physically still much as it had been left by the Persian sack of 480, and its gods were inadequately housed.

Attempts to restore Athens' leadership among the Greek cities

Hostilities among the Greek states had also come to an end in the Five Years' Truce of 451. Pericles now embarked on a policy designed to secure Athens' cultural and political leadership in Greece. It had already dominated the alliance that had continued the Persian War after Sparta's withdrawal in 478, a leadership strengthened by the transfer of the alliance's considerable treasury from Delos to Athens in 454. If peace with Persia did not end the alliance, it may have ended the annual tribute paid to that treasury. Whether to regain this tribute, or simply to assert Athenian leadership, Pericles summoned a conference of all Greek states to consider the questions of rebuilding the Greek temples destroyed by the Persians, the payment of sacrifices due to the gods for salvation, and the freedom of the seas. Sparta would not cooperate, but Pericles continued on the narrower basis of the Athenian alliance. Tribute was to continue, and Athens would draw heavily on the reserves of the alliance for a magnificent building program centred on the Acropolis. In 447 work started on the temple later known as the Parthenon and on the gold and ivory statue of Athena (by Phidias), which it was to house; the Acropolis project was to include, among other things, a temple to Victory and the Propylaea (started 437), the entrance gateway, far grander and more expensive than any previous Greek secular building.

There was domestic criticism, however. Thucydides, son of Melesias (not the historian) and a relative of Cimon, who had inherited some of his political support, denounced both the extravagance of the project and the immorality of using allied funds to finance it. Pericles argued that the allies were paying for their defense, and, if that was assured, Athens did not have to account for how the money was actually spent. The argument ended in ostracism in 443; Thucydides went into exile for ten years, leaving Pericles unchallenged. It cannot be determined whether the glamour of the project had completely caught Athenian imagination or whether Pericles was now simply thought to be indispensable. Plutarch attributed to Pericles a desire to stimulate economic activity and employment in Athens, but these motives may be anachronistic and in actuality may not have influenced the voters very much.

Revolts within the Athenian Empire

There was also some initial allied resentment at the continuation of tribute, and some scattered revolts. Pericles met the situation in part by extending a network of Athenian settlements throughout what may now be called the empire, thus strengthening Athenian control and providing new land for the growing Athenian population. In establishing one of these, Pericles engaged in his most admired campaign, the expulsion of barbarians from the Thracian Chersonese (Gallipoli). A more serious crisis came in 447 or 446, however, when the cities of Boeotia, under Athenian control since 458, beat a small Athenian army and successfully revolted. Euboea, crucial

to Athenian control of the sea and food supplies, and Megara soon followed suit. The strategic importance of Megara was immediately demonstrated by the appearance, for the first time in 12 years, of a Spartan army north of the Isthmus in Attica. Pericles thought and acted swiftly. The details were never fully known, but, possibly by bribery and certainly by negotiation, it was arranged that Athens would give up its mainland possessions and confine itself to a largely maritime empire. The Spartan army retired, Euboea was quickly reduced, and the arrangement was ratified by the Thirty Years' Peace (winter 446–445). For Athens, the essential loss was that of Megara, which meant that a Spartan army could appear in Attica at any time. That Pericles doubted the stability of the settlement and saw the need to develop an alternative basic strategy for Athens is shown by his immediate construction of a third Long Wall to improve the defenses of Athens and the port of Piraeus. Henceforth, in effect, Athens could be turned into an island at will.

Political and military achievements. There was a break in tensions for the moment. After Thucydides' ostracism, Pericles had little domestic opposition. His position rested on his continual re-election to the generalship and on his prestige, based, according to the historian Thucydides, on his manifest intelligence and incorruptibility. From his youthful demagogy, he had moved to a more middle ground in politics, and there are traces in his later life of his being outflanked by more radical spokesmen. Athens was, Thucydides says, in name a democracy but, in fact, governed by its first man. Though Athenian democracy never gave more than severely limited powers to the executive, the assembly gave Pericles what he wanted. Thucydides, obsessed with the power of intellect, takes little note of the need of a statesman to work hard, and it is Plutarch who provided the glimpses of a man who took no interest in his own estates, who was never seen on any road but that to the public offices, and who was only recalled to have gone to one social occasion, which he left early.

Pericles' personal life

This picture is softened somewhat by what is known of his personal life. The identity of his wife, however, though certainly of wealth and high birth, is unknown. He married her in his late 20s but, as they were incompatible, divorced her some ten years later. Close to 50, he took Aspasia of Miletus into his house. By his own law, marriage was impossible, and, after the death of his two legitimate sons, their son Pericles had to be legitimated. Although she is clouded by scandal and legend, it is easy to believe she possessed great charm and intelligence. There is no reason to doubt that she was free and of good birth in her own city with its great intellectual traditions. It is clear that her own behaviour and Pericles' attitude toward her were surprising phenomena in Athens, where upper-class women were kept secluded. That Pericles was known to kiss her on leaving for and returning from work gave rise to speculation about her influence on him and, thus, on Athenian politics.

As the building program continued, Pericles demonstrated Athenian superiority in other ways. In 443 a Panhellenic colony was founded under Athenian auspices at Thurii, in south Italy, but did not form a continuing centre of Athenian influence in the west, as may have been hoped. At an unknown date, Pericles took a fleet into the Black Sea to demonstrate Athenian power and secure the corn route from south Russia. As the buildings on the Acropolis rose, celebrations of the festival of the Panathenaea grew more and more elaborate, and much was done to enhance the splendour of the Mysteries of Eleusis, symbolic, among other things, of the Athenian claim to have brought corn and civilization to mankind.

Pericles' last major campaign was the one interruption in these years. In 440, Samos, one of Athens' principal allies with a substantial fleet of its own, revolted, and, despite a victory by Pericles against superior numbers, the revolt nearly succeeded. The campaign to recover Samos, although long and costly, was completely successful, and became a model against which later Athenian generals measured their achievements.

There had been a serious possibility that Sparta and its allies might intervene on this occasion, but they did not, and the Thirty Years' Peace was upheld until the end of the 430s. Tension grew as the decade progressed, particularly with regard to Corinth, Sparta's ally, whose interests conflicted more obviously with those of Athens. By 433 the situation was serious enough for Athens' finances to be put on a war basis, and, thereafter, the drift to war continued. Pericles' policy was one of firmness, coupled with careful manipulation of the diplomatic position to keep Athens technically in the right. The firmness was a puzzle to contemporaries, particularly his determination to enforce decrees excluding Megarian trade from the Athenian Empire. Was he, it was asked, influenced by some private grievance of Aspasia? Was he trying to divert attention from personal attacks on himself and friends by making war? Thucydides tells just enough to make his own interpretation plausible, that Megara was a small matter in itself but crucial as a symbol of Athenian determination to maintain its position. Consideration of Megara's strategic importance, which Thucydides consistently undervalues, may suggest further the possibility that the Megarian decrees were not the immediate cause of the war but the first blow in a war Pericles thought inevitable and that began in spring 431.

The drift toward war

Pericles' main strategic ideas are clear. He was an admiral rather than a general, and Athens' naval resources were immeasurably superior to its land power. He would evacuate the Athenian countryside, bring the population into the Long Walls, decline battle with the Spartan army, and rely on the fleet to assure Athenian food supplies and secure the empire on whose resources the expensive naval policy depended. Expenditure on building had been counterbalanced by annual savings from the tribute, and enough capital had been reserved, he thought, for a long war, though expenditure turned out heavier than he could have calculated. This is essentially Thucydides' analysis, though he failed to explain what end to the war, other than a stalemate, Pericles wanted or expected. There are some indications that Periclean strategy included more aggressive elements, such as the recovery of Megara, which would have considerably improved Athens' position.

Weakness of Pericles' strategy

This strategy, however, had marked political weaknesses. The Athenian population had deep roots in the countryside, and great firmness was required to bring them to abandon their land to Spartan ravages without a fight. The middle class army suffered in morale, and the living conditions of the lower classes, though they were allowed activity in the fleet, deteriorated in the overcrowded city. The overcrowding had an unforeseeable consequence in a plague, which in the second summer of the war took a quarter of the population. No obvious success counterbalanced the discomforts of war, and Pericles was deposed from office and fined. He was soon re-elected, but he took no new initiatives before his death in autumn 429.

After the first campaigning season of the war, he had delivered the funeral speech over the fallen, which Thucydides reports at length. They had fallen, he said, in preserving a way of life that he described in detail. Athenian life often fell short of this Periclean ideal, but he conceived it with clarity and made it generally recognized. He conceived his Athens as "an education to Greece." If the last speech attributed to him by Thucydides is any guide, he cannot be accused of ignoring that the realities of power that made the Periclean age possible might also bring it down.

Periodicity, Biological

Continuous change characterizes both living organisms and their physical environment. Many of these changes occur irregularly and are termed aperiodic. Examples include the irregular variations in temperature, light, humidity, and other physical factors associated with the passage of weather systems; aperiodic, also, are the biological fluctuations in response to them. In contrast, are periodic fluctuations, relatively regular changes repeated at constant intervals of time. Clearly periodic, for example, are the natural fluctuations in daylight and in tides. Similarly periodic are the daily and tidal variations in plants and animals as they respond and adjust to these periodic changes. Phenomena that recur with such regularity are termed rhythmic. Fluctuations of organisms in direct responses to long term environmental fluctuations are termed phenological; such are migratory movements, flowering, breeding periods, etc.

GENERAL FEATURES

The range of biological rhythms

Rhythmic variations in living systems are commonplace and span a very wide gamut of intervals. Among those possessing short periods and hence a high frequency of recurrence are wing beats of insects (20 to 2,000 cycles per second), brain waves (1 to 60 c/sec), walking and chewing rhythms (1 to 8 c/sec), heartbeats (20 to 1,000 c/min), and respiratory rhythms (4 to 250 c/min).

Other biological rhythms have only a few cycles per day. Examples are the variations in activity of very young infants, in depth of sleep of adults, in metabolism of chick embryos, in spiralling of growing plant tips, and in a number of bodily processes of the human during certain illness. Longer periods include the well-known several-day recurrences of fever in malaria and the few-day to several-month reproductive rhythms of mammals. Still lower frequency rhythms include the several- to many-year cycles of reproduction in the periodic cicadas, of abundance in animal populations, of prosperity in business, and of outbreaks of wars.

Fluctuations in living creatures occur at every level from the cell to activities of the organism as a whole and are evident in altered chemistry, physiology, and behaviour, including changing responsiveness to all factors of the environment.

Periodic biological phenomena fall into two more or less distinct different categories: those correlated with periodic changes of the planet (geophysical correlates) and those having no such correlates. Biological rhythms correlated with ocean tides, days, months, and years clearly relate the activities of organisms to the fluctuations of their physical environment as a consequence of the movements of the earth. These rhythms possess properties that clearly set them apart from rhythms without external correlates, such as heartbeat and respiratory rate. The frequencies of these latter rhythms can be altered in response to changes in the immediate environment. Their frequencies also are altered readily by drugs and other chemicals and, as with metabolic rate itself, altered greatly as body-temperature changes. On the contrary, rhythmic variations with geophysical correlates have relatively fixed periods and are resistant to alteration in their frequency either by temperature or chemicals.

This extraordinary stability of the periods of the biological rhythms with geophysical correlates is not dependent upon direct responses to light and temperature rhythms. It was demonstrated more than two centuries ago that the capacity of plants to display their daily rhythm in sleep movements, the daytime raising and nighttime lowering of their leaves, persisted even when the plants were shielded from light changes and maintained in a relatively constant temperature. More recently, daily rhythms in a wide variety of living things, from single-celled forms to mammals and flowering plants, have been shown similarly to continue under constant conditions of light and temperature. Tidal rhythms in many shore organisms persist even after the organism is removed from the tidal environment. Comparably, semimonthly, monthly, and annual rhythmic variations continue even when organisms possessing them are deprived of every obvious periodic cue. Such organisms behave as if they possess the ability independently to time all Earth's major natural periods.

Adaptive significance of periodicity

A timing capacity, geared to the rhythmic variations of the natural environment, is indeed a most useful attribute. A time sense enables organisms to anticipate and exploit the most favourable portions of the day, tide, month, etc. It can be used by members of a species to synchronize their urge to breed. A time sense may serve, in conjunction with the sun, moon, and stars, as a means of geographic orientation for the migratory and homing activities of many organisms, just as a chronometer and a sextant enable a navigator to find his position or to plot a course.

BIOLOGICAL RHYTHMS AND NATURAL GEOPHYSICAL CYCLES

Living things are extraordinarily well adapted to their rhythmic environments and have become periodic in diverse aspects of their physiology and behaviour. The biological rhythms that have resulted are in part direct responses to the environment and in part indirect ones via the complex clock-timed organization.

Solar-day rhythms. Twenty-four-hour rhythms of organisms in nature are the rule; they are variously called solar day, circadian, diel, daily, diurnal, and nycthemeral. The evolution of life on earth has proceeded in the direction of maximal utilization of every habitable niche, with species specialized to deal with virtually every kind of environmental site. This specialization is related not only to space but also to time. Some organisms have become specialized for the darker, cooler, more humid nighttime; others for the lighter, warmer, drier daytime; and still others for the transitional twilight periods. The environment is in use full-time, but for maximal efficiency organisms are organized to work largely in "shifts." The night shift includes animals such as mice, cockroaches, scorpions, moths, owls, bats, skunks, opossums, and raccoon; the day shift includes songbirds, hawks, lizards, butterflies, and honeybees. Green plants alternate between the daytime use of sunlight in photosynthesis and the nighttime emphasis on growth and assimilation. Many plants undergo a daily sleep rhythm, their leaves drooping at night and rising by day. Some plants open their blossoms only at night, others only by day, with times commonly synchronized to the activity schedules of animals that pollinate them.

In each organism's daily pattern, a multiplicity of supporting chemical and physiological variations occur as the organism's whole being is thrown periodically into activity. In man, as an example, the daily alternation of sleep and wakefulness is accompanied by many changes, including activities of the nervous and endocrine systems and the liver and kidneys. Daily variations occur in body temperature, in heart and respiratory rates, and in pressure and composition of the blood. There are daily variations, also, in chemical syntheses and in cell divisions. Such rhythmically recurring phenomena are each set to the most efficient time of day for the organism and collectively contribute to the characteristic 24-hour phase map, or activity record, of that individual (Figure 1).

Daily variations in responsiveness

One of the very striking manners in which the presence of fundamental 24-hour variations is reflected in man and other animals is in changing reponsiveness or susceptibility to physical and chemical insults. The following are a few examples. Doses of X-rays that at one time of day can kill every individual exposed will at another time kill only a few individuals or none. Doses of powerful poisons, fully lethal at one time of day, leave animals unharmed at another. Noise that can induce fatal convulsions in mice at one time of day fail to do so at another. The ability of histamines to induce inflammatory response, and the effectiveness of alcohol, insulin, and even aspirin vary systematically with time of day. In insects the degree of resistance to insecticides or to exposures to high temperatures also depends upon the time of day.

Lunar tidal rhythms. Another major environmental period is the lunar tidal rhythm, the regular ebb and flow of the ocean tides, a cycle that subjects seashore plants and animals to a rhythmic change with typically two high and two low tides occurring each lunar day of about 24

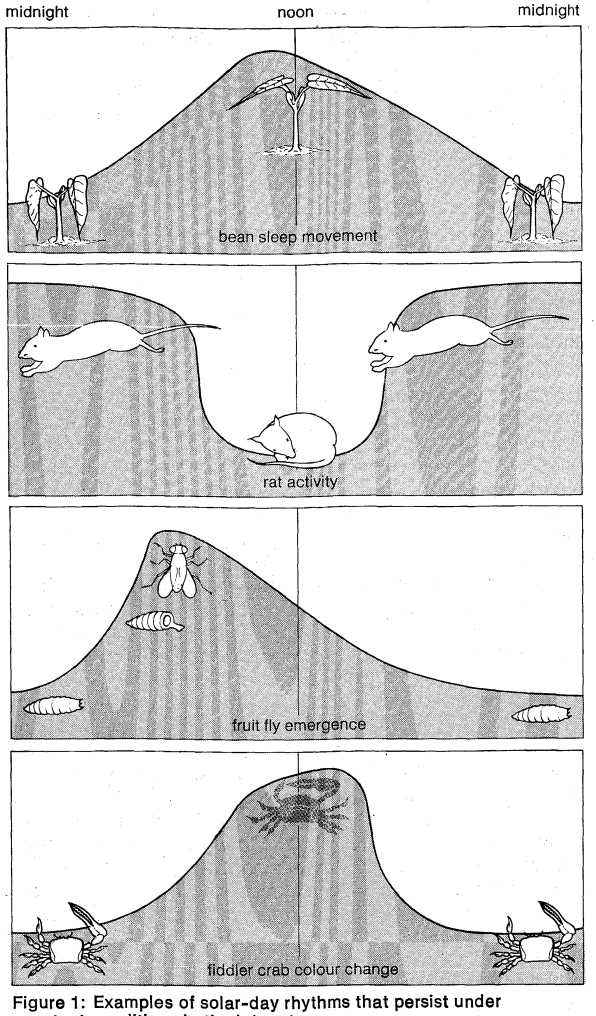

Figure 1: Examples of solar-day rhythms that persist under constant conditions in the laboratory.
Adapted from F.A. Brown, "Living Clocks," *Science*, vol. 130, pp. 1535–44 (December 4, 1959), in R.L. Smith, *Ecology and Field Biology* (1966); Harper & Row

hours' 50 minutes' duration. Some intertidal organisms, such as barnacles, green crabs, snails, clams, and oysters, are most active when submerged by the rising tide. Others such as shorebirds and fiddler crabs, are especially adapted to feed on beaches exposed at ebb tide. Some single-celled algae called diatoms move down into the sand and mud when the beaches are submerged and rise onto the surface to permit photosynthesis when the tide recedes. The diatoms and many of the shorebirds are active only when the beaches are exposed during daylight. Such organisms, therefore, display simultaneously 24-hour and tidal rhythms, which steadily undergo changing phase relations with respect to one another, coming into the same relationships exactly once each half-month. Indeed, all the organisms of the intertidal region must deal with both the daily light and temperature changes and the tidal ones. Fiddler crabs, for example, show concurrently a daily rhythm of skin colour change adaptively set to the times of day and night and a tidal rhythm of locomotor activity adjusted to the local tidal schedule.

Although the ocean tides are affected chiefly by the moon, the gravitational attraction of the sun also has an influence. The sun and moon "cooperate" at new and full moons to produce the greatest tidal ranges of each month, the so-called spring tides. At the moon's quarters the moon and sun maximally oppose one another, resulting in the smallest tidal ranges. As a consequence, inhabitants of the seashore that occupy the highest and the lowest levels of the intertidal zone experience periodic tidal submergences or exposures only for brief intervals once each half-month. One species of marine snail that inhabits the upper level of the beaches has been reported to show a semimonthly activity rhythm.

Any living creature that possesses both tidal and daily variations will exhibit day-by-day patterns of variation that systematically change from one day to the next as the peaks and troughs in the tidal cycles, like the tides themselves, occur at progressively later times of day. The specific pattern of organismic variation through any given day will repeat itself exactly a half month later.

Animal navigation

An interesting expression of these rhythmicities is evident in the reported phenomenon of celestial navigation by animals. Such animals as birds, fishes, turtles, spiders, insects, and crustaceans have been variously described to navigate or to "home" by using the relative positions of the sun or the moon or, in the case of birds, even the constellations as geographic navigational guides. Such sun-compass, moon-compass, or star-compass navigation requires that the animals be able systematically to alter their orientational angle at rates to compensate exactly for the earth's rotation relative to each of these celestial references.

Monthly rhythms. The synodic month, averaging 29.5 days, and the semimonth can be sensed by organisms, as noted earlier, through "beats" between their lunar tidal and circadian rhythms. Another kind of environmental monthly variation involves nighttime moonlight. Synodic monthly variations occur in such unlikely phenomena as rat and hamster running activity, light responsiveness of guppies, human colour vision, potato metabolic rate, and light responses of freshwater flatworms, even when shielded from all moonlight.

Among the biological activities linked to the synodic month are reproductive cycles of many different kinds of marine animals and plants. Best known and most studied of these are the monthly reproductive rhythms of palolo worms of the southwest Pacific, the fireworms of Bermuda, the grunions of the California coast, and the brown marine algae *Dictyota*. These rhythms are sufficiently precise in their relation to moon phase and season of the year as to be predictable. The changing relations of the solar-day and lunar-day physical rhythms appear to time these breeding cycles, since the phase of moon at which, for example, *Dictyota* breeds is related to the times of occurrence within the lunar day of the local high tides, which differ from place to place. The grunion's breeding is timed to within a few minutes of high tide on the local beach on the nights of its breeding, and the breeding times of palolo worms and fireworms are very accurately timed to within a few minutes in the day.

Precision timing of sea lily reproduction

The most spectacular precision in timing of a month- and year-related reproductive rhythm has been described for a deep-sea sea lily near Japan. This echinoderm liberates its sex cells once each year in October at about 3 PM on the day of one of the moon's quarters. In succeeding years the time of sex cell release changes, among the moon's two quarters, first–third–first, to progressively slightly earlier dates in October. The triplets are repeated until about the first of the month whereupon the following year it jumps abruptly to near the end of the month to start the advancing triplet progression again. The result is an 18-year cycle, which is essentially the period of regression of the moon's orbital plane. There have been reports of monthly menstrual cycles in some Primates with initiation of menstruation linked to the new moon. Reproductive swarming of mayflies has also been related to moon phase.

Little is known about the timing of such cycles as the human menstrual cycle, the approximately semimonthly estrus cycles of sheep, the three-week cycles of cattle and pigs, and the six-month cycles of dogs. Three kinds of hypotheses have been offered for their timing: (1) they are timed by fully independent periodic oscillations within the organism; (2) they are dependent for their timing on periodic interference between 24-hour and lunar-day clocks, since most of them appear to be simple multiples of a quarter month; and (3) they depend for timing on monthly variations in moonlight (directed chiefly at the primate menstrual cycle). Some recent studies have given strong support for a long-held belief that the menstrual period is in some manner regulated by the moon ("menses" means lunar month). In a study of a number of women with variable onset of menstrual periods, artificial

illumination of the bedroom through the 14th to 17th nights following the onset of menstruation resulted in a regularization of the period, with the period length coming very close to 29.5 days, the natural synodic month. That this period is a biologically significant one for the human species is further suggested by the fact that the average duration of pregnancy (from ovulation to birth) in the human is rather precisely nine 29.53-day synodic months.

Associated with the human menstrual cycle are related variations in almost every measurable bodily factor: temperature, blood chemistry, weight, heart rate, blood-cell counts, and pain thresholds are among the described variations. These factors pass through maxima and minima at different times but in such characteristic time relationships to one another that phase maps for the menstrual rhythm, comparable to those for the circadian, can be determined.

Annual rhythm. Another major rhythmic period for living things is the year. In most parts of the world substantial seasonal changes in light and temperature are correlated with rhythmic biological phenomena predominantly related to activity, reproduction, and growth. For example, in higher plants in the temperate zones, growth, flowering, and seed production typically occur over the course of the warmer months. In the oceans and fresh waters there are annual rhythms in plankton abundance. Annual reproductive rhythms in animals are typically set to the time of year that provides the optimum opportunity for birth and rearing of young. Annual rhythms include also hibernation to bridge the coldest period of the year and estivation to avoid hot-summer droughts.

The readily observable systematic annual variations in the activities of the plants and animals are accompanied by innumerable less obvious changes within their bodies, variations that pass through their peaks and depressions with such regularity that annual phase maps can be made.

Seasonal variations in human biology

Seasonal rhythms occur in man and are evident in such phenomena as birthrate and weight and in growth rate of children. There are annual variations also in innumerable other factors, among them body temperature, heart rate, basal metabolic rate, blood-cell counts, and blood chemistry. Not surprising, also, are reports of annual variations for many noninfectious diseases of the skin, nervous, circulatory, respiratory, and gastrointestinal systems, and even for mortality. Many infectious diseases of man are well known to exhibit peaks at characteristic times of year, while diseases without such evident annual fluctuations could perhaps be expected to display an annual variation in degrees of complications and mortality as a consequence of a probable annual variation in susceptibility related to the rhythmically changing biochemical and physiological states.

Too little investigated for man but difficult to treat because of the long period involved is the degree of phase shifting possible for the annual rhythms by manipulation of such physical factors as photoperiod and temperature.

Epochal rhythms. There are innumerable natural geophysical periods both shorter and longer than a year resulting from periodic activities in the sun and from relative movements of the earth, sun, moon, planets, and stars. Among the well-known shorter periods are the sun-generated ten-cycles per second electromagnetic fields, suggestively similar to the ten-cycles per second alpha rhythm of the human brain. Variations in climate, rainfall, temperature, and light have been claimed to be correlated with many longer periods. Among the periods, and perhaps the best known, are the 11- and 22-year sunspot cycles, the 18.6-year period of lunar "wobble" (nutation), and the 26,000-year precession of the earth's rotational axis. Beyond the solar system are the fluctuating galactic fields. Probably the longest physical period that has been suggested is the approximately 250,000,000-year period of rotation of the galaxy, which some believe to be correlated with terrestrial glacial periods. All these periods are accompanied by subtle alterations in the gravitational and electromagnetic fields of the terrestrial environment and so influence all living things.

Numerous several- to many-year biological periodicities involving a wide variety of phenomena have been described. Perhaps most familiar are the three–four-year cycles of lemming migrations and the eight–ten-year cycles in abundance of the Canadian lynx, varying hare, and ruffed grouse. Still other biological periodicities described from tree rings, shell deposition in mollusks, fossil depositions, business, and wars have been claimed. Very commonly reported are cycles of about 9, 11, 18, and 22 years. Although it seems plausible that such geophysically correlated biological periodicities are real, their long-period durations, together with their cycle irregularities, tend to make difficult the critical establishment of their exact lengths or causal associations with environment periodicities.

THE BIOLOGICAL CLOCK

Natural time. Many organisms, man included, when removed from their natural surroundings and placed in a laboratory under constant conditions, can often repeat a rhythmic pattern that they had experienced before such isolation. It is concluded from such behaviour that the organism can time the length of the natural day and even determine the points and measure durations of relatively detailed periods within a single day. This timing capacity is essentially uninfluenced by temperature changes and all ordinary drugs and chemicals. Every living system studied behaves as if it contains a highly dependable clock. The specialized properties of this clock suggest that it involves some unique biological mechanism indissociable from life itself; however, the clock can be investigated only indirectly, through observing the more conventional biochemical, physiological, and behavioural processes timed by it.

Biological clocks that time the solar day, the period of the earth's rotation relative to the sun, have been the most extensively studied. Except possibly for the bacteria, the same kind of clock exists in members of every major group of living creatures. Single-celled animals and plants appear to possess just as accurate and effective clocks as do the most highly differentiated multicellular organisms.

A number of general properties of the clock-timed solar-day rhythms have been discovered. One such property is that under constant conditions in the laboratory the rhythms usually change slightly, becoming instead a little longer or shorter than 24 hours. This commonly observed deviation from the 24-hour period under these conditions led to the concept of circadian (about a day) rhythms. (The explanation for such variance is discussed below.) In day-active (diurnal) vertebrates circadian rhythms, in constant light and temperature, are typically shorter than 24 hours, while in night-active (nocturnal) ones they are typically longer. The periods of circadian rhythms under these conditions rarely exceed the range of 20 to 28 hours and usually are within an hour or so of 24 hours.

The basic circadian rhythm

When an organism is returned to its normal 24-hour light–dark environment, it soon resumes an accurate solar-day rhythm. The transitions from light to darkness and darkness to light appear to be the signals for readjusting the organism's daily physiological cycles. A nocturnal mammal, for example, adjusts its time of activity to the time of darkness, a diurnal songbird to the time of daylight. Such resetting or phase-adjusting factors for the rhythms are termed daily clues, phase setters, or synchronizers.

Involved in adjusting an organism's daily activity pattern to the appropriate time of day is a rhythmic variation in the influence of the light as a resetting factor. This variation has been termed a response curve. A light change near the time of the beginning of an organism's activity pattern advances slightly the phases of the cycle to an earlier time of day; a comparable light change near the end, on the other hand, extends it. At other times during the cycle comparable light changes have little or no phase-shifting influence. Although response curves appear to possess the same general form regardless of the kind of organism, each individual possesses its own detailed form of response curve, which adjusts its activity pattern to the light–dark cycles in its own characteristic manner.

Whereas light appears to be the dominant phase setter in adjusting clock-timed rhythms to natural 24-hour cycles,

temperature is also effective. Many organisms are able to adjust their activity patterns to 24-hour rhythms in temperature in the absence of light variations. Still other phase setters have been reported, including sound, feeding time, and social interactions.

Modifiable clock-timed rhythms. The circadian rhythms that continue under experimental conditions of constant light and temperature are termed free running; they reflect the underlying natural rhythms of an organism. The free-running period can usually be altered, but only very slightly, by changing the intensity of the illumination or the temperature. A 10° C temperature increase seldom changes a circadian period more than 10 percent, and in most organisms the period is shortened. For fiddler crabs in constant darkness the free-running period, of exactly 24 hours, remains unchanged over a 20° C range. In contrast to these relatively resistant rhythms, the rates for ordinary biochemical or physiological processes typically double or triple for each 10° C rise in temperature. Free-running rhythms sometimes cease spontaneously, only to resume at a later time as if the rhythms had been continuing undetected during the intervening time. In other words, a clock-timed phenomenon within the organism may become uncoupled from the underlying clock. Circadian rhythms sometimes fade out over the course of a few cycles under constant conditions; in other cases they appear to continue indefinitely, sometimes even with increasing amplitude and sharpness.

Free running rhythms

Although chemical inhibitors or stimulants of general metabolic processes can influence rhythmic processes, they appear not to affect the underlying clock in any way. Some powerful metabolic inhibitors such as cyanide will eliminate all overt rhythmic variation in an organism, but upon removal of the inhibitor, the rhythm returns as if it had been uninterrupted. On the other hand, exposure to near-freezing temperatures inhibits rhythmic changes in such organisms as fiddler crabs and cockroaches; but when the temperature is elevated again, the restored rhythms have been phase shifted by the approximate duration of the time of chilling.

There appears to be a genetic component to circadian organization. Organisms reared from eggs in constant light and temperature may display circadian rhythms spontaneously or may be induced to do so by a single abrupt light or temperature change, a signal that itself conveys no information as to period length. Furthermore, bean plants selected and interbred for longer and for shorter circadian periods under a given set of constant environmental conditions will beget offspring with, respectively, longer and shorter circadian periods under these same experimental conditions. The length of the free-running period is clearly genetically determined in part.

The influence of heavy water, which is D_2O, on circadian rhythms is of particular interest. Treatment of organisms as different as algae and mice results in a lengthening of the free-running periods. Under a 24-hour, light–dark regime, heavy water appears to alter the phase relations of the activity patterns of organisms to the light cycles.

Clock-timed circadian rhythms have been observed during rapid geographic translocations of organisms eastward or westward by airplane to other time belts. Investigations of this type, performed with fiddler crabs and honeybees, confirmed that the organisms carry circadian rhythms still adjusted to the light cycles of their former location (Figure 2). To reset them to the new local time requires several days of exposure to the local phase setters. This phenomenon is quite familiar to persons who have travelled long distances rapidly by jet airplane. The resultant rhythmic dislocation and the need for gradual adjustment over two to ten days at the end of such a trip is often referred to as the "jet syndrome."

Time dislocation: The "jet syndrome"

It is well-known that among the innumerable periodic changes that underlie and support the overt rhythms of behaviour of organisms; the peak values occur in a characteristic sequence over the day. A description of these comprises what is called a phase map. Such a sequence and spacing reflects the order and temporal relationships of cause–effect in the normal interactions of the various

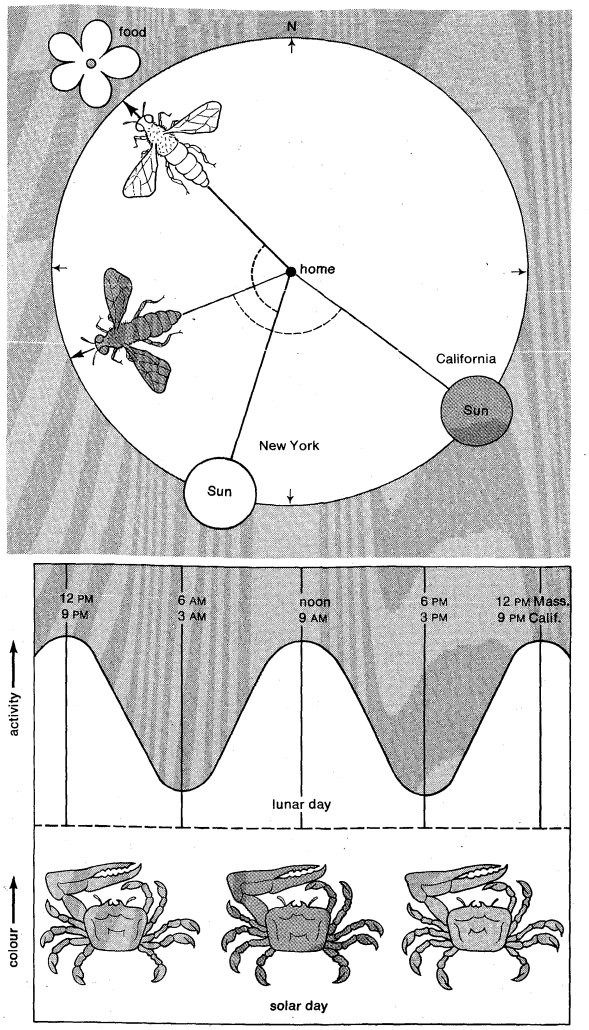

Figure 2: *The persistence of natural rhythms.*
(Above) Bees trained in New York to fly northwest to a feeding station at 1 PM fly southwest at 10 AM when transported to California, following the sun's position as learned in New York. (Below) Fiddler crabs, moved from Massachusetts to California and kept in unvarying illumination, show activity, rhythms, and colour changes identical to their East Coast counterparts, regardless of the local time.

bodily processes. Phase maps may undergo transitory disruptions when an organism is compelled to make a rapid phase adjustment as, for example, after a rapid move to a new geographic longitude. Under such circumstances the various individual 24-hour components comprising the circadian phase map do not reset their phases to the new environmental times at the same rate. They may become somewhat displaced in their relations to one another. This dissociation of rhythmic components is probably the major cause of the fatigue and the lowered efficiency that characterizes the jet syndrome in human beings.

Another remarkable property of free-running rhythms is their capacity sometimes to maintain well beyond chance, and for extended periods, precise 24-hour periods and, in some cases, even to set their active period to their normal time of day without any obvious daily clues. The former has been described for fiddler crabs, gila monsters, mice, and kangaroo rats. The latter capacity has been observed in chicks and some lizards. These animals are apparently able to set their newly developed behavioral system to times of outside day and night by the use of subtle and as yet not fully identified signals.

The biological clock also times other natural environmental periods. Many plants and animals whose activities vary rhythmically with the tides have been found, when taken into the laboratory, to continue rather accurately their tidal rhythms. The period of these rhythms is about

12 hours 25 minutes, or 24 hours 50 minutes for the double-cycle, which is called a lunar day. The period of the tidal changes is correlated with the rotation of the earth relative to the moon. The tide, as does the moon, rises on the average of 50 minutes later each day.

The properties of the tidal, clock-timed rhythms differ in significant ways from the circadian ones. Although they possess the same high degree of temperature and drug independence of their period lengths, they will not synchronize to a 24-hour light–dark environment. Instead, tidal rhythms continue to move over the day at the tidal rate. This failure to follow the light cycles is obviously adaptive, since in nature the phase relationship of the tides to time of day systematically changes.

The clock-timed tidal rhythm can be adaptively adjusted to the tidal schedule of a specific beach. Fiddler crabs transported to a foreign beach with different tidal times gradually, over a few days, reset their tidal rhythms accordingly. The phase-resetting clues for the tidal rhythms remain unknown, though a number of factors such as mechanical wave action and periodic drying have been suggested.

Drifting of tidal rhythms

Clock-timed tidal rhythms commonly exhibit a tendency, under constant conditions of the laboratory, to drift away from their tidal setting until they approximate the actual time of lunar day. Oysters and fiddler crabs taken from their home beaches and kept in the laboratory gradually, during a week or so, reset their tidal rhythms to display their maximum activity at the times of the upper and lower transits of the moon, as if some subtile synchronizers associated with the lunar tides of the atmosphere were now replacing the unknown local tidal ones.

There are clocked-timed synodic monthly rhythms of 29.5 days, the period from one new moon to the next. This is the period produced by "beats" between the solar days and lunar days—in other words, the interval between the times when the solar day and lunar day begin together. The moon rises close to the same time of day once each synodic month. The organismic clock-timed monthly rhythms in some instances appear to depend upon a comparable interaction between tidal or lunar-day rhythms and solar-day ones. Interactions between 12.4-hour tidal rhythms and 24-hour circadian rhythms would yield semimonthly "beats," and between 24.8 hour double tidal cycles and 24-hour ones monthly "beats." Evidence for such clock-timed rhythms is seen in the occurrence of semimonthly colour changes in crabs kept under constant conditions. These exhibit phase differences among populations in their semimonthly rhythms accountable in terms of the differing phase relationships between their local tides and time of day.

The clock that times monthly rhythms appears to be just as dependable as those timing circadian and tidal rhythms. Monthly rhythms can, comparably, be phase shifted relative to the actual moon phases. In addition to the phase setting by changes in some factors associated with local tidal movement, moonlight variations through the month have been suggested as a phase-setting factor for semimonthly and monthly rhythms, particularly the breeding rhythms of sea worms and the menstrual cycle for Primates, including women.

Clock-timed annual rhythms, persisting in unvarying regimes of illumination and temperature and every other obvious clue as to the yearly period, have been reported for widely different kinds of organisms and phenomena. An alga, on the one hand, and the laboratory rat, on the other, have displayed annual variations in enzymatic activities. Seeds show annual variations in capacity to sprout, and newly germinated seedlings exhibit annual variations in their metabolic rate. Some birds show rather precise annual, and others *circa*-annual, reproductive cycles. Food intake of woodchucks has been reported to vary systematically with time of year. As for the other periods, the clock that times annual rhythms appears to be independent of temperature and uninfluenced by all attempts to alter its period chemically. The normal patterns of annual variation of many plants and animals can, however, be altered in response to changes in relative lengths of light and darkness (photoperiodism), much in the manner analogous to the phase resetting of the clock-timed circadian rhythm by times of light onset and termination. On the other hand, annual rhythms such as that of woodchuck food intake appear to be unalterable in phase by manipulation of either temperature or light.

Persistent clock-timed rhythms. There is another class of periodicities in organisms, rhythms that persist under the most carefully controlled laboratory conditions but that possess properties different from those described in the preceding account. These have precise solar-day, lunar-day, monthly, and annual periods. These have been discovered for respiratory or activity rates in a wide variety of animals and plants. The activity of an organism, other factors equal, varies systematically with local time of day, time of lunar day, time of month, and time of year. The potato, for example, shows a clear-cut sidereal-day (23-hour 56-minute period of rotation of the earth relative to the stars) variation in its metabolic processes. These periodisms can not be reset or phase shifted. Moreover, there is no evidence to suggest that they are adaptive. The range of their variations is least for the sidereal day and most for the annual period.

Fluctuating activity. Aperiodic, hour-by-hour fluctuations in metabolic rate or activity of organisms under presumably constant conditions continue to show correlations with weather changes, indicating beyond reasonable doubt that changing physical factors somehow continue to reach and influence the organisms, even in their experimental isolation. How do these external factors pervade the controlled environments of the laboratory? The answer perhaps may be found in a very highly specialized sensitivity of organisms to weak geoelectromagnetic fields that pervade the universe. Aperiodic biological fluctuations do coincide with fluctuations in such factors as background radiation, terrestrial magnetism, and primary cosmic radiation.

Influence of magnetism and radiation

The exogenous derivation (external to the organism) of these variations is indicated by the universality of response: the rhythmic patterns of these geophysically dependent fluctuations tend to show, among organisms spanning the gamut of kinds of living creatures, either the same general form or mirror images of parts or the whole of them, suggesting that all the organisms are responding to the same specific geophysical changes and that they have freedom only to determine the sign, positive or negative, of their responses to them.

The nature of the biological clock. As more information becomes available, it seems clearer that there are two kinds of rhythms, one resulting from response to the subtle geophysical environment, the other being rhythmic organismic responses to more obvious changes.

The timer for the first of these kinds of rhythms obviously lies outside the organism, and hence these rhythms are termed geophysically dependent. The detailed character of the biological cyclic pattern, however, is just as obviously determined by the nature of the biological response. The widespread general uniformity of the pattern for all organisms suggests that the response is generated at a very fundamental level of cellular organization. It must still depend upon the organism as an organized continuum whose composition and reactivity at any given point in time are related to past and future. The organism is, therefore, not a fully passive system in the generation of its exogenous metabolic periodisms. It may be an effective stimulus-filtering system.

The clock that times the overt, adaptive circadian, tidal, monthly, and annual rhythms is far less evident. Two kinds of hypotheses have been advanced. One, the internal-timer hypothesis, is that living systems can oscillate, fully independent of all environmental periodisms with close to, but not exactly, all major geophysical frequencies. Free-running rhythms are assumed to reflect directly the periods of the somewhat inaccurate internal clocks. Exact organismic solar-day, tidal, monthly, and annual periods are assumed to depend upon continuing corrections of the poorly accurate clocks by the environmental light, temperature, and tidal rhythms. The rates at which the clocks run are believed to be speeded or slowed to a small degree by changed levels of temperature and illumi-

The internal-timer hypothesis

nation as well as by certain chemical factors. The clock periods are assumed to be inherited, the approximation to the geophysical periods having resulted from natural selection.

By describing the rhythms as oscillations resembling in properties those of physical systems that become entrained or synchronized to other slightly different imposed frequencies and treating them mathematically as such, surprisingly satisfactory descriptions of the observed dynamics of biological rhythms and phase setting of the rhythms can be obtained, useful predictions made, and new experiments suggested. Despite intensive research, progress has not yet been made in elucidating an internal oscillator system with the clock properties. The problem is compounded by the inability to differentiate between a biochemical or biophysical reaction that is in reality a clock element and one that is merely timed by the clock.

The external-timer hypothesis

Another hypothesis is that living things have evolved the capacity to use the subtle rhythmic input of geophysical periods to time their own processes to the most adaptive rhythmic patterns. In terms of this hypothesis the clocks are not inaccurate but quite precise (24-hour, 24.8-hour, 29.5-day, and 365¼-day clocks, for example). As long as the organism remains in its natural rhythmic environment, the clocks and the environmental rhythms of light, temperature, and tides have the same frequencies. When, however, the organism is placed under constant conditions, its circadian rhythm gradually drifts off phase. There will be phase advances alternating with phase delays in a cyclic manner as the constant light and temperature react at different points along the response curve. The recurring patterns will gradually shift to earlier hours if the advancing response is stronger than the delaying one or shift toward later hours if the delaying one is the stronger. This corresponds well with the observation that circadian periods deviate slightly in practice from 24 hours.

The self-setting to specific clock hour of solar day or lunar day or time of month or of year sometimes observed in constant conditions, as well as the very existence of the geophysically dependent periodisms, would find consistent explanation. The accuracy of the clocks during rapid east–west translocations would require either influence of a universal time-varying geophysical factor, phase-synchronized at all longitudes, as, for example, ionospheric charge, or a capacity to rephase its own rhythmic pattern in relation to a rapidly shifted exogenous local-time cycle effected by the metabolic inertia inherent in a continuing functional system.

In brief, some of the properties of biological periodicities definitely require for their explanation that timing information continuously flows inward from the environment, even in what have commonly been deemed constant conditions. Many other phenomena are equally compatible with either hypothesis, internal or external timing. Possibly both kinds of clocks are utilized by organisms. An environmentally dependent clock element may be responsible for the remarkable resistance to timing interference by temperature and chemical agents and for the long-term, relatively precise persistence of daily rhythms and particularly for the stability of the longer period monthly and annual ones. An environmentally independent clock element, on the other hand, may be essential for bridging shorter intervals of time within cycles but with perhaps a precision by itself inadequate to account for the observed regularity and dependability of clock-timed rhythms.

FACTORS AFFECTING BIOLOGICAL PERIODICITIES

The rhythmic patterns of variation of organisms differ from one species to another and also from one individual to another, even in response to essentially the same external conditions. The nervous and endocrine systems in interaction with the parts of the body that are coordinated and integrated by them contribute to these patterns. Under ordinary circumstances, activities comprising the patterns are arranged to meet an organism's demands anticipated over the period. Pathological or otherwise induced alterations in the organism alter the cycle forms. The periods, following those of the physical environment, usually remain unchanged. Reported, however, have been instances in blinded mice of circadian periods becoming free-running ones differing from 24 hours, resembling the state of affairs commonly seen when comparable mice are held in continuous darkness. Light, operating through the eyes, would appear in such instances to be the essential phase-setting agent.

The role played by the animals' total functional complex in determining the cycle form has been illustrated in respiratory patterns of unhatched chick embryos and in the activity of human infants. In conditions of constant temperature and light, chick embryos up to six days old show a daily activity variation with several peaks each day. By the seventh day, when they have just completed the development of a functioning sensory-neuro-motor system, the daily variation changes to one with a broad daytime higher activity and lower nighttime one. Well known, too, is the change in sleep-activity rhythms of infants. Up to about 15 weeks there are several cycles a day, but afterward the cycle simplifies to essentially a single longer period of wakefulness by day and sleep by night. It might be argued that the infant simply adopts the social pattern of the household, but in the chick the change in pattern with time seems clearly genetically determined.

The sleep-activity cycle of infants

It was mentioned earlier that evolution, involving natural selection, has suited species to fit each niche at a particular time within a cycle. In the continuing course of events a species is usually rigorously held to its rhythmic schedule by the competition of other species present at other times. It is an interesting observation, however, that some large day-active game animals in Africa, whose populations had been decimated by hunters, altered their natural patterns to become night active but resumed diurnal habits when their numbers again had increased. It is likely that comparable adaptive phenomena may be more widespread in nature than has been reported.

Man in his cultural evolution has greatly modified his patterns of rhythmic behaviour. The eight-hour occupational period accurately clock timed to particular hours of the day provides its imprint. There is evidence of diverse kinds that an 8-hour work schedule at one time of day is not exactly like that of another time. The efficiency of man varies with a characteristic 24-hour pattern, performance being best from 7 to 11 AM and worst at 3 AM (Figure 3). Other daily rhythmic factors concurrently operate.

From J. Hardy, *Physiological Problems in Space Exploration* (1964); Charles C. Thomas, Publisher

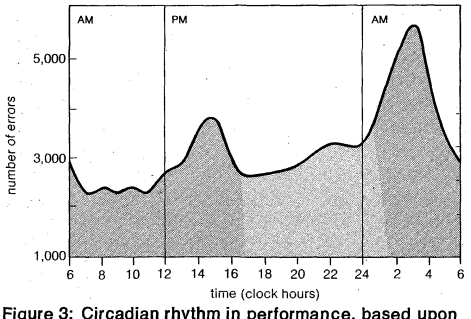

Figure 3: Circadian rhythm in performance, based upon the number of errors made in the routine checking of gas meters at different clock hours.

The week, with its day or two of rest or altered scheduling, obviously imposes a weekly rhythm upon man. It has been suggested that the week is a natural period for him, as also for other organisms as well, perhaps related to quarterly lunar phases.

Man is increasingly modifying his environment, from the conditioning of his living and working quarters through more extensive changes associated with life in submarines, sea labs, and space vehicles. At a fearsome rate, technological man is altering the earth's atmosphere physically and chemically with consequent modification of illumination, temperature, and a host of other periodic parameters. One of the vast areas of concern for man and for all living creatures is what such changes might ultimately do to the periodicities that characterize life on this

planet and whose critical regulatory roles are only beginning to be appreciated.

ASCHOFF (ed.), *Circadian Clocks* (1965), comprise the published proceedings of three broadly oriented international symposia on biological rhythmicity participated in by the leading investigators of the subject. F.A. BROWN, JR., *Biological Clocks* (1962), is a brief, elementary account of the nature of, and problems related to, the phenomena of plant and animal periodicities. More advanced and detailed general accounts of bio-rhythmicity are: E. BUNNING, *The Physiological Clock*, rev. 2nd ed. (1967), particularly good for the earlier literature and classical views; J.L. CLOUDSLEY-THOMPSON, *Rhythmic Activity in Animal Physiology and Behaviour* (1961), best for its treatment of ecological significances; J.E. HARKER, *The Physiology of Diurnal Rhythms* (1964), emphasizing the periodicities associated with day–night; and B.M. SWEENEY, *Rhythmic Phenomena in Plants* (1969). In a class by itself is A. SOLLBERGER, *Biological Rhythm Research* (1965), a comprehensive, well-indexed, and documented reference work containing more than 2,500 literature citations, well-balanced in distribution over the subject. F.A. BROWN, JR., J.W. HASTINGS, and J.D. PALMER, *The Biological Clock: Two Views* (1970), is a succinct presentation of the two currently held alternative hypotheses, internal and external timing of the rhythms, together with the evidence upon which they are based. G.G. LUCE, *Biological Rhythms in Psychiatry and Medicine* (1970), is a readable, informative, extensively documented account of occurrence and significances of daily, lunar, and annual periodicities for man.

(F.A.B.)

Periodic Law

Dmitry I. Mendeleyev discovered in the mid-19th century that the chemical elements show a periodic recurrence of properties when they are arranged in a certain order, which is approximately the order of increasing atomic weight. The statement of this fact, which has been of inestimable value in the development of the science of chemistry, is called the periodic law; a tabular arrangement of the elements that brings those with similar properties into juxtaposition is called the periodic table or periodic system of the elements.

It was recognized during the second decade of the 20th century that the order of elements in the periodic system is that of their atomic numbers, the integers which are equal to the positive electrical charges of the atomic nuclei expressed in electronic units; and in subsequent years great progress was made in explaining the periodic law in terms of the electronic structure of atoms and molecules. This clarification has increased the value of the law, which is used as much today as it was at the beginning of the 20th century, when it expressed the only known relationship among the elements.

History of the periodic law. The classification of the chemical elements is a comparatively recent problem, for it was not until about the beginning of the 19th century that chemists clearly recognized that the chemical elements represent unique, chemically indivisible species, which appear in various combined forms as chemical compounds. The early years of the century witnessed a rapid development in analytical chemistry—the art of distinguishing different chemical substances—and the consequent building up of a vast body of knowledge of the chemical and physical properties of both elements and compounds. This rapid expansion of chemical knowledge soon necessitated classification, for on the classification of chemical knowledge are based not only the systematized literature of chemistry but also the laboratory arts by which chemistry is passed on as a living science from one generation of chemists to another. The elementary substances are few in number (105 now are known and physicists are hopeful that more will be discovered in high-energy experiments), with distinctive properties; whereas compound substances are extremely numerous, with properties correspondingly diversified and often overlapping. Relationships could be discerned more readily among the compounds than among the elements; it thus occurred that the classification of elements lagged many years behind that of compounds. In fact, no general agreement had been reached among chemists as to the classification of elements for nearly half a century after the systems of classification of compounds had become established in general use.

J.W. Döbereiner in 1817 showed that the combining weight, meaning atomic weight, of strontium lies midway between those of calcium and barium; and some years later he showed that other such "triads" exist (chlorine, bromine, and iodine [halogens] and lithium, sodium, and potassium [alkali metals]). J.-B.-A. Dumas, L. Gmelin, E. Lenssen, Max von Pettenkofer, and J.P. Cooke expanded Döbereiner's suggestions between 1827 and 1858 by showing that similar relationships extended further than the triads of elements, fluorine being added to the halogens, and magnesium to the alkaline-earth metals; while oxygen, sulfur, selenium, and tellurium were classed as one family, and nitrogen, phosphorus, arsenic, antimony, and bismuth as another family of elements. Triads of elements

Attempts were made subsequently to show that the atomic weights of the elements could be expressed by an arithmetic function, and in 1862 A.-E.-B. de Chancourtois proposed a classification of the elements based on the new values of atomic weights given by Stanislao Cannizzaro's system of 1858. De Chancourtois plotted the atomic weights on the surface of a cylinder with a circumference of 16 units, corresponding to the approximate atomic weight of oxygen. The resulting helical curve brought closely related elements onto corresponding points above or below one another on the cylinder, and he suggested in consequence that "the properties of the elements are the properties of numbers," a remarkable prediction in the light of modern knowledge.

Several years later, in 1865, J.A.R. Newlands proposed a system of classification of the elements in the order of increasing atomic weights, the elements being assigned ordinal numbers from unity upward and divided into seven groups having properties closely related to the first seven of the elements then known: hydrogen, lithium, beryllium, boron, carbon, nitrogen, and oxygen. This relationship was termed the law of octaves, by analogy with the seven intervals of the musical scale.

Then in 1869, as a result of an extensive correlation of the properties and the atomic weights of the elements, with special attention to valency (that is, the number of single bonds the element can form), Mendeleyev proposed the periodic law, by which "the elements arranged according to the magnitude of atomic weights show a periodic change of properties." Lothar Meyer had independently reached a similar conclusion, published after the appearance of Mendeleyev's paper in a Russian journal and an account of it in German.

Mendeleyev's periodic table of 1869 contained 17 columns, with two nearly complete periods (sequences) of elements, from potassium to bromine and rubidium to iodine (see Figures 2 and 3), preceded by two partial periods of seven elements each (lithium to fluorine and sodium to chlorine), and followed by three incomplete periods. In an 1871 paper Mendeleyev presented a revision of the 17-group table, the principal improvement being the correct repositioning of 17 elements. He, as well as Lothar Meyer, also proposed a table with eight columns obtained by splitting each of the long periods into a period of seven, an eighth group containing the three central elements (such as iron, cobalt, nickel; Mendeleyev also included copper, instead of placing it in Group I), and a second period of seven. The first and second periods of seven were later distinguished by use of the letters "a" and "b" attached to the group symbols, which were the Roman numerals. The first periodic table

With the discovery of the noble gases helium, neon, argon, krypton, radon, and xenon by Lord Rayleigh (John William Strutt) and Sir William Ramsay in 1894 and the following years, Mendeleyev and others proposed that a new "zero" group to accommodate them be added to the periodic table. The "short-period" form of the periodic table, Figure 1, with Groups 0, I, II, . . . VIII, became popular, and remained in general use until about 1930.

Based upon an earlier (1882) model of T. Bayley, J.

Group 0	I		II		III		IV		V		VI		VII		VIII

*Lanthanum and the lanthanons

Figure 1: Short-period form of periodic system of elements.

Thomsen in 1895 devised a new table. This was interpreted in terms of the electronic structure of atoms by Niels Bohr in 1922. In this table, Figure 2, there are periods of increasing length between the noble gases; the table thus contains a period of 2 elements, two periods of 8 elements, two periods of 18 elements, a period of 32 elements, and an incomplete period. The elements in each period may be connected by tie lines with one or more corresponding elements in the following period. The principal disadvantage of this periodic table is the large space required by the period of 32 elements and the difficulty of tracing a sequence of closely similar elements along the slanting tie lines. A very satisfactory compromise, shown in Figure 3, is to compress the period of 32 elements into 18 spaces by omitting the 14 lanthanons (lanthanides) and the 14 actinons (actinides) and listing them in a special double row below the other periods.

Alternate long forms of the periodic table have been proposed from time to time. One of the earliest of these, described by A. Werner in 1905, is notable because it divides each of the shorter periods into two parts, one at either end of the table over the elements in the longer periods that they most resemble. The multiple tie lines connecting the periods in the Bayley-type table are thereby dispensed with. This class of table, too, can be greatly simplified by removing the lanthanon and actinon elements to a separate area. By the mid-20th century this version of the table (Figure 4) had become the most commonly used.

Predictive value of the periodic law

The great value of the periodic law was made evident by Mendeleyev's success in 1871 in finding that the properties of 17 elements could be correlated with those of other elements by moving the 17 to new positions from those indicated by their atomic weights. This change indicated that there were small errors in the previously accepted atomic weights of several of the elements and large errors for several others, for which wrong multiples of the combining weights had been used as atomic weights (the combining weight being that weight of an element that combines with a given weight of a standard). Mendeleyev was also able to predict the existence, and many of the properties, of the then undiscovered elements ekaboron, ekaaluminum, and ekasilicon, now identified with the elements scandium, gallium, and germanium, respectively. Similarly, after the discovery of helium and argon, the periodic law permitted the prediction of the existence of neon, krypton, xenon, and radon. Moreover, Bohr pointed out that the missing element 72 would be expected, from its position in the periodic system, to be similar to zirconium in its properties rather than to the rare earths; this observation led G. de Hevesy and D. Coster in 1922 to examine zirconium ores and to discover the unknown element, which they named hafnium.

In spite of the corrections made by the redetermination of atomic weights, some of the elements in the Mendeleyev and Lothar Meyer periodic tables of 1871 were still required by their properties to be put in positions somewhat out of the order of atomic weights. Thus, with three pairs of elements—argon and potassium, cobalt and nickel, and tellurium and iodine—the first element of each pair has the greater atomic weight but the earlier position in the periodic system. The eventual solution to this difficulty was found only when the structure of the atom was better understood.

About 1910, Sir Ernest Rutherford's experiments on the scattering of alpha particles by the nuclei of heavy atoms led to the determination of the nuclear electrical charge. The ratio of the nuclear charge to that of the electron was noted to be roughly one-half the atomic weight. In 1911 A. van den Broek suggested that this quantity, the atomic number, might be identified with the ordinal number of the element in the periodic system (following the lead of Newlands, it had become customary to number the elements according to their position in the table). This suggestion was brilliantly confirmed in 1913 by H.G.J. Moseley's measurements of the wavelengths of the characteristic X-ray spectral lines of many elements, which showed that the wavelengths did indeed depend in a regular way upon the atomic numbers—identical with the ordinal numbers of the elements in the table. There is no longer any uncertainty about the position of any element in the ordered series of the periodic system. All of the elements from 1 to 105 are now known, and it is to be expected that new elements beyond 105 will be made by nuclear reactions.

That the exact atomic weight of an element is of small significance with regard to its position in the periodic system is shown by the existence of isotopes of every element, atoms with the same atomic number but with different atomic weights. The chemical properties of the different isotopes of an element are essentially the same, and all of the isotopes of an element occupy the same place in the periodic system in spite of their differences in atomic weight.

Detailed understanding of the periodic system has developed along with the quantum theory of spectra and the electronic structure of atoms, beginning with the work of Bohr in 1913. Important forward steps were the formulation of the general rules of the old quantum theory by W. Wilson and A. Sommerfeld in 1916, the discovery of the exclusion principle by W. Pauli, in 1925 (see ATOMIC STRUCTURE), the discovery of the spin of the electron by G.E. Uhlenbeck and S. Goudsmit in 1925 (see ELECTRON), and the development of quantum mechanics (see MECHANICS, QUANTUM) by W. Heisenberg and E. Schrödinger during the same year. The development of the electronic theory of valence and molecular structure (see MOLECULAR STRUCTURE), beginning with the postulate of the shared electron pair by G.N. Lewis in 1916, also played a very important part in explaining the peri-

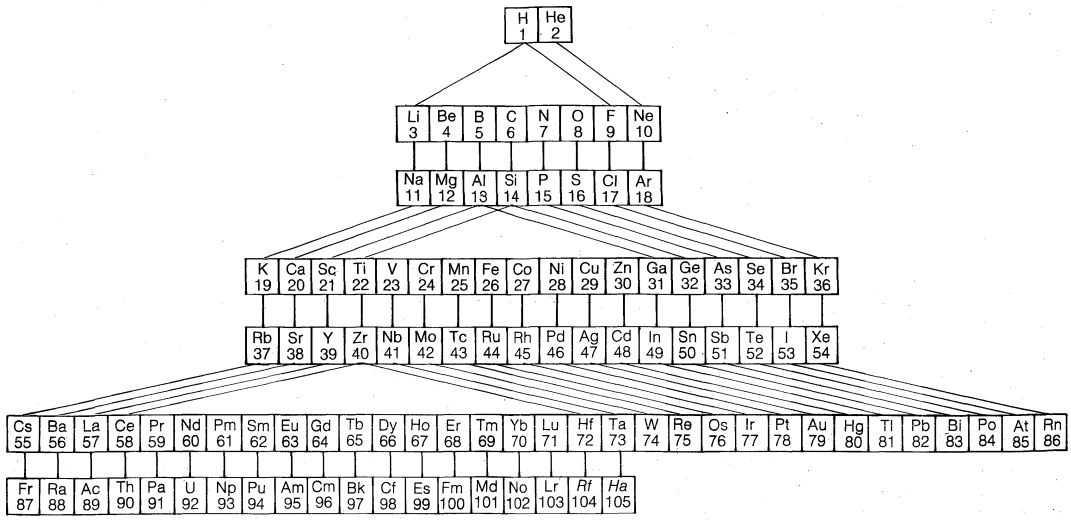

Figure 2: Periodic system of elements with periods demarcated by noble gases.

odic law (see CHEMICAL BONDING; and CHEMICAL REACTION, MECHANISMS OF).

The long form of the periodic table. The long-period form of the periodic system of the elements, presented here in two forms, Figures 3 and 4, contains all of the chemical elements that have been discovered or made; they are arranged, in the order of their atomic numbers, in seven horizontal periods, with the lanthanons (lanthanum, 57, to lutetium, 71) and the actinons (actinium, 89, to lawrencium, 103) indicated separately below (unless otherwise stated, Figure 3 will be used as reference). The periods are of varying lengths. First there is the hydrogen period, consisting of the two elements hydrogen, 1, and helium, 2. Then there are two periods of eight elements each: the first short period, from lithium, 3, to neon, 10; and the second short period, from sodium, 11, to argon, 18. There follow two periods of 18 elements each: the first long period, from potassium 19, to krypton, 36; and the second long period, from rubidium, 37, to xenon, 54. The very long period of 32 elements, from cesium, 55, to radon, 86, is condensed into 18 columns by the omission of the lanthanons (which are indicated separately below), permitting the remaining 18 elements, which are closely similar in their properties to corresponding elements of the first and second long periods, to be placed directly below these elements. The last period is incomplete. The properties of these elements indicate that this period is a second very long period of 32 elements, which would be completed at element 118.

Periods

The six noble gases, helium, neon, argon, krypton, xenon, and radon, occur at the ends of the six completed periods and constitute the 0 group of the periodic system. (It is customary to refer to horizontal series of elements in the table as periods and vertical series as groups.) The seven elements lithium to fluorine and the seven corresponding elements sodium to chlorine are placed, in Figure 3, in the seven groups, I, II, III, IV, V, VI, and VII, respectively. The 17 elements of the fourth period, from potassium, 19, to bromine, 35, are distinct in their properties and might well be considered to constitute 17 subgroups of the periodic system. Largely for historical reasons (the use of the short-period form of the periodic system,

Figure 3: Long-period form of periodic system of elements.

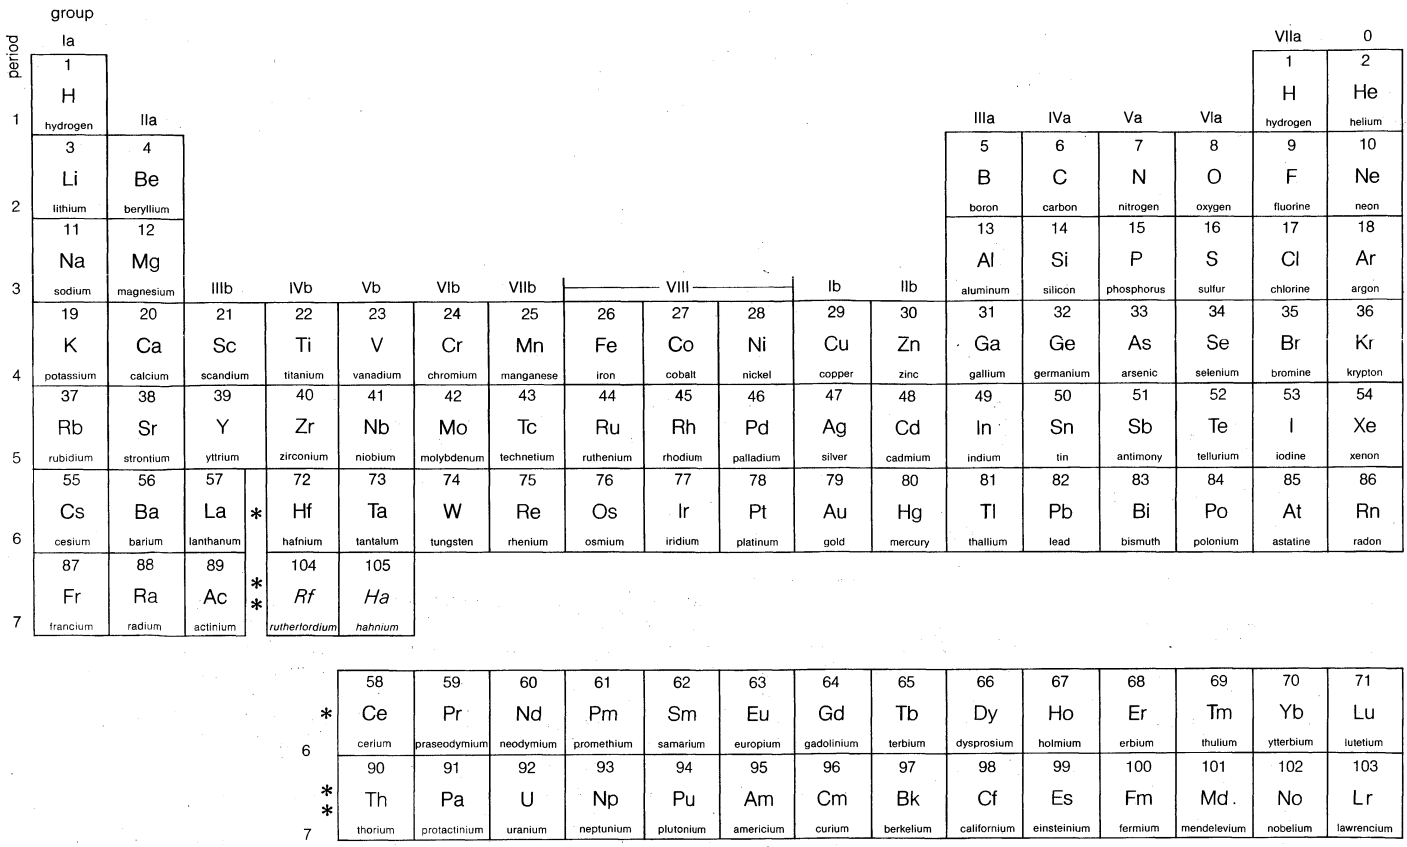

Figure 4: A modern version of the periodic table of elements.

Figure 1), however, it is customary to describe them as constituting 15 subgroups, the three consecutive elements iron, cobalt, and nickel and their congeners in the succeeding periods being placed in a single group, VIII. The elements potassium, 19, to manganese, 25, are assigned to subgroups Ia, IIa, IIIa, IVa, Va, VIa, and VIIa, respectively; and the elements copper, 29, to bromine, 35, are assigned to subgroups Ib, IIb, IIIb, IVb, Vb, VIb, and VIIb. (In some modern versions of the periodic system, the members of subgroups a and b in Groups III and above are the reverse of the arrangement shown here. There is no one standard form of the system.)

The first group, the alkali metals, thereby includes, in addition to lithium and sodium, the metals from potassium down the table to francium, but not the much less similar metals of subgroup Ib (copper, etc.). Also the second group, the alkaline-earth metals, is considered to include beryllium, magnesium, calcium, strontium, barium, and radium but not the elements of subgroup IIb. The properties of the elements do not indicate unambiguously whether the boron group might be considered better to include the subgroup IIIa or the subgroup IIIb, although the former is often so included. The other four groups are as follows: the carbon group, IV, consists of carbon, silicon, germanium, tin, and lead; the nitrogen group, V, includes nitrogen, phosphorus, arsenic, antimony, and bismuth; the oxygen group, VI, includes oxygen, sulfur, selenium, tellurium, and polonium; and the halogen group, VII, includes fluorine, chlorine, bromine, iodine, and astatine.

Although hydrogen is included in Group I in some version of the table, it is not closely similar to either the alkali metals or the halogens in its chemical properties. It is, however, assigned the oxidation number $+1$ in compounds such as hydrogen fluoride, HF, and -1 in compounds such as lithium hydride, LiH; and it may hence be considered as being similar to a Group Ia element and to a Group VII element, respectively, in compounds of these two types, taking the place first of Li and then of F in lithium fluoride, LiF. Hydrogen is, in fact, the most individualistic of the elements: no other element resembles it in the way that sodium resembles lithium, chlorine resembles fluorine, and neon resembles helium. It is a unique element, the only element that cannot conveniently be considered a member of a group.

A number of the elements of each long period are called the transition metals. These are usually taken to be scandium, 21, to zinc, 30 (the iron-group transition metals); yttrium, 39, to cadmium, 48 (the palladium-group transition metals); and hafnium, 72, to mercury, 80 (the platinum-group transition metals). By this definition, the transition metals include Groups IIIa to VIIa, VIII, and Ib and IIb (Figure 3) in the long periods.

Periodic properties

The periodicity in properties of the elements arranged in order of atomic number is strikingly shown by the consideration of the physical state of the elementary substances and such related properties as the melting point, density, and hardness. The elements of Group 0 are gases that are difficult to condense. The alkali metals, in Group I, are soft, metallic solids with low melting points. The alkaline-earth metals, in Group II, are harder and have higher melting points than the adjacent alkali metals. The hardness and melting point continue to increase through Groups III and IV and then decrease through Groups V, VI, and VII. The elements of the long periods show a gradual increase in hardness and melting point from the beginning alkali metals to near the centre of the period and then at Group VIb an irregular decrease to the halogens and noble gases.

The valence of the elements (that is, the number of bonds formed with a standard element) is closely correlated with position in the periodic table, the elements in the main groups (the "a" groups, as opposed to the transition elements or "b" groups) having maximum positive valence, or oxidation number, equal to the group number, and maximum negative valence equal to the difference between eight and the group number.

The general chemical properties described as metallic or base forming, metalloid or amphoteric, and nonmetallic, or acid forming, are correlated with the periodic table in a simple way: the most metallic elements are to the left and to the bottom of the periodic table, and the most nonme-

tallic elements are to the right and to the top (ignoring the noble gases). The metalloids are adjacent to a diagonal line from boron to polonium. A closely related property is electronegativity, the tendency of atoms to retain their electrons and to attract additional electrons. The degree of electronegativity of an element is shown by ionization potential, electron affinity, oxidation-reduction potential, the energy of formation of chemical bonds, and other properties. It is shown to depend upon the element's position in the periodic table in the same way that nonmetallic character does, fluorine being the most electronegative element and cesium (or francium) the least electronegative (most electropositive) element.

Atomic sizes

The sizes of atoms of elements vary regularly throughout the periodic system. Thus, the effective bonding radius (or one-half the distance between adjacent atoms) in the elementary substances in their crystalline or molecular forms decreases through the first short period from 1.52 angstrom (angstrom unit = 10^{-8} cm) for lithium to 0.73 angstrom for fluorine; at the beginning of the second period, the bonding radius rises abruptly to 1.86 angstrom for sodium and gradually decreases to 0.99 angstrom for chlorine. The behaviour through the long periods is more complex: the bonding radius decreases gradually from 2.31 angstrom for potassium to a minimum of 1.25 angstrom for cobalt and nickel, then rises slightly, and finally falls to 1.14 angstrom for bromine. The sizes of atoms are of importance in the determination of coordination number (that is, the number of groups attached to the central atom in a compound) and hence in the composition of compounds. The increase in atomic size from the upper right corner of the periodic table to the lower left corner is reflected in the formulas of the oxygen acids of the elements in their highest states of oxidation, as shown in the Table.

Formulas of Oxygen Acids of Elements in Their Highest Oxidation State

$H_2Be(OH)_4$	H_3BO_3	H_2CO_3	HNO_3		
	$HAl(OH)_4$	H_4SiO_4	H_3PO_4	H_2SO_4	$HClO_4$
		H_4GeO_4	H_3AsO_4	H_2SeO_4	
		$H_2Sn(OH)_6$	$HSb(OH)_6$	H_6TeO_6	HIO_4
				and	and
				H_2TeO_4	H_5IO_6

The smallest atoms group only three oxygen atoms about themselves; the next larger atoms, which coordinate a tetrahedron of four oxygen atoms, are in a diagonal belt; and the still larger atoms, which form octahedral oxygen complexes (stannic acid, antimonic acid, telluric acid, paraperiodic acid), lie below and to the left of this belt. Only the chemical and physical properties of the elements are determined by the extranuclear electronic structure; these properties show the periodicity described in the periodic law. The properties of the atomic nuclei themselves, such as the magnitude of the packing fraction and the power of entering into nuclear reactions, are, although dependent upon the atomic number, not dependent in the same periodic way.

The electronic structure of atoms as the basis of the periodic system. The noble gases, helium, neon, argon, krypton, xenon, and radon, have the striking chemical property of forming few chemical compounds. This property would depend upon their possessing especially stable electronic structures (that is, structures so firmly knit that they would not yield to accommodate ordinary chemical bonds). During the development of modern atomic physics and the theory of quantum mechanics (*q.v.*), a precise and detailed understanding was obtained of the electronic structure of the noble gases and other atoms that explains the periodic law in a thoroughly satisfactory manner.

Quantum numbers

The Pauli exclusion principle states that no more than two electrons can occupy the same orbit—or, in quantum-mechanical language, orbital—in an atom and that two electrons in the same orbital must be paired (that is, must have their spins opposed). The orbitals in an atom may be described by a principal quantum number, n, which may assume the values 1, 2, 3, . . . , and by an azimuthal quantum number, l, which may assume the values 0, 1, 2, . . . , $n - 1$. There are $2l + 1$ distinct orbitals for each set of values of n and l. The most stable orbitals, which bring the electron closest to the nucleus, are those with the smallest values of n and l. The electrons that occupy the orbital with $n = 1$ (and $l = 0$) are said to be in the K shell of electrons; the L, M, N, . . . shells correspond respectively to $n = 2, 3, 4, \ldots$. Each shell except the K shell is divided into subshells corresponding to the values 0, 1, 2, 3, . . . of the orbital quantum number l; these subshells are called the s, p, d, f, . . . subshells, and they can accommodate a maximum of 2, 6, 10, 14, . . . electrons. (There is no special significance to the letter designations of the quantum numbers or of the shells and subshells.)

The approximate order of stability of the successive subshells in an atom is indicated in the Table below. The number of electrons in the atoms of the elements increases with increasing atomic weight, and the added electrons go, of necessity, into successively less stable shells. The most stable shell, the K shell, is completed with helium, which has two electrons. The L shell is then completely filled at neon, with atomic number 10. The atoms of the heavier noble gases do not, however, have a completed outer shell but instead have s and p subshells only. The outer shell of eight electrons is called traditionally an octet. The d subshells and f subshells subsequently are also filled with electrons after the initially less stable orbitals are occupied, an inversion of stability having occurred with increasing atomic number.

The electron occupancy of the shells in the noble gas atoms is as follows:

Electrons in		*K*	*L*	*M*	*N*	*O*	*P*	*Q*	shell
He	2:	2							
Ne	10:	2	8						
Ar	18:	2	8	8					
Kr	36:	2	8	18	8				
Xe	54:	2	8	18	18	8			
Rn	86:	2	8	18	32	18	8		
	118:	2	8	18	32	32	18	8	

The numbers 2, 8, 18, and 32 correspond to filling the s; s and p; s, p, and d; and s, p, d, and f subshells, respectively.

Periods and electron shells

The first period of the periodic table is complete at helium, when the K shell is filled with two electrons. The first and second short periods represent the filling of the $2s$ and $2p$ subshells (completing the L shell at neon) and the $3s$ and $3p$ subshells (at argon), leaving the M shell incomplete. The first long period begins with the introduction of electrons into the $4s$ orbital. Then, at scandium, the five $3d$ orbitals of the inner M shell begin to be occupied. It is the successive occupancy of these five $3d$ orbitals by their complement of ten electrons that characterizes the ten elements of the iron-group transition series. At krypton the M shell is complete and there is an octet in the N shell. The second long period, of 18 elements, similarly represents the completion of an outer octet and the next inner subshell of $10d$ electrons.

The very long period of 32 elements results from the completion of the $4f$ subshell of 14 electrons, the $5d$ subshell of 10 electrons, and the $6s$, $6p$ octet. The filling of the $4f$ orbitals corresponds to the sequence of 14 lanthanons, and that of the $5d$ orbitals to the 10 platinum-group transition metals.

The next period, which is incomplete, involves the $5f$ subshell of 14 electrons, the $6d$ subshell of 10 electrons, and the $7s$, $7p$ octet. The filling of the $5f$ orbitals corresponds to the actinons, the elements beginning with thorium, 90.

The successive periods of the system hence correspond to the introduction of electrons into the following orbitals:

The very short period, H, He.	2 elements. $1s$.
The first short period, Li to Ne.	8 elements. $2s$, $2p$.
The second short period, Na to Ar.	8 elements. $3s$, $3p$.
The first long period, K to Kr.	18 elements. $3d$, $4s$, $4p$.
The second long period, Rb to Xe.	18 elements. $4d$, $5s$, $5p$.
The very long period, Cs to Rn.	32 elements. $4f$, $5d$, $6s$, $6p$.
The incomplete period, Fr to 118.	32 elements. $5f$, $6d$, $7s$, $7p$.

There are advantages to replacing the K, L, M, . . . shells by a different grouping of the subshells, in which those with nearly the same energy are grouped together, in close correlation with the periodic system. The new set of shells is the following:

The helium shell.	2 electrons. $1s$.
The neon shell.	8 electrons. $2s$, $2p$.
The argon shell.	8 electrons. $3s$, $3p$.
The krypton shell.	18 electrons. $4s$, $4p$, $3d$.
The xenon shell.	18 electrons. $5s$, $5p$, $4d$.
The radon shell.	32 electrons. $6s$, $6p$, $5d$, $4f$.
The eka-radon shell.	32 electrons. $7s$, $7p$, $6d$, $5f$.

Periodicity in properties of the elements. *The main groups.* The periodicity of properties of the elements is caused by the periodicity in electronic structure. The noble gases are chemically unreactive, or nearly so, because their electronic structures are stable—their atoms hold their quota of electrons strongly, have no affinity for more electrons, and have little tendency to share electrons with other atoms. An element close to a noble gas in the periodic system, on the other hand, is reactive chemically because of the possibility of assuming the stable electronic configuration of the noble gas, by losing one or more electrons to another atom, by gaining one or more electrons from another atom, or by sharing electrons. The alkali metals, in Group I, can assume the noble-gas configuration by losing one electron, which is loosely held in the outermost (valence) shell, to another element with greater electron affinity, thus producing the stable singly charged positive ions. Similarly the alkaline-earth metals can form doubly charged positive ions with the noble-gas electronic configuration by losing the two loosely held electrons of the valence shell; the positive ionic valences of the elements of the first groups are hence equal to the group numbers. The elements just preceding the noble gases can form negative ions with the noble-gas configuration by gaining electrons; the negative ionic valences of these elements are equal to the difference between eight and their group numbers. The covalence (or number of shared electron pairs) of an atom is determined by its electron number and the stable orbitals available to it. An atom such as fluorine, with seven electrons in its outer shell, can combine with a similar atom by sharing a pair of electrons with it; each atom thus achieves the noble-gas configuration by having three unshared pairs and one shared electron pair in its valence shell.

Properties and electronic structure

The properties of elements in the same group of the periodic system are, although similar, not identical. The trend in properties from the lighter to the heavier elements may be attributed to changes in the strength of binding of the outer electrons and especially to the increasing size of the atoms.

The transition elements. The nature of the three transition series can be seen by taking the iron elements as an example, since the other two series are similar to it. In potassium and calcium the valence electrons, outside of the argon shell, occupy the $4s$ orbital. Additional valence electrons, in scandium, titanium, etc., enter not the $4p$ subshell but the $3d$ subshell, which is then completely filled, along with $4s$, in zinc. The elements potassium, calcium, scandium, titanium, vanadium, chromium, and manganese have maximum oxidation numbers that range from one to seven in that order, corresponding to their successive positions following argon. The atoms titanium to manganese are, however, not similar to the corresponding atoms carbon to fluorine or silicon to chlorine in the short periods because they are not directly followed by a noble gas, whose stable structure they might achieve by gaining or sharing electrons. Instead, these atoms have a strong tendency to form bipositive or tripositive ions by losing two or three electrons, the remaining valence electrons occupying the $3d$ orbitals, which for these positive ions are more stable than the $4s$ orbital.

The iron series

The elements copper and zinc, by losing one or two electrons, respectively, can form the ions Cu^+ and Zn^{2+} with completed M shells of electrons. If the $4s$ and $4p$ orbitals were much less stable than the $3d$ orbitals, instead of about equally stable, this electronic configuration would be similar to the neon configuration; and nickel would be a noble gas, copper an alkali metal, and zinc an alkaline-earth metal. The actual, different properties of nickel, copper, and zinc result from their ability to use the $4s$ and $4p$ orbitals in forming chemical bonds. Nevertheless, the effect of the 18-electron-shell configurations (of Cu^+, Ag^+, Au^+) is evident in the normal valences of the elements of subgroups Ib, IIb, IIIb, IVb, which are equal to the group numbers. Some of these elements may also assume other valences, one or two greater (by losing additional electrons, leaving the $3d$ subshell incomplete) or two less (by having the $4s$ orbital occupied by an unshared electron pair).

It is convenient to consider ten of the elements in each long period or very long period to be transition elements, corresponding to the introduction of ten electrons in a d subshell. There is some arbitrariness in the selection of these elements, because the sharp differentiation of s, p, and d subshells for the outer electrons of an atom in a molecule or crystal is not possible; these subshells are precisely defined only for a system with spherical symmetry; *i.e.*, for a system containing only one nucleus.

The lanthanons. The existence of a long series of very closely related elements, the lanthanons, or rare-earth elements, has been clarified by the development of the understanding of the electronic structure of atoms. With increase in the atomic number of the elements, the seven $4f$ orbitals become increasingly stable until at cerium, 58, these orbitals begin to be occupied. In the tripositive gadolinium ion, 64, the $4f$ subshell is half filled, with one electron in each of the seven orbitals; and in the lutetium ion, 71, it is completely filled with its complement of 14 electrons.

The lanthanons thus comprise the 14 metals from cerium to lutetium, with the same electronic structure except for the variation from 1 to 14 in the number of $4f$ electrons. Often lanthanum, with the same electronic structure but with no $4f$ electrons in the terpositive ion, is also included among the lanthanons, increasing their number to 15.

The $4f$ orbitals are deep within the atoms; there is a stable noble-gas shell of eight $5s$ and $5p$ electrons outside them, as well as—in the neutral atoms—two valence electrons in the $6s$ orbital, and perhaps one in a $5d$ orbital. Because the $4f$ orbitals are in an inner shell, the properties of the atom or ion are changed only slightly by changes in the number of electrons that occupy them; hence the lanthanons are closely similar to one another in physical and chemical behaviour and are often called an inner transition series. This similarity is made strikingly evident by the great difficulty of separating these elements from the complex mineral mixtures in which they occur in nature, a circumstance that caused their discovery to be spread over a period of more than a century.

The lanthanons all have +3 as their principal oxidation state, corresponding to the loss of the three valence electrons to more electronegative atoms. Cerium, praseodymium, and terbium also occur in oxidation state +4, and samarium, europium, and ytterbium in oxidation state +2.

The actinons. The only important general question about the periodic system, to which the answer remains doubtful, concerns the nature of the last period. Because thorium is more closely similar to hafnium than to cerium in many of its properties, and uranium is more closely similar to tungsten than to neodymium, it had been thought that the uranium elements constitute the beginning of a transition period similar to the two long periods and involving the occupancy of the $6d$ subshell. G.T. Seaborg, however, pointed out that the properties of the transuranium elements suggest that these elements are members of a second inner transition series of the lanthanon type beginning at thorium and corresponding to a filling of the $5f$ orbitals, as the lanthanons correspond to the filling of the $4f$ orbitals. It is true that uranium is unlike the lanthanons in that the +6 oxidation state is the most stable of its oxidation states (+6, +5, +4, +3), but neptunium, instead of being similar to rhenium, is reported not to have a stable +7 state; instead, neptunium and plutonium are said to have the same oxidation states as uranium but with a general shift in stability toward the lower oxidation states.

Second inner transition series

An answer to this question can be given by the consideration of the stability and nature of the electronic orbitals involved. Although d orbitals contribute to the formation of strong covalent bonds, inner f orbitals are not useful in

this way, as is shown by the small tendency of the lanthanons to form covalent compounds. The fact that uranium does form covalent compounds shows that the *6d* orbitals are stable enough to be used for this purpose; and the stability of the +6 oxidation state shows that the *5f* orbitals of uranium are not sufficiently stable to attract any of the six valence electrons very strongly. Hence the uranium period differs from the immediately preceding period in that the *5f* orbitals are less stable relative to the *6d* orbitals than are the *4f* relative to the *5d* orbitals.

With increase in atomic number, however, the *5f* orbitals increase in stability more rapidly than the *6d* orbitals, and ultimately the *5f* orbitals are filled. It is likely that this process begins at neptunium, and presumably it is completed at element 103, which is similar to lutetium in structure and properties, with probably a greater tendency to the formation of covalent compounds.

The *6d*, *7s*, and *7p* subshells are thus successively occupied, with element 118, eka-radon, as the next noble gas, though probably able to form some chemical compounds. The 14 elements from thorium to lawrencium are called the actinons or actinides.

Thus this great generalization, the periodic law, which first showed its value through Mendeleyev's prediction of the existence and properties of undiscovered elements, is again being put to the same use, the undiscovered elements of present interest being those that have greater atomic number than the known elements. The undiscovered elements are being sought not in nature's minerals but in preparations made by man.

Perissodactyla

The order Perissodactyla is a group of herbivorous mammals characterized by the possession of either one or three hoofed toes on each hindfoot. The name (Greek *perissos*, "odd," and *daktylos*, "finger") was introduced to separate the odd-toed ungulates from the even-toed ones (Artiodactyla), all of which had previously been classified as members of a single group.

GENERAL FEATURES

The Perissodactyla comprise three families of living mammals: six species of horses (Equidae), four species of tapirs (Tapiridae), and five species of rhinoceroses (Rhinocerotidae). These families are remnants of a group that flourished during the Tertiary Period (from 65,000,000 to 2,500,000 years ago), a time when it was much richer in species and in variety of form than at present and played a dominant role in the fauna of the world.

The horses, asses, and zebras are long-legged, running forms with one functional digit in each foot and with high-crowned, molariform (*i.e.*, modified for grinding) cheek teeth. The tapir is a rather rounded, piglike, semi-amphibious forest and woodland animal with a small proboscis (trunklike snout) and a coat of short, bristly hairs. Tapirs have primitive features, such as four hoofed toes in the forefoot and three in the hind, and they have rather simple molar teeth. Rhinoceroses are massive, graviportal (ponderous) creatures with a thick and nearly hairless hide and three digits on each foot. They bear hornlike structures on the head.

The Perissodactyla are of particular scientific interest because their fossil history is so well-known. The evolution of horses from the tiny "dawn horse" (*Hyracotherium*, formerly *Eohippus*) to the present form is a classic sequence, knowledge of which has played an important role in evolutionary thought. The order also provides a notable example of parallel evolution. Following completely different evolutionary paths, both perissodactyls and artiodactyls (*e.g.*, cattle, antelope, swine) independently evolved features such as high-crowned grinding teeth and elongated limbs with a reduced number of digits, in adaptation to a similar running (cursorial), herbivorous mode of life.

Living perissodactyls are of medium or large size. Asses and tapirs, the smallest representatives of the order, attain a length of approximately two to 2.5 metres (6½–eight feet), stand one metre or more at the shoulder, and weigh up to 250 or 300 kilograms (550–650 pounds). The largest forms are the Indian and square-lipped rhinoceroses (*Rhinoceros unicornis* and *Ceratotherium simum*, respectively), which are four to five metres long and measure up to two metres at the shoulder. The maximum weight has not been well established, but a figure of 2,070 kilograms (4,560 pounds) has been recorded. *Baluchitherium*, relative of the rhinoceroses known from the Oligocene, (about 30,000,000 years ago), was the largest known land mammal, standing about 5.5 metres (18 feet) at the shoulder.

Indian and square-lipped rhinoceroses

Ecologically, the Perissodactyla were the dominant large herbivore group during the Tertiary, a position now held by the Artiodactyla. All feed either by grazing (*i.e.*, cropping grasses) or by browsing (taking shoots and leaves from trees and bushes). The Equidae in particular were abundant and important members of the Old World fauna until their numbers were reduced by modern man. Zebras are still numerous and ecologically important in a few parts of Africa. The importance of the domestic horse and the ass in the history of mankind is very great indeed. Both have served extensively as pack, draft, and riding animals. The horse is sometimes eaten by man, and its flesh is widely used as pet food; through centuries of domestication, it has been developed into a number of different breeds (see HORSE).

The living wild Equidae are confined to the Old World. Zebras and the true wild ass (*Equus asinus*) are African, with the zebras confined to the southern and eastern parts, while the ass originally ranged over northern and northeastern Africa.

The wild horse (*Equus caballus*), ancestor of the domestic horse, occupied the low country north of the great mountain ranges from Europe across central Asia; it may now be extinct as a wild animal. The half-asses, races of *E. hemionus*, were found in the arid zone of Asia from Persia to the Gobi Desert, as well as in Arabia, Syria, and northwestern India.

The living rhinoceroses are also Old World forms, with two species in Africa and three in Asia. There are three species of tapirs in the New World tropics, one in Middle America and two in South America. The fourth species of tapir is Asiatic.

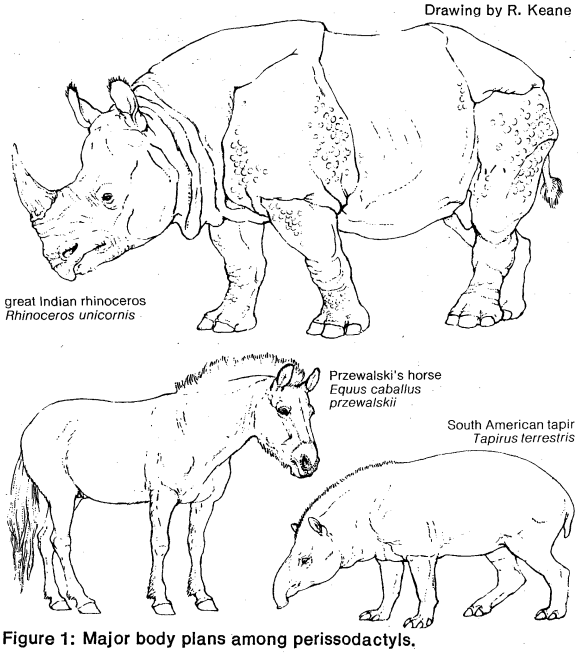

Figure 1: Major body plans among perissodactyls.

NATURAL HISTORY

Distribution, ecology, and conservation. The Equidae are highly specialized for a cursorial, herbivorous mode of life. They are absent from forests and other densely vegetated regions, but apart from this limitation, the range of the group is relatively unrestricted by the type of vegetation, climate, and topography. The species replace one another geographically for the most part, and each occupies a somewhat different habitat.

Dietary needs as range factors

Grass plays a major role in the diet; the zebras, for example, are known to feed on tall, coarse grasses avoided by most antelopes. Some species also take shrubs, herbs, and even bulbs. Water requirements vary in different species. In South Africa, Burchell's zebra has been found to drink about once every 36 hours. By contrast the mountain zebra (*Equus zebra*), Przewalski's horse (*Equus caballus przewalskii*) and the half-ass, all living in semidesert areas, are reported to survive if they can drink once in three or four days. The ass, too, can manage with less water than the horse. The mountain zebra and Przewalski's horse dig for water in dry riverbeds and depressions.

Zebras. The mountain zebra occupies parts of the arid rocky escarpment separating the interior plateau of the southern African subcontinent from the coast lowlands. The race *E.z. hartmannae*, still relatively numerous over much of its original range in South West Africa and southern Angola, enjoys legal protection and is represented in game reserves. Conflict between these zebras and farm livestock for the meagre pasture of the semidesert regions, however, has led to a reduction in zebra numbers. The race *E.z. zebra* was originally common in the mountain ranges of the Cape Province, but now survives only as a remnant of perhaps 100 animals. About one-half of these have sanctuary in a national park.

Burchell's zebra, (*E. quagga*) formerly inhabited a great area of grassland and savanna from the Cape to the southern Sudan. The southernmost race (*E. q. quagga*), which was only partly striped, became extinct in the 19th century. The populations of the other races have been much reduced in many places and the range of the species has shrunk considerably. There are large populations in reserves, however, and the species is not in any immediate danger of extermination. Grevy's zebra (*E. grevyi*), which shares a narrow zone in northern Kenya with Burchell's zebra, is confined to sparsely wooded, semidesert plains and low hills in northern Kenya, southern and eastern Ethiopia, and western Somaliland. Its status appears to be generally satisfactory.

Asses. The true ass (*Equus asinus*), ancestor of the domestic donkey, is the equid of arid North Africa whose range extends south to approximately 6° N latitude. Its natural distribution probably included all habitable parts of North Africa. At present, asses are known from semidesert country extending from the east bank of the Nile (in the Sudan) to the Red Sea, and in parts of Eritrea, Ethiopia, and Somalia. There are also isolated pockets in the Tibesti Mountains in the Sahara, and in the countries of central and western Africa. There is a great deal of uncertainty about the identity of all asses now described as "wild." Some may be merely feral (escaped or released) donkeys, and interbreeding with feral donkeys is likely to have occurred in many, if not all, existing populations.

The two surviving races of wild horses

The wild horse. The wild horse was widely distributed in Eurasia north of the mountain chains. The Romans encountered it in Spain. Two races have survived to modern times. A gray race, known as the tarpan, was the horse of southern Russia. It became extinct in the Ukraine during the mid-19th century. Przewalski's horse (*E.c. przewalskii*), a small, reddish-brown race considered a species by some authors, still survived as a truly wild animal until 1950, and small numbers may yet exist in the remote, semidesert steppe country on the boundary between Mongolia and China. Wild horses enjoy legal protection in Mongolia and China, but nomadic pastoralists have been encroaching on previously uninhabited country and competing with the horses for pasture and the scarce water supplies.

The half-asses, races of *Equus hemionus*, occupied the dry belt from Mongolia through Central Asia to Syria, with a northern limit at about 50° N latitude. The chigetia or kulan (*E. h. hemionus*), which was formerly widespread over an immense region of the Gobi, now occurs only in semidesert steppe country in central Mongolia. Hunting and competition for water by pastoral tribesmen are responsible for its decline. The kulan is slightly smaller than the kiang, (*E. h. kiang*), which is found on the cold, arid steppes of Sadak, Nepal, Sikkim, and western Tibet at altitudes of 4,270 metres (14,000 feet) and more. The kiang is now said to be rare but not endangered. The Persian onager, (*E. h. onager*) lives in a lower semidesert or desert environment, with a range that formerly included northeastern Iran, northwestern Afghanistan, and Russian Turkestan. It is now extremely rare and unlikely to survive outside northeastern Iran and the Badkhyz Reserve in Turkmeniya. A small nucleus has sanctuary in the semidesert salt plains of the recently established Kavir Protected Region in Iran. The Indian wild ass is a closely related, probably identical, form sometimes distinguished as the race *E. h. khur*. A fairly small population occupies salt flats in the Rann of Kutch, a remnant of the thousands found there at the end of World War II. The Syrian onager (*E. hemionus hemippus*) is the smallest member of the group and stands about one metre (3 feet) at the shoulder. It was once found in the desert region of Palestine, Syria, and Iraq, and was domesticated by the ancient Sumerians before the introduction of the domestic horse into Mesopotamia. This race may survive in the Djezireh Desert, Syria, or north of the Syrian–Turkish border; if so, the number must be extremely small.

"White" and "black" rhinos of Africa

Rhinoceroses. The two African species of rhinoceros are the black or prehensile-lipped rhinoceros (*Diceros bicornis*) and the white or square-lipped rhinoceros (*Ceratotherium simum*). The terms black and white are misleading, since both species are grayish to brownish, but the names are well established in common usage.

The black rhinoceros was originally widespread from the Cape to southwestern Angola and throughout eastern Africa as far as Somalia, parts of Ethiopia and The Sudan. Its range also extended westward through the northern savanna zone to Lake Chad, the northern Cameroons, Volta, and the northern Ivory Coast. The animal was extremely numerous in some parts. It now occupies a much smaller area, within which it is found in scattered pockets, many of them in parks and reserves. South Africa has an important population of some 300 of them in its Zululand reserves. The species still occurs in northern South West Africa and southwestern Angola, Rhodesia, Mozambique, Malawi, Zambia, and Zaire. Northern Tanzania and Kenya have more black rhino than any other country but the future of the animals outside the parks and reserves is far from secure. The species is also found in parts of Somalia, Ethiopia, northern Uganda, and The Sudan, and remnants remain in the Central African Republic and northern Cameroon. The decline in numbers is largely the result of expanding human settlement and of poaching to obtain the horns, which fetch high prices.

The black rhinoceros occupies a variety of habitats, frequenting open plains, sparse thorn scrub, savannas, thickets, and dry forests, as well as mountain forests and moorlands at high altitudes. It is a selective browser, and grass plays a minor role in its diet. Succulent plants, such as euphorbias, assume great importance in dry habitats, and where these plants are abundant the animals appear to be able to survive without free water. Where water is available, drinking is regular and frequent; the animals also may dig for water in dry riverbeds.

The much larger white rhinoceros is a grazing species with a broad, square muzzle. It prefers short grasses seven to ten centimetres (about three to four inches) high. The animal makes much use of shade trees for resting and is dependent on surface water. The range of the white rhinoceros is markedly discontinuous. South of the Zambesi River it was once extremely common over a fairly large area of bushveld. It has since become confined to the game reserves in Zululand, where the population has

risen to some 1,700; some of the animals have been redistributed to several other parks and reserves in southern Africa.

A northern race formerly inhabited the southern Sudan and adjacent areas of Uganda and Zaire, extending westward into the Central African Republic. It has also been much reduced, but considerable populations still survive in the Parc National de la Garamba (Zaire) and in the Bahr el Ghazal region of The Sudan, and a small remnant has found sanctuary in the Ruwenzori National Park, Uganda.

The smallest living rhinoceros

The smallest of the three Asian rhinoceroses (also the smallest living member of the family) is the Sumatran, or Asiatic, two-horned rhinoceros, *Didermocerus* (or *Dicerorhinus*) *sumatrensis*, standing one to one and a half metres (three to five feet) at the shoulder. It was originally found from eastern Pakistan and Assam throughout Burma, much of Thailand, Indochina (Cambodia, Laos, and Viet Nam), Malaya, Sumatra, and Borneo. Small isolated populations still occur in a few widely separated localities in Burma, Thailand, Malaya, Sumatra, and Sabah, and possibly in other nearby territories. The total population is thought to number between 100 and 170. Some of the survivors in Sumatra are protected in reserves.

The Javan, or lesser one-horned, rhinoceros (*Rhinoceros sondaicus*) occupied the islands of Java, Borneo, and Sumatra, the Malay Peninsula, and a region extending northwards through Burma into Assam and eastern Bengal. It is now restricted to the Udjung Kulon Reserve in western Java where there are at least 25 and perhaps as many as 50 to 60 animals.

Both the Sumatran and Javan rhinoceroses inhabit forests as well as marshy areas and regions of thick bush and bamboo, climbing actively in mountainous country. They are mainly browsers.

The great Indian, or one-horned, rhinoceros (*Rhinoceros unicornis*) is more or less equivalent in size to the square-lipped rhinoceros and is distinguishable from the smaller Javan rhinoceros by the presence of a large horn, tubercles on its skin, and a different arrangement of skinfolds. It previously occupied an extensive range across northern India and Nepal from Assam in the east to the Indus Valley in the west. It is found in a range of habitats —open grassland, savanna, forests, and hilly country— and appears to be mainly a grazer, raiding grain fields in some areas. Hunting and the pressure of expanding human populations have greatly reduced both the range and numbers of this animal. It is now found almost entirely in eight reserves or sanctuaries in India, notably the Kaziranga Sanctuary in Assam (estimated population 300) and in the Rapti Valley region of the Nepal Terai. The total population is estimated at about 600 animals, and the prospects for survival appear to be reasonably good.

Tapirs. The Malayan tapir (*Tapirus indicus*), largest member of the family Tapiridae, is found in Sumatra and the Malay Peninsula, as far north as the Burmo-Siamese border in latitude 18° N. It is found from sea level to high altitudes and occupies forests and thickets but may feed in more open areas. It is still abundant and widespread.

Distribution of New World tapirs

The three New World species occupy distinct, nonoverlapping but contiguous ranges. The mountain tapir (*Tapirus pinchaque*), the smallest and most primitive, inhabits the temperate-zone forests and bordering grasslands of the Andes in Colombia and Ecuador and in northern Peru, up to altitudes of nearly 4,600 metres (about 15,000 feet). Agricultural and pastoral expansion have resulted in some decline in the status of this species, but it is still fairly common. The Central American, or Baird's, tapir (*T. bairdii*) is the largest of the American species. It is essentially middle American, with a range extending from Mexico into coastal Ecuador, and it occupies undisturbed climax rain forest. It is shy and adjusts poorly to the disturbance caused by settlement. This disturbance, together with the destruction of habitat accompanying human occupation, has greatly reduced its range and numbers. The species is said to be much in need of active conservation. The most widespread species is the Brazilian tapir (*T. terrestris*), which is found throughout the Brazilian subregion east of the Andes and in a small area west of the Andes in northwestern Venezuela and northern Columbia. Like the other species, it is largely a forest form requiring the proximity of water. The three New World tapirs are mainly browsers and are remarkably similar in habits.

Behaviour. *Expression and communication.* The Equidae communicate by means of calls and changes in facial expression. Six different sounds are made by Burchell's zebra. A whinny, consisting of a series of two- or three-syllabic "ha" sounds, serves to maintain contact between members of a group. The repertoire includes an alarm call ("i-ha"), an alarm snort, a drawn-out snort of satisfaction, and a squeal of pain and fear. Other species utter similar sounds, the whinny of the horse and the bray of the ass being well-known examples. Characteristic facial expressions have been described for greeting ceremonies (mouth open, ears up), threat (mouth open, ears back), and submission (mouth open, nibbling movements, ears down). In all species studied except the horse, females assume a particular expression ("mating face") when permitting the male to mount.

In the rhinoceroses and tapirs snorting, squealing, bellowing, and, in some forms, whistling sounds play a major role in communication. Visual signals are not well developed in these nonsocial animals, but a few facial expressions are used.

Feeding. The Perissodactyla are mainly grazers or browsers. The quality and quantity of grasses available to grazing species may vary considerably with the season and the area. The animals may accordingly move great distances to reach attractive sources of food. Migrations of Burchell's zebras to succulent pastures during the rainy season are a feature of the Serengeti Plains and the Etosha National Park in Africa. The distribution of asses, half-asses, and horses inhabiting arid areas largely follows that of rainfall and pasture.

The food of the browsers is fairly readily available throughout the year; thus, species in this category are relatively sedentary. The browsing rhinoceroses may break down trees and shrubs, and use their forelimbs to help get at otherwise inaccessible leaves and twigs. Food is plucked with the lips. In the tapirs, the upper lip is fused with the short proboscis. The rhinoceroses (excluding the white) have a pointed upper lip with a fingerlike process that is used to pluck leaves and twigs. The white rhinoceros, with its broad square muzzle, is the most specialized grazing rhinoceros, feeding on grass.

Herd behaviour among equids

Social organization and territory. In both the mountain and Burchell's zebras the family group is the basic social unit. It generally consists of a single adult male and two or three adult females with their foals. The groups are stable, apparently because of strong mutual ties among the females rather than because of herding by the male. The stallion is dominant, and there is a hierarchy among the mares, the highest ranking (alpha) animal usually leading the group. Other males are either solitary or live in bachelor groups of two or three, sometimes up to ten. Juveniles leave the family group when they attain sexual maturity at one and one-half to two years. When large aggregations occur on favoured grazing grounds, the groups retain their identity. Among Grevy's zebras and wild asses, territorial males, mixed groups of mares and foals and of stallions are found. There is no evidence for territorial behaviour among any of the zebras except Grevy's. Individual groups occupy home ranges that overlap to some degree with those of other groups.

The social organization of other equids is not as well documented. Observers studying the wild horse and half-asses have noted that females and juveniles form a group dominated by a single stallion, which keeps them together by active herding; the unattached males are solitary or live in small herds.

The pattern of social organization among the rhinoceroses is quite different from that of the Equidae. Dominant adult males of the white rhinoceros occupy territories that, in the Natal reserves, average about 200 hectares

(500 acres). Within its area a male may tolerate subadult or aged bulls, which have subordinate status. Adult females accompanied by their calves inhabit home ranges encompassing the territories of six or seven dominant bulls. Juveniles consort with other juveniles or with calfless females, but groups of more than two usually do not stay together long.

The black rhinoceros is basically solitary. Adults of both sexes usually occupy home ranges of 1,000 hectares (2,500 acres) or more, the size depending on the characteristics of the environment; occasionally the ranges may be as small as 200 hectares, however. There is a good deal of overlap in the utilization of these home ranges.

The Asiatic rhinoceroses also are essentially solitary, but detailed information on the nature of the areas they inhabit is not available. Individual great Indian rhinoceroses are said to occupy tracts as small as 8 to 20 hectares (20 to 50 acres).

Little is known about the social organization or territorial behaviour of the tapirs. All species are reported to be found alone or in pairs.

Scent marking and territories

Male zebras and horses follow mares in estrus. The stallion, after smelling the spot where a mare has urinated or defecated, exhibits "flehmen" (a characteristic display in which the head is lifted and the upper lip raised) and then urinates or defecates on the same spot. In similar fashion, members of stallion groups often urinate or defecate consecutively; communal dung heaps formed by five to eight animals often arise in this way. The significance of such behaviour is not clear.

Among the Rhinocerotidae excretory products play an important role in marking territories and home ranges. Dominant male white rhinoceroses defecate almost entirely on heaps within their territories. They then scatter the material by kicking vigorously, presumably leaving an individual scent mark in this manner. In addition, they urinate in a ritualized fashion, spraying the urine in powerful jets in a manner peculiar to them and shown by no other sex or age group. Other members of the population also use dung heaps (either in territories or in communal areas, such as along paths) but not exclusively, and they do not scatter dung.

In the black rhinoceros, dung-scattering behaviour does not appear to be exclusive to dominant males. The function of the communal heaps may be mainly to establish the presence of the inhabitant in his home range, and to maintain contact between known animals.

Dung heaps and urine spraying are also observed among other species of rhinoceroses and among tapirs; their significance is presumably of a similar nature.

Fighting. The pattern of fighting is related to the amount of lethal equipment the various groups possess. The Equidae, unarmoured, do not employ stylized fighting techniques to reduce the danger of serious injury—as among certain other species. Fighting is largely confined to adult males competing for estrous mares. Various techniques occur in the zebras, which may serve as an example of the family. Circling, neck fighting, biting (either in a standing or sitting position), rearing combined with biting and kicking, and kicking on the run all are used, either alone or in combination. No set pattern is followed.

Fights among rhinoceroses consist of charges and striking with the horns, usually accompanied by vocal threats. Goring is not common, the stylized pattern having probably been evolved to minimize the danger of serious injury from the formidable horns.

Mutual grooming and greetings

Amicable behaviour. Mutual grooming is well known among horses. Two animals stand facing in opposite directions and groom each other by nibbling at the root of the tail and the base of the neck. Burchell's zebra behaves similarly and so, presumably, do other members of the family.

Zebras greet each other simply by nose-to-nose contact, except that adult stallions go through a ceremony involving nose-to-genital contact. Nose-to-nose greeting is also characteristic of tapirs and rhinoceroses. The latter also rub their bodies together.

Courtship and mating. Courtship is relatively simple among the social equids. The true ass is apparently exceptional. The partners are strangers when the first approaches are made and the female requires violent subjugation by the male, which bites, kicks, and chases her before she will stand for him. This may be the result of separation of the sexes outside the mating season. The wild horse and Burchell's zebra are not at all violent. The stallion often grooms the mare before attempting to mount. The estrous mare (especially, or exclusively, young mares in the case of Burchell's zebra) adopts a typical posture with legs slightly apart, tail lifted, and, except in the horse, a characteristic facial expression (the "mating face" already mentioned).

The more or less solitary rhinoceroses and tapirs go through a more elaborate courtship, presumably because the partners are strangers. After a chase, the male and female may engage in low-intensity fighting, ending with the male laying his head on the female's rump and then mounting and copulating for an extended period. Several males may mate with an estrous female.

Relations between parent and offspring. The perissodactyls bear well-developed (precocial) young, usually a single offspring. After the mother has assisted in removing the placenta and has licked her offspring in the usual mammalian fashion, the young animal soon attempts to stand. A Burchell's zebra foal has been observed to stand quite firmly 14 minutes after birth, and a black rhinoceros calf 25 minutes after birth.

Newly born equids follow any nearby object during the first few days of life. At this time, zebra mares drive away all other zebras from their foals. The behaviour ensures that the foal will form a bond with its mother during the initial period of imprinting. Foals follow their mothers closely and are groomed frequently.

Although precocial, black rhinoceros calves appear to have a lying-out period; that is, an initial period when they rest quietly in thick cover except when being suckled. Thereafter they follow their mothers closely. A young white rhinoceros tends to walk ahead of the mother and may be guided by her horn.

Most young perissodactyls remain with their mothers until the next offspring is born. A young rhinoceros may, therefore, accompany its mother until it is two and one-half years old, or older. Although grazing starts early, suckling proceeds for a considerable time, perhaps for its psychological rather than its physiological value.

Play. As in other mammals, play is a prominent form of behaviour among young perissodactyls. Zebras up to the age of one year frequently engage in running games. Foals gallop wildly about on their own, jumping and kicking up their heels, sometimes chasing other animals, such as gazelles, mongooses, or birds. In groups they play catching games, running after one another in close succession. Mock fighting sometimes takes place. Groups of adults have also been seen to chase foal groups in play, and indeed stallion groups carry out playful gallops. Stallions also engage in play greeting and in mock fights.

Running games and mock fighting

Playful romping and mock fighting with the horns are common among rhinoceros calves. Young tapirs play running games.

Rolling and wallowing. Behaviour for the care of the body is widespread among the perissodactyls. Equids frequently roll in dry, loose soil forming rolling hollows—a common feature of zebra country.

Wallowing, which may help regulate body temperature, probably is mainly a form of self-grooming; it is practiced by all species of rhinoceroses. They often spend hours lying in pools during the middle of the day in hot weather. Mud of suitable consistency induces wallowing, which may be followed by sand bathing. Prolonged rubbing on tree trunks or suitable stumps follows a wallow; old rubbing stumps and stones may take on a shine from repeated use.

Tapirs may have the most pronounced tendency to bathe and wallow, but few details of their behaviour are known. They are also said to enter water when disturbed.

Reproduction. Female equids of all the species for which information is available attain puberty at about one year, but are not normally successfully mated before the age of two to two and one-half years, and possibly as

late as three to four years in the case of Grevy's zebra. Zebras probably breed until about 20 years of age. The domestic species are seasonally polyestrous (repeatedly fertile), coming into breeding condition in spring and, unless mated, undergoing repeated estrous cycles at intervals of approximately three weeks until the end of the summer. The wild species studied also tend to mate seasonally; most young are born in spring and summer.

Reproductive potential of equids

The gestation period of equids is between 11 and 12 months. In most species a postpartum estrus occurs, usually within two weeks of the birth of the young; thus, the maximal potential reproductive rate is one young per year. This potential is not always attained. Only about 50 percent of domestic mares that are mated produce foals, and nearly half of a study group of Burchell's zebra mares bore only one foal in three years.

The gestation period of three species of rhinoceroses is about 15 to 17 months. For the Sumatran rhinoceros the period is said to be only seven months. No information is available for the Javan rhinoceros. Female white and black rhinoceroses attain sexual maturity at the age of four to five years and are capable of calving at intervals of approximately 2½ years. Rhinoceroses probably breed until between 30 and 40 years old. The white tends to have a mating peak in spring, corresponding with the flush of green grass, and a calving peak in autumn.

The Malayan and Brazilian tapirs have gestation periods of 13 months' duration. The Brazilian tapir is reported to mate before the onset of the rainy season.

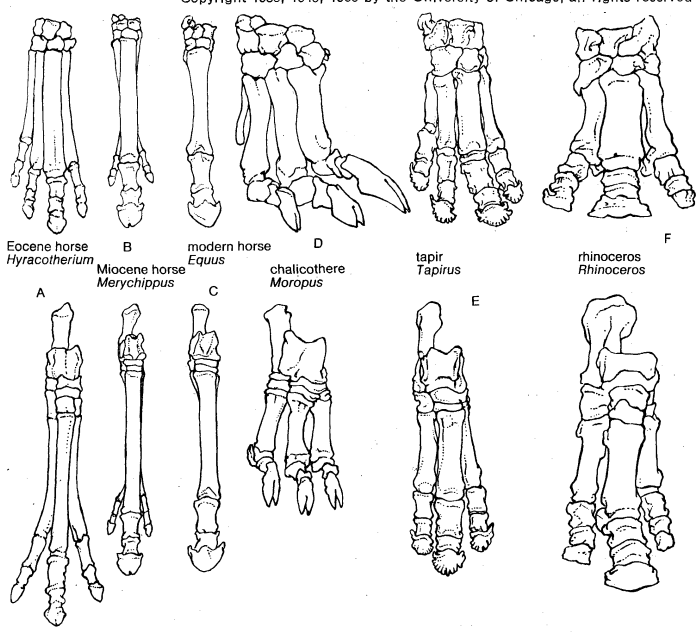

Figure 2: Forelimbs (above) and hindlimbs (below) of some recent and fossil perissodactyls.

FORM AND FUNCTION

Integument. The skin of rhinoceroses is extraordinarily thick. The great Indian and Javan rhinoceroses are covered with large, practically immovable plates, separated by joints of thinner skin to permit movement. The two species differ in the arrangement of the folds. The hair of all rhinoceroses is sparse or absent except that of young Sumatran rhinoceroses, which have a dense coat of crisp, black hair. The skin of the tapirs is also thick with a sparse covering of short hairs arranged in irregular groups. The equids have a normal hide with a well-developed hairy coat.

Structure of rhinoceros horns

The "horns" of the rhinoceroses are noteworthy structures of epidermal origin. The horn is composed of a mass of fused epidermal cells that are impregnated with a tough, fibrous protein (keratin) and that rest on a roughened bony cushion on the fused nasal bones. The male Javan rhinoceros has a short horn about 25 centimetres (10 inches) long; the horn of the female is rudimentary. The great Indian rhinoceros has a single horn up to 60 centimetres (25 inches) long. The other species of rhinoceroses have a second horn that stands on a protuberance of the bones (frontals) between the eyes. Hornlike structures were also present in the titanotheres and extinct rhinoceroses.

In all living perissodactyls the terminal digital bones are flattened and triangular, with evenly rounded free edges, and are encased by keratinous hooves derived from the integument. The single hoof of the equids—the only mammals to walk on the tips of single digits—is the most highly developed structure of this kind among mammals. The keratinous wall is analogous to the nail of mammals that have claws or nails.

Skeleton. *Backbone.* The vertebral column acts as a firm girder, with high dorsal (neural) spines on the thoracic vertebrae, above the forelimbs and ribs. Spines and ribs serve as compression struts above and below. The column balances largely on the forelegs and is pushed from behind by the hindlegs, which are the main propellants. This skeletal structure permits running and also enables great weights to be borne in such animals as the rhinoceroses. There are never fewer than 22 thoracolumbar (trunk) vertebrae.

The neck, or cervical, vertebrae are opisthocoelous; *i.e.*, with the bodies (centra) of the vertebrae hollowed behind to take the convex heads of the succeeding centra. This feature facilitates rotatory movement of the neck and is most highly developed in the horses.

Limb girdles. The shoulder blade is long and narrow with a small coracoid process (a ridge to which muscles are attached) and a low spine. There is no clavicle (collarbone). The pelvic girdle has a broad, vertically raised ilium to which are attached the large gluteal (thigh) muscles, important for locomotion, and the abdominal muscles, which carry the weight of the belly.

Limbs. There is a clear evolutionary tendency in the Equidae for the limbs to become long and slender, with a reduction in the number of digits in the swift-running forms. These changes are accompanied by an increase in rigidity and specialization for movement fore and aft. The upper (proximal) segments, the humerus of the forelimb and the femur of the hindlimb, have remained short. In contrast the lower (distal) parts, consisting of an anterior radius and posterior ulna in the forelimb and an anterior tibia and posterior fibula in the hindlimb, have become longer and slimmer. The humerus is short and broad. Its articulation with the radius and ulna only permits fore-and-aft movement. The proximal end of the stout femur has a third projection, or trochanter, in addition to the usual mammalian two, which serves as an additional point of attachment for the large locomotory muscles of the hindlimbs.

Evolution of swift-running forms

The anatomical feature of the order now considered most significant is that the axis of symmetry of the limbs passes through the third or middle toe, the most strongly developed and the one on which most of the weight is borne. This is called the mesaxonic condition and is contrasted with the paraxonic condition of the Artiodactyla, in which the axis passes between the third and fourth toes.

Originally the five toes of the limb were held in the semidigitigrade position—*i.e.*, with the weight of the body being borne on the soles of the toes and on the lower ends of the elongate metacarpal and metatarsal bones of the forefeet and hindfeet. The upper (proximal) ends of these bones were raised above the ground, a condition still to be seen in the tapirs.

As the third digit became increasingly dominant, it became longer and thicker. The upper ends of the third metacarpus and metatarsus broadened and forced the other digits to the side. The first (inner) digit was the first to disappear. The earliest known forms already bore only three digits on the hindfoot. The loss of the first toe on the front foot led to the four-toed condition common in the Eocene; the fifth digit persisted, although it was somewhat weak. The tapirs, with four toes in front and three behind, have retained this early condition.

The fifth digit of the hindfoot was the next to disappear

in the evolutionary sequence, and all known forms beyond the lower Oligocene had only three toes in each foot. The living rhinoceroses illustrate this condition. A massive limb with a broad foot is essential in such heavy animals. The feet have cushions of elastic connective tissue well suited to bear the weight of the body.

In the most highly specialized forms, the second and fourth digits also underwent reduction. These digits are retained in the living Equidae only as functionless, vestigial slivers of bone on either side of the third metacarpal and metatarsal.

Growth of the third digit's terminal joint

With reduction in the number of digits, the third has assumed a progressively more vertical position. Its terminal joint, or phalanx, has become larger and the hoof surrounding it bigger and thicker. At the same time the ulna, the smaller bone of the forelimb, decreased in size until, in the modern Equidae, its upper end fused with the radius and its lower end remained merely as part of the articulating surface of the radius with the wrist bones (carpals). In the hindlimb, the fibula became reduced in similar fashion. It articulates with the ankle bones (tarsals) only in a few extinct forms, such as the titanotheres. In the tapirs and rhinoceroses it is slender. In the equids the proximal end remains as a small splint of bone, while the distal end has fused with the tibia.

The arrangement of the small bones of the carpus ("wrist") and tarsus (ankle) is another characteristic feature of perissodactyl limbs. In most other mammalian orders, the carpals and tarsals provide the limbs with regions of flexibility. Their development in the perissodactyls has been toward increasing rigidity, following the trend in the limbs as a whole. The basic mammalian arrangement is one of three rows of bones: a proximal row of three, adjacent to the lower arm and leg bones; an intermediate row of four (the centralia); and a distal row of five (carpalia of the forefoot, tarsalia of the hind), one to each digit. The centralia, carpalia, and tarsalia are numbered one to four or five, beginning on the side of the thumb and big toe. In all orders the number of wrist and ankle bones has been reduced. Usually only one of the centralia, known as the navicular, remains, while there are the same number of carpalia and tarsalia as there are digits.

An interlocking plan is characteristic of the Perissodactyla. In the forefoot, the third distal carpal (the magnum or capitate) is enlarged and interlocks with the proximal carpals. The elongated third metacarpal thrusts up against these interlocked bones. In the equids, distal carpal I (the trapezium) is absent, and the arrangement in the hindfoot is similar. In the most advanced, modern forms metatarsus III thrusts against the enlarged and flattened tarsal III (ectocuneiform), and this in turn is in contact with the large, flat navicular (centrale II and III). The navicular abuts on the flattened astragalus (or talus), the intermediate bone of the proximal row. The articulation between the upper surface of the astragalus and the tibia is pulley-like and permits only fore-and-aft movement of the limb.

Teeth. The full complement of mammalian teeth consists of three incisors, one canine, four premolars, and three molars in each half of each jaw. The arrangement may be expressed by the formula $\frac{3 \cdot 1 \cdot 4 \cdot 3}{3 \cdot 1 \cdot 4 \cdot 3} = 44$ teeth. The figures represent the number of incisors, canines, premolars, and molars in each half of the upper (above the line) and lower (below) jaws, respectively.

Fully-toothed early hoofed mammals

The Condylarthra, a group of mammals that first appeared in the Paleocene (about 65,000,000 years ago) and were ancestral to most of the later and recent hoofed mammals, had a full complement of teeth. In many of the early perissodactyls, only the first lower premolar had been lost. The subsequent evolutionary sequence led to losses and specializations of the incisors and canines. Lengthening of the facial part of the skull resulted in the formation of a gap, the diastema, between the incisors and the premolars. The first upper premolar was reduced or lost in consequence. The canines, when present, were situated in this diastema, as they are in male horses.

Among the living perissodactyls, the tapirs have the least specialized battery of teeth. In this, as in many other features, they have remained primitive. The dental formula of the family Tapiridae is: $\frac{3 \cdot 1 \cdot 4 \cdot 3}{(2\text{–}3) \cdot 1 \cdot 3 \cdot 3} = 40\text{–}42$ teeth. The first upper premolar is noteworthy in being the only premolar with a milk, or deciduous, predecessor.

The cutting teeth are reduced in the Rhinocerotidae. Incisors and canines are absent in the two African forms, although rudimentary incisors occasionally are found in young animals. The Asiatic species have one or two upper, but generally no lower, incisors in each half of the jaw. They have no upper canines; the Javan and Sumatran rhinoceroses have one short, sharp lower canine on each side. There are three upper and lower molar teeth in all five species. The white and Sumatran rhinoceroses have three premolars, and the others have three or four premolars. The dental formula for the family is set up, therefore, as follows: $\frac{(0\text{–}2) \cdot 0 \cdot (3\text{–}4) \cdot 3}{0 \cdot (0\text{–}1) \cdot (3\text{–}4) \cdot 3} = 24\text{–}30$ teeth. The dental formula of the Equidae is $\frac{3 \cdot 1 \cdot (3\text{–}4) \cdot 3}{3 \cdot 1 \cdot 3 \cdot 3} =$ 40–42 teeth. The canines are rudimentary in females and the first upper premolar is extremely small, often falling out.

The form of the premolars and molars is of great interest and their evolutionary history has been studied in some detail. Primitive, browsing members of the order had brachydont cheek teeth (*i.e.*, with low crowns and long, narrow root canals), with separate low, rounded cusps—the bunodont condition. Increasing specialization for grazing resulted in fusion of the cusps into ridges (lophs), thus teeth of this kind are called lophodont. Lower molars typically have two transverse lophs, the protoloph and the metaloph. In the upper molars these ridges are fused with a longitudinal ridge (ectoloph), which runs along the outer edge of the tooth. Further development leads to a convoluted arrangement of the lophs, such teeth being termed selenolophodont. Two extinct perissodactyl groups did not follow this trend. In the titanotheres the inner cusps remained bunodont, and in the chalicotheres there was no protoloph.

Associated with these changes in the tooth surfaces is a tendency for the crown to become higher. High-crowned teeth are termed hypsodont. Their roots remain open until a fairly advanced age, a condition associated with continuous growth, which compensates for wear. The hollows between the lophs of hypsodont teeth are filled with a deposit of secondary cement, which strengthens the teeth and makes them more resistant to wear. A further evolutionary trend is for premolars to become as large as molars. Where the process of molarization is complete, as in horses, all grinding teeth are identical.

From *Horses: The Story of the Horse Family in the Modern World and Through Sixty Million Years of History*, by G.G. Simpson. Copyright 1951 by Oxford University Press, Inc. Reprinted by permission

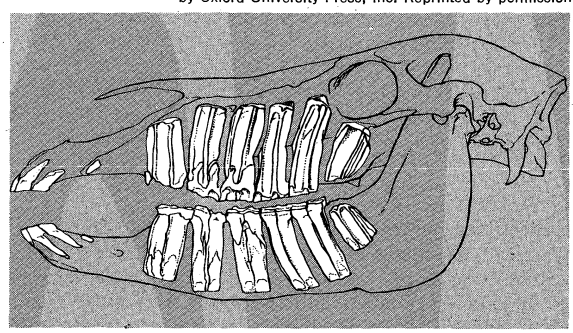

Figure 3: Skull and dentition of horse, *Equus caballus*, cut away to show roots of teeth.

The Tapiridae have primitive brachydont premolars and molars. They possess two simple transverse lophs, and are thus termed bilophodont. They lack secondary cement on the crowns.

The Sumatran rhinoceros, the most primitive of the living rhinoceroses, and the Javan rhinoceros have similar brachydont, lophodont cheek teeth. The great Indian rhinoceros, which is less of a specialized browser, has hypselodont (hypsodont and selenodont) premolars, with a layer of cement on the crowns. The black rhinoceros

has brachydont and lophodont teeth, with a thin layer of cement. The white rhinoceros is more specialized, for the cheek teeth are hypselodont and have a thick cement layer.

The grinding teeth of the Equidae are highly specialized, high crowned, with a complicated selenodont surface and thick cement deposits.

Comparative size of the stomach

Digestive system. The stomach of perissodactyls is small, simple, and undivided. In the horse its capacity is only 8.5 percent of the whole digestive system. The comparable figure for the ox is 71 percent. The intestine is very long and the cecum (blind gut) and colon are huge and sacculated (*i.e.*, with many blind pockets). Here food is macerated and fermented and the fibrous portions are dissolved. The liver has no gall bladder.

EVOLUTION AND PALEONTOLOGY

The Perissodactyla appeared early in the Eocene, about 55,000,000 to 40,000,000 years ago. Together with most other ungulate mammals, they were probably derived from the Condylarthra. The condylarths were abundant in Europe and North America, mainly during the Paleocene (65,000,000 to 55,000,000 years ago). Condylarths were unspecialized mammals, rather carnivore-like in appearance. The larger species attained the size of tapirs. The limbs were fairly short and primitive but the third toe was somewhat enlarged and the phalanges ended in hooves. There was a full complement of teeth with some specializatin of bunodont molars for herbivorous diet.

Horses. The earliest horses appeared during the lower Eocene in Europe and North America. They are generally known as *Eohippus* ("dawn horse"), but *Hyracotherium* is the correct taxonomic designation. Some species of these little forest-dwelling, browsing animals were no larger than a terrier. They had moderately long, slender limbs with only four toes in the forefoot and three in the hindfoot, all equipped with hooves. The molars were essentially bunodont (with low, rounded cusps) and the premolars simple.

Hyracotherium-like animals persisted in Europe until the end of the Eocene. Another group, the paleotheres or "native" European horses, evolved as a specialized side branch, which died out in the Oligocene. North America was the centre of horse evolution. During the Eocene, *Hyracotherium* was succeeded by forms such as *Orohippus* and *Epihippus*, which are known only from that epoch. They were notable only for minor advances, such as the development of a molar configuration in two premolars.

The Oligocene (40,000,000 to 26,000,000 years ago) saw a major change with the appearance of three-toed horses, *Mesohippus*, *Miohippus*, and others. All of the premolars were similar to the molars, low-crowned but lophodont (ridged). *Anchitherium* was an early Miocene form as large as a modern pony, which migrated from North America to Europe. These primitive three-toed horses or anchitheres survived until Pliocene times, some of their descendants attaining the size of a rhinoceros, as in the late giant representative *Megahippus*.

The main course of horse evolution entered a third stage in North America in the Miocene Period (26,000,000 to 7,000,000 years ago). A line of grazing horses developed, almost certainly to exploit the new grasslands that were spreading over the surface of the earth. The degree of lophodonty of the molariform teeth increased, changing the pattern of the crests on the surface and increasing their grinding efficiency. Of greater importance, these teeth became hypsodont (high-crowned) and thus maintained a good grinding surface as grinding of the harsh, siliceous grass caused them to wear down. Another substance, cement, came to supplement the dentine and enamel forming the teeth of earlier types, and provided additional material to resist abrasion. The evolution of these specialized teeth was a tremendous advance.

Trends in horse evolution

The limbs of the grazing horses became increasingly rigid and specialized for fore-and-aft movement, better fitting the animals for running in open country. In *Merychippus* the ulna was fused with the radius and the fibula was much reduced. In some advanced forms the central toe was much larger than the two lateral toes and carried most of the weight of the body on a hoof much like that of modern horses.

A number of evolutionary lines developed during the Pliocene, which lasted from 7,000,000 to 2,500,000 years ago. *Pliohippus* of North America is probably the line from which modern horses have come. The genus *Equus* is characteristic of the Pleistocene when it developed in North America and spread to all continents except Australia. By the end of the Pleistocene, horses had become extinct in the New World.

Titanotheres. Another group entirely, the titanotheres (Brontotheriidae), evolved independently from *Hyracotherium*-like ancestors and became abundant in North America during the Eocene and Oligocene, but disappeared by the Miocene. They were also found in Asia and Eastern Europe. The end forms, such as *Brontops* and *Brontotherium*, were huge, the largest standing 2½ metres (8 feet) at the shoulder. They had long, low skulls and a small brain. Many species bore a pair of large, hornlike processes on the front of the head.

By courtesy of the Field Museum of Natural History, Chicago

Figure 4: Reconstruction of fossil Perissodactyla. *Brontops*, an Oligocene titanothere, some individuals of which were about 2.5 metres (eight feet) at the shoulder. Detail of a painting by Charles R. Knight.

Chalicotheres. The chalicotheres (Chalicotheriidae) were moderately large animals that appeared in Eurasia and North America during the Eocene. Thereafter they evolved mainly in the Old World, disappearing from America in the mid-Miocene, but persisting in Asia and Africa until they died out in the Pleistocene. Early members of the group such as *Paleomoropus*, from the lower Eocene, resembled contemporary equids. The Miocene *Moropus* typifies the peculiar characteristics of later forms. It was horselike, but the front legs were longer than the rear. Each foot bore three toes which ended in large, fissured phalanges bearing claws that may have been used for digging up roots and bulbs.

Tapirs. The fossil and living tapirs, together with similar extinct forms such as the lophiodonts, constitute a small, fairly uniform group.

Homogalax, *Lophiodon* and other tapir-like animals appeared in the Eocene. Some were close to the ancestry of both rhinoceroses and tapirs, and other evolutionary lines left no descendants. *Protapirus* from the Oligocene of Europe and North America was the forerunner of the modern tapirs. These tapirids persisted until the Pleistocene, when climatic changes led to their extinction.

Rhinoceroses. The fossil history of the rhinoceroses is far more complex. They evolved from the early tapiroids but diverged from that group. Unlike the equids, they have tended to grow large, with short, stout limbs with

little reduction in the digits. Although the premolars have tended to molarize, the molar cusp pattern is simple; the teeth seldom become hypsodont, and cement occurs rarely.

The Hyracodontidae, or running rhinoceroses, from the Eocene and Oligocene of North America and Asia were the most primitive. *Hyracodon* had long, slender legs with three toes on each foot and typically rhinocerotid cheek teeth.

The amynodonts are known from the late Eocene and Oligocene of Eurasia and America and lived in Asia until the Miocene. They were a side branch, perhaps derived from primitive hyracodonts. *Metamynodon* and some other forms were about as large as hippopotamuses and may have lived in rivers. The premolars were simple and the incisors reduced, but canines and molars were enlarged.

True rhinoceroses are probably also descended from early hyracodonts. They became numerous in the Oligocene as large animals with molariform premolars. Many side branches evolved. *Trigonias* still had four front toes but *Caenopus*, another Oligocene representative, had the three toes common to all later rhinoceroses. Like its relatives of that period, *Caenopus* was fairly small, about the size of a tapir, and hornless.

One spectacular group contained giant hornless creatures, such as *Baluchitherium* and *Indricotherium* from the Oligocene and Miocene of Asia; the largest of known land mammals, they stood 5.5 metres (about 18 feet) high at the shoulder and had a long neck and long forelegs.

Rhinoceroses died out in North America during the Pliocene, but in Eurasia many different species survived to the Pleistocene. One of the most familiar of these later rhinoceroses is the woolly rhinoceros (*Coelodonta*), which was depicted by Stone Age artists and is known from nearly intact specimens. The surviving rhinoceroses represent remnants of once varied and abundant stock; the genera have little direct relationship to one another.

CLASSIFICATION

Importance of skeletal features

Distinguishing taxonomic features. Skeletal features are of greatest importance in classifying the Perissodactyla. They are, of course, the only criteria applicable to fossil forms. Distinguishing characteristics of the skull include the relative length of the facial region, length and form of the nasal bones, presence of a postorbital bar and of hornlike structures. The form and number of teeth, presence of a diastema, number of molariform premolars, the height of the cheek teeth, their cusp structure and the presence or absence of cement on the grinding surfaces all are particularly valuable taxonomic features. The limb structure is also a useful aid to classification, especially the length of upper and lower portions, the degree to which the ulna and the fibula are reduced and fused, respectively, with the radius and the tibia, the number and form of carpal and tarsal bones, and the number and relative size of the digits.

Among living perissodactyls, body size, form of the upper lip, number and length of horns, structure of the skin and colour pattern are the most important features for classification.

Annotated classification. The classification presented here follows that of U.S. paleontologist George Gaylord Simpson, which is generally accepted but modified in some fairly minor ways by other authors. The term Mesaxonia, introduced by the 19th century paleontologist O.C. Marsh, is essentially synonymous with Perissodactyla. Simpson used it as a convenient designation for the superorder containing the single order Perissodactyla, as he used the parallel name Paraxonia for the superorder with the one order Artiodactyla.

Groups indicated by a dagger (†) are known only as fossils.

ORDER PERISSODACTYLA

Herbivorous ungulates with either 3 digits or 1, at least in the hindfeet. Early forms digitigrade, this feature either retained or completely replaced by the unguligrade condition in later representatives. The body weight borne mainly or entirely on the third digit through which the long axis of the limb passes (mesaxonic condition). The talus (heel bone) with only 1, proximal, keeled surface, articulating with the tibia, no duplication of keel on the distal surface, as in artiodactyls. Nasals broad at the posterior end, alisphenoid canal present. Posterior premolars molariform; cheek teeth bunodont in early forms, typically lophodont or selenolophodont, rectangular; wide diastema separates them from incisors and canines, which may be reduced or absent. Testes inguinal, occasionally scrotal; mammary glands inguinal, with 2 teats; uterus bicornuate. Fifteen living species, but more than 200 fossil forms.

Suborder Hippomorpha

Superfamily Equoidea

Dentition complete, upper molars with 6 tubercles, the 2 external ones united to form an ectoloph, median and internal tubercles generally fused into a single loph. Tendency to molarization of premolars and reduction of lateral digits.

†*Family Palaeotheriidae* (paleotheres or "native horses"). Lower Eocene to lower Oligocene; Europe and Asia. Size variable, from that of fox (shoulder height about 40 centimetres or 16 inches) to that of a rhinoceros; body form tapirlike. Three digits in each foot. Dentition complete or first premolars absent; premolars molariform, separated from canines by diastema. Cheek teeth brachydont, lophodont, with or without cement. Orbits without postorbital bar. Eurasian "native horses," seven genera.

Family Equidae (horses and relatives). A progressive group with tendency to molarization of premolars and development of cement.

†*Subfamily Hyracotheriinae* (hyracotheres). Eocene: Europe and North America. Size about that of a fox; 4 toes in forefoot, 3 in hindfoot. Dentition complete, premolars simple or last 2 slightly molariform, molars brachydont, bunodont, diastema short. Skull short, without postorbital bar. Three genera. Basic stock from which other members of family evolved.

†*Subfamily Anchitheriinae* (anchitheres). Lower Oligocene to lower Pliocene. Fossils from North America, Europe, Asia. Browsing horses. Early forms collie-sized (shoulder height about 60 centimetres), end forms as large as a rhinoceros. Three toes in each foot, central toe somewhat enlarged; metapodials elongated. First premolars reduced, second to fourth molariform. Cheek teeth brachydont, lophodont; ectoloph (longitudinal outer crest) above typically W-shaped cross-lophs retained distinct cusps; hypostyle at back edge of upper molars prominent. Lower cheek teeth with 2 crescent-shaped lophs and double cusp at junction. Diastema long, no postorbital bar. Six genera.

Subfamily Equinae (horses, asses, half-asses, and zebras). Lower Miocene to Pleistocene of North America; Pleistocene of South America; lower Pliocene to Recent of Europe, Asia, and Africa. Most forms as large as ponies or modern horses. Feet with 3 toes in early forms, 1 in later forms (but metapodia 2 and 4 persist as remnants), limbs with progressively elongated lower segments and reduced or fused ulna and fibula. Calcaneum without articulating surface for fibula. First premolars reduced or absent, others molariform; cheek teeth hypsodont, selenolophodont, with cement; canines in long diastema. Skull long, with postorbital bar in upper Miocene and later forms; nasals long and narrow. Some Recent forms with striped coat.

†*Superfamily Brontotherioidea*

†*Family Brontotheriidae* (titanotheres). Lower Eocene to lower Oligocene. Fossils from North America and Asia. Early forms as large as tapirs, end forms huge, standing 2.5 metres at the shoulder. Graviportal browsers; 4 toes in forefoot, 3 in hindfoot. Dentition complete, premolars small and simple in early forms; later forms with incisors and first premolars reduced or absent, remaining premolars only partly molarized. Molars large, bunolophodont, above with W-shaped ectoloph as in early equids, lower with double V resembling equid pattern but lacking reduplication of cusp at union of V's. Skull elongated, low, without postorbital bar, with large rough, hornlike process in later forms. About 39 genera.

†Suborder Ancylopoda

†*Family Chalicotheriidae* (chalicotheres). Upper Eocene to lower Pliocene. Fossils from North America, Europe, Asia. Early forms equivalent in size (and similar) to contemporary horses, *Hyracotherium*; later representatives larger, up to size of a modern horse. Most with forelegs longer than hindlegs and 3 toes in each foot; rudimentary metacarpal V retained in forefoot, most with clawlike digits. Incisors or canines reduced or absent; first premolar absent, remainder small and simple. Molars bunolophodont, cusp pattern similar to Brontotheriidae. About 13 genera. Aberrant perissodactyls which may have used claws to dig for bulbs and roots.

Suborder Ceratomorpha
Superfamily Tapiroidea

Brachydont forms, molars with simple ectoloph and strongly developed transverse protoloph and metaloph. Forefoot generally with 4 toes, hindfoot with 3.

†*Family Isectolophidae.* Lower to upper Eocene. Fossils from North America and Asia. Limb structure similar to that of *Hyracotherium*, teeth already tapiroid. Four genera.

†*Family Helaletidae.* Lower Eocene to middle Oligocene. Fossils from North America and Asia. Skull advanced in structure; premolars much simpler than molars, molars of simple lophodont form. Ten to 12 genera.

†*Family Lophiodontidae* (lophiodonts). Lower to upper Eocene; Europe and probably Asia. Skull not tapir-like, lophs of molariform teeth oblique. About 6 genera.

Family Tapiridae (tapirs). Lower Eocene to Recent. Fossils from North and South America, Europe, Asia, Africa. Recent species in Central and South America and Southeast Asia. Limited to tropical equatorial forests of South America and Asia. Browsers. Skull greatly modified; premolars completely molarized, first sometimes absent; transverse lophs strongly developed in molariform teeth, ectoloph simple. Limb structure primitive; 4 toes in forefoot; 3 in hindfoot. Six genera but only 1 extant.

Superfamily Rhinocerotoidea

Molars brachydont, upper with 2 transverse lophs fused with a well-developed ectoloph; lower with 2 asymmetrical crescents. Premolars more or less molariform. Rough processes on nasals (for horns) frequently present; forefoot with three or four toes.

†*Family Hyrachyidae.* Lower to upper Eocene; North America and probably Asia. Small animals; forefoot 4-toed; molariform teeth with separate tubercles. Four genera.

†*Family Hyracodontidae* (hyracodonts or running rhinoceroses). Middle Eocene to upper Oligocene. Fossils from North America and probably Asia. Relatively small; feet 3-toed, legs long and slender. Molariform teeth typically rhinocerotid. About 7 genera.

†*Family Amynodontidae* (amynodonts). Upper Eocene to middle Oligocene. Fossils from North America, Europe, Asia. Hippopotamus-like; forefoot 4-toed, hindfoot with 3 toes. Skull short, heavy, premolars and incisors reduced, premolars simple, canines and molars enlarged. Six genera.

Family Rhinocerotidae (rhinoceroses). Middle Eocene to present. Fossils from North America, Europe, Asia, and Africa. Now restricted to tropical Africa and Asia.

Large; most forms 3-toed. Skull elongated, raised at posterior end. Dentition incomplete, upper canines always absent, some incisors usually enlarged as cutting teeth; premolars molariform, last upper molar simple. About 34 genera, 4 extant.

Status of the chalicotheres

Critical appraisal. Systems of classification frequently differ in the status given to the chalicotheres. Simpson takes the view that their ancestry was probably equid and almost certainly hippomorph. He holds that the significance of their claws has been over-emphasized and has tended to distract attention from their true affinities. Accordingly he places them in the superfamily Chalicotheroidea of the suborder Hippomorpha. In the classification presented above they are given their own suborder, Ancylopoda, following the views of Alfred S. Romer, another authority on the group.

The forms united in the family Lophiodontidae by Simpson, followed here, are thought by some recent workers to warrant separation into three families. Romer distinguishes the families Lophialetidae, Deperetellidae, and Lophiodontidae. The affinities of certain primitive genera such as *Hyrachus* and *Colonoceras* remain controversial; Simpson places them in the family Hyrachyidae, superfamily Rhinocerotoidea. Romer considers them to be early tapiroids and assigns them to the Helatidae (superfamily Tapiroidea). The difference of opinion is slight, for it is generally agreed that the hyrachids are close in the common stem of the tapiroids and rhinocerotoids.

BIBLIOGRAPHY. Information on the ungulates as a group is contained in J. SIDNEY, "The Past and Present Distribution of Some African Ungulates," *Trans. Zool. Soc. Lond.* vol. 30 (1965), a comprehensive account, both geographical and temporal; and J.R. ELLERMAN and T.C.S. MORRISON-SCOTT, *Checklist of Palaearctic and Indian Mammals, 1758 to 1946*, 2nd ed. (1966).

Permafrost

Permafrost, or perennially frozen ground, is naturally occurring material that has a temperature colder than 0° C (32° F) continuously for two or more years. This layer of frozen ground is designated exclusively on the basis of temperature. Part or all of its moisture may be unfrozen, depending upon the chemical composition of the water or depression of the freezing point by capillary forces. Permafrost with saline soil moisture, for example, may be colder than 0° C for several years but would contain no ice and would not be firmly cemented. Most permafrost, however, is consolidated by ice; permafrost with no water, and thus no ice, is termed dry permafrost. The upper surface of permafrost is called the permafrost table. In permafrost areas the surface layer of ground that freezes in the winter (seasonally frozen ground) and thaws in summer is called the active layer. The thickness of the active layer depends mainly on the moisture content, varying from less than a foot in thickness in wet, organic sediments to several feet in well-drained gravels.

This article treats the origin and physical characteristics of permafrost. For further information on general soil properties, see SOILS; for discussions of climatic regimes and permafrost in the past, see CLIMATE; CLIMATIC CHANGE; and PLEISTOCENE EPOCH. See also ROCKS, PHYSICAL PROPERTIES OF, for information on the strength of natural materials, and GLACIATION, LANDFORMS PRODUCED BY, for relevant descriptions of physical features.

From T. Pewe, *The Periglacial Environment; Past and Present*, (1969); McGill-Queens University Press

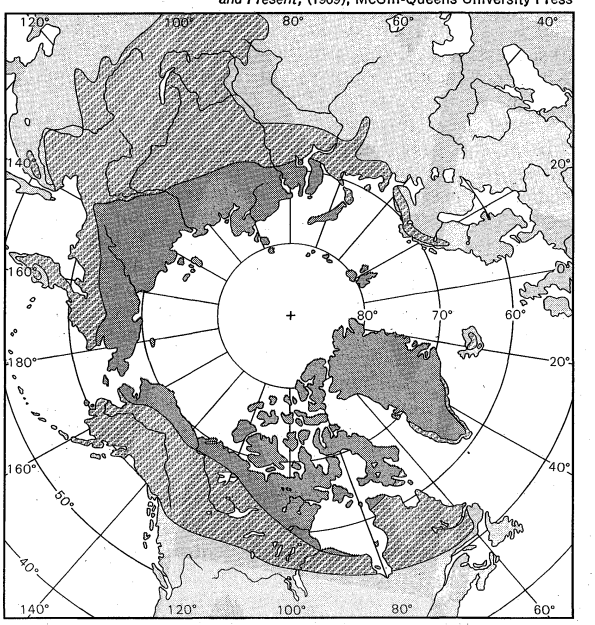

Figure 1: Distribution of permafrost in the Northern Hemisphere.

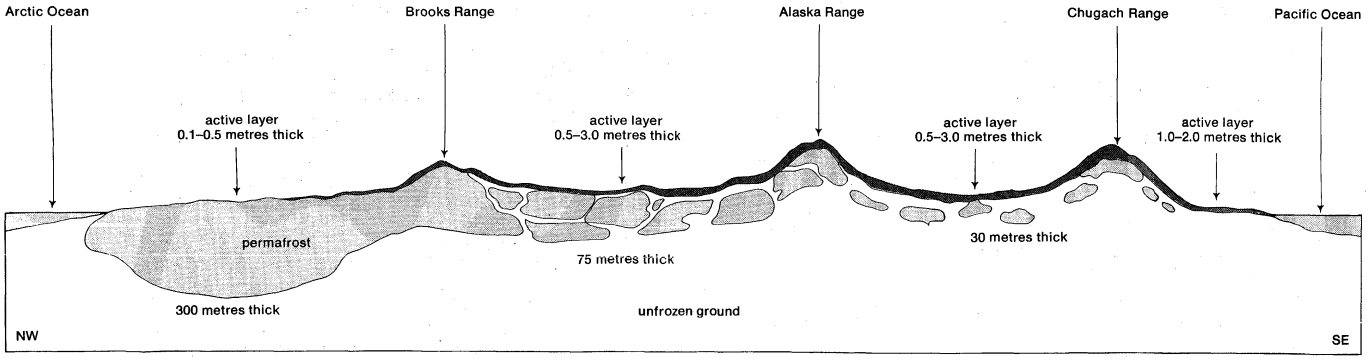

Figure 2: Approximate distribution of permafrost in Alaska.

Permafrost is widespread in the northern part of the Northern Hemisphere (Figure 1), and it is estimated to underlie 20 percent of the world's land surface. It occurs in 85 percent of Alaska, 50 percent of the U.S.S.R. and Canada, and probably all of Antarctica. In the Northern Hemisphere, permafrost is more widespread and extends to greater depths in the north than in the south. It is 5,000 feet (1,525 metres) thick in northern Siberia, 2,000 ft (610 m) thick in northern Alaska, and thins progressively toward the south (Figure 2). Permafrost can be differentiated into two broad zones; the continuous and the discontinuous, referring to the lateral continuity of permafrost. In the continuous zone of the far north, permafrost is nearly everywhere present except under the lakes and rivers that do not freeze to the bottom. The discontinuous zone includes numerous permafrost-free areas that increase progressively in size and number from north to south. Near the southern boundary, only rare patches of permafrost exist.

Permafrost forms and exists in a climate where the mean annual air temperature is 0° C or colder. Such a climate is generally characterized by long, cold winters with little snow and short, relatively dry, cool summers. Permafrost, therefore, is widespread in the Arctic, sub-Arctic, and Antarctica. There is a fairly good correlation between the southern boundary of Northern Hemisphere permafrost and the position of the 0° C mean annual air isotherm.

Although the existence of permafrost was known to the inhabitants of Siberia for centuries, scientists of the Western world did not take seriously isolated reports of thick frozen ground existing under northern forest and grasslands until 1836. Then, Alexander Theodor von Middendorff measured temperatures to depths of approximately 350 ft (107 m) of permafrost in the Shargin shaft, an unsuccessful well dug for the governor of the Russian-Alaskan Trading Company, at Yakutsk, and estimated that the permafrost was 700 ft (214 m) thick.

Carcass preservation

A most interesting aspect of permafrost is the preservation of carcasses and partial carcasses of modern and extinct Ice Age mammals within it. Frozen carcasses have been known in the north for centuries. The first direct report of a carcass of a mammoth in frozen ground of Siberia was by E. Yssbrants Ides in 1692. At least one or two almost complete, frozen mammoths have been reported from Siberia. Although no such famous frozen carcasses as those found in Siberia have been reported from North America, partial carcasses of mammoth, bison, musk ox, moose, horse, lynx, caribou, and ground squirrel have been found in Alaska.

Perhaps the most celebrated find of an Alaskan frozen carcass was the partial forequarters of a baby mammoth collected in 1948. The well-preserved hide of the head, neck, trunk, and one front leg was about one-quarter of an inch thick and almost hairless. A most interesting and important discovery of a partial carcass of an extinct superbison was made in 1951 in central Alaska (Figure 3); the age given for it by the radiocarbon laboratory of the Geological Survey of Sweden is 31,400 years.

Stories have been reported for many years of mammoth meat served at banquets, mammoths dying with buttercups in their mouths, and mammoths perishing as cataclysmic climatic changes took place that turned tropical

Figure 3: Partial carcass of an extinct bison *(Bison crassicornis)* discovered in frozen silt in Dome Creek, near Fairbanks, Alaska. An age of 31,400 (+2,040 or −1,815) years was obtained by testing a piece of hide for radioactive-carbon activity.
Troy L. Pewe

climates into frigid Arctic conditions. It is not necessary, however, to entertain fantasies about the distribution, preservation, and extinction of Ice Age mammals. Work in Alaska demonstrates that all the carcasses are between 10,000 and 70,000 years old and could not have been older because they would not have survived the preceding interglacial warm period when the ground and its enclosed carcasses thawed. In order to preserve the carcasses in nature's deep freeze, it is evident that most of the permafrost present today, in central Alaska at least, has existed since latest glacial times. Geological relationships and radiocarbon dates indicate that the carcasses are remains from the last glacial cold period and are not "a million years old" as casually announced on occasion. All evidence suggests that most carcasses represent natural deaths in a cold, harsh climate.

Permafrost affects many of man's activities in the Arctic and sub-Arctic, causing problems not experienced elsewhere and requiring that conventional engineering techniques be modified at additional costs. Agriculture, mining, water supply, sewage disposal, and construction are seriously affected by subsidence caused by thawing of perennially frozen ground as well as by associated problems brought on by soil flowage and frost action. Without a thorough understanding of thermal and mechanical problems unique to permafrost, impassable roads, unusable air strips, and abandoned buildings may result.

ORIGIN AND STABILITY OF PERMAFROST

In areas where the mean annual air temperature becomes colder than 0° C, some of the ground frozen in the winter will not be completely thawed in the summer; therefore, a layer of permafrost will form and continue to grow downward gradually each year from the seasonally frozen

ground. The permafrost layer will become thicker each winter, its thickness controlled by the thermal balance between the heat flow from the earth's interior and that flowing outward into the atmosphere. This balance depends upon the mean annual air temperature and the geothermal gradient. The average geothermal gradient is an increase of 1° C for every 100–200 ft (30.5 to 61 m) of depth. Eventually the thickening permafrost layer reaches an equilibrium depth at which the amount of geothermal heat reaching the permafrost is on the average equal to that lost to the atmosphere. Thousands of years are required to attain a state of equilibrium where permafrost is hundreds of feet thick.

Geothermal gradient

An example of the change of temperature of frozen ground with depth and the upper and lower limit of permafrost is illustrated in Figure 4. The annual fluctuation

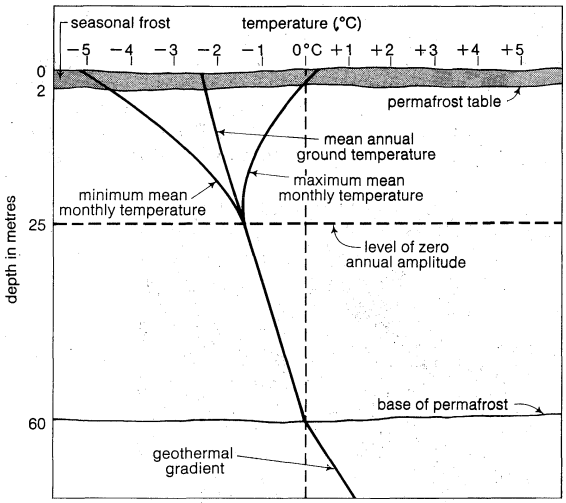

Figure 4: Hypothetical example of a temperature profile and thickness of permafrost in central Alaska.

of air temperature from winter to summer is reflected in a subdued manner in the upper few feet of the ground. This fluctuation diminishes rapidly with depth, being only a few degrees at 25 ft (7.6 m), and is barely detectable at 50 ft (15.2 m). The level of zero amplitude, at which fluctuations are hardly detectable, is 30–50 ft (9.2–15.2 m). If the permafrost is in thermal equilibrium, the temperature at the level of zero amplitude is generally regarded as the minimum temperature of the permafrost. Below this depth the temperature increases steadily under the influence of heat from the earth's interior. The temperature of permafrost at the level of zero amplitude is close to the average temperature of the ground surface, being, however, 2°–6° C warmer than the mean annual air temperature determined from the U.S. Weather Bureau-type surface installations (at a height of 5 ft [1.5 m] above ground level). The temperature of permafrost at the depth of minimum annual seasonal change varies from near 0° C at the southern limit of permafrost to −10° C in northern Alaska and −13° C in northeastern Siberia.

Climatic controls

As the climate becomes colder or warmer, but maintaining a mean annual temperature colder than 0° C, the temperature of the permafrost correspondingly rises or declines resulting in changes in the position of the base of permafrost. The position of the top of permafrost will be lowered by thawing when the climate warms to a mean annual air temperature warmer than 0° C. The rate at which the base or top of permafrost is changed depends not only on the amount of climatic fluctuation but also on the amount of ice in the ground and the composition of the ground, conditions that in part control the geothermal gradient. If the geothermal gradient is known and if the surface temperature is stable for a long period of time, it is, therefore, possible to predict from a knowledge of the mean annual air temperature the depth of permafrost in a particular area remote from water bodies.

Permafrost is the result of present climate. Many temperature profiles show, however, that permafrost is not in equilibrium with present climate at the sites of measurement. Some areas show, for example, that climatic warming since the last third of the 19th century has caused a warming of the permafrost to a depth of a few hundred feet. Here some of the existing perennially frozen ground would disappear with rising base of permafrost if present surface conditions were to persist for several thousands of years. Actually, in such areas much of the permafrost is a product of a colder, former climate.

It is thought that permafrost first occurred in conjunction with the onset of glacial conditions near the beginning of the Quaternary Period about 2,500,000 to 3,000,000 years ago. The oldest permafrost known in North America, however, is about mid-Quaternary in age, or less than 2,000,000 years old. In the sub-Arctic at least, most permafrost probably disappeared during the interglacial times and reappeared in glacial times. Most existing permafrost probably formed in the cold (glacial) period of the last 70,000 years.

LOCAL THICKNESS AND ICE CONTENT

The thickness and areal distribution of permafrost is directly affected by snow and vegetation cover, topography, bodies of water, the interior heat of the earth, and the temperature of the atmosphere as mentioned earlier.

The most conspicuous change in thickness of permafrost is related to climate. At Barrow, Alaska, the mean annual air temperature is −12° C and the thickness is 1,300 ft (396.5 m). At Fairbanks, Alaska, in the discontinuous zone of permafrost in central Alaska, the mean annual air temperature is −3° C and the thickness is about 300 ft (91.5 m). Near the southern border of permafrost, the mean annual air temperature is about 0° or −1° C and the perennially frozen ground is only a few feet thick.

If the mean annual air temperature is the same in two areas, the permafrost will be thicker where the conductivity of the ground is higher and the geothermal gradient is less. A.H. Lachenbruch of the U.S. Geological Survey reports an interesting example from northern Alaska. The mean annual air temperatures at Cape Simpson and Prudhoe Bay are similar, but permafrost thickness is 1,000 ft (305 m) at Cape Simpson and about 2,000 ft (710 m) at Prudhoe Bay because rocks at Prudhoe Bay are more siliceous and have a higher conductivity and a lower geothermal gradient than rocks at Cape Simpson.

Effect of water bodies

Bodies of water, lakes, rivers, and the sea have a profound effect on the distribution of permafrost. A deep lake that does not freeze to the bottom during the winter will be underlain by a zone of thawed material. If the minimum horizontal dimension of the deep lake is about twice as much as the thickness of permafrost nearby, there probably exists an unfrozen vertical zone extending all the way to the bottom of permafrost. Such thawed areas extending all the way through permafrost are widespread under rivers and sites of recent rivers in the discontinuous zone of permafrost and under major, deep rivers in the far north. Under the wide floodplains of rivers in the sub-Arctic, the permafrost is sporadically distributed both laterally and vertically. Small, shallow lakes that freeze to the bottom each winter are underlain by a zone of thawed material, but the thawed zone does not completely penetrate permafrost except near the southern border of permafrost.

Inasmuch as south-facing hillslopes receive more incoming solar energy per unit area than other slopes, they are warmer; permafrost is generally absent on these in the discontinuous zone (Figure 5) and is thinner in the continuous zone.

The main role of vegetation in permafrost areas is to shield perennially frozen ground from solar energy. Vegetation is an excellent insulating medium and removal or disturbance of it, either by natural processes or by man, causes thawing of the underlying permafrost. In the continuous zone the permafrost table may merely be lowered by the disturbance of vegetation, but in a discontinuous zone permafrost may be completely destroyed in certain areas.

Snow cover also influences heat flow between the ground and the atmosphere and therefore affects the distribution

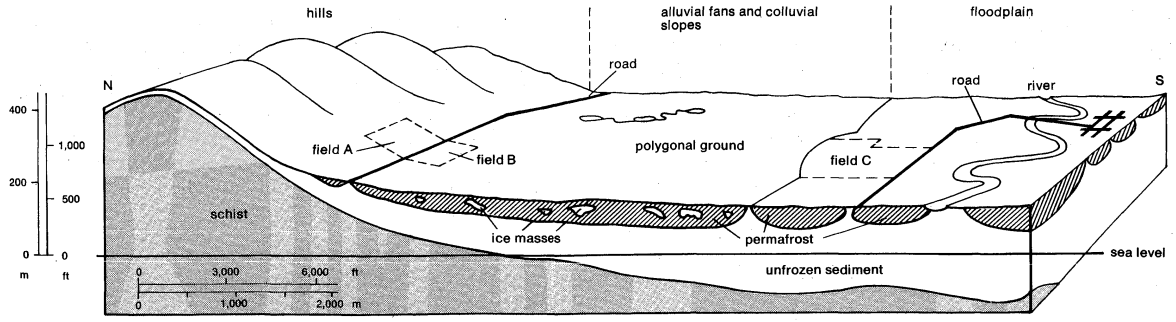

Figure 5: Character and distribution of permafrost in Fairbanks, Alaska, area.
From T. Pewe, *Permafrost and its Effect on Life in the North* (1966); Oregon State University Press

of permafrost. If the net effect of timely snowfalls is to prevent heat from leaving the ground in the cold winter, permafrost becomes warmer. Actually, local differences in vegetation and snowfall in areas of thin and warm permafrost are critical for the formation and existence of the perennially frozen ground. Permafrost is not present in areas of the world where great snow thicknesses persist throughout most of the winter.

Types of ground ice. The ice content of permafrost is probably the most important feature of permafrost affecting human life in the north. Ice in the perennially frozen ground exists in various sizes and shapes and has definite distribution characteristics. The forms of ground ice can be grouped into five main types: (1) pore ice; (2) segregated, or Taber, ice; (3) foliated, or wedge, ice; (4) pingo ice; and (5) buried ice.

1. Pore ice, which fills or partially fills pore spaces in the ground, is formed by pore water freezing *in situ* with no addition of water. The ground contains no more water in the solid state than the ground could hold if the water were in liquid state.
2. Segregated, or Taber, ice includes ice films, seams, lenses, pods, or layers generally 1/16 inch to 5 inches (0.16 to 12.7 centimetres) thick that grow in the ground by drawing in water as the ground freezes. Small ice segregations are the least spectacular but one of the most extensive types of ground ice, and engineers and geologists interested in ice growth and its effect on engineering structures have studied them considerably. Such observers generally accept the principle of bringing water to a growing ice crystal, but they do not completely agree as to the mechanics of the processes. Pore ice and Taber ice occur both in seasonally frozen ground and in permafrost.
3. Foliated ground ice, or wedge ice, is the term for large masses of ice growing in thermal contraction cracks in permafrost.
4. Pingo ice is clear, or relatively clear, and occurs in permafrost more or less horizontally or in lens-shaped masses. Such ice originates from groundwater under hydrostatic pressure.
5. Buried ice in permafrost includes buried sea, lake, and river ice and recrystallized snow, as well as buried blocks of glacier ice in permafrost climate.

Ice content

World estimates of the amount of ice in permafrost vary from 48,000 to 120,000 cubic miles (200,000 to 500,000 cubic kilometres), or less than 1 percent of the total volume of the earth. Based on an examination of ice in the ground in many bore holes near Barrow, Alaska, and extrapolation of this bore hole information to the rest of the Coastal Plain by use of aerial photographs and geologic maps, it has been estimated that 10 percent by volume of the upper 10 ft (3.05 m) of permafrost on the Coastal Plain of Alaska is composed of foliated ground ice (ice wedges). Taber ice is the most extensive type of ground ice, and in places it represents 75 percent of the ground by volume. It is calculated that the pore and Taber ice content in the depth between 1.5 and 10 ft (0.46 and 3.05 m; surface to 1.5 feet is seasonally thawed) is 61 percent by volume, and between 10 and 30 ft (3.05 and 9.15 m) it is 41 percent. The total amount of pingo ice is less than 0.1 percent of the permafrost. The total ice content in the permafrost of the Arctic Coastal Plain of Alaska is estimated to be 360 cu mi (1,500 cu km), and below 30 ft (9.15 m) most of that is present as pore ice.

Ice wedges. The most conspicuous and controversial type of ground ice in permafrost is that formed in large ice wedges or masses with parallel or subparallel foliation structures. Most foliated ice masses occur as wedge-shaped, vertical, or inclined sheets or dikes 1 in. to 10 ft (2.54 cm to 3.05 m) wide and 1–30 ft (0.305 to 9.15 m) high when viewed in transverse cross section (Figure 6).

Troy L. Pewe

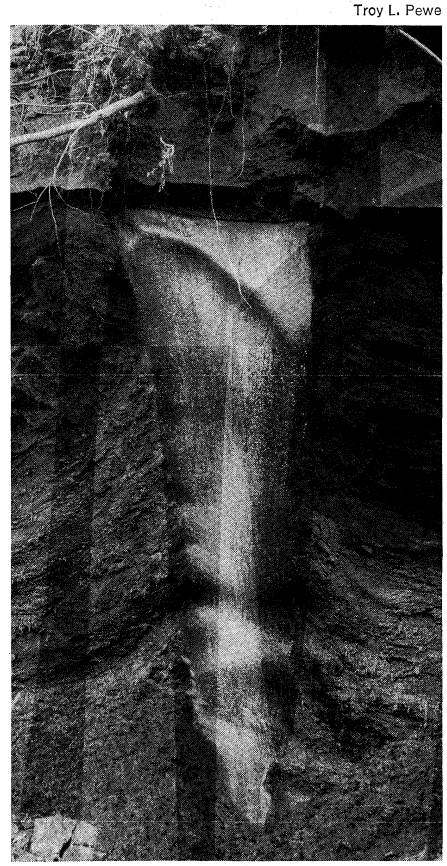

Figure 6: Foliated ground-ice mass (ice wedge) in organic rich silt exposed by gold-mining operations on Wilber Creek, near Livengood, Alaska.

Some masses seen on the face of frozen cliffs may appear as horizontal bodies a few inches to 10 ft (3 m) in thickness and 1–45 ft (0.305 to 13.7 m) long, but the true shape of these ice wedges can be seen only in three dimensions. Ice wedges are parts of polygonal networks of ice enclosing cells of frozen ground 10–100 ft (3–30 m) or more in diameter.

Thermal contraction theory

The origin of ground ice was first studied in Siberia, and discussions in print of the origin of large ground-ice masses in perennially frozen ground of North America have gone on since Otto von Kotzebue recorded ground ice in 1816 at a spot now called Elephant's Point in Eschscholtz Bay of Seward Peninsula. The theory for the origin of ice wedges now generally accepted is the thermal

contraction theory that, during the cold winter, polygonal thermal contraction cracks, about an inch wide and several feet deep, form in the frozen ground; then when, in early spring, water from the melting snow runs down these tension cracks and freezes, a vertical vein of ice is produced that penetrates into permafrost; when the permafrost warms and re-expands during the following summer, horizontal compression produces upturning of the frozen sediment by plastic deformation; then during the next winter, renewed thermal tension reopens the vertical ice-cemented crack, which may be a zone of weakness; another increment of ice is added in the spring when meltwater again enters and freezes. Over the years the vertical wedge-shaped mass of ice is produced (Figure 6).

Ice wedges may be classified as active, inactive, and ice-wedge casts. Active ice wedges are those that are actively growing. The wedge may not crack every year, but during many or most years cracking does occur, and an increment of ice is added. Ice wedges require a much more rigorous climate to grow than does permafrost. The permafrost table must be chilled to −15° C to −20° C for contraction cracks to form. On the average, it is assumed that ice wedges generally grow in a climate where the mean annual air temperature is −7° or −8° C or colder.

The area of active ice wedges appears to roughly coincide with the continuous permafrost zone. From north to south across the permafrost area in North America, a decreasing number of wedges crack frequently. The line dividing zones of active and inactive ice wedges is arbitrarily placed at the position where it is thought most wedges do not frequently crack.

Inactive ice wedges are those that are no longer growing. The wedge does not crack in winter and, therefore, no new ice is added. A gradation between active ice wedges and inactive ice wedges occurs in those wedges that crack rarely. Inactive ice wedges have no ice seam or crack extending from the wedge upward to the surface in the spring. The wedge top may be flat (Figure 6), especially if thawing has lowered the upper surface of the wedge at some time in the past.

Indication of former temperature

Ice wedges in the world are of several ages, but none appear older than the outset of the last major cold period, about 70,000 years ago. Wedges dated by radiocarbon analyses range from 3,000 to 32,000 years in age.

In many places in the now temperate latitudes of the world, in areas of past permafrost, ice wedges have melted, and resulting voids have been filled with sediments collapsing from above and the sides. These ice-wedge casts, or fossil ice wedges, are important as paleoclimatic indicators and indicate a climate of the past with at least a mean annual air temperature of −7° or −8° C or colder.

SURFACE MANIFESTATIONS OF PERMAFROST AND SEASONALLY FROZEN GROUND

Many distinctive surface manifestations of permafrost exist in the Arctic and sub-Arctic, including such geomorphic features as polygonal ground, thermokarst phenomena, and pingos. In addition to the above, there are many features caused in large part by frost action that are common in but not restricted to permafrost areas, such as solifluction (soil flowage) and frost-sorted patterned ground.

Areas underlain by permafrost. One of the most widespread geomorphic features associated with permafrost is the microrelief pattern on the surface of the ground generally called polygonal ground, or tundra polygons (Figure 7). This pattern, which covers thousands of square miles of the Arctic and less in the sub-Arctic, is caused by an intersecting network of shallow troughs (delineating polygons 10–100 ft (3.05 to 30.5 m) in diameter. The troughs are underlain by more or less vertical ice wedges (Figure 6) 2–10 ft (0.71 to 3.05 m) across on the top that are joined together in a honeycomb network. These large-scale polygons should not be confused with the small-scale polygons or patterned ground produced by frost sorting.

Ice-wedge polygons

The ice-wedge polygons may be low centred or high centred. Upturning of strata adjacent to the ice wedge may make a ridge of ground on the surface on each side of the wedge, thus enclosing the polygons. Such polygons are lower in the centre and are called low-centre polygons or raised-edge polygons and may contain a pond in the centre. Low-centre, or raised-edge, polygons indicate that ice wedges are actually growing and that the sediments are being actively upturned. If erosion, deposition, or thawing is more prevalent than the up-pushing of the sediments along the side of the wedge or if the material being pushed up cannot maintain itself in a low ridge, the low ridges will be absent, and there may be either no polygons at the surface or the polygons may be higher in the centre than the troughs over the ice wedges that enclose them. Both high-centre and low-centre tundra polygons are widespread in the polar areas and are good indicators of the presence of foliated ice masses; care must be taken, however, to demonstrate that the pattern is not a relic and an indication of "fossil ice" wedges.

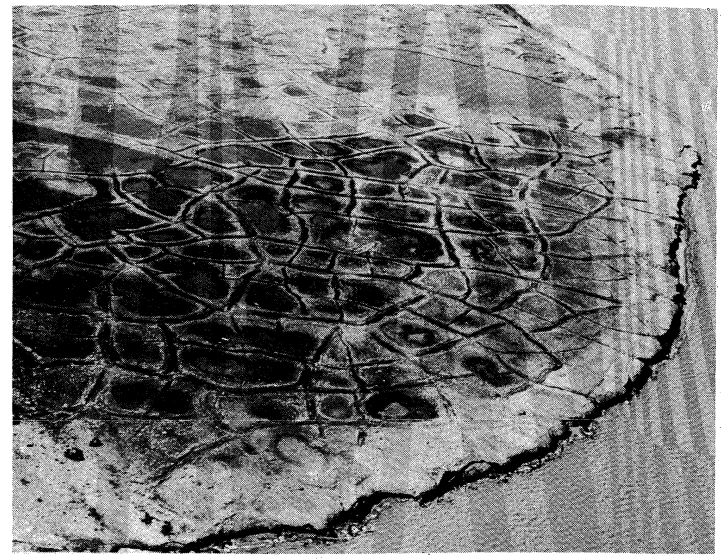

Figure 7: Raised-edge ice wedge polygons on the seacoast near Barrow, Alaska, in summer. The polygons are from seven to 15 metres in diameter.
By courtesy of the U.S. Army (CRREL); photograph, Robert Lewellen

In many parts of the temperate latitudes of Asia, Europe, and North America, incompletely developed or poorly developed polygonal ground occurs on the same scale as in the Arctic. These large-scale polygons in the nonpermafrost areas are excellent evidence of the former extent of permafrost and ice wedges in the last glacial period.

In many areas of the continuous permafrost zone surface, drainage follows the troughs of the polygons (tops of the ice wedges); and at ice wedge junctions, or elsewhere, melting may occur to form small pools. The joining of these small pools by a stream causes the pools to resemble beads on a string, a type of stream form called beaded drainage. Such drainage indicates the presence of perennially frozen, fine-grained sediments cut by ice wedges.

Thermokarst topography and pingos

The thawing of permafrost creates thermokarst topography, an uneven surface that contains mounds, sinkholes, tunnels, caverns, and steep-walled ravines caused by melting of ground ice. The hummocky ground surface resembles karst topography found in limestone areas. Thawing may result from artificial or natural removal of the vegetation or from warming of the climate (Figure 8).

Thawed depressions filled with water (thaw lakes, thermokarst lakes, cave-in lakes) are widespread in permafrost areas, especially in those underlain with perennially frozen silt. They may occur on hillsides or even on hill tops and are good indicators of ice-rich permafrost. Locally, deep thermokarst pits 20 ft (6.1 m) deep and 30 ft (9.15 m) across may form as ground ice melts. These openings may exist as undetected caverns for many years before the roof collapses. Such collapses in agricultural or construction areas are real dangers. Thermokarst mounds are polygonal or circular hummocks 10–50 ft (3.05 to 15.25 m) in diameter and 1–8 ft (0.305 to 2.84 m) high

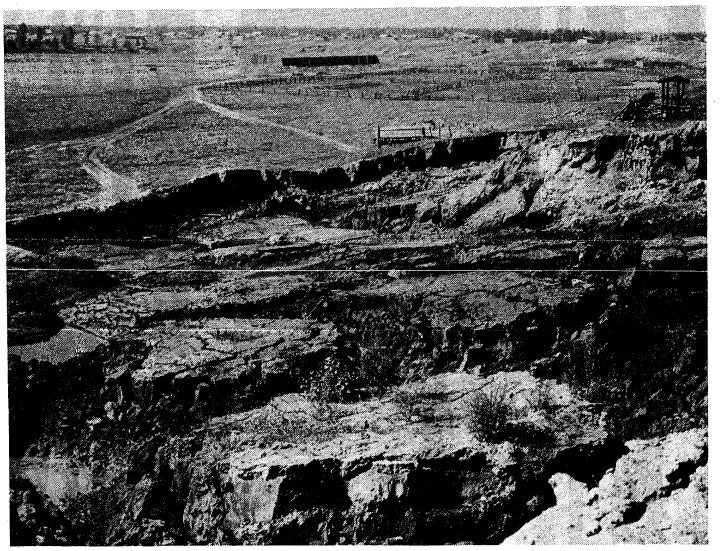

Figure 8: Modern thermokarst formation at Maya, near Yakutsk, Siberia.
Troy L. Pewe

that are formed as a polygonal network of ice melts and leaves the inner-ice areas as mounds.

The most spectacular landforms associated with permafrost are pingos, small ice-cored circular or elliptical hills of frozen sediments or even bedrock, 10 to more than 200 ft (3.05 to 61 m) high and 50 to 1,500 ft (15.25 to 457.5 m) in diameter. Pingos are widespread in the continuous permafrost zone and are quite conspicuous because they rise above the tundra. They are much less conspicuous in the forested area of the discontinuous permafrost zone. They are generally cracked on top with summit craters formed by melting ice. There are two types of pingos, based on origin. The closed-system type forms in level areas when unfrozen groundwater in a thawed zone becomes confined on all sides by permafrost, freezes, and heaves the frozen overburden to form a mound. This type is larger and occurs mainly in tundra areas of continuous permafrost. The open-system type is generally smaller and forms on slopes when water beneath or within the permafrost penetrates the permafrost under hydrostatic pressure. A hydrolaccolith (water mound) forms and freezes, heaving the overlying frozen and unfrozen ground to produce a mound.

Present pingos are apparently the result of postglacial climate and are less than 4,000–7,000 years old. Pingos were present in now temperate latitudes during the latest glacial epoch and are now represented by low circular ridges enclosing bogs or lowlands.

Near the southern border of permafrost occur palsas, low hills and knobs of perennially frozen peat about 5–20 ft (1½ to 6 m) high, evidently forming with accumulation of peat and segregation of ice.

Features related to seasonal frost. Many microgeomorphic features common to the periglacial environment may or may not be associated with permafrost. Intense seasonal frost action, repeated freezing and thawing throughout the year, produces small-scale patterned ground. Repetitive freezing and thawing tends to stir and sort granular sediments, thus forming circles, stone nets, and polygons a few inches to 20 ft (6 m) in diameter. The coarse cobbles and boulders form the outside of the ring and the finer sediments occur in the centre. The features require a rigorous climate with some fine-grained sediments and soil moisture, but they do not necessarily need underlying permafrost. Permafrost, however, forms an impermeable substratum that keeps the soil moisture available for frost action. On gentle slopes the stone nets may be distorted into garlands by downslope movement or, if the slope is steep, into stone stripes 1–2 ft (0.305 to 0.61 m) wide and 100 ft (30.5 m) long.

Stone stripes, stone nets, patterned ground, and solifluction

In areas underlain by an impermeable layer (seasonally frozen ground or perennially frozen ground), the active layer is often saturated with moisture and is quite mobile. The progressive downslope movement of saturated detrital material under the action of gravity and working in conjunction with frost action is called solifluction. This material moves in a semifluid condition and is manifested by lobelike and sheetlike flows of soil on slopes. The lobes are up to 100 ft (30.5 m) wide and have a steep front 1–5 ft (0.305 to 1.52 m) high. An outstanding feature of solifluction is the mass transport of material over low-angle slopes. Solifluction deposits are widespread in polar areas and consist of a blanket 1–6 ft (0.305 to 1.83 m) thick of unstratified or poorly stratified, unsorted, heterogeneous, till-like detrital material of local origin. In many areas the terrain is characterized by relatively smooth, round hills and slopes with well-defined to poorly defined solifluction lobes or terraces. If the debris is blocky and angular and fine material is absent, the lobes are poorly developed or absent. Areas in which solifluction lobes are well formed lie almost entirely above or beyond the forest limit.

In many areas the frost-rived debris contains few fine materials, little water, and consists of angular fragments of well-jointed, resistant rock. Under such circumstances, solifluction lobes do not often occur, but instead striking sheets or streams of angular rubble form. These are called rock streams or rubble sheets.

PROBLEMS POSED BY PERMAFROST

Development of the north demands an understanding of and the ability to cope with problems of the environment dictated by permafrost. Although the frozen ground hinders agricultural and mining activities, the most dramatic, widespread, and economically important examples of the influence of permafrost on life in the north involve construction and maintenance of roads, railroads, airfields, bridges, buildings, dams, sewers, and communication lines. Engineering problems are of four fundamental types: (1) those involving thawing of ice-rich permafrost and subsequent subsidence of the surface under unheated structures such as roads and airfields; (2) those involving subsidence under heated structures; (3) those resulting from frost action, generally intensified by poor drainage caused by permafrost; and (4) those involved only with the temperature of permafrost that causes buried sewer, water, and oil lines to freeze.

A thorough study of the frozen ground should be part of the planning of any engineering project in the north. It is generally best to attempt to disturb the permafrost as little as possible in order to maintain a stable foundation for engineering structures, unless the permafrost is thin; then, it may be possible to destroy the permafrost. The method of construction preserving the permafrost has been called the passive method; alternately, the destroying of permafrost is the active method.

Because thawing of permafrost and frost action are involved in almost all engineering problems in polar areas, it is advisable to consider these phenomena generally. The delicate thermal equilibrium of permafrost is disrupted when the vegetation, snow cover, or the active layer is compacted. The permafrost table is lowered, the active layer is thickened, and considerable ice is melted. This process lowers the surface and provides (in summer) a wetter active layer with less bearing strength. Such disturbance permits a greater penetration of summer warming. It is common procedure to place a fill, or pad, of gravel under engineering works. Such a fill generally is a good conductor of heat and, if thin, may cause additional thawing of permafrost. The fill must be made thick enough to contain the entire amplitude of seasonal temperature variation—in other words, thick enough to restrict the annual seasonal freezing and thawing to the fill and the compacted active layer. Under these conditions no permafrost will thaw. Such a procedure is quite feasible in the Arctic, but in the warmer sub-Arctic it is impractical because of the enormous amounts of fill needed. Under a heated building, profound thawing may occur more rapidly than under roads and airfields.

Frost action, the freezing and thawing of moisture in the ground, has long been known to seriously disrupt and destroy structures in both polar and temperate latitudes.

Frost action and man-made structures

In the winter the freezing of ground moisture produces upward displacement of the ground (frost heaving), and in the summer excessive moisture in the ground brought in during the freezing operation causes loss of bearing strength. The intensity of frost action is regulated by temperature, the texture of the ground, and the amount of soil moisture. Frost action is best developed in silt-sized and silty clay-sized sediments in areas of rigorous climate and poor drainage. Polar latitudes are ideal for maximum frost action because most lowland areas are covered by fine-grained sediments, and the underlying permafrost causes poor drainage.

Piles are used to support many, if not most, structures built on ice-rich permafrost. In regions of cold winters, many pile foundations are in ground subject to seasonal freezing and, therefore, possibly subject to the damaging effect of frost heaving, which tends to displace the pile upward and thus to disturb the foundation of the structure. The displacement of piling is not limited to the far north, though maximum disturbance probably is encountered most widely in the sub-Arctic. Expensive maintenance and sometimes complete destruction of bridges, school buildings, military installations, and other structures have resulted from failure to understand the principles of frost heaving of piling.

The need for careful geological location of highways, railroads, airfields, and pipelines is very important anywhere in the world; but it is absolutely essential in permafrost areas in order to avoid constant, costly maintenance—if not complete abandonment. Such location studies were not frequently considered in construction work before the 1950s in North America and perhaps before the 1930s in Asia. Even late in the 20th century, many construction projects proceeded with inadequate location studies.

Highways in polar areas are relatively few and mainly unpaved. They are subject to subsidence by thawing of permafrost in summer, frost heaving in winter, and loss of bearing strength on fine-grained sediments in summer. Constant grading of gravel roads permits maintenance of a relatively smooth highway. Where the road is paved over ice-rich permafrost, the roadway becomes rough and is much more costly to maintain than are unpaved roads. Many of the paved roads in polar areas have required resurfacing two or three times in a ten-year period.

Railroads particularly have serious construction problems and require costly upkeep in permafrost areas because of the necessity of maintaining a relatively low gradient and the subsequent location of the roadbed in ice-rich lowlands that are underlain with perennially frozen ground. The Trans-Siberian Railroad, the Alaska Railroad, and some Canadian railroads in the north are locally underlain by permafrost with considerable ground ice. As the large masses of ice melt each summer, constant maintenance is required to level these tracks. In winter, extensive maintenance is also required to combat frost heaving when local displacements of 1–14 in. (2.54–35.6 cm) occur in roadbeds and bridges.

Heated buildings in polar areas can have a conventional basement if they are built in areas of no permafrost or of bedrock and gravel with little or no ice. Construction of such buildings on ice-rich permafrost, however, requires a technique that enables the cold winter air to circulate under the building to counteract the heat generated in the building. The most common way to build structures above the ground with large spaces under the foundation for airflow is to construct on piles, a technique perfected both in the U.S.S.R. and in North America. The piles must be erected so that they do not move. If the piles are jacked up in the winter by frost action, the building will be disturbed and can be destroyed. It is therefore important that the pile be adequately anchored in permafrost or it be isolated from the heaving of the ground by a movable collar.

Groundwater and agriculture

Both surface and subsurface water supplies in the north are beset by problems uncommon in temperate latitudes. Groundwater sources are above the permafrost, in unfrozen zones within the permafrost, and below the permafrost. Sources above permafrost may be seasonal and subject to contamination from cesspools. Sources from unfrozen zones within the permafrost are common in the discontinuous zones where water also can be obtained below permafrost. In the far north, however, little water is available in the permafrost, deep drilling (1,000–2,000 ft [305 to 610 m]) is expensive, and the sediments generally lack sufficient groundwater.

Distribution of water and sewage presents unique problems in permafrost areas. In addition to requiring a heated distribution system to prevent freezing in permafrost or seasonal frost areas, utility distribution lines are subject to problems because of frost action and thawing of permafrost. The most successful construction method generally used in such situations is to place all services in heated distribution boxes called utilidors, which enclose water, steam, gas, sewage, and other utilities. The utilidor may be either under or above ground.

Permafrost affects agricultural developments in many parts of the discontinuous permafrost zone. Its destructive effect on cultivated fields in both the U.S.S.R. and North America results from the thawing of large masses of ice in the permafrost. If care is not exercised in selecting areas to be cleared for cultivation, thawing of the permafrost may necessitate abandonment of fields or their reduction to pasturage. As illustrated in Figure 5, Field A, on the southward-facing hillside, is not affected by permafrost; Field B, on the alluvial fan, however, is underlain with permafrost containing large masses of ground ice. When Field B is cleared, thermokarst topography will form. Field C, on the floodplain, is underlain with permafrost without large ice masses, and so no thermokarst pits and mounds will form when this ground is cleared.

In summary, it can be said that in construction and maintenance of railroads, buildings, water and sewer lines, dams, roads, bridges, and airfields, normal techniques must often be modified at additional costs because of permafrost. But, despite special problems unique to polar areas, development of the permafrost regions will continue at an ever-increasing rate. Man has already learned to cope with the problems, and improvements of scientific and engineering approaches, with careful geological site selection and study of the permafrost problem, will allow successful expansion into polar areas.

Permian Period

Identification and definition

The Permian Period is a geological interval of time from about 280,000,000 to 225,000,000 years ago, during which the rocks of the Permian System were formed. This system was next to the last to be defined and is the only one not based on a type area in central or western Europe. In 1841 the Czar of Russia invited Sir Roderick Murchison, renowned British geologist, to carry out a comprehensive reconnaissance of the vast territories of European Russia, which at that time were little known geologically. Along the western slopes of the Ural Mountains, Murchison recognized a sequence of beds that proved to be younger than rocks of the Carboniferous Period (345,000,000 to 280,000,000 years ago) in England, which he knew well. Murchison assigned these rocks to a new system that he called Permian, after the district of Perm, U.S.S.R., in which they typically occurred. Murchison also recognized the equivalence of these rocks with sequences that had been described in Germany as Rotliegendes and Zechstein by earlier observers. In his original (1845) description, Murchison included the lower part of the Buntsandstein, which is now regarded as Triassic (225,000,000 to 190,000,000 years ago) in age.

Although the concept of the Permian Period was accepted by most geologists well before the end of the 19th century, proposals to discontinue its use were discussed as late as 1948, and the U.S. Geological Survey did not officially recognize it until 1941.

The most important Permian economic deposits are rock salt and potash salts, coal, oil, and gas. Economically important evaporites (salts formed by chemical precipitation under generally arid conditions) of Permian age are found in the United States, especially in west Texas; in Europe, in the Upper Permian Zechstein Basin of northern Germany, from where they extend in the subsurface into The Netherlands, England, Denmark, the North Sea, and Poland. The largest area of Permian salt deposition was in eastern European Russia, extending in a broad arch from the Dnepr River to the Caspian Sea and northward along the length of the Ural Mountains. In the Southern Hemisphere, Permian salt deposits are known only from South America (northeastern Brazil, Peru), where they are not of economic importance.

Permian coals (*q.v.*) occur in great quantity and excellent quality in many parts of the world. The most important deposits are in central and northern Siberia, northern and eastern China, India, Australia, South Africa, Rhodesia, and the Congo. No important coal deposits of Permian age are known in the Western Hemisphere.

Oil and gas are produced from Permian rocks in Oklahoma, Texas, eastern European Russia, and, increasingly, in The Netherlands, Germany, and the North Sea.

Phosphorites (*q.v.*) of Permian age crop out in Montana, Idaho, Wyoming, and Utah and also occur in the U.S.S.R. west of the Ural Mountains.

A copper-bearing deposit, known as *Kupferschiefer* (copper shale), occurs in Germany, where it has long been mined. It is a rare deposit formed under anaerobic (oxygen deficient) conditions in a basin with restricted circulation. Copper also is associated with sedimentary rocks of Permian age in Texas and Oklahoma.

Standard subdivisions

The rocks of the Permian Period generally are subdivided into a Lower Permian Series and an Upper Permian Series. The boundary between the two series is placed either at the base or the middle of the Guadalupian Stage of marine deposits in west Texas. Some authors have adopted a threefold division and use Middle Permian in their stratigraphic discussions, which is not recognized internationally. When so used, it generally includes the Artinskian and the lower half of the Guadalupian (Table 1).

Investigations during the 19th and especially the 20th century indicated that in its type locality the Permian was represented by marine and continental sediments. Marine stages are the Asselian, Sakmarian, and Artinskian. The Kungurian and Kazanian stages are of restricted marine type, containing a fauna that is not comparable with faunas in other parts of the world, and the uppermost stage, the Tartarian, comprises sediments of continental origin. Marine deposits of Late Permian age occur in other parts of the world, however. The question of worldwide correlation of the youngest Permian rocks is as yet unresolved.

Table 1: Marine Stages of the Permian System

	name	typical locality
Upper Permian	Dzhulfian	Armenian S.S.R.
	Chhidruan	Salt Range, Pakistan
	Guadalupian	West Texas
Lower Permian	Roadian	West Texas
	Artinskian, Sakmarian, Asselian	Perm Province, Ural Mountains

In parts of the world where relationships of strata of local significance with the standard reference sequences are not clear, independent stage classifications have been proposed (Table 2).

This article treats the rocks, life, and environment of Permian time. For coverage of adjacent intervals of geological time, see CARBONIFEROUS PERIOD, UPPER; and TRIASSIC PERIOD; an overview including the Permian Period is presented in PALEOZOIC ERA, UPPER. See also, FOSSIL RECORD; STRATIGRAPHIC BOUNDARIES; and MOUNTAIN BUILDING PROCESSES for further details on Permian life and environments; CLIMATIC CHANGE and CONTINENTAL DRIFT for the problem of Permian paleography; and PETROLEUM for oil and gas deposits.

PERMIAN ROCKS

Permian rocks are widely distributed in the geosynclinal belts (primarily, the modern mountain belts) of the world, although complete sections are rare because of much subsequent folding and metamorphism (changes due to temperature and pressure).

Major sequences

Thick Permian sequences occur in western North America and are best known in Texas, Nevada, and Utah. In the east–west geosynclinal belt of Europe and Asia, generally referred to as Tethys, important Permian occurrences are found from Sicily in the west to the island of Timor in the east, although in no single locality is the system represented in its entirety. Thick sequences of Permian rocks, mostly carbonates, are known in Anatolia, the Middle East, Iran, Transcaucasia, the Salt Range of Pakistan, Siberia, Central Asia, and Kashmir. In the circum-Pacific geosynclinal belt, Permian rocks are best known from China, Japan, western North America (including northern Mexico), Peru, and from New Zealand.

From the geosynclines, shallow seas spread over adjacent continental areas, especially in Early and early Late Permian times. Deposits in these seas, usually sandstone and shale and partly carbonate rocks, typically occur in the midcontinent of North America and in the Russian platform. Thick accumulations of Permian sediments are found in the Sverdrup Basin of the Canadian Arctic Archipelago and in East Greenland.

A special case is that of the Ural Geosyncline, which through much of Paleozoic time separated Europe from Asia. Permian sediments accumulated in great thickness but were folded during the Late Permian when the two continents were welded into one land mass.

Continental and restricted basin sediments are characteristic of western and central Europe north of the Tethys, peninsular India, and most continents of the Southern Hemisphere. In Australia, marine sediments occur in several large sedimentary basins along the west coast and in a broad belt in the east, extending from Tasmania to northern Queensland. Continental sediments of Permian age are rare in the west, but in the eastern belt they generally form the upper part of the Permian sequence. The predominantly continental development of the Permian in the Southern Hemisphere and peninsular India has been called the Gondwana Facies.

Igneous rocks commonly are associated with sedimentary deposits in the geosynclinal areas and less commonly in epicontinental or shallow-shelf areas.

Like other geological systems the Permian is represented

Table 2: Standard Stage Sequences of the Permian in Some Important Areas

	Ural Mountains	Central and Southwestern Asia		Texas		New Zealand
Upper Permian	Tartarian	Pamirian	Dzhulfian	Ochoan		Makarewan
			Chhidruan			Waiitian
	Kazanian	Murghabian		Capitanian	Guadalupian	Purnhanan

				Leonardian		Mangapirian
	Sakmarian / Asselian	Karachatyrian		Wolfcampian		Telfordian ?

Sedimentation and facies

by a great variety of sedimentary rocks. Limestone occurs widely in the miogeosynclines (shallow, near-continent, depositional troughs) and shallow shelves of the Northern Hemisphere. It includes ancient coral reef-like formations in the Guadalupe Mountains of New Mexico and Texas and in the subsurface of west Texas. Elsewhere, Permian reef formations are known from Germany, the eastern Alps, the western Urals, Caucasus, and from Chile.

The world's eugeosynclines (deep-sea depositional troughs associated with volcanic deposits), such as those situated in western North America, the Urals, and New Zealand, contain huge accumulations of clastic rocks mixed with products of extensive igneous activity, both intrusive and extrusive. Thick limestone sequences are also present locally. Areas of maximum deposition include west Texas (5,000 metres or 16,000 feet), the miogeosyncline of Nevada and Utah (4,000 metres or 13,000 feet), and parts of Central Asia: Tien Shan (3,900 metres or 12,800 feet); Pamir (3,700 metres or 12,100 feet).

Clastic sediments prevail almost entirely in the great basins on the eastern and western side of Australia. In the eastern basins, especially in New South Wales and Queensland, much igneous activity accompanied sedimentation; and basalt, andesite, and other volcanic rocks were formed. In the western basins, great columns of sedimentary rocks accumulated—*e.g.*, 4,600 metres or 15,000 feet of Permian marine rocks in the Carnarvon Basin of Australia. Clastic marine rocks of Permian age are also widely distributed in Southwest Africa, western South Africa, and eastern Argentina.

Tillite, a name applied to ancient glacial tills, is widely distributed in the Permian record. The term also has been applied to other glacial and nonglacial deposits, however, and this has caused some confusion.

Rocks of continental origin are mostly sandstone but include conglomerate and shale, and these are widely distributed in the southwestern United States (Supai Formation, Coconino Sandstone of Arizona, Yeso Formation of New Mexico and Texas) and in Europe (Rotliegendes of Germany, New Red of England, Verrucano of Switzerland). In peninsular India, the Permian is represented by more than 3,000 metres or 9,800 feet of continental beds, mostly sandstone and shale (lower part of Gondwana System), containing coal and some marine intercalations. A similar facies prevails in Africa south of the Sahara, most completely developed in South Africa (lower part of Karroo System), and in southern Brazil (Paraná Basin) and western Argentina (Precordillera).

PERMIAN LIFE

No break exists between Carboniferous and Permian life in the fossil record (*q.v.*). This statement is true for invertebrates, vertebrates, and, with some qualifications, plants. Evolutionary lineages of many marine invertebrate groups, such as fusulines, corals, brachiopods, mollusks, and ostracods, extend from the Carboniferous into the Permian. All families of the Fusulinacea present in the Carboniferous, for example, continued into the Permian. The same is probably true for corals. Of 66 families of brachiopods that existed in the Carboniferous, 46 survived into the Permian, and only three new families were added during that period. Lineages of nautiloid and ammonoid cephalopods were continuous across the boundary. Of the six trilobite families of the Carboniferous, four continued into the Permian.

A paleontological census published in 1958 revealed that 8,560 species and subspecies of invertebrate fossils had been described from Permian rocks up to that time. Nearly 30 percent of these are brachiopods, and more than 25 percent cephalopods.

Marine fishes of Permian age are not well known. Shark-like forms, which predominated, were survivors from Carboniferous time. Freshwater fishes are known in much greater variety, and most lineages extended from the Carboniferous Period into the Permian Period. There is no significant break between Pennsylvanian and Permian amphibian faunas.

Reptile evolution

Although reptiles arose in the Carboniferous, their first major evolution took place in the Permian. Three principal groups were present in the Permian: cotylosaurs, the stem group ancestors of Mesozoic dinosaurs and modern reptiles and birds; pelycosaurs, the bizarre sail-backed reptiles leading to the therapsids; and the therapsids, the mammal-like reptiles that lived in great numbers and variety in South Africa and European Russia.

The Lower Permian is characterized by a plant assemblage in which the descendants of Carboniferous ferns (pteridophytes) and seed ferns (pteridosperms) predominate. A sharp change in vegetation occurred at the transition from Early to Late Permian when conifers increased in numbers to lend the flora a decidedly Mesozoic aspect. It may be said that a "Mesophytic" era began in the Late Permian.

In eastern Asia and western North America (Texas), the predominant plant was the fern *Gigantopteris*. The southern continents and peninsular India are characterized by *Glossopteris*, a genus recently shown to have been related to the seed ferns.

Guide and zone fossils

The most useful guide and index fossils of the Permian are fusulinaceans and ammonoids. Where either one of these groups occurs in reasonable numbers, correlation of beds with international standard divisions is greatly facilitated. Both groups exhibit easily recognizable evolutionary trends—the shell size and shape and internal structure of fusulines and the shell shape and suture patterns of ammonoids.

Based on the occurrence of fusulines, Permian strata are divided into five biostratigraphic zones (see STRATIGRAPHIC BOUNDARIES). In a similar manner, six ammonoid zones may be distinguished (Table 3). The most abundant fossils in the Permian record, the brachiopods, were a slowly developing group and have limited use for long-range stratigraphic correlation. Vertebrate fossils are too rare and serve as guide fossils only in the Lower Beaufort Beds, South Africa.

Although the Rotliegende in Europe and the Dunkard Group in the United States are zoned by plants, the *Glossopteris* flora of the Gondwana area and eastern Siberia is too uniform in composition throughout the time of its

Table 3: Fusuline and Ammonoid Zones

stage	substage	fusulines	ammonoids

Asselian			

existence for zonal sequence recognition. Plants are generally of limited use for zonation purposes in Permian rocks.

During the transition from the Carboniferous to the Permian Period, the evolution of animal and plant life proceeded evenly, without startling changes. An exception was the sudden appearance of the *Glossopteris* flora in the Gondwana area, where it replaced a Carboniferous flora of widespread type. Evolutionary rates in fusulines and ammonoids were rapid, making genera and species of these groups excellent zone fossils for this system. Trilobites continued their decline, which had begun in the Late Devonian, and became extinct before the end of Permian time. The corals showed a decline in diversity and numbers from their peak in the Devonian and Carboniferous.

At the end of Permian time, however, more spectacular evolutionary events occurred; and many forms of life, especially among invertebrates, became extinct, whereas others survived into Triassic and later times. The extinctions affected the faunas worldwide and the floras of the Gondwana area, where the *Glossopteris* flora gave way to the Triassic *Dicroidium* flora. In the Northern Hemisphere, as already stated, the principal change in floral evolution had taken place in the beginning of the Late Permian, and the conifer flora that had achieved predominance survived the Permian with little change.

Many major animal groups, entire orders and suborders, disappeared at the end of the Permian or survived only for a very short time thereafter. Most spectacular was the extinction rate of brachiopods. Of a total of between 130 and 140 genera present in Upper Permian rocks, only two survived into the Triassic (one of them only questionably represented in the Permian). Fewer than 30 new genera arose in the Early Triassic. In addition, a handful of genera survived locally and for a very short time only.

Among Foraminiferida, only the fusulines, of which 40 genera existed in the Late Permian, became extinct at the end of the period. Other foraminiferal suborders contain many genera that ranged virtually unchanged from the Paleozoic into the Mesozoic and even Recent.

Out of ten families of ammonoid cephalopods existing at the end of the Permian, only two survived in the Triassic for a short time, and these were constituted by different genera. On the other hand, out of eight families of non-ammonoid cephalopods, five survived into the Triassic and remained well established for varying times. At least three nautiloid genera are common to the Permian and Triassic. The Permian and Triassic representatives of many invertebrate groups such as sponges, bryozoans, and gastropods are not sufficiently well known to allow evaluation of their evolutionary behaviour.

The survival of the vertebrates is similar. How the irregularity of these extinction patterns can be explained is not entirely clear. Certainly no one single cause can be invoked, although suggestions have not been lacking: changes in ocean salinity, climatic change, neuroendocrinal reactions, geomagnetic polarity reversals, cosmic radiation, and supernovae have been suggested as causes. The most probable explanation is related to unusual combinations of factors that continuously influence the course of the evolution of life, such as transgressions and regressions (advance and retreat of seas), nonsedimentation, climatic changes, orogenies (mountain building), changes in ocean current patterns, cosmic radiation, mutations, genetic shifts, changing supplies of nutrients, and the appearance of predators, viruses, parasites, and pests of all kinds.

STRATIGRAPHIC BOUNDARY PROBLEMS

Stratigraphic boundaries (*q.v.*) within and between geologic systems are determined on the basis of zone fossils. Where rocks are formed in the marine environment, marine fossils, usually invertebrates, are used. In continental rock sequences, plant fossils usually serve this purpose.

Lower Permian boundary

In areas where Lower Permian marine rocks conformably overlie Upper Carboniferous (Pennsylvanian) rocks and where sedimentation was continuous from one period to the next, location of the boundary between the two systems is arbitrary. The midcontinent of the United States is such an area and, consequently, in the course of time numerous proposals for the placement of this boundary have been made. This boundary is also transitional in places in the western American geosyncline (*e.g.*, Oquirrh Formation of Utah) and in the subsurface of west Texas (*e.g.*, Horseshoe Atoll). Continuous Carboniferous–Permian sections exist, probably over wide areas, also in China and in the Soviet Union (western Urals).

Because of widespread crustal movement in the latter part of the Carboniferous and subsequent Early Permian transgressions of the sea, the lower boundary of the Permian is well marked in most places.

If fusulines or ammonoids are present in the strata near the boundary, its position can be determined with great confidence. Other groups such as sponges, brachiopods, and gastropods are of highly dubious value for zonation and correlation; where such groups prevail, the position of the boundary commonly is in doubt.

Because widespread emergence of land occurred during the Late Permian, rocks of this age are less widely distributed than Lower Permian rocks, or they are represented by strata of nonmarine facies. An upper boundary of the Permian System that is of worldwide validity can be determined only in stratigraphic sections in which uppermost Permian rocks are conformably overlain by lowermost Triassic rocks and where sedimentation was apparently continuous from the Permian into the Triassic Period. Few such sections are known (East Greenland, Armenia-Azerbaijan, central Iran, Pakistan, Kashmir, southern China). It is becoming apparent that in some of these areas a small vertical interval exists in which Permian-type and Triassic-type faunal elements are mixed. Ideas on the placement of the boundary therefore differ. Viewed on a worldwide scale, however, the inconsistencies are of minor nature and are being eliminated.

PERMIAN PALEOGEOGRAPHY

Permian paleogeography is one of the most vigorously disputed topics in contemporary geology. A majority of earth scientists today favour the hypothesis of continental drift (*q.v.*) in one form or another. Most of these authors reassemble the southern continents and peninsular India into one supercontinent (Pangaea, Gondwanaland), which is believed to have existed in Paleozoic times. Many different versions exist, however, that agree with each other in only one point, namely the fit of the opposing coasts of South America and Africa. Great differences in interpretation of the relative positions of all other continents exist.

Criticisms of the drift hypothesis that are relevant to the Permian record include the following:

1. On a continent that is larger in size than Asia at present, not enough moisture can exist in the atmosphere to allow major ice accumulations. The coldest place on earth today outside Antarctica is Verkhoyansk, in eastern Siberia, which is not glaciated now and was not glaciated during the Pleistocene.

2. Formation of coal deposits would suffer from the same moisture deficiency. The extensive distribution of Permian coal in Siberia, on the other hand, is in harmony with widespread marine transgressions in the same general area.

3. Paleozoic and Triassic rocks of marine character are widespread on the Gondwana continents, but their origin and presence are rarely mentioned and never explained.

Examples from the Permian are: beds with *Eurydesma* in eastern Argentina and Southwest Africa; a *Productus* (brachiopod) limestone fauna in Madagascar; marine intercalations with Tethys affinities in the Gondwana Series of India; thick sequences (up to 4,000 metres) of predominantly marine Permian rocks containing a Tethys fauna in the great sedimentary basins of Western Australia (overlain by marine Triassic rocks).

4. Vertebrates in Australia similar to those occurring in the Permian of South Africa and India are absent.

5. Distribution of the Cathaysian flora in east Asia, Sumatra, Turkey, and western North America is scattered.

6. A widespread Carboniferous flora changed to a provincial (restricted) Permian one.

These facts are reconcilable with modified continental relocation and with the assumption of stable continents. It is not possible to compile a Permian paleogeography that would satisfy every specialist and be compatible with all known data. Future work may resolve this difficulty.

One of the outstanding features of Permian paleogeography was the Tethys, a persistent marine belt that extended roughly between 30 and 40° N lat. from the western Mediterranean eastward and southeastward as far as Indonesia. A southern branch extended along the west coast of Australia as far as 30° S lat. The Tethys was complex, including both shallow- and deep-water regions.

Towards the northeast, Tethys connected with the epicontinental seas covering China and with the Japanese geosyncline of complex structure and history. Connected with Tethys to the north was the Uralian Geosyncline.

In central and western Europe and eastern North America continental and restricted marine conditions prevailed. Western North America was the site of a complex geosyncline, consisting of an eastern miogeosyncline and western eugeosyncline characterized by volcanic activity resembling that of island arcs (*q.v.*) of the East Asian type. This may have extended southward into Peru.

Toward the end of Permian time the sea withdrew from large areas which it had covered in the Early and early Late Permian. Desert conditions must have been widespread in North America and in Siberia during this latest Permian time.

Orogeny and volcanism

The Late Paleozoic was a time of widespread mountain building and volcanism, although in some parts of the world exact dating of these events is difficult. In eastern North America, the Appalachian Mountains were probably most intensely folded in the Permian; this Appalachian Revolution came to an end late in the period. In the west, there were probably continuous crustal movements in the Cordilleran Eugeosyncline involving intense igneous activity.

In Europe, orogenic and igneous activities were on a much smaller scale than they had been in the Carboniferous. Here, two minor orogenies (episodes of mountain building) are generally named Pfälzian (post-Early Permian) and Saalian (Late Permian). Volcanism was widespread in the Early Permian but died down in the Late Permian.

The Ural Mountains were folded in the late Permian and Europe became welded to Asia. The mobile belt of central Asia went through a complex history of foldings, metamorphism, and intensive and extensive igneous activity, which included granite intrusions in the Pamir, Kazakhstan, and elsewhere, and the eruption of acid and intermediate lavas, ignimbrites, and tuffs.

Similarly, in the Pacific mobile belt, diabase, diorites, and gabbros were formed and were penetrated by granite intrusions. In Japan, two orogenies occurred—one in the early Artinskian, one in the early part of Late Permian time. Mountain building also took place in Peru.

In Australia, folding and igneous activity were essentially restricted to Queensland and northern New South Wales, where the large New England Batholith was emplaced. In New Zealand, the Permian was characterized by intrusive and extrusive volcanic activity.

PERMIAN CLIMATES

The Permian Period began with widespread glaciations and ended in aridity. Sedimentary rocks of glacial origin, such as true tillites and fluvio-glacial deposits, laid down either in the sea or in lakes, are known from Argentina, southern Brazil, Uruguay, and the Falkland Islands; from many places in South Africa, including Southwest Africa, and from central Africa as far north as Lake Kivu and Gabon; from Madagascar; from peninsular India and from the Salt Range of Pakistan; in many places from the Australian continent and Tasmania; and from Antarctica. New Zealand is the only southern country with a near-complete record of Permian sedimentary rocks in which glacial sediments are absent.

Although the glacial series are found below or at the base of sedimentary sequences that are demonstrably of Permian age, the glacial rocks themselves are either unfossiliferous or contain specialized faunas. These consist of cold-water forms (*e.g., Eurydesma*) that are difficult to compare and correlate with faunas of the standard sections. It is, therefore, not known with certainty whether all the above-mentioned occurrences are in fact the results of one strictly contemporaneous event. The assumption that they were has been one argument set forth in favour of continental drift. By rearranging the southern continents and peninsular India in a manner first proposed by Afred Wegener, it is possible to reduce the area covered by glacial deposits to an allegedly credible size. The difficulty with this theory, as previously mentioned, is that on a very large continent (Gondwanaland) there would be insufficient moisture to allow formation of a huge ice cap.

It is now almost certain that not all these glacial beds were formed at the same time. Glacial deposits in Uruguay have been shown to be of mid-Pennsylvanian (Upper Carboniferous) age; those in the Salt Range of Pakistan are very Early Permian; and some occurrences in Australia (New South Wales, Tasmania) are of Artinskian, Kungurian, and even Tartarian age. The earliest glaciation in Australia was mountain glaciation of Middle Carboniferous age. Further, although many glacial deposits undoubtedly were laid down in water, others were not and are the result of highland and mountain glaciation rather than continental glaciation. This kind of origin is well established for the Congo, India, and eastern Australia. Lastly, the glacial origin of at least some of the deposits is not undisputed, and an interpretation of mud-flow origin is favoured by some investigators.

In summary, evidence furnished by the distribution and nature of glacial deposits does not necessarily favour the hypothesis that the southern continents and peninsular India formed one supercontinent in Permian time. It is possible that world temperatures in the Early Permian were comparatively low on a global scale. This postulate is supported by the conclusion that the climate of Central Asia at that time was cool temperate to cold, and it would explain occurrence of glacial deposits outside peninsular India—in the Salt Range, for example. In general, climatic conditions improved somewhat during the Permian; a warm, dry climate is indicated by extensive evaporite deposits in the Northern Hemisphere, and temperate conditions by widespread coal formation in the Southern Hemisphere.

Pernambuco

Pernambuco, a state (*estado*) of Brazil, is located in the Northeast region of the country, near the eastern tip of South America's bulge into the Atlantic. It is bounded on the east by the ocean, on the south by the states of Alagoas and Bahia, on the west by Piauí, and on the north by Ceará and Paraíba. The region has long been the most economically depressed in Brazil. The area of the state is 37,947 square miles (98,281 square kilometres) and its population in 1970 was 5,252,590. The state capital is Recife. (See also the article RECIFE.)

History. In 1526 Cristóvão Jacques founded a trading post on the mainland near the Rio Iguaraçú. The place was abandoned in 1530 after a devastating attack from French interlopers, but it was restored by the Portuguese two years later. The first permanent settlement of Pernambuco was at Olinda in 1535 by Duarte Coelho, who the previous year had been granted a captaincy extending from the mouth of the São Francisco River northward to that of the Iguaraçú. The place where the present-day state capital of Recife is located offered a sheltered anchorage but was at first used only for loading and unloading cargo. During the Dutch occupation (1630–54), a well-planned town was built there that became, under the name Mauritzstad, the administrative capital. Adjacent to Duarte Coelho's grant, on the north, was the captaincy of Itamaracá, which covered the remainder of the present state. Pernambuco was ably governed and prospered with the production of sugar in the plantations established in the rich alluvial soil along the coast. It took an active part in the expulsion of the French from the trading posts northward to Maranhão. It was one of the only two captaincies that met financial success; the other was São Vicente, in the modern state of São Paulo. The Dutch were attracted to Pernambuco mainly by its valuable sugarcane lands. Although an active guerrilla warfare was waged against their administration during large part of their occupation, the Dutch did much to promote the commercial interests of the colony, especially under the able governorship of Count John Maurice of Nassau-Siegen.

A bitter rivalry developed between Olinda, the administrative capital of the captaincy and residence of the rich aristocratic plantation owners, and Recife, inhabited by traders, ship chandlers, and warehouse workers, mostly Portuguese. This rivalry came to a head in 1709, when the growing importance of Recife was recognized by the royal government, and it was given a separate municipal organization (*vila*). There followed some bloody clashes, known as the Peddlers' War, between the two factions, which lasted until 1711 when a new, and more conciliating, governor for the captaincy arrived. Recife continued to prosper while Olinda declined. In 1823 Recife was elevated to the category of city (*cidade*) and in 1827 was made the capital of the province, including Olinda in its municipal district.

19th-century history

In 1817 Pernambuco was the scene of a revolutionary outbreak that resulted in the temporary separation of the present states of Alagoas and Rio Grande do Norte, Ceará and Paraíba having been detached in 1799. There was another insurrection in 1822, when the Portuguese were expelled; and in 1824 dissatisfaction with the arbitrary proceedings of Dom Pedro I at Rio de Janeiro led to a separatist revolution for the formation of a new state, to be called the Confederação do Equador. There was another outbreak in 1831 and frequent disorders to 1848, which culminated in another unsuccessful revolution. The population of the Pernambuco *sertão* (the inland plateau) became noted for its turbulent, lawless character, due partly to the distance of the *sertão* from the populated coast, partly to poor communications, and partly to the fact that this region became the refuge of criminals from coast towns.

The natural environment. Pernambuco's Atlantic coastline, which extends approximately 116 miles (187 kilometres) from south to north, is relatively short when compared to the state's east–west extent of 447 miles (720 kilometres). The coastal zone is also comparatively narrow and is separated from the high inland plateau by an intermediate zone formed by the terraces and slopes between the two. Its surface is much broken by the remains of the ancient plateau, which has been worn down by erosion, leaving escarpments and ranges of flat-topped mountains, called *chapadas*, capped in places by horizontal layers of sandstone. The coastal zone is low, well wooded, and fertile. The coastal zone has a hot, humid climate, relieved to some extent by the southeast trade winds. This region is known locally as the *zona da mata* ("forest") though most of the forest is gone. The middle zone, called the *agreste* region, has a drier climate and lighter vegetation. The *sertão*, sometimes called *zona de caatinga*, is high, stony, and dry and frequently is devastated by prolonged droughts (*sêcas*). The climate of the *sertão* is characterized by hot days and cool nights. For the state as a whole there are two clearly defined seasons, rainy from March to July and dry for the remainder.

The rivers of the state include a number of small plateau streams flowing southward to the São Francisco River and several large streams in the eastern part flowing eastward to the Atlantic. The former are dry the greater part of the year. The largest of the coastal rivers are the Goiana, which drains a rich agricultural region in the northeast part of the state, the Capibaribe and the Beberibe, which flow eastward to the Atlantic at Recife, the Ipojuca, which reaches the coast south of Recife, the Sirinhaém, and the Una; a large tributary of the Una—the Rio Jacuípe—forms part of the boundary with Alagoas.

Population. Beginning in the 16th century and continuing through the colonial period, large numbers of Negro slaves were brought by the Portuguese from Africa to work the sugar plantations in Pernambuco. Thus, like the other former sugar-plantation districts, the population of the state includes a high percentage of Negroes and mulattoes, especially in the coastal region. As with most of the other northeastern states, the greater part of the population lives within 200 miles or less of the coast.

Cities and towns

Recife (*q.v.*), the capital, with a population (1970) of 1,046,454 is the largest city in the state. There are a number of other large towns, the more important being Olinda, the old colonial capital, which has a population of almost 190,000, and Caruaru, the largest city in the interior, with a population of 101,000.

The population density of about 140 persons per square mile (54 persons per square kilometre) makes it one of the six most densely populated of Brazil's states.

Administration and social conditions. The seat of the state government is at Recife, the capital, which is also the site of the principal government offices. The state has its own constitution and laws; the governor and members of the legislature are elected.

Ilha Fernando de Noronha, off the coast, for many years has been attached to the state for administrative purposes. Like the other states of the Northeast, Pernambuco has received considerable financial assistance from the federal government. A national department created to combat the drought in the nine northeastern states and parts of the interior state of Minas Gerais has built in those states a number of reservoirs to alleviate the effects of periodic drought. Direct federal assistance is channeled primarily through the Superintendência do Desenvolvimento do Nordeste (Sudene; Northeast Development Agency), with its main offices in Recife.

Living conditions are in general better in the coastal region than in the interior, as are public health and education. Elementary education is compulsory. Higher education in law, medicine, engineering, commerce, the fine arts, agriculture, and teacher-training is available in Recife at the Federal University of Pernambuco, the Catholic University of Pernambuco, and the Rural University of Pernambuco.

Economy. Pernambuco's resources are varied. Agriculture is the leading activity, although grazing, commerce, manufacturing, and mining also contribute to the economy.

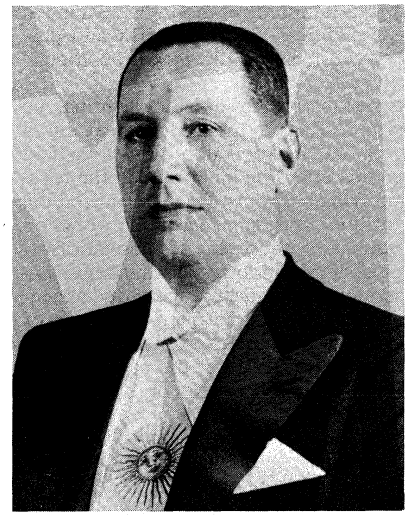
Since the 16th century the coastal plain has been devoted to the production of sugarcane, largely for export abroad and to other areas of the state and nation. Tropical and semi-tropical fruits (bananas, oranges, coconuts) and food crops (sweet potatoes, maize, manioc, rice) are also grown commercially in the coastal zone. The principal crops of the *agreste* region are cotton, coffee, beans, manioc, onions, tomatoes, and maize. Tobacco, formerly an important export commodity, is now grown chiefly for local consumption. Livestock raising is the chief activity in the *sertão*, but in areas of adequate rainfall or irrigation, cotton, sisal, castor beans, and food crops are also produced.

Pernambuco's large herds of cattle and goats are the source of meat, hides, skins, and leather. The traditional manufactures are refined sugar, cotton cloth, and cigars. Sugar processing continues to be the major industry, although a broad range of other industries, such as steel manufacture and the processing of non-ferrous metals, have been introduced in response to tax incentives offered Brazilian and foreign firms.

Transportation. Although it serves a chronically depressed area, Pernambuco's port of Recife is one of the country's most important because of its location on the continent's bulge into the Atlantic. Its two-mile long breakwater is sheltered by reefs and breakwaters. It is equipped with cranes, conveyors, and warehouses serving the ships engaged in the import and export trade. The railways of the area converge on the port, as does the system of surfaced roads. Recife also is the site of an airport served by national and international airlines and has national and international cable, telegraph, telephone, and radio communications.

Location of the port of Recife

Cultural life and institutions. The state's cultural life and institutions also are concentrated in Recife. The major universities and other educational institutions are located there, as are the state museum and public library. It is also the site of the church of São Francisco de Assis, as well as other churches, the Santa Isabel theatre and many historic landmarks, including the old Dutch fort of Cinco Pontas and Restoration Square, which commemorates the end of Dutch domination. Olinda, a national monument, is of great touristic interest because of its old churches and houses, as well as the quaint streets that have preserved their colonial character.



BIBLIOGRAPHY. The literature in English on Pernambuco is restricted largely to general works on Brazil and specialized monographs that deal with the Brazilian Northeast. Pernambuco's leading scholar, GILBERTO FREYRE, has written by far the most important study of the evolution of the traditional sugar plantation society and culture in *Casa-Grande y Senzala*, 12th ed., 2 vol. (1964; Eng. trans., *The Masters and the Slaves*, 2nd ed. rev., 1956; abridged ed., 1964). Significant episodes of the colonial history of Pernambuco may be found in C.R. BOXER, *The Dutch in Brazil, 1624–1654* (1957) and *The Golden Age of Brazil, 1695–1750* (1962). Twentieth-century developments are surveyed in T. LYNN SMITH, *Brazil: People and Institutions*, 4th ed. (1972), while alternative approaches to the contemporary problems of Pernambuco are examined in STEFAN H. ROBOCK, *Brazil's Developing Northeast* (1963); and JOSUE DE CASTRO, *Death in the Northeast* (1966).

(R.E.P./R.d'E.)

Perón, Juan

Whether in office as president of Argentina (1946–55), or in his subsequent long exile, Juan Domingo Perón stands out as one of the most remarkable Latin American political leaders of the 20th century. For good and for evil, he altered the society of his country, established himself as one of the earliest populist–nationalist–military leaders of the developing nations, and proved in exile that he could remain a significant political factor in his homeland. Perón's strength as a leader derived from his acute political opportunism, his sensitive attunement to the needs of Argentine social sectors (especially labour), and his personal magnetism.

By courtesy of the OAS

Perón, 1954.

Born on October 8, 1895, in a town on the Pampas of the province of Buenos Aires, Perón had a typical Argentine inheritance. He was a creole—a descendant of families that have been settled in Argentina for several generations—yet he also had non-Spanish European ancestors (Italian and French) as do most Argentines, for they live in a land dominated by immigrants and their descendants.

Early career

His early career was in many ways typical of the upwardly mobile, lower-middle class, male youth. He entered military school at 16 and made somewhat better than average progress through the officer ranks. But he had superior attributes. A strongly built six-foot-tall youth, Perón was the champion fencer of the army and a fine skier and boxer. He served in Italy during the late 1930s as a military attaché, and observed the successes of the Fascists and Nazis. He had a bent for history and political philosophy and published in those fields.

In 1943 he joined a clique of military plotters that overthrew the ineffective civilian government of Argentina, a government that had failed to solve the pressing problems of social and economic justice for a people ideologically split by the issues of World War II.

The military regimes of the following three years came increasingly under the influence of Perón, who had shrewdly requested for himself only the minor post of secretary of labour and social welfare. By 1945, he had also become vice president and minister of war. Clearly, he was bidding for undisputed power, based on the support of the underprivileged labourers (the descamisados, or shirtless ones) and on his popularity and authority in the army.

In early October 1945, Perón was ousted from his positions by a coup of constitutionally-minded civilians and officers. But his beautiful and dynamic mistress, Eva Duarte, and associates in the labour unions rallied the workers of greater Buenos Aires, and Perón was released from custody on October 17, 1945. That night, from the balcony of the presidential palace, he addressed 300,000 people, and his address was broadcast to the nation on radio. He promised to lead the people to victory in the pending presidential election and to build with them a strong and just nation. A few days later he married Eva, or Evita, as she was popularly called, who would help him rule Argentina in the years ahead.

After a campaign marked by repression of the liberal

opposition by the federal police and by strong-arm squads, Perón was elected president in February 1946 with 56 percent of the popular vote.

Perón set Argentina on a course of industrialization and state intervention in the economy, calculated to provide greater economic and social benefits for the working class. He also adopted a strong anti-United States and anti-British position, preaching the virtues of his Third Position—between Communism and capitalism—both domestically and in international relations. He extended Argentina's influence widely in Latin America and particularly sought to establish its political and ideological hegemony over South America.

If he did not structurally revolutionize Argentina, he did reshape the nation. Basing his government on a foggy doctrine he called Justicialismo, the President showered needed benefits upon the labourers, in the form of wage increases and fringe benefits. He nationalized the railroads and other utilities and financed public works on a large scale. The funds for those costly innovations—and for the graft that early began to corrode his regime—came from the foreign exchange accumulated by Argentine exports during World War II and from the profits of the state agency that set the prices for agricultural products. Perón dictated the political life of the nation by his command of the armed forces. He severely restricted and in some areas eliminated constitutional liberties.

Re-elected by a somewhat larger margin in 1951, Perón modified some of his policies. But he was overthrown and fled to Paraguay on September 19, 1955, after an army–navy revolt led by democratically inspired officers who reflected growing popular discontent with inflation, corruption, demagoguery, and oppression.

Exile to Paraguay

Perón finally settled in Madrid. There in 1961 he married for the third time (his first wife had died of cancer, as had Evita in 1952); his new wife was the former María Estela Martínez, an Argentine and a dancer whom he met in 1956. In his villa in the most fashionable suburb of the Spanish capital, the former dictator tended his roses, though he also followed a rigorous schedule of writing, interviews, and conferences. These were calculated to ensure, if not his return to Argentina, at least the eventual assumption of power by the millions of Peronista followers, whose memory of his regime improved with time and with the incapacity of the Argentine governments that succeeded Perón's decade of power.

In election after election the Peronistas emerged as a large, indigestible mass in the Argentine body politic. Neither the civilian nor the military regimes that precariously ruled in Argentina after 1955 were able to solve the relatively rich nation's condition of "dynamic stagnation," in part, because they refused to give political office to the Peronistas.

The military regime of General Alejandro Lanusse, which took power in March 1971, proclaimed its intention to restore constitutional democracy by the end of 1973 and allowed the re-establishment of political parties, including the Peronista Party. The long-hidden remains of Eva Perón—still a political issue because of the cult she had inspired—were exhumed by the government's orders and sent to Perón. Upon invitation from the military government, Perón returned to Argentina for a short time in November 1972. In the elections of March 1973, Peronista candidates captured the presidency and majorities in the legislature, and in June Perón was welcomed back to Argentina with wild excitement. In October, in a special election, he was elected president and, at his insistence, his wife—whom the Argentines disliked and, because of her obvious efforts to emulate Evita, resented—became vice president.

While in exile Perón had wooed the left-wing Peronistas and had supported the most belligerent labour unions. Once returned to power, however, he formed close links with the armed forces and other previously opposition right-wing groups. When he died—on July 1, 1974—he left his widow and successor as president an untenable situation. Divisions in the Peronista movement and in the government that had been present when Perón was alive were brought into the open. Mrs. Perón failed to obtain the firm support of any power group, not even the labour unions. Terrorist activity and political violence increased. By this time, too, inflation was running at an annual rate of more than 600 percent. On March 24, 1976, the armed forces took power, removed Mrs. Perón from office, and set up a military junta.

Perpetual Motion

Perpetual motion describes the action of a device that once set in motion would theoretically continue in motion indefinitely without receiving any additional energy from an external source. The perpetual motion machines most frequently proposed by inventors are not designed simply to stay in motion but are meant as well to be capable of delivering useful work. Since, in theory, such machines require no external energy source, they hold out the hope of delivering virtually free and limitless quantities of power. No perpetual motion machine that has ever actually been built has ever run or produced power for any significant period of time; no perpetual motion machine that has ever been proposed has successfully withstood careful scientific scrutiny. It must be noted, however, that over the past five centuries a number of promoters have built devices that gave the illusion of perpetual motion, which they used to enhance either their reputations or their pocketbooks.

Perpetual motion machines of the first kind. The reason perpetual motion machines fail to work is that their principles must inevitably violate either the first or second law of thermodynamics. The first law of thermodynamics states that energy is neither created nor destroyed, but is always conserved. It was proposed about the middle of the 19th century by three scientists working independently along different lines of attack. Julius Robert von Mayer (1814–78) of Germany based his reasoning on observations of the human body, having observed that the body takes in fuel (food) and converts it to work and heat. James Prescott Joule (1818–89) of England was able to show the experimental equivalence of work and heat by way of a cleverly designed apparatus that converted mechanical work into heat. And lastly, Hermann von Helmholtz, also of Germany, convinced the international scientific community that the principle of energy conservation was valid by first assuming the impossibility of a perpetual motion machine.

In 1847, when he was 26, Helmholtz presented his formulation of the first law before the Physical Society of Berlin. Beginning his analysis by declaring that perpetual motion machines were axiomatically impossible, Helmholtz pointed out that no one had yet built a successful perpetual motion machine, and, proceeding from that axiom, next showed that the failure of perpetual motion machines had to lead logically to the conclusion that energy is conserved. He went on to demonstrate that both heat and work were forms of energy and that what was conserved was the total of the two forms rather than either heat or work taken separately. Furthermore, Helmholtz showed that the findings of Joule's experiments were in general agreement with calculations of the kind made by Mayer.

Helmholtz' formulation

A perpetual motion machine that purports to deliver more energy from a falling or turning body than is required to restore the device to its original state is called a perpetual motion machine of the first kind. Most of the devices most often proposed by inventors through the centuries have been of this kind, and the oldest recorded scheme for achieving perpetual motion is such a device. It was suggested by Villard de Honnecourt, a 13th-century French architect, who so far as is known was the first man to suggest the idea of an overbalanced wheel (Figure 1). The inventors of overbalanced wheels believe that they can ex-

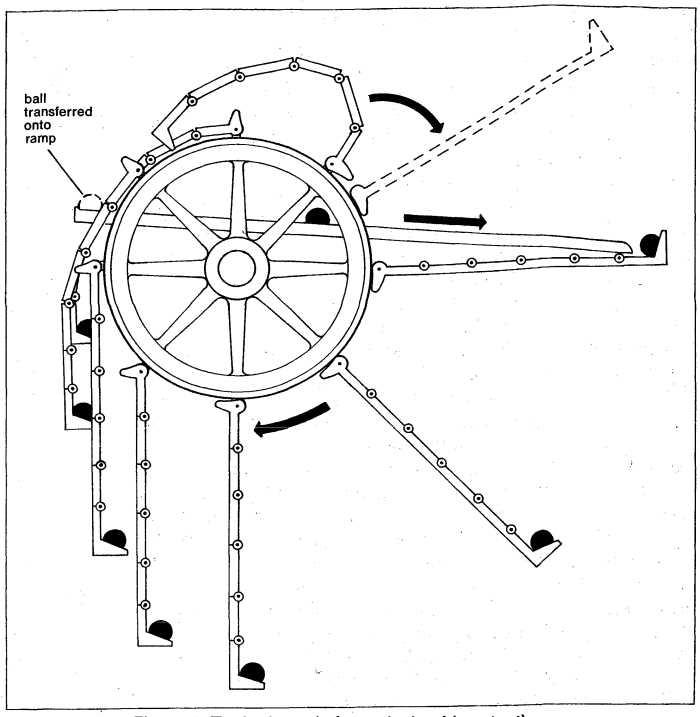

Figure 1: Typical overbalanced wheel (see text).
From S. Angrist, *Perpetual Motion Machines*, Copyright © 1968 by Scientific American, Inc.; all rights reserved

tract more energy from falling weights on one side of the wheel than is required to raise those weights on the other. This belief is based on the assumption that such weights deliver more effort if they are farther removed from the centre of rotation than if they are closer.

Two of the earliest and best known inventors of would-be perpetual motion machines based on overbalanced wheels were Edward Somerset, 2nd marquis of Worcester (1601–67), and Jean Ernest Elie Bessler (1680–1745), who was generally known as Orffyreus. Each of these men built rather large wheels that were capable of giving impressive demonstrations of apparent perpetual motion due probably to their large inertia which kept them turning for long periods of time once set into motion. Within a few years of 1640, probably around 1638 or 1639, Somerset operated his device for Charles I and his court. A Dutch physicist, W.J. Gravesande (1688–1742), inspected Orffyreus' last wheel and in many ways was impressed with its construction. In a long and detailed letter to Sir Isaac Newton, he described the externals of the wheel. On grounds that he did not want to be robbed of the secret of perpetual motion that he had discovered, Orffyreus refused to allow Gravesande to inspect its interior.

Before the end of the 14th century almost every English manor that was situated on a stream, roughly, that is, a third of all the manors in the Domesday Book, had its own water mill to grind flour, saw wood and full woollens. Villagers and townspeople who had no access to running water naturally sought alternative sources of power. The solution to this problem most commonly suggested was the closed-cycle water mill such as that proposed by the English physician Robert Fludd in 1618 (Figure 2). If the water that turns a mill wheel could be collected from the race at the foot of the wheel and somehow put back into the reservoir above the wheel, the need for a source of running water would disappear. It was reasoned that the wheel could drive a pump that would recycle the mill's water supply. At the time Fludd proposed this device and for more than 200 years after, there was no scientific reason to believe that it would not work, though, of course, all practical efforts failed to achieve perpetual motion by this route. All of the countless closed-cycle mills that have been proposed down through the centuries were supposed to work because their inventors believed that the falling water would give up more energy than was required to return the water to the race above the wheel. Such devices are another variation of the overbalanced wheel and thus constitute perpetual motion machines of the first kind.

John Wilkins, bishop of Chester and an early official of the Royal Society, envisioned in the 1670s three natural power sources that might be harnessed to provide perpetual motion. These in his words, were "Chemical Extractions," "Magnetical Virtues," and "the Natural Affection of Gravity." Wilkins' third power source embraces the entire family of overbalanced wheels. He specifically mentioned only one formula for chemical extraction; its underlying concept may have arisen from a misunderstood observation of the ceaseless motion of small particles visible in a fluid that is known today as Brownian movement. Wilkins also designed, but almost certainly never tried to build, a machine to utilize magnetic attraction. A lodestone on top of a pedestal was supposed to pull a bullet up an inclined ramp where it would fall through a hole and roll back to its starting position. Of course, any magnet strong enough to pull the bullet up the ramp would not let it drop through the hole.

Wilkins' magnetic device was probably the first in a long series of devices designed to use electric or magnetic forces to produce perpetual motion. Machines that have been proposed more recently usually have some mechanical arrangement designed to interpose a shield to isolate one portion of the machine temporarily from an existing magnetic or electric field. Invariably inventors of such devices fail to account for the work required to push the isolator through the field and into place in order that isolation may be achieved.

Would-be perpetual-motion-machine inventors have also directed their attention toward machines that would supposedly make use of hydrodynamic and capillary principles. In 1686 the Abbé de la Roque, editor of the *Journal des sçavans*, suggested as a source of perpetual motion the use of a beaker-like vessel that gives its liquid contents a large surface area on top and narrows to a small cross section on the bottom. A small tube running from the bottom of the beaker along the outside was permitted to discharge on to the top surface of the liquid in the beaker. De la Roque hoped (in vain) that the water in the wide section at the top would force liquid to flow continuously out of the bottom of the beaker and be returned to the top by means of the narrow tube. Sir William Congreve, a member of Parliament in the early 19th century, also proposed to use water to achieve an eternal source of free power. His scheme was based on an inclined plane that had a continuous chain of sponges looped around it; the sponges were forced to pass through a water bath. On top of the sponges a chain of heavy weights was fastened. The plan was that while one section of the sponges was filling with water thereby making that section heavier, another portion of the sponges was being squeezed dry by the heavy weights thereby making them lighter. Congreve's hope was that since one section of the sponge chain would be perpetually heavier than the section that was being squeezed dry, the chain would be kept in motion around

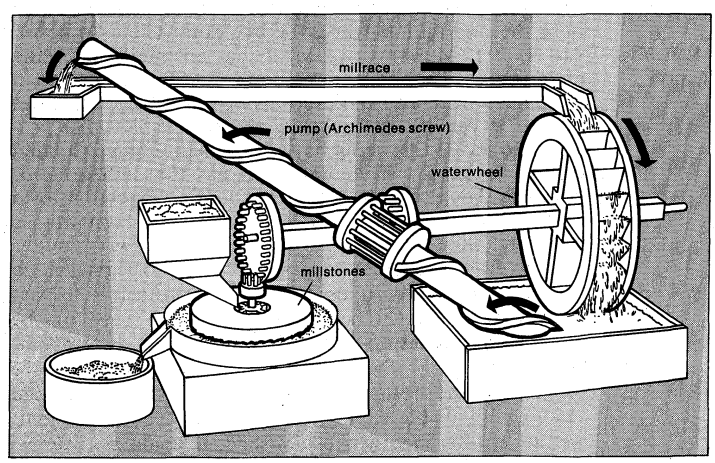

Figure 2: Closed-cycle water mill.

some appropriately arranged pulleys. The plan obviously failed to allow for the work that would have to be exerted on the sponges to remove the water from them.

Perpetual motion machines of the second kind. There is, however, one class of perpetual motion machines that is fundamentally different from the ones just described; they do not violate the first law in that energy in these machines is always conserved. They are impossibilities nonetheless because they attempt instead to circumvent the second law of thermodynamics. The foundations of the second law were laid down by French physicist Sadi Carnot (1796–1832) who wanted to find out whether improved design could eliminate all energy losses in steam engines. Although the first law states that a fixed amount of mechanical work can always be converted into the equivalent amount of heat, the most casual observation of a heat engine in operation makes plain that the reverse of the first law's axiom is not precisely true: a fixed amount of heat cannot be completely converted into the same amount of work. Some of the initial energy is unavoidably wasted. After much thought Carnot realized that a complete conversion of heat into work was impossible. It is this law that inventors of perpetual motion machines of the second kind try to violate.

Gamgee's zeromotor

One attempt to construct such a device was made by John Gamgee, a professor from London working in Washington, D.C. during the 1880s. He developed a heat engine that was much like an ordinary steam engine; he called it a zeromotor because its normal operating temperature was zero degrees centigrade. This engine used ammonia instead of water as the working fluid; liquid ammonia vapourizes into a gas at a low temperature, and at 0° C (32° F) the gas exerts a pressure of four atmospheres. Gamgee reasoned that the transfer of heat from the environment, rather than the energy supplied by the combustion of fuel, would be enough to transform the ammonia working fluid from a liquid to a gas. He reasoned further that the ammonia gas on driving the piston back and expanding, would cool, condense, and drain into a reservoir, whereupon the cycle could begin again. Gamgee and his supporters, though undoubtedly sincere, had either incorrectly calculated or had failed to calculate at all the zeromotor's temperature requirements. The heat transfer from the environment was indeed sufficient to convert ammonia from a liquid to a gas, but this advantage is nullified in the system as a whole by the cooling of the gas on expansion. Starting at 0° C and a pressure of four atmospheres, the temperature of the gas falls to −33° by the time its volume has quadrupled. If the gas is to condense into a liquid, both the condenser and the reservoir must be at a temperature lower than −33°. Gamgee had not provided for this cooling, and if he had, the cooling process would of course have required more energy than the zeromotor could produce.

The Gamgee zeromotor attempted to get work from thermal energy already at the temperature of the surroundings, which the second law expressly forbids. That statement of the second law that denies the possibility of such devices has been assaulted many times but no assault has been more persistent nor none taken more seriously than the one initiated in 1871 by James Clerk Maxwell (1831–79). Maxwell suggested that an intelligent being endowed with superordinary powers and who was small enough to deal with the motions of individual molecules would be capable of violating the second law. He proposed to locate this being he called a demon in an isolated enclosure that initially contained a gas at a uniform temperature. The enclosure was divided into two sections by a partition with a small door in it and the demon was to open and close the door to permit molecules with greater than average velocities to pass from left to right and to permit molecules with less than average velocities to pass from right to left. The higher the mean speed of the molecules making up a gas, the higher the gas temperature. The gas in the right-hand half of the enclosure would become hotter and the gas in the left-hand side colder without the expenditure of energy. Once the temperature difference was established, it could be used to drive a heat engine that would deliver useful work.

Maxwell's demon

Maxwell's demon bothered physicists for almost 100 years until Louis M. Brillouin, a French physicist, pointed out that the demon needed information about the individual molecules if he was going to open and close the door at the appropriate time. As the demon peers into either side of the isolated enclosure at uniform temperature, the uniformity of radiation throughout does not permit him to see anything, unless he is supplied with a source of radiation to illuminate the molecules. Brillouin showed that the energy that must be expended in the radiation source to illuminate the molecules is greater than any work that could be derived from a heat engine that could be made to operate off the temperature difference that the demon produced by means of his sorting abilities; thus Maxwell's demon does not violate the second law and does not constitute a perpetual motion machine.

Perpetual motion machines of the third kind. Sometimes the term "perpetual motion of the third kind" may be used to refer to the continuous motion that a device would have if it were completely freed from the action of all nonconservative forces, that is, forces such as electrical resistance or friction; the forces that always irreversibly remove energy from a system. Experience has shown that such forces can be reduced, for example, by lubrication in the case of friction, but can never be eliminated without the expenditure of additional energy. Studies of materials at very low temperatures have revealed that certain dissipative phenomena like friction or electrical resistance can be made to disappear for as long as the material is maintained below certain very low transition temperatures. For example, 24 pure metals and many alloys and intermetallic compounds are superconductors—that is, their electrical resistance disappears completely at their transition temperatures, usually below about 20° K. Zero electrical resistance can be demonstrated by inducing a current in a closed ring of superconductive metal; by placing a compass needle near the ring and noting its deflection one can demonstrate that this current will flow in the ring as long as the metal is kept below its transition temperature. Such persistent currents have been maintained for more than a year without diminishing in strength.

Persistent currents

A similar phenomenon has been observed with liquid helium below a temperature of 2.18° K, called its lambda point, or transition temperature. At any temperature below this point liquid helium loses all resistance to flow through capillaries of less than 10^{-4} centimetres in diameter. A current allowed to flow continuously in a superconducting ring or helium in the superfluidic state allowed to flow through a capillary loop does not constitute perpetual motion because considerable energy must be expended to maintain such systems at the extremely low temperatures required to cause the material to lose its resistance to flow. The energy expended on cooling is always greater than any work that might be derived from the superconducting or superfluidic flows.

Fictitious perpetual motion machines. A number of schemes have been proposed (and many of them realized) to utilize the radiant energy of the sun to produce systematic mechanical motion. For example, clocks that wind themselves by making use of changes in atmospheric temperature or pressure are really using some of the energy that the sun delivers to the earth each day. Because such devices do receive energy from an external source they do not constitute perpetual motion machines. Early in the 20th century R.J. Strutt (later the fourth baron Rayleigh) caused a sensation when he constructed an apparatus he called a radium clock. As the radium contained within the glass structure decayed by emitting alpha particles, it caused thin gold leaves also located within the structure to become charged. After a while the leaves discharged and moved to the collapsed position; the process repeated indefinitely. The half-life of radium is 1,620 years, so the motion of the clock would continue a long time. For a time it was thought that such a clock was really a perpetual motion machine but as the atom became better understood it was realized that the energy for operating the leaves is released as the radium nucleus is transformed from one unstable chemical element to another; thus the

radium clock has an energy source, though it is considerably different from the mainspring found in most watches and clocks.

As early as 1775 the French Academy of Sciences passed a resolution refusing to entertain any future communications concerning perpetual motion. The British Patent Office has also had a long-standing policy against reviewing patent applications for perpetual motion machines. The U.S. Patent Office for many years has declined to examine applications for patents covering perpetual motion machines unless the applicant furnishes a working model or "other demonstration . . . of the operativeness of the invention," a ruling that has produced much hostile correspondence but no working models.

In spite of such official opposition public sophistication regarding the possibility of building perpetual motion machines was slow to develop. One of the most ingenious and certainly the longest-lived swindles involving a supposed perpetual motion machine began in 1874, when

John E.W. Keely

John E.W. Keely unveiled a combined "generator" and engine at his home in Philadelphia. Keely's generator was an elaborate combination of metal globes, tubes, petcocks, nozzles, valves, and gauges. For almost 25 years Keely brought a steady stream of investors into his laboratory to demonstrate the "power" his generator could extract from water. "People have no idea of the power in water," Keely would say. "A bucket of water has enough of this vapor to produce a power sufficient to move the world out of its course." With time his demonstrations with his apparatus became more polished and indeed were so successful that Keely and his associates were able to capitalize the Keely Motor Company for over $1,000,000, with much of this amount coming from New York businessmen. Keely died in 1898. The son of one of his major backers promptly rented his Philadelphia house and explored the premises in the company of reputable witnesses. They found concealed beneath the floor a giant metal tank evidently used as a reservoir for compressed air. In the walls was located a network of brass tubing that conducted the compressed air to the generator. In the course of his long career Keely may have broken a number of laws, but he left the first and second laws of thermodynamics, which forbid perpetual motion machines, inviolate.

Persepolis

Persepolis (Old Persian Parsa) was an ancient capital of the Achaemenian kings of Iran. Its site, now called Takht-e Jamshīd (the Throne of Jamshīd, a mythical Persian hero), is located about 32 miles northeast of Shīrāz in the *ostān* (province) of Fars, southwest Iran, near the confluence of the small river Pulvār (Rūdkhāneh-ye Sīvan) with the Rūd-e Kor.

History. Though archaeologists have discovered evidence of prehistoric settlement, inscriptions indicate that the construction of the city began under Darius I the Great (reigned 522–486 BC), who, as a member of a new branch of the royal house, made Persepolis the capital of Persia proper, replacing Pasargadae, the burial place of Cyrus the Great. Built in a remote and mountainous region, Persepolis was an inconvenient royal residence and was visited mainly in the spring. Effective administration of the Achaemenian empire was carried on from Susa, Babylon, or Ecbatana. This accounts for the fact that the Greeks were not acquainted with Persepolis until Alexander the Great's invasion of Asia. In 330 BC Alexander plundered the city and burned the palace of Xerxes, probably to symbolize the end of his Panhellenic war of revenge. In 316 BC Persepolis was still the capital of Persis as a province of the Macedonian empire. The city gradually declined in the Seleucid period and after, its ruins attesting its ancient glory. In the 3rd century AD the nearby city of Istakhr became the centre of the Sāsānian Empire.

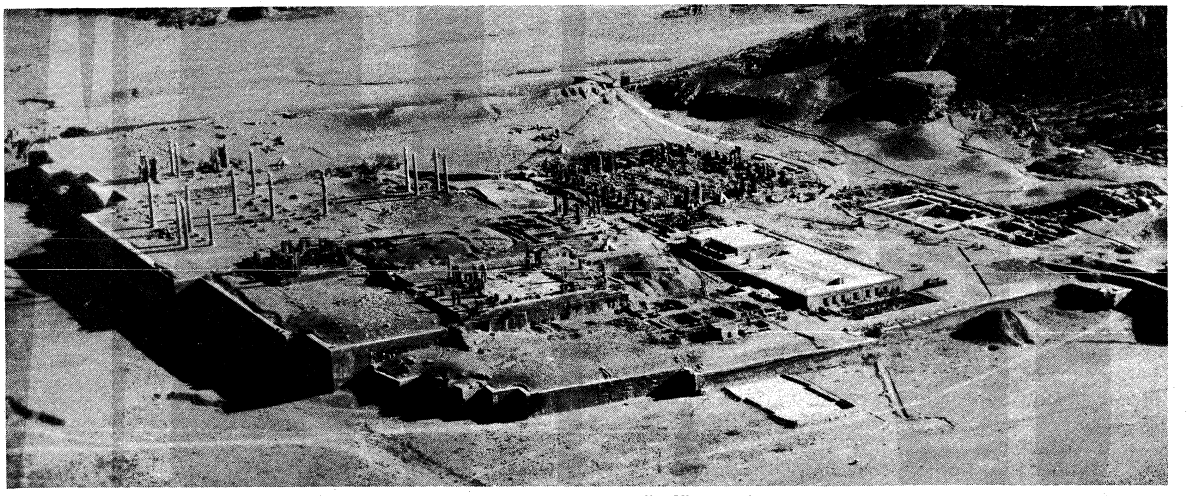
City of Persepolis.

Archaeology. The site is marked by a large terrace with its east side leaning on Kūh-e Raḥmat (the Mount of Mercy). The other three sides are formed by a retaining wall, varying in height with the slope of the ground from 13 to 41 feet; on the west side a magnificent double stair in two flights of 111 easy stone steps leads to the top. On this terrace are the ruins of a number of colossal buildings, all constructed of a dark gray stone, often polished to the consistency of marble, from the adjacent mountain. The stones, of great size, cut with the utmost precision, were laid without mortar, and many of them are still in place. Especially striking are the huge columns, 13 of which still



The 100 Columns

stand in Darius the Great's audience hall, known as the apadana, the name given to a similar hall built by Darius at Susa (there are two more columns in the propylaeum, or entrance hall, of his son, Xerxes). These ruins have been named "Sad-Sotūn" (the 100 Columns).

In 1933 two sets of gold and silver plates recording in the three forms of cuneiform, Ancient Persian, Elamite, and Babylonian, the boundaries of the Persian Empire were discovered in the foundations of Darius' hall of audience. A number of inscriptions, cut in stone, of Darius I, Xerxes I, and Artaxerxes III indicate to which monarch the various buildings are to be attributed. The oldest of these on the south retaining wall gives Darius' famous prayer for his people: "God protect this country from foe, famine and falsehood." There are numerous reliefs of Persian, Median, and Elamite officials, and 23 scenes separated by cypress trees depict representatives from the remote parts of the empire who, led by a Persian or a Mede, made appropriate offerings to the king at the national festival of the vernal equinox.

Cliff tombs

Behind Takht-e Jamshīd are three sepulchres hewn out of the mountainside; the facades, of which one is incom-

The ruins of Persepolis from the south, showing the terrace and retaining walls. The apadana of Darius I, of which 13 stone pillars are still standing, and the propylaeum of Xerxes, marked by two pillars, are at the top left.

plete, are richly ornamented with reliefs. About eight miles north by northeast, on the opposite side of the Pulvār, rises a perpendicular wall of rock in which four similar tombs are cut at a considerable height from the bottom of the valley. This place is called Naqsh-e Rostam (the Picture of Rostam) from the Sāsānian carvings below the tombs, which were thought to represent the mythical hero Rostam. That the occupants of these seven tombs were Achaemenian kings might be inferred from the sculptures, and one of those at Naqsh-e Rostam is expressly declared in its inscriptions to be the tomb of Darius I, son of Hystaspes, whose grave, according to the Greek historian Ctesias, was in a cliff face that could be reached only by means of an apparatus of ropes. An inscription beside the entrance to Darius' tomb describes his character and states that God had given him two special qualities, wisdom and activity. The three other tombs at Naqsh-e Rostam, besides that of Darius I, are probably those of Xerxes I, Artaxerxes I, and Darius II. Xerxes II, who preceded Darius II, reigned for a very short time and could not have obtained so splendid a monument; still less could Sogdianus (Secydianus), who usurped his brother's throne and reigned for less than a year. The two completed graves behind Takht-e Jamshīd probably belong to Artaxerxes II and Artaxerxes III. The unfinished one might be that of Arses, who reigned at the longest two years, but is more likely to be that of Darius III, the last of the Achaemenian line, who was overthrown by Alexander the Great.

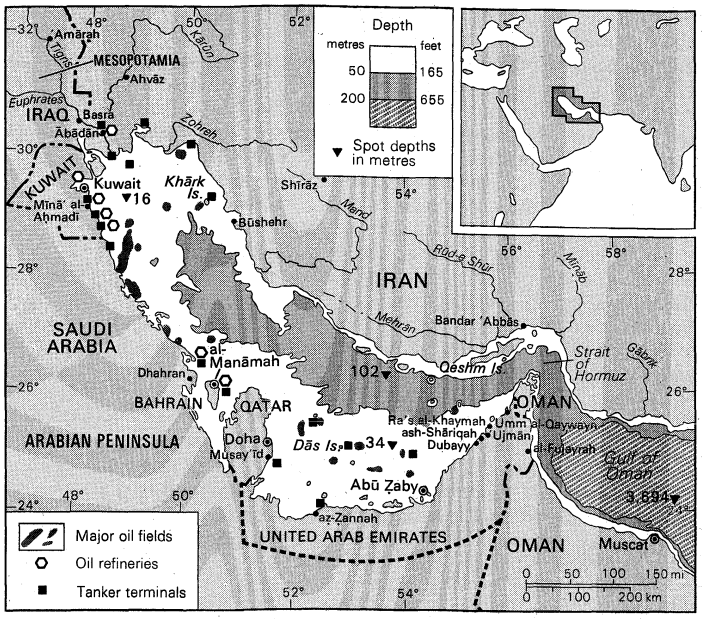
Persian Gulf



The Persian Gulf (known to the Arabs as the Arabian Gulf) is the shallow marginal sea of the Indian Ocean that lies between the Arabian Peninsula and southeast Iran. The sea has an area of 92,500 square miles (240,000 square kilometres). Its length is 615 miles, and its width varies from a maximum of 210 miles to a minimum of 35 miles in the Strait of Hormuz. It is bordered on the north, northeast, and east by Iran, on the northwest by Iraq and Kuwait, on the west and southwest by Saudi Arabia, Bahrain, and Qatar, and on the south and southeast by the United Arab Emirates and part of Oman. The term Persian Gulf is often used to refer not only to the Persian Gulf proper but also to its outlets, the Strait of Hormuz and the Gulf of Oman, which open into the Arabian Sea. This article deals with the Persian Gulf alone (see also TIGRIS–EUPHRATES RIVER SYSTEM).

Physiography. The Iranian shore is mountainous, and there are often cliffs; elsewhere a narrow coastal plain with beaches, intertidal flats, and small estuaries borders the gulf. The coastal plain widens north of Būshehr on the eastern shore of the gulf and passes into the broad deltaic plain of the Tigris, Euphrates, and Kārūn rivers. Cliffs are rare on the Arabian shore of the gulf, except around the base of the Qatar Peninsula and in the extreme southeast around the Strait of Hormuz. Most of the Arabian shore is bordered by sandy beaches, with many small islands enclosing small lagoons.

The gulf is very shallow, rarely deeper than 300 feet, although depths exceeding 360 feet are found at its entrance and at isolated localities in its southeastern part. It is noticeably asymmetrical in profile, with the deepest water occurring along the Iranian coast and a broad shallow area, which is usually less than 120 feet deep, along the Arabian coast. There are numerous islands, some of which are salt plugs or domes and others merely accumulations of coral and skeletal debris.

The Persian Gulf receives very small amounts of river-borne sediment except in the northwest, where the Tigris, Euphrates, and Kārūn, together with other small streams, empty into the gulf. The rivers reach their peak flow in spring and early summer, when the snow melts in the mountains; disastrous floods sometimes result. There are some ephemeral streams on the Iranian coast south of Būshehr, but virtually no freshwater flows into the gulf on its southwest side. Large quantities of fine dust are, however, blown into the sea by predominant northwest winds from the desert areas of the surrounding lands. Biological, biochemical, and chemical processes lead to the production of considerable calcium carbonate in the form of skeletal debris and fine mud. The deeper parts of the Persian Gulf adjacent to the Iranian coast and the area around the Tigris–Euphrates Delta are mainly floored with gray-green muds rich in calcium carbonate. The shallower areas to the southwest are covered with whitish-gray or speckled skeletal sands and fine carbonate muds. Often the sea floor has been hardened and turned to rock by the deposition of calcium carbonate from the warm, salty waters. Chemical precipitation is abundant in the coastal waters, and sands and muds are produced that mix with the skeletal debris of the local sea life. These sediments are thrown up by the waves to form coastal islands that enclose lagoons. The high salinities and temperatures result in the precipitation of calcium sulfate and sodium chloride to form extensive coastal salt flats.

Sea floor

The Persian Gulf.

Geology. The present-day Persian Gulf, together with its northwestern continuation now infilled by the deposits of the Mesopotamian rivers, is thought by some to be the remains of a once much larger northwest-to-southeast-aligned basin of deposition that existed throughout a large part of geological history. In this basin many thousands of feet of sediments accumulated, consisting mostly of limestone and marls (loose, crumbling earthy deposits containing calcium carbonate), together with evaporites and organic matter, which ultimately produced the area's vast oil resources.

Climate. The gulf has a notoriously bad climate. Temperatures are high, though winters may be quite cool at the northwestern extremities. The sparse rainfall occurs mainly as sharp downpours between November and April and is higher in the northeast. Humidity is high. The little cloud cover is more prevalent in winter than in summer. Thunderstorms and fog are rare, but dust storms and haze occur frequently in summer. The wind blows predominantly from a north–northwest direction —the so-called *shamāl* (Arabic: "north wind")—is seldom strong, and rarely reaches gale force. Squalls and waterspouts are common in autumn, when winds sometimes reach speeds of 95 miles per hour in as little as five minutes. Intense heating of the land adjacent to the coasts leads to gentle offshore winds in the mornings and strong onshore winds in the afternoons and evenings.

Hydrography. The small freshwater inflow into the gulf is mostly from the Tigris–Euphrates–Kārūn rivers. The water temperatures range from 75° to 90° F (24° to 32° C) in the Strait of Hormuz to 60° to 90° F (16° to 32° C) in the extreme northwest. These high water temperatures and a low influx of freshwater result in evaporation in excess of freshwater inflow; high salinities result, ranging from 37 to 38 parts per thousand in the entrance to 38 to 41 parts per thousand in the extreme northwest. Even greater salinities and temperatures are found in the waters of the lagoons on the Arabian shore.

Tides

The tidal range varies from about four to five feet around Qatar and increases to ten to 11 feet in the northwest and nine to ten feet in the extreme southeast. When onshore winds are strong, the level of the coastal waters, particularly in the southern gulf, may rise by as much as eight feet, causing extensive flooding of the low coastal plains. Tidal currents are strong (five miles per hour) in the entrance of the gulf but elsewhere—except between islands or in estuaries and lagoon entrances—rarely exceed one to two miles per hour. The wind affects local currents and may sometimes even reverse them.

Waves rarely exceed ten feet in height and are largest in the southern gulf. The swell from the Indian Ocean affects only the water at the entrance of the gulf; when it is opposed by wind, very turbulent conditions result. The general circulation pattern appears to be caused by water entering from the Indian Ocean, evaporating, becoming denser, and sinking to flow out into the Indian Ocean beneath the inflowing open ocean water.

The waters of the area support many plants and animals, but the high temperatures and salinities lead to a diminution in the variety of forms; many Indian Ocean forms penetrate only a small way into the gulf.

Economic resources. Until the discovery of oil in Iran in 1908, the Persian Gulf area was important mainly for fishing, pearling, the building of dhows (Arab lateen-rigged boats), sailcloth making, camel breeding, reed-mat making, date growing, and the production of other minor products, such as red ochre from the islands in the south. The arid lands surrounding the gulf produced little else and, except for the rich alluvial lands of the Mesopotamian plain, supported a small population of fishermen, date growers, and nomads. Today these traditional industries have declined, and the economy of the region is dominated by the production of oil. The Persian Gulf and the surrounding countries produce approximately 31 percent of the world's total oil production and have 63 percent of the world's proved reserves. The area has been explored only in a preliminary way, and there are still fewer drill holes in the area than are put down in a single month in the United States. Offshore exploration below the shallow waters of the gulf has revealed the presence of large reserves of oil and gas. These discoveries have led to numerous legal wrangles between states about exact territorial limits. Large quantities of oil are refined locally at Ābādān, in Iran, in Bahrain, and elsewhere, but most of it is exported to northwestern Europe and other parts of the world as crude oil.

Oil

Other exploitable mineral deposits appear to be rare, but only cursory surveys have been made; exploration was actively being pursued in the area in the early 1970s.

Fishing is becoming highly commercialized. The traditional pearl-fishing industry has declined since the introduction of the Japanese cultivated pearls in the 1930s. Large fishing industries have been set up in Kuwait, Qatar, and Bahrain; in 1968, 10,000 tons of prawns were exported by Kuwait.

There has always been a considerable sea trade carried on by local craft between the Persian Gulf and Africa and India; this is now completely dominated by an incessant flow of large tankers that carry oil from the large marine terminals at Khārk Island, Kuwait, Dhahran, Bahrain, Musay'īd, aẓ-Ẓannah, and Dās Island to all parts of the world. The heavy traffic and the offshore oil installations have produced many hazards, despite the use of a system of radio-navigational stations.

Prospects for the future. The Persian Gulf area will probably remain an important source of world oil for a long period. The abundance of cheap power should make it possible to set up local extractive industries using raw materials that are too low grade to be exploited elsewhere: a large aluminum-smelting plant is already being constructed in Bahrain. This abundance of cheap power should also allow the exploitation of the highly saline coastal lagoon waters for chemicals such as magnesium, sodium, and chlorine. Although large underground reserves of freshwater have been found in the area, the general lack of freshwater and the unfavourable climate make agriculture difficult. The vast oil wealth, however, should make it possible to develop solar desalination plants to overcome this problem.

Personality, Measurement of

The study of personality as it is treated here is an effort to identify and to describe distinctive human characteristics and to apply these in predicting the behaviour of people. Descriptions of personality made in ordinary conversation are often highly personal, informal, and of unknown reliability and validity. A statement that someone "has a lot of personality" or "has personality problems" is too vague and imprecise for careful study. Personality descriptions toward which psychologists strive contain objective statements about one's personal attributes that are predictive of his future behaviour and that have theoretical significance in scientific research.

The measurement of personal characteristics is the subject matter of the field of psychology today called personality assessment. Assessment is an end result of gathering information intended to advance psychological theory and research, and to increase the probability that wise decisions will be made in applied settings (*e.g.*, in selecting the most promising people from a group of job applicants). The approach taken by the specialist in personality assessment is based on the assumption that much of the observable variability in behaviour from one person to another results from differences in the extent to which individuals possess particular underlying personal characteristics (traits). The assessment specialist seeks to define these traits, to measure them objectively, and to relate them to socially significant aspects of behaviour.

Personality assessment

A distinctive feature of the scientific approach to personality measurement is the effort, wherever possible, to describe human characteristics in quantitative terms. How *much* of a trait manifests itself in an individual? How *many* traits are present? Quantitative personality measurement is especially useful in comparing groups of people as well as individuals. Do groups of persons from different cultural and economic backgrounds differ when considered in the light of their particular personality attributes or traits? How large are the group differences?

Overt behaviour is a reflection of interactions among a wide range of underlying factors, including the bodily state of the individual and the effects of his past personal experiences on him. Hence, a narrowly focussed approach is inadequate to do justice to the complex human behaviour that occurs under the constantly changing set of challenges, pleasures, demands, and stresses of everyday life. The sophisticated measurement of human personality inescapably depends on the use of a variety of concepts to provide trait definitions and entails the application of a diversity of methods of observation and evaluation. Personality theorists and researchers seek to define and to understand the diversity of human traits, the many ways people have of thinking and perceiving and learning and emoting. Such human dimensions, types, and attributes are constructs—in this case, inferences drawn from observed behaviour. Widely studied personality constructs include: anxiety, hostility, emotionality, motivation, and introversion-extroversion. Anxiety, for example, is a concept, or construct, inferred from such acts of behaviour as what a person says, the expression on his face, and the manner in which he moves his body.

Efforts to measure personality constructs stem from a variety of sources. Frequently they grow out of theories of personality; anxiety and repression (the forgetting of unpleasant experiences), for example, are among the central concepts of the theory of psychoanalysis. It is understandable that efforts would be made to quantify one's degree of anxiety, for example, and to use the score thus obtained in the assessment of and in the prediction of his future behaviour. Among the major issues and sources of controversy that characterize the study of personality measurement is the question of which of the many personality constructs that have been quantified are basic or fundamental and which can be expected to involve wasted effort in their measurement because they represent poorly defined combinations of more elemental constructs; which measurement techniques are most effective and convenient for the purpose of assessment; whether it is better to interview people in measuring personality, or to ask them to say, for example, what an inkblot or a cloud in the sky reminds them of.

Efforts to measure any given personality construct can fail, coming to naught because of many combinations of inadequacies in formulating or defining the trait to be measured and weaknesses in the assessment methods employed. An investigator might desire to specify quantitatively the degree to which individuals are submissive in social and competitive situations. His effectiveness will depend on the particular theory of submissiveness he brings to bear on the problem; on the actual procedures he selects or devises to measure submissiveness; and on the adequacy of the research he performs to demonstrate the usefulness of the measure. Each of these tasks must be considered carefully in evaluating efforts to measure personality attributes.

The methods used in personality description and measurement fall into several categories that differ with regard to the type of information gathered and the methods by which it is obtained. While all should rely on data that come from direct observations of human behaviour if they are to have at least the semblance of scientific value, all may vary with regard to underlying assumptions, validity, and reliability (consistency, in this case).

PERSONALITY EVALUATION WITHOUT TESTS

The interview. In an interview the individual under assessment must be given considerable latitude in "telling his story." Interviews have both verbal and nonverbal (*e.g.*, gestural) components. The aim of the interview is to gather information, and the adequacy of the data gathered depends in large part on the questions asked by the interviewer. In an employment or personnel interview the focus of the interviewer reasonably will be on the job candidate's work experiences, on his general and specific attitudes, and on his occupational goals. In a diagnostic medical or psychiatric interview considerable attention would be paid to the history of the patient's bodily health and to any symptoms of behavioral disorder he may have displayed over the years.

Two broad types of interview may be delineated. In the interview designed for use in research, face-to-face contact between an interviewer and interviewee is directed toward eliciting information that may be relevant to particular practical applications under general study or to those personality theories (or hypotheses) being investigated. Another type, the clinical interview, is focussed on assessing the status of a particular individual (*e.g.*, a psychiatric patient); such an interview is action oriented (*i.e.*, it may indicate appropriate treatment). Both research and clinical interviews frequently may be conducted to obtain an individual's life history and biographical information (*e.g.*, identifying facts, family relationships), but they differ in the uses to which the information is put.

Although it is not feasible to quantify all of the events occurring in an interview, personality researchers have devised ways of categorizing many aspects of the content of what a person has said. In this approach, called content analysis, the particular categories used depend upon the researchers' interests and ingenuity, but the method of content analysis is quite general and involves the construction of a system of categories that hopefully can be used reliably by an analyst or scorer. The categories may be straightforward (*e.g.*, the number of words uttered by the interviewee during designated time periods), or they may rest on inferences (*e.g.*, the degree of personal unhappiness the interviewee appears to express). The value of content analysis is that it provides the possibility of using frequencies of uttered response to describe verbal behaviour and defines behavioral variables for more-or-less precise study in experimental research. Content analysis has been used, for example, to gauge attitudinal changes as they occur within a person with the passage of time. Changes in the frequency of hostile references a neurotic makes toward his parents during a sequence of psychotherapeutic interviews, for example, may be detected and assessed as may the changing self-evaluations of psychiatric hospital inmates in relation to the length of their hospitalization.

Erroneous conclusions

Sources of erroneous conclusions that may be drawn from face-to-face encounters stem from the complexity of the interview situation, the attitudes, fears, and expectations of the interviewee, and the interviewer's manner and training. Research has been conducted to identify, control, and, if possible, eliminate these sources of interview invalidity and unreliability. By conducting more than one interview with the same interviewee and by using more than one interviewer to evaluate his behaviour, light can be shed on the reliability of the information derived and may reveal differences in influence among individual interviewers. Standardization of interview format tends to increase the reliability of the information gathered; for example, all interviewers may use the same set of questions. Such standardization, however, may restrict the scope of information elicited; and even a perfectly reliable (consistent) interview technique can lead to incorrect inferences.

Behavioral observation. In every type of assessment situation behaviour is sampled in some way; *i.e.*, not every bit of the individual's behaviour (past and future, for example) can be observed. The behaviour sampled in the interview may be that of self-description in which the individual indicates how he perceives himself. Other behavioral observations (*e.g.*, of facial expression) are also made in interviews as well as in specially devised test and everyday situations. A situational test permits observation of specific aspects of one's behaviour, which may be predictive of his future behaviour. The specially devised test takes the form of a miniature life situation; during World War II, for example, situational tests were used by a number of governments to select individuals who were judged capable of withstanding the inquisition and grilling to which a captured spy might be subjected. The tests typically took the form of stressful situations in which the individual was required to attain specified goals (*e.g.*, completing an assigned project under trying, frustrating conditions).

Another approach to behavioral observations involves the establishment of quantitative base lines against which to compare the future behaviour of individuals. Does the frequency with which a child seeks out other children, for example, increase with the number of play-therapy sessions in which he participates? Such observations permit quantitative description of someone's response repertory at a given point in time and can provide a basis for measuring therapeutic effectiveness.

Behavioral observation. In every type of assessment ways. One of these is to keep track of the frequency with which people make designated responses during a given period of time (*e.g.*, the number of times a psychiatric patient makes his own bed or the number of times a child asks for help in a novel situation). Another approach involves asking raters to support their judgments of others by citing specific behaviour (critical incidents); a shop foreman, for example, may rate a worker as depressed by citing incidents when the worker burst into tears. Critical incidents not only add validity to ordinary ratings; they also suggest behavioral details that might be promising predictors of success on the job, response to psychiatric treatment, or level of academic achievement.

Behavioral observations are widely made in interviews and in a variety of workaday settings. Employers, supervisors, and teachers—either formally or informally—make use of behavioral observations in making decisions about people for whom they have responsibility. Unfortunately the subject may know he is being studied or evaluated and, therefore, may behave atypically (*e.g.*, by working harder than usual, or by growing tense). The observer may be a source of error by being biassed in favour of or against the subject. Disinterested observers clearly are to be preferred (other things being equal) for research and clinical purposes. The greater the care taken to control for such contributions to error, the greater the likelihood that observations will prove to be reliable.

Rating scales. Some observations do not lend themselves to quantification as readily as do simple counts of motor behaviour (such as the number of times a worker leaves his lathe to go to the bathroom). It is difficult, for example, to quantify how charming an office receptionist is. In such cases, one may fall back on relatively subjective judgments, inferences, and relatively imprecise estimates, as in deciding how disrespectful a child is.

One approach to securing such judgments of the behaviour of others is through the use of rating scales, which have much in common with self-report questionnaires described below. The rating scales present an observer with scalar dimensions along which those who are observed are to be placed. A teacher, for example, might be asked to rate his students on the degree to which the behaviour of each reflects leadership capacity, shyness, or creativity. Peers might rate each other along dimensions such as friendliness, trustworthiness, and social skills. Several standardized, printed rating scales are available for describing the behaviour of psychiatric hospital patients. Relatively objective rating scales have also been devised for use with other groups; for example, the Fels Parent Behavior Scales are available for assessing parental behaviour toward their children in the home situation.

Psychiatric ratings

Rating scales are among the most venerable and versatile of the paper-and-pencil methods of personality measurement. They often take a graphic form:

To what degree is John shy?

A number of requirements should be met to maximize the usefulness of rating scales. One is that they be reliable: the ratings of the same person by different observers should be consistent. Other requirements are reduction of sources of inaccuracy in personality measurement; the so-called halo effect results in an observer's rating someone favourably on a specific characteristic because the observer has a generally favourable reaction to the person he is rating. One's tendency to say only nice things about others or his proneness to think of all people as average (to use the midrange of scales) represent other methodological problems that arise when rating scales are used.

Factual information: unobtrusive and physiological measurement. In an interview there is an opportunity for direct observations of expressive behaviour (*e.g.*, speech patterns, poise, gestures) and for gathering the subject's life history and other types of information. While an interviewee usually is aware that he is an object of interest and inquiry, behavioral observations may be recorded whether the subject is or is not aware that his behaviour is under study. If he is aware, his behaviour may be influenced significantly by that fact, and he may strive to create a good impression. There are, however, ways of gathering data that are resistant to the biases this creates.

One type of information that is sometimes overlooked because of its very simplicity consists of the subject's life history and present status.

Much of this information may be gathered through direct interviews with a subject or with an informant, through questionnaires, and through searches of records and archives. The information might also be gathered by examining the subject's personal documents (*e.g.*, letters, autobiographies) and medical, educational, or psychiatric case histories. The information might concern the individual's social and occupational history, his cultural background, his present economic status, and his past and present physical characteristics. Life-history data can provide clues to the precursors and correlates of present behaviour. This information may help the investigator avoid needlessly speculative or complex hypotheses about the causation of personality traits when simple explanations might be superior. Failure on the part of a personality evaluator to be aware of the fact that someone had spent two years during World War II in a concentration camp could result in misleading inferences and conjectures about the subject's present behaviour.

Searches of records and archives

Even if an individual knows he is being studied or evaluated, he may not know which of his personality attributes

are of special interest to the assessor. One often unwittingly or uncontrollably reveals feelings and thoughts that he desires to keep private. Experienced personality assessors (*e.g.*, psychiatric clinicians) come to be adept at observing expressive nuances (subtleties in behaviour) that an individual either believes are being successfully suppressed or that he is unaware of himself. Slight variations in gestures, intonations, and mannerisms illustrate these expressive aspects of behaviour.

Physiological measurement

Along with expressive behaviour, measures of bodily functioning may reveal data that are related to the motivation and behaviour of the individual. Aspects of physique, the levels of hormones or sugar in the blood, tests of neurological functioning (*e.g.*, the knee jerk), and characteristics such as alterations in the resistance of the skin to electric current (the galvanic skin reaction) and changes in the dilation of the pupils of the eyes are among the bodily measures that have been used in personality assessment. With technological advances, it is becoming increasingly feasible and convenient to gauge unobtrusively the internal physical state of the individual. The activity of the sweat glands, the heartbeat, one's total bodily blood volume and blood pressure, and the amount of different substances in his bloodstream can be recorded and used to predict his social behaviour, the intensity of his drives (motivation), and the presence or absence of specified emotionally significant states such as frustration and stress.

One of the challenges confronting assessment psychologists is the fact that personal characteristics are not only not constant but may vary even from moment to moment with changes in the conditions of life. Electronic and mechanical devices so adapted as continuously to monitor changes in bodily functioning that are related to periodic ratings of mood and to other physiological states provide measures of stability and change within the individual.

PERSONALITY TESTS

The aim of personality assessment is to secure accurate and useful (valid) statements about persons. While there may be general agreement about the theoretical and practical value of characterizing individuals, it is not immediately obvious how this can be accomplished; disagreements about methodological matters in personality assessment thus have been widespread. The success that has attended the use of convenient intelligence tests in providing reliable, quantitative (numerical) indices of individual ability has stimulated interest in the possibility of devising similar tests for measuring personality. Procedures now available vary in the degree to which they achieve scorability and convenience. These desirable attributes can be partly achieved by restricting in designated ways the kinds of responses a subject is free to make. A test that restricts the subject to true–false answers, for example, is likely to be convenient to give and easy to score. So-called personality inventories tend to have these characteristics, in that they are relatively restrictive, objectively scorable, and convenient to administer. Other techniques (such as inkblot tests) for evaluating personality possess these characteristics to a lesser degree.

Personality inventories. In the early history of personality measurement, most tests were constructed on the basis of so-called face validity; that is, they simply appeared to be valid. Items were included simply because, in the fallible judgment of the person who constructed or devised the test, they were indicative of certain personality attributes. In other words, face validity need not be defined by careful, quantitative study; rather, it typically reflects one's more-or-less imprecise, possibly erroneous, impressions. Personal judgment, even the personal judgment of an expert, is no guarantee that a particular collection of test items will prove to be reliable and meaningful in actual practice.

Self-report inventories

A widely used early self-report inventory, the so-called Woodworth Personal Data Sheet, was developed during World War I to detect soldiers who were emotionally unsuited for combat. Among its ostensibly face-valid items were these: Does the sight of blood make you sick or dizzy? Are you happy most of the time? Do you sometimes wish you had never been born? Recruits who answered these kinds of questions in a way that could be taken to mean that they suffered psychiatric disturbance were detained for further questioning and evaluation. Clearly, however, symptoms revealed by such answers are exhibited by many people who are relatively free of emotional disorder.

Present-day self-report measures that take the form of personality inventories consist of many and varied statements or questions to which the subject is asked to respond in a particular way. His task might be to decide whether or not each of a series of statements is characteristic of his own feelings or behaviour; or he might respond true or false to a series of questions about the world in which he lives. Several inventories require that each of a series of statements be placed on a rating scale in terms of the frequency or adequacy with which the statements are judged by the individual to reflect his tendencies and attitudes. Regardless of the way in which the subject responds, most inventories yield several scores each intended to identify a distinctive aspect of personality.

One of these, the *Minnesota Multiphasic Personality Inventory* (MMPI), is probably the personality inventory in widest use in the English-speaking world at the present time. Also available in other languages, it consists in one version of 550 items (*e.g.*, "I like tall women.") to which subjects are to respond "true," "false," or "cannot say." Work on this inventory began in the 1930s, when its construction was motivated by the need for a practical, economical means of describing and predicting the behaviour of psychiatric patients. In its development efforts were made to achieve convenience in administration and scoring and to overcome many of the known defects of earlier personality inventories. Varied types of items were included and emphasis was placed on making these printed statements (presented either on small cards or in a booklet) intelligible even to persons with limited reading ability.

Most earlier inventories lacked subtlety; many people were able to fake or bias their answers since the items presented were easily seen to reflect gross disturbances; indeed, in many of these inventories maladaptive tendencies would be reflected in either all true or all false answers. Perhaps the most significant methodological advance to be found in the MMPI was the attempt on the part of its developers to measure tendencies to respond, rather than actual behaviour, and to rely but little on assumptions of face validity. The true–false item "I hear strange voices all the time" has face validity for most people in that to answer "true" to it seems to provide a strong indication of abnormal hallucinatory experiences. But some psychiatric patients who "hear strange voices" can still appreciate the socially undesirable implications of a "true" answer and may therefore actually try to conceal their abnormality by answering "false." A major difficulty in placing great reliance on face validity in test construction is that the subject may be as aware of the significance of his responses as is the test constructor and thus may be able to put his "best foot" forward and mislead the tester. Nevertheless, the person who hears strange voices and yet answers the item "false" clearly is responding to something—his answer still is a reflection of his personality, even though it may not be the aspect of personality to which the item seems to refer; thus, careful study of responses beyond their mere face validity often proves to be profitable.

Reactions to the testing environment

Much study has been given to the ways in which response sets and test-taking attitudes influence behaviour on the MMPI and other personality measures. The response set called acquiescence, for example, refers to one's tendency to respond with "true" or "yes" answers to questionnaire items regardless of what the item content is. It is conceivable that two people might be quite similar in all respects except for their tendency toward acquiescence. This difference in response set can lead to misleadingly different scores on personality tests. One person might be a "yea-sayer" (someone who tends to answer true to test items); another might be a "nay-

sayer"; a third individual might not have a pronounced acquiescence tendency in either direction.

Acquiescence is not the only response set; there are other test-taking attitudes that are capable of influencing personality profiles. One of these, already suggested by the example of the person who hears strange voices, is social desirability. A person who has convulsions might say "false" to the item "I have convulsions" because he believes that others will think less of him if they know he has convulsions. The intrusive potentially deceiving effects of the subjects' response sets and test-taking attitudes on scores derived from personality measures can sometimes be circumvented by varying the content and wording of test items. Nevertheless, users of questionnaires have not yet completely solved problems of bias such as those arising from response sets. Indeed, many of these problems first received widespread attention in research on the MMPI and research on this and similar inventories has significantly advanced understanding of the whole discipline of personality testing.

The MMPI as originally published consists of nine clinical scales (or sets of items), each scale having been found in practice to discriminate a particular clinical group, such as people suffering from schizophrenia, depression, or paranoia (see PSYCHOSES). Each of these scales (or others produced later) was developed by determining patterns of response to the inventory that were observed to be distinctive of groups of individuals who had been psychiatrically classified by other means (*e.g.*, by long-term observation). The responses of apparently normal subjects were compared with those of hospital patients with a particular psychiatric diagnosis; for example, with symptoms of schizophrenia. Items to which the greatest percentage of "normals" gave answers that differed from those more typically given by patients came to constitute each clinical scale.

In addition to the nine clinical scales and many specially developed scales, there are four so-called control scales on the inventory. One of these is simply the number of items placed by the subject in the "cannot say" category. The L (or lie) scale was devised to measure the tendency of the test taker to attribute socially desirable attributes to himself. In response to "I never tell a lie," such a person is apt to answer true; for "I get angry sometimes" he should tend to mark false; extreme L scorers in the other direction appear to be too good, too virtuous. Another so-called F scale was included to provide a reflection of the subjects' carelessness and confusion in taking the inventory (*e.g.*, "Everything tastes the same" tends to be answered true by careless or confused people). More subtle than either the L or F scales is what is called the K scale. Its construction was based on the observation that some persons tend to exaggerate their symptoms because of excessive openness and frankness and may obtain high scores on the clinical scales; others may exhibit unusually low scores because of defensiveness. On the K-scale item "I think nearly anyone would tell a lie to keep out of trouble," the defensive person is apt to answer false, giving the same response to "I certainly feel useless at times." The K scale was designed to reduce these biassing factors; by weighting clinical-scale scores with K scores, the distorting effect of test-taking defensiveness may be reduced.

In general, it has been found that the greater the number and magnitude of one's unusually high scores on the MMPI, the more likely it is that he is in need of psychiatric attention. Most professionals who use the device refuse to make assumptions about the factualness of the subject's answers and about his personal interpretations of the meanings of the items. Their approach does not depend heavily on theoretical predilections and hypotheses. For this reason the inventory has proved particularly popular with those who have strong doubts about the eventual validity that many theoretical formulations will show in connection with personality measurement after they have been tested through painstaking research. The MMPI also appeals to those who demand firm experimental evidence that any personality assessment method can make valid discriminations among individuals.

In recent years there has been growing interest in actuarial personality description; that is, in personality description based on traits shared in common by groups of people. Actuarial description studies yield rules by which persons may be classified according to their personal attributes as revealed by their behaviour (on tests, for example). Computer programs are now available for diagnosing such disorders as hysteria, schizophrenia, and paranoia on the basis of typical group profiles of MMPI responses. Computerized methods for integrating large amounts of personal data are not limited to this inventory and are applicable to other inventories, personality tests (*e.g.*, inkblots), and life-history information. Computerized classification of MMPI profiles, however, has been explored most intensively.

Diagnosis with computers

The MMPI has been considered in some detail here because of its wide usage and because it illustrates a number of important problems confronting those who attempt to assess personality characteristics. There are many other personality inventories and paper-and-pencil assessment techniques that are used in applied settings and in research. The *California Psychological Inventory* (CPI), for example, is keyed for several personality variables that include sociability, self-control, flexibility, and tolerance. Unlike the MMPI, it was developed specifically for use with "normal" groups of people. Whereas the judgments of experts (usually psychiatric workers) were used in categorizing subjects given the MMPI during the early item-writing phase of its development, nominations by peers (one's equals or associates) were relied upon in work with the *California Psychological Inventory*. Its technical development has been evaluated by test authorities to be of high order, in part because its developers profited from lessons learned in the construction and use of the MMPI. It also provides measures of response sets and has been subjected to considerable research study.

Another instrument, the *Eysenck Personality Inventory*, was created in England and provides measures of neuroticism and extroversion. Its use has been closely linked with English psychologist Hans J. Eysenck's theories of personality. The device is short and easily administered, the neuroticism factor being designed to measure emotional instability and neurotic predispositions to break down under stress (see PSYCHONEUROSES). The extroversion items on this inventory are held to sample one's tendency to exhibit sociable, out-going behaviour.

The *Edwards' Personality Preference Schedule* is a so-called forced-choice personality inventory. For each item the subject is required to characterize himself by choosing between paired statements of equal apparent desirability or undesirability. Such a task can be distasteful to many test takers; it may require, for example, being forced to describe oneself as either "stupid" or "ugly." Among others, the *Edwards' Personality Preference Schedule* yields measures of one's needs for achievement, heterosexuality, and social dominance. The strength of each need is not expressed in absolute terms but in relation to the intensity of the individual's other needs.

Beyond personality inventories, there are other self-report approaches to personality measurement available for research and applied purposes. Mention was made earlier of the use of rating scales filled out by observers. An individual also can use rating scales as a vehicle for his own self-description. The so-called semantic differential is a rating-scale technique that permits quantification of an individual's reactions to himself, to others, and, in fact, to any object or concept in terms of a standard set of semantic (word) polarities such as "hot–cold" or "good–bad." It is a general method for assessing the meanings of these semantic concepts to individuals.

Self-description techniques

Another method called the Q-sort is devised for problems similar to those for which rating scales are used. In a Q-sort a person is given a set of sentences, phrases, or words (usually presented individually on cards) and is asked to use them to describe himself (as he thinks he is or as he would like to be) or someone else. This description is carried out by having the subject sort the items on the cards in terms of their degree of relevance so that they can be distributed along what amounts to a rating scale.

Examples of descriptive items that might be included in a Q-sort are "worries a lot," "works hard," and "is cheerful."

Typical paper-and-pencil instruments such as personality inventories involve verbal stimuli (words) intended to call forth designated types of responses from the individual. There are clearly stated ground rules under which he makes his responses. Paper-and-pencil devices are relatively easy and economical to administer and can be scored accurately and reliably by relatively inexperienced clerical workers. They are generally regarded by professional personality evaluators as especially valuable assessment tools in screening large numbers of people, as in military or industrial personnel selection. Assessment specialists do not assume that self-reports are accurate indicators of personality traits. They are accepted, rather, as samples of behaviour for which validity in predicting one's everyday activities or traits must be established empirically (*i.e.*, by direct observation or experiment). Paper-and-pencil techniques have moved from their early stage of assumed (face) validity to more advanced notions in which improvements in conceptualization and methodology are clearly recognized as basic to the determination of empirical validity.

Projective techniques. One group of assessment specialists holds that the most meaningful path to personality description and classification requires that the person who is assessed be given the opportunity to respond as freely as possible so as to reflect his unique (idiosyncratic) ways of thinking and behaving. Inkblots and other ambiguous stimuli comprise a number of tests that have been used widely in clinical situations (*e.g.*, in psychiatric hospitals) in this type of assessment. Such ambiguous stimuli are used to provide so-called projective techniques (since they allow one relative freedom to project his own interests and feelings into them, reacting in any way that seems appropriate).

Personality inventories and projective techniques do have some elements in common; inkblots, for example, are ambiguous, but so also are many of the statements on inventories such as the MMPI. These techniques differ in that the subject is given substantially free rein in responding to projective stimuli rather than merely answering true or false, for example. Another similarity between projective and questionnaire or inventory approaches is that all involve the use of relatively standardized testing situations.

While projective techniques are often lumped together as one general methodology, in actual practice there are several approaches to assessment from a projective point of view. Although projective techniques share the common characteristic that they permit the subject wide latitude in responding, they still may be distinguished broadly as follows: (1) *associative techniques*, in which the subject is asked to react to words, to inkblots, or to other stimuli with the first associated thoughts that come to mind; (2) *construction techniques*, in which the subject is asked to create something—for example, make up a story or draw a picture of himself; (3) *completion techniques*, in which the subject is asked to finish a partially developed stimulus, such as adding his own last words to an incomplete sentence; (4) *choice or ordering techniques*, in which the subject is asked to choose from among or to give some orderly sequence to stimuli—for example, to choose from or arrange a set of pictures or inkblots; (5) *expressive techniques*, in which the subject is asked to express himself freely in some manner, as in finger painting.

Types of projective techniques

These techniques allow the subject wide latitude in making his responses. Because of this freedom, projective techniques are held by some theorists to be sensitive to unconscious dimensions of personality. Hidden personality defense mechanisms, latent emotional impulses, and inner anxieties all have been attributed to test takers by making theoretical inferences from data gathered as they responded in projective situations. While projective stimuli are ambiguous, they are usually administered under fairly standardized conditions. Quantitative (numerical) measures can be derived from subjects' responses to them. These include the number of responses one makes to a series of inkblots and the number of responses to the blots in which the subject perceives what seem to him to be moving nonhuman animals.

The Rorschach Inkblot Test. The Rorschach inkblots were developed by a Swiss psychiatrist, Hermann Rorschach, in an effort to reduce the time required in psychiatric diagnosis. His test consists of ten cards, half of which are in colour and half in black and white. The test is administered by showing the subject the ten blots one at a time; the subject's task is to describe what he sees in the blots or what they remind him of. The subject is usually told that the inkblots are not a test of the kind he took in school and that there are no right or wrong answers.

Rorschach's work was stimulated by his interest in the relationship between perception and personality. He held that a person's perceptual responses to inkblots could serve as clues to basic personality tendencies. Despite Rorschach's original claims for the validity of his test, subsequent negative research findings have led many users of projective techniques to become dubious about the role assigned the inkblots in delineating relationships between perception and personality. In recent years, emphasis has tended to shift to the analysis of nuances of the subject's social behaviour during the test and to the content of his verbal responses to the examiner; whether, for example, he seeks to obtain the assistance of the examiner in "solving" the inkblots presented to him, sees "angry lions" or "meek lambs" in the inkblots, is apologetic or combative about his responses.

Evaluation of Rorschach validity

Over the years, considerable research has been carried out on Rorschach's inkblots; important statistical problems in analyzing data gathered with projective techniques have been identified, and researchers have continued in their largely unsuccessful efforts to overcome them. There is a vast experimental literature to suggest that the Rorschach technique lacks empirical validity.

A similar method, the *Holtzman Inkblot Test*, has been developed in an effort to eliminate some of the statistical problems that beset the Rorschach test. It involves the administration of a series of 45 inkblots, the subject being permitted to make only one response per card. The Holtzman has the desirable feature that it provides an alternate series of 45 additional cards for use in retesting the same person.

Research with the Rorschach and Holtzman has proceeded in a number of directions; many studies have compared psychiatric patients and other groups of special interest (delinquents, underachieving students) with ostensibly normal people. Some investigators have sought to derive indices or predictions of future behaviour from responses to inkblots, and have checked, for example, to see if anxiety and hostility (as inferred from content analyses of verbal responses) are related to favourable or unfavourable response to psychotherapy. A sizable area of exploration concerns the effects of special conditions (*e.g.*, experimentally induced anxiety or hostility) on the inkblot perceptions reported by the subject and the content of his speech.

Thematic Apperception Test (TAT). There are other personality assessment devices, which, like the Rorschach, are based on the idea that an individual will project something of himself into his description of an ambiguous stimulus.

The *Thematic Apperception Test*, for example, presents the subject with pictures of persons engaged in a variety of activities (*e.g.*, someone with a violin). While the pictures leave much to one's imagination, they are more highly specific, organized visual stimuli than are inkblots. The test consists of 30 black and white pictures and one blank card (to test imagination under very limited stimulation). The cards are presented to the subject one at a time and he is asked to make up a story that describes each picture and that indicates the events that led to the scene and the events that will grow out of it. He is also asked to describe the thoughts and feelings of the persons in his story.

Although some content-analysis scoring systems have been developed for the TAT, attempts to score it in a stan-

dardized quantitative fashion tend to be limited to research and have been fewer than has been the case for the Rorschach. This is especially the state of affairs in applied settings in which the test is often used as a basis for conducting a kind of clinical interview; the pictures are used to elicit a sample of verbal behaviour on the basis of which inferences are drawn by the clinician.

In one popular approach, interpretation of a TAT story usually begins with an effort to determine who is the hero (*i.e.*, to identify the character with whom the subject seems to have identified himself). The content of the stories is often analyzed in terms of a so-called need-press system. Needs are defined as the internal motivations of the hero. Press refers to environmental forces that may facilitate or interfere with the satisfaction of needs (*e.g.*, in the story the hero may be physically attacked, frustrated by poverty, or suffer the effects of rumours being spread about him). In assessing the importance or strength of a particular inferred need or press for the individual who takes the test, special attention is given to signs of its pervasiveness and consistency in different stories. Analysis of the test may depend considerably on the subjective, personal characteristics of the evaluator, who usually seeks to interpret the subjects' behaviour in the testing situation; the characteristics of his utterances; the emotional tone of the stories; the kinds of fantasies he offers; the outcomes of the stories; and the conscious and unconscious needs speculatively inferred from the stories.

Word-association techniques. The list of projective approaches to personality assessment is long, one of the most venerable being the so-called word-association test. The Swiss psychiatrist Carl Jung used associations to groups of related words as a basis for inferring personality traits (*e.g.*, the inferiority "complex"). Administering a word-association test is relatively uncomplicated; a list of words is presented one at a time to the subject who is asked to respond with the first word or idea that comes to mind. Many of the stimulus words may appear to be emotionally neutral (*e.g.*, building, first, tree); of special interest are words that tend to elicit personalized reactions (*e.g.*, mother, hit, love). The amount of time the subject takes before he begins each response and the response itself are used in efforts to analyze a word association test. The idiosyncratic, or unusual, nature of one's word-association responses may be gauged by comparing them to standard published tables of the specific associations given by large groups of other people.

Word stimulus responses

Sentence-completion techniques. The sentence-completion technique is a logical extension of word-association methods. In administering a sentence-completion test, the subject is presented with a series of partial sentences that he is asked to finish in his own words (*e.g.*, "I feel upset when . . . "; "What burns me up is . . . "). Users of sentence-completion methods in assessing personality typically analyze them in terms of what they judge to be recurring attitudes, conflicts, and motives reflected in them.

ASSESSING ASSESSMENT TECHNIQUES

Assessment, whether it is carried out with interviews, behavioral observations, physiological measures, or tests, is intended to permit the evaluator to make meaningful, valid, and reliable statements about individuals. What makes John Doe tick? What makes Mary Doe the unique individual that she is? Whether these questions can be answered depends upon the reliability and validity of the assessment methods used. The fact that a test is *intended* to measure a particular attribute is in no way a guarantee that it really *accomplishes* this goal. Assessment techniques must themselves be assessed.

An objective of research in personality measurement is to delineate the conditions under which the methods do or do not make trustworthy descriptive and predictive contributions. One approach to this problem is to compare groups of people known through careful observation to differ in a particular way. It is helpful to consider, for example, whether the MMPI or TAT discriminates significantly between those who show progress in psychotherapy and those who do not, whether they distinguish between law violators of record and apparent nonviolators. Experimental investigations in which the conditions under which subjects perform are varied systematically also make contributions.

Another area of research on assessment has to do with the role of the assessor himself as an evaluator and predictor of the behaviour of others. In most applied settings he subjectively (even intuitively) weighs, evaluates, and interprets the various assessment data that are available. How successful he is in carrying out his interpretive task is critical as is knowledge of the kinds of conditions under which he is effective in processing such diverse data as impressions gathered in an interview, test scores, and life-history data. The typical clinician usually does not use a statistical formula that weighs and combines test scores and other data at his disposal. Rather, he integrates the data using impressions and hunches based on his past clinical experience and on his understanding of psychological theory and research. The result of this interpretive process usually includes some form of personality description of the person under study and specific predictions or advice for that person; *e.g.*, perhaps a recommendation that the person consult a brain surgeon or a physician who treats syphilis.

Evaluating the evaluator

The degree of success an assessor has when he responds to the diverse information that may be available about a particular person is the subject of research that has been carried out on the issue of clinical versus statistical prediction. It is reasonable to ask whether a clinician will do as good a job in predicting behaviour as does a statistical formula or "cookbook"; *i.e.*, a manual that provides the empirical, statistically predictive aspects of test responses or scores based on the study of large numbers of people. An example would be a book or table of intelligence test norms (typical scores) used to predict how well children perform in school. Another book might offer specific personality diagnoses (*e.g.*, neurotic or psychotic) based on scores such as those yielded by the different scales of the MMPI. Many issues must be settled before the deceptively simple question of clinical versus statistical prediction can be answered definitively.

When statistical prediction formulas (well-supported by research) are available, for combining clinical information, however, experimental evidence clearly indicates that they will be more valid and less time-consuming than will a clinician (who may be subject to human error in trying to simultaneously consider and weigh all of the factors in a given case). The clinician's chief contributions to diagnosis and prediction are in situations for which satisfactory formulas and quantified information (*e.g.*, test scores) are *not* available. Clinicians are especially to be thought of when what are being evaluated are rare and idiosyncratic personality characteristics that have escaped rigorous, systematic empirical study. The greatest confidence obtains when both statistical and subjective clinical methods simultaneously converge (agree) in the solution of specific clinical problems; unfortunately, they often disagree.

Although much progress has been made in efforts to measure personality, all available instruments and methods have defects and limitations that must be borne in mind when using them; responses to tests or interview questions, for example, often are easily controlled or manipulated by the subject and thus are readily "fakeable." Some tests, while useful as group screening devices, empirically exhibit only limited predictive value in individual cases, yielding frequent (sometimes tragic) errors. These caveats are especially poignant when significant decisions about a person are made on the basis of his personality measures. Psychiatric institutionalization or discharge, and hiring or firing, are weighty personal matters indeed and can wreak great injustice when based on faulty assessment. In addition, many personality assessment techniques require the probing of highly private areas of the individual's thought and action. Those who seek to measure personality for descriptive and predictive reasons must concern themselves deeply with the ethical and legal implications of their work.

A major methodological stumbling block in the way of

establishing the validity of any method of personality measurement is that there always is an element of subjective judgment in selecting or formulating criteria against which measures may be validated. This is not so serious a problem when popular, socially valued, fairly obvious criteria are available that permit ready comparisons between such groups as convicted criminals and ostensible noncriminals, or psychiatric hospital patients and noninstitutionalized individuals. Many personality characteristics, however, cannot be validated in such directly observable ways (*e.g.*, one's inner, private experiences such as anxiety or depression). When such straightforward empirical validation of an untested measure hopefully designed to measure any personality attribute is not possible, efforts at establishing a less impressive kind of validity (so-called construct validity) may be pursued. A construct is a theoretical statement concerning some underlying, unobservable aspect of an individual's characteristics or of his internal state. ("Intelligence," for example, is a construct; one cannot hold "it" in his hand, or weigh "it," or put "it" in a bag, or even look at "it.") Constructs thus refer to private events inferred or imagined to contribute to the shaping of specific public events (observed behaviour). The explanatory value of any construct has been considered by some theorists to represent its validity. Construct validity, therefore, refers to evidence that endorses the usefulness of a theoretical conception of personality. A test designed to measure an unobservable construct (such as "intelligence" or "need to achieve") is said to accrue construct validity if it usefully predicts the kinds of empirical criteria one would expect it to; *e.g.*, achievement in academic subjects.

The degree to which a measure of personality is empirically related to or predictive of any aspect of behaviour observed independently of that measure contributes to its validity in general. A most desirable step in establishing the usefulness of a measure is called cross-validation. The mere fact that one research study yields positive evidence of validity is no guarantee that the measure will work as well the next time; indeed, often it does not. It is thus important to conduct additional, cross-validation studies to establish the stability of the results obtained in the first investigation. Failure to cross-validate is viewed by most testing authorities as a serious omission in the validation process. Evidence for the validity of a full test should not be sought from the same sample of people that was used for the initial selection of individual test items. Clearly this will tend to exaggerate the effect of traits that are unique to that particular sample of people and can lead to spuriously high (unrealistic) estimates of validity that will not be borne out when other people are studied. Cross-validation studies permit assessment of the amount of "shrinkage" in empirical effectiveness when a new sample of subjects is employed. When evidence of validity holds up under cross-validation, confidence in the general usefulness of test norms and research findings is enhanced. Establishment of reliability, validity, and cross-validation are major steps in determining the usefulness of any psychological test (including personality measures).

Progress in personality measurement depends upon answers to both methodological and theoretical questions. Scholarly interest in theories of personality (see PERSONALITY, THEORIES OF), pressing practical problems (such as the need to screen or diagnose patients efficiently), and the intriguing results of incomplete research provide the impetus for those who seek to devise objective, meaningful measures of personal characteristics. In devising these measures a number of frustrating, but crucial, questions remain to be answered. The pursuit of empirical answers to such questions has been partially rewarding and provides hope that progress will continue to be made in the relatively youthful field of personality measurement.

BIBLIOGRAPHY. C.S. HALL and G. LINDZEY, *Theories of Personality*, 2nd ed. (1970), surveys the major theories of personality. E.F. BORGATTA and W.W. LAMBERT (eds.), *Handbook of Personality Theory and Research* (1968), integrates several of these theories and the research methods that characterize the discipline. Examples and reviews of personality research are contained in I.G. SARASON, *Personality: An Objective Approach* (1966), and (ed.), *Contemporary Research in Personality*, 2nd ed. (1969). L.J. CRONBACH, *Essentials of Psychological Testing*, 3rd ed. (1970), surveys general approaches of assessment; while O.K. BUROS (ed.), *Personality: Tests and Reviews* (1970), provides a valuable compendium of personality tests and measurement devices. D.N. JACKSON and S. MESSICK (ed.), *Problems in Human Assessment* (1970), deals with selected aspects of personality assessment.

(I.G.S.)

Personality, Theories of

Theories of human personality presumably have existed in some form ever since men began to speculate about why people act as they do. The term personality has been given many meanings, but at the core of all of them the reference is to the organization of traits or characteristics within the individual. There are two emphases in this identification of the concept of personality: the individual shares his characteristics (*e.g.*, happiness or ugliness) in common with other people; and each individual is distinguished from all others on the basis of his unique combination of these characteristics and of the degree to which he manifests them.

To suggest that there is a single widely accepted definition of the term personality, however, is misleading. A definition commonly encountered in many textbooks on the subject is comprehensive, defining personality as the sum total of the characteristics of the individual. In contrast, an alternative definition is implied in the everyday practice of suggesting that a person "has a lot of personality," in which usage the reference is to positive, desirable characteristics that give a person social competence and attractiveness. The latter popular definition, which is evaluative, has received relatively little use in the scholarly consideration of theories of personality (see also PERSONALITY, MEASUREMENT OF).

The fullest range of ideas about personality pervades the literary, legal, religious, and philosophical literature about man, just as there are myriad assumptions about what constitutes the nature of man. The notion that whole peoples (*e.g.*, ethnic or racial groups) differ in basic personality characteristics is common; the resulting study of culture and personality in modern times has received attention especially among anthropologists. Fundamental definitions and principles underlying this type of scientific pursuit, however, were clearly enunciated in the writings of the German psychologist Wilhelm Wundt in the mid-19th century. More journalistic forms of ethnic-group personality description are found in earlier writings and essays dating as far back as known history; the ancient Romans, for example, recorded a great variety of personality traits held to be characteristic of the barbarian peoples who lived in the borderlands of the military empire of the Caesars. In more recent journalistic and fictional literature, there are still to be found assertions such as that the French (as an entire people) are volatile, that the Italians are hot-blooded, that the Scandinavians are phlegmatic, and so forth; such statements bear implications that alleged group differences in personality are hereditary rather than being based on culture. Indeed, in the discussion of scientific efforts to establish personality types (which follows below), it should be noted that some human types are defined in terms of heritable bodily characteristics. Since such bodily traits are found to be associated with geographical location, it may be that assertions of ethnic or national tendencies to manifest specific personality traits are not necessarily farfetched.

Early studies of personality traits

Assumptions about the nature of man that are commonly found as aspects of religious, moral, and philosophical writings often assume a model of man based on selected qualities; these may be drawn from myths of human origins or from the characteristics attributed to local gods. Thus, in some cultures, humans may be said to have the characteristics of "mother earth," from whom they are believed to spring. Or humans may be portrayed as having both good and evil in them, corresponding to good spirits and bad spirits held to exist in some religions.

Often in the religions of technologically advanced peoples, these characteristics are outlined in great detail in sacred writings, and inferences about the nature of men may be drawn from examples and incidents recorded in these writings. Thus, the personality model of a saviour (*e.g.*, the Messiah) may imply both the good example and the bad contrast, with emphasis being placed on the socially important aspects of behaviour. Distinctions among unobservable internal "entities" (*e.g.*, "mind," "spirit," "conscience," "true self") may be contrasted with manifest (observable) behaviour, and there may be considerable controversy about problems of moral and behavioral conflict.

Historically, the precursors of the 19th-century study of personality theory were often concerned with the ultimate or essential nature of man. Drawing from concepts outlined by the ancient Greeks, and from other sources, philosophers of the 1600s and 1700s speculated about human personality and went into theoretical detail at times about human perception and personality traits or dispositions. In the writings of the 18th-century economist Adam Smith, philosophical notions of human personality are postulated with great specificity. Smith's theory of man as an economic creature ("economic man") required him to assert the primacy of particular characteristics of personality (*e.g.*, greed) for his analysis to have any basis.

In the paragraphs that follow, some emphasis is placed on formulations of human personality that have been advanced as theories (that is, as more or less speculative guesses). This does not mean, however, that concern with the objective, nontheoretical aspects of personality is not pervasive in society. The behaviour of every person involves some guessing about associates and family and acting according to these hypotheses. Legal rules, drawn to regulate social behaviour, imply definitions and expectations about "normal" personality, about what may happen in an undesirable ("abnormal") way, and are designed to limit such classes of unwanted behaviour. The nature of man thus is the urgent concern of lawmakers, and in relatively sophisticated legal systems there is considerable concern with defining the personality of a legally accountable, responsible person.

TYPE THEORIES OF PERSONALITIES

Classical biochemical theories. Theories of personality invariably involve some notions of types (or classes) of people, if only because particular aspects of the person (*e.g.*, his appearance or his mood) are stressed in describing his unique structure and function. Any rigid classification of people into specific personality types might seem to suggest that a given person must fall into one class only, and that he is distinctly, qualitatively unlike others who exhibit different personality types. Such a rigid point of view is an oversimplification of the observable evidence. Though the degree of specificity with which personality types are advanced may vary considerably, the convenience that derives from thinking of persons as being of one distinct personality type or another has been appealing to many theorists. Since there are so many descriptive terms that relate to personality in any given language, the potential variety of type theories is enormous. A classical theory of human types, offered by ancient Greek physicians, focussed on the emotional (temperamental) attributes of human personality and was based on a relatively primitive understanding of human biology (specifically, bodily physiology), which prevailed at that time. According to these early theorists, emotional equilibrium (indeed, general health) depended on an appropriate balance among four fluids (humours) within the body. It was held that physiological imbalance (produced by an excess of one of the humours, for example) would be reflected in bodily illness and in exaggerated personality traits. Thus, if a person had an excess of blood (one of the four humours), he was expected to have a sanguine temperament; that is, to be optimistic, enthusiastic, and excitable. The modern term hot-blooded may be a survival of this Greek theory of human personality; the notion was so influential that for many centuries physicians throughout the Western world continued the practice of bleeding people who suffered from medical and psychiatric disorders. Such people are still said to be in "bad humour."

The four humours

Too much of a humour called black bile (congealed blood from the spleen) was believed to produce a melancholic temperament. The term melancholia literally means black bile, and there are literary allusions to venting one's spleen. When someone was oversupplied with yellow bile (the yellow-green gall secreted by the liver and stored in the gall bladder), he was held to become choleric; that is, to be angry, irritable, and to view his world with a jaundiced eye. Jaundice remains in modern medical language as a disease of the liver or gall bladder in which bile is present in the body to such a degree that the eyeballs and body may turn yellow. Finally, with an abundance of the humour called phlegm (as secreted in the throat), people were supposed to become stolid, apathetic, and undemonstrative; that is, to grow phlegmatic.

As biological science has progressed, these primitive concepts of body chemistry have been replaced by more subtle and complex biological theories of personality. Thus, the chemical factors associated with given psychological dispositions are now more likely to be understood in terms of hormones (as from the thyroid gland), nerve impulses, and so-called psychotropic drugs such as tranquillizers.

Morphological theories. Somewhat less subtle than the biochemical theories of personality are those that distinguish different classes of people through relatively gross characteristics of bodily build (shape or morphology). A morphological theory developed by a German psychiatrist, Ernst Kretschmer (1888–1964), is possibly the most widely known. Kretschmer distinguished among his patients three types of bodily structure (somatotypes). What he called the pyknic type was characterized by a thick trunk, short limbs, and a tendency to put on weight, especially with increasing age. According to his observations in the psychiatric hospital where he worked, sufferers of major fluctuations in mood (so-called manic-depressive psychotics, alternatively called extreme cyclothymic personalities) were more likely to show the pyknic somatotype than were other inmates. By contrast, Kretschmer delineated an asthenic (leptosomic) body type, characteristically displaying a slim trunk, long legs, and a tendency to be tall and lean. These leptosomes tended to appear temperamentally withdrawn or introverted and seemed more prone than other people to develop symptoms of a group of psychiatric disorders now labelled schizophrenia (see PSYCHOSES). The so-called athletic somatotype, with broad shoulders and slim hips, while no less susceptible to psychiatric disturbance, apparently favoured neither schizophrenia nor the manic-depressive psychosis.

Kretschmer's body types

Despite early hopes that somatotypes might be useful in diagnosing personality characteristics or in identifying psychiatric difficulties, the relationships observed by Kretschmer were not found to be sufficiently clear-cut for practical application. Subsequent and much more elaborate studies reported in the 1940s in the United States also yielded three somatotypes: endomorphy (roughly pyknic with similar temperament called viscerotonia); ectomorphy (crudely equivalent to Kretschmer's asthenics, and temperamentally characterized as cerebrotonic); and mesomorphy (comparable to the athletic body type, and called somatotonic in temperament).

This system did not serve practical needs any more effectively than had Kretschmer's, even though it had been based on much more painstaking work. In this context, other physical characteristics, such as head shape (physiognomy) and bumps on the skull (phrenology), have been found so wanting as bases for personality theories that they have not received much serious attention in the current century. The all-encompassing, exaggerated claims made for these theories of physical morphology first drew enthusiasm and finally generated the reaction of disappointment. Nevertheless, structural differences in the body do seem to have some significance in pointing to such aspects of personality as intelligence and emotion.

In cases of a form of mental deficiency called mongolism, for example, distinctive "Asian" facial features and squat bodily structure are readily recognizable even to untrained observers.

ANALYTIC AND SOCIAL THEORIES

Psychoanalytic theories. *Freud.* Freud's psychoanalytic theories of personality have been among the most influential in the modern era of psychological study. The interest they attract stems in part from Freud's efforts to address himself to the practical problems of dealing with psychiatric disturbances, an orientation quite different from that typically found among academic psychologists. Freud wrote on so many different questions in attempting to explain the origins of psychiatric disorders that it is still difficult to put him in proper historical perspective. Freud's contributions have received many divergent interpretations, and many of his ideas are now viewed as models, suggestions, and intellectual metaphors.

Id, ego, and superego

Freud's key view of human personality as a system involved three concepts: the id, the ego, and the superego, each of which was held to constitute a portion of the total personality, and each of which was said to have a unity of its own. The three segments, however, were supposed to operate in interaction, and the behaviour of the individual was said to be the consequence of this interaction. Separately, the id was seen as the original "structure" of the personality system and as consisting of inborn, primitive, inherited characteristics or tendencies. It was depicted as the source of psychological energy initially, and the ego and the superego were held to develop from this source. The id was associated with what Freud called the "pleasure principle," reflected in the tendency of the person to maintain a pleasant, tolerable energy level through the relief of inner tension. The "pleasure principle" may be described in more mundane language as applying to the activities of the individual in achieving pleasure and avoiding pain. Thus, the loud crying of a hungry infant was called an id activity, it being assumed that the baby was responding to his inborn tendency to avoid the discomfort of an empty stomach.

The ego, associated with what Freud called the "reality principle," was held to develop from the id so that the individual could negotiate realistically with the objective world. The infant who experienced pain on touching a hot object was said to be developing his ego (reality contact) by learning to avoid the object. Thinking realistically provides one with means for the satisfaction of his primitive needs and thus serves as a secondary means for tension reduction. The ego was portrayed as controlling intellectual and perceptual functions (the so-called higher mental processes) involved in the control of behaviour. The ego was held to be coordinated to satisfy the inborn instincts (implicit in the id) but primarily to be oriented in a direction that serves to maintain the individual comfortably in relation to his environment.

The superego was theorized to be the third segment of the personality to develop and to represent the person's adoption (internalization) of social values; *e.g.*, the table manners he learns from his parents. Morality is said to be incorporated into the superego, which is supposed to evaluate the correctness of one's behaviour from the point of view of the standards of society. What is called conscience was held to be manifested by part of the superego. This theoretical division of the personality was seen to function in controlling sexual and aggressive impulses that derived from the id. With regard to the ego, the superego was held to impose "higher" moral goals as substitutes for "lower" realistic (ego) aims. In general, the superego might be said to represent the behavioral ideal.

Freud's theory of *Triebe*

Freud's view of personality rested firmly on his theory of *Triebe* (German: "needs," "drives," "urges," or "instincts"), with biological factors conceived as giving the driving force to the personality through the id. This source of psychic energy was said to be manifested as the person's wishes (corresponding to specific needs). *Triebe* were said to be of two types: (1) so-called life instincts, including the primary drives of sex, hunger, and thirst, were identified with Freud's term libido (or life energy). The orientation of the personality system was theorized to be directed toward satiation of these instincts (see also MOTIVATION). The psychic (libidinal) energy involved could also be dissipated by alternate means; expending energy in this substitute way is known as sublimation or displacement. (2) Correspondingly, there were said to be death instincts, of which an important group is labelled the aggressive motives. These id instincts were said to be controlled and harnessed by the ego, which drew psychic energy from them. The ego, as the "manager" of the personality, became crucial in psychoanalytic theory to the understanding of the learning processes involved in identification and displacement.

There are many aspects of Freud's theory, including his analysis of stages of human sexual development (see HUMAN BEHAVIOUR, DEVELOPMENT OF: *Personality Theories*). Concepts such as these have been among the most controversial in Freud's theory. Critics of the theory have emphasized its nonexperimental, empirically unverifiable aspects; id, ego, and superego are not observable entities. Some Freudian writings, including a description of the origin of the incest tabu, have been taken by some social scientists as being speculative, imaginative, and unsupportable in any rigorous way. While his critics see little empirically based science in Freud's formulations, his followers most enthusiastically seem to endorse and use them in efforts to treat sufferers of mental disorder.

Jung. Once a follower of Freud's, the Swiss psychiatrist Carl Gustav Jung had a substantial influence in the field of personality theory but did not develop the kind of massive following Freud did. Jung had considerable contact with Freud during the early period of their work, until, beginning in 1914, there were clear signs of a break between them, apparently prompted at least in part by Jung's rejection of Freud's pervasive concern with the sex drive as a basis for psychoanalytic interpretation. Jung agreed with Freud in attaching great importance to unconscious motivations but, unlike Freud, he placed even greater emphasis on interpreting behaviour as consciously purposive and as guided by one's awareness of goals and aspirations.

Recognition was given to the biological basis of personality; for Jung, much in the way of predispositions in human personality is referred to the biological history of man as an animal species. In this context, Jung theorized the inborn existence in each person of a "collective unconscious" that represents one's inherited accumulation of "memories" of ancestral experience dating from the earliest prehistoric man. The emphasis of this concept is on the common biological heritage that a species develops, all men being said to share a similar physical structure and correspondingly similar potential for behaviour.

In Jung's theory of personality, the ego constitutes the conscious "mind," reflected in the person's own feelings of self-identity. In addition (beyond the "collective unconscious"), Jung proposed for each person a "personal unconscious" in which one's unique, individual history of experience resides.

Jung agreed with Freud in holding that the effects of prior experiences that have been pushed back (repressed) out of consciousness may be drawn from the "personal unconscious." Jung's theory is full of historical, speculative, and imaginative references and analogues; his notion of personality as persona, for example, derives from the ancient (Etruscan?) name for the masks worn by actors. In this sense, personality is conceived as the mask the individual advances in maintaining his conventional place in society. As persona, personality is seen to be one's public presentation of himself in a manner likely to be socially acceptable. Jung also held persona to be consistent with the primordial images (archetypes) that he supposed were drawn from the "collective unconscious," which theoretically served as the repository of ancestral memories. The reappearance of deluge, or flood, myths (*e.g.*, that of Noah and the ark) in many different cultures worldwide was offered by Jung as evidence for a common set of archetypes shared by all people.

Jung's archetypes

Adler. While the writings of Freud and Jung may be contrasted with more experimentally grounded, so-called eclectic scientific theories of personality, many other authors were strongly influenced by Freudian and Jungian notions. More recent analytic theories have tended to stress social factors, emphasizing the malleability of the individual and the effects of social experience on the formation of his personality. Some theories, such as the "Individual Psychology" of Alfred Adler, an Austrian psychiatrist who once was a prominent associate of Freud and Jung, gave little or no weight to sexual and archetypal motives. Adler's theory of personality is known for its emphasis on a human "drive to power" (superiority) and on the importance of conscious (rather than unconscious) activities. Adler wrote extensively that all individuals must cope with feelings of inferiority, stressing compensatory processes (*e.g.*, as exhibited by the short person who compensates by being aggressive). In striving for social acceptance and influence, the person was viewed by Adler as constantly struggling toward the goal of what many theorists call self-realization.

Social analytic theories. Most of the socially oriented analytic theories of personality are of relatively recent vintage; what is common to these various approaches is that they are not basically experimental, having arisen largely in clinical settings and from intuitive thinking. To the extent that they have removed the conceptual rigidities and mysticism of the Freudian fountainhead from which they were largely drawn, such theories have tended to gain acceptance more readily among academic, empirically oriented psychologists such as Henry A. Murray, whose system for defining and measuring the strength of human needs has influenced research extensively. Concern with the study of what Murray called need-achievement, for example, is a major emphasis among social psychologists who seek to subject human behaviour to objective, statistical analysis.

The theories of Murray and Allport

Murray's list of human needs seems to show considerable correspondence to sets of personality characteristics that have been delineated through the painstaking statistical analysis of the responses given by large groups of people to items on personality tests. What is most characteristic of theories such as Murray's is evidence that they have been generated in much broader investigative contexts than was the case for their Freudian forebear. Thus, Murray sought to adapt his theory to a wide range of research data from psychological, anthropological, and sociological studies. Murray particularly worked toward the quantitative, empirical validation of his speculative concepts, constructing the Thematic Apperception Test (see PERSONALITY, MEASUREMENT OF) in an effort to translate his concerns with unconscious and other subtle motivational aspects of personality into measurable dimensions.

The view of personality presented by the U.S. psychologist Gordon W. Allport represents a focus on the individual as a unique, qualitatively different (idiographic) entity in each case. Allport, for example, initiated efforts to measure morality or values in personality and helped to develop a well-known personality inventory called the Allport-Vernon-Lindzey Study of Values. He viewed human behaviour as being motivated by relatively stable personality characteristics, or traits; his theorizing tended to be eclectic and to be compatible with clearly defined scientific tradition. Allport also is known particularly for the introduction of such concepts as that of functional autonomy, which describes the tendency of learned motives to be self-sustaining long after the historic reason for them has ceased to exist. Thus, an adult neurotic who suffers from an abnormal fear of heights (acrophobia) may have learned the trait as an infant by responding to the anxious behaviour of oversolicitous parents. Yet, long after the parental signs of alarm have ceased, often long after the parents have died, the acrophobia persists as a functionally autonomous personality characteristic.

RECENT ECLECTIC THEORIES

Contemporary personality study is characterized by a tendency of investigators to interpret their research findings on the basis of the eclectic use of many theories rather than in terms of a single, universally applicable, "grand" theory of personality. Indeed, this very practice may seem to support (possibly unfair) conclusions that the discipline of personality study suffers from comparative scientific immaturity, even though it has a rich history dating back to the earliest recorded human cultures (see PSYCHOLOGY, HISTORY OF). It also must be observed that lay people and workers in other fields who are not aware of the various developments in the growth of academic psychology and sociology may not recognize the evidence that many topics in personality theory were well developed early in the history of these disciplines. Contributions such as those of the U.S. psychologist William James (born 1842), concerning the analysis of human instincts and learned behaviour, are reasonably well known.

Role theories. On the other hand, monumental and incisive work on the development of human personality that was the contribution of an American, James Mark Baldwin, is less known, even among modern investigators and clinicians. Baldwin presented the skeleton and much of the fleshing of what can be described as a behaviourist theory of personality socialization and had an important influence on the U.S. sociologist Charles Horton Cooley. Cooley's volume on *Human Nature and the Social Order* at the turn of the century provided for a generation an eclectic and more or less scientifically respectable introduction to a social psychology focussed on the individual and his social behaviour. This tradition led subsequently to further elaboration and theoretical development in the description of learning processes through which the human infant is brought into society and develops the behavioral characteristics of a socially active person. This particular behaviouristic orientation has been associated with the concept that much social interaction has symbolic meaning to the participants, particularly in the social roles they play. So-called role theory has not yet produced a coherent body of empirically based generalizations; still, proponents of this approach (the study of personality as social role playing, as persona) have the advantage of being relatively free of the stifling constraints imposed by some rigidly dogmatic theories of personality.

Trait theories. An alternative approach to human personality among academic psychologists is found in the work of a British psychologist, William McDougall, and others who have outlined various classifications of personality traits. Though McDougall once was widely criticized for his use of the term instinct in specifying the driving forces of human personality, the notion of instinct (*q.v.*) has today recaptured considerable respectability in scientific circles. McDougall ordered personality characteristics as primary (inherited) propensities and as secondary (acquired or learned) tendencies. Such a stratification of personality characteristics is common to many theoretical attempts to organize personality traits.

McDougall's notion of instinct

In more modern dress personality theory drawn directly from the empirical study of human traits has attracted the attention of many psychologists. In part, this movement grew from developments in educational psychology, particularly from progress in the construction of psychological tests. The idea of using tests for measuring intellectual characteristics was well established by their successful use in the psychological screening of military personnel during World War I. By the 1930s the statistical technique called factor analysis (a procedure for the examination of the structure of a test) had stimulated this type of development. Contemporary psychologists published masses of empirical data showing the tests to measure sets of statistically distinct "factors" or behavioral dimensions that could be used to define personality traits. Efforts have been made to demonstrate parallel sets of factors derived from empirical biological data and from psychological tests designed to measure personality traits at the level of verbal behaviour. There has been some debate on the quality of evidence thus far offered to demonstrate psychobiological parallelism (or

Factor analysis

even unity) in human personality, but there is gross evidence that spectacular personality changes can be induced biologically (*e.g.*, by drugs).

Factor-analytic studies at times may appear to be exploratory and atheoretical, but intrinsically the theory that underlies them is that of all empirical science. In particular, the theory for these approaches rests on the axiom that there are generalizations about human personality that are empirically discoverable and verifiable. Indeed, agreement in repeated factor-analytic studies of personality measures by independent researchers has been considerable. One approach to the description of personality, for example, is through ratings of an individual by others. Factor-analytic studies of such ratings repeatedly have provided evidence for such generalized personality characteristics as assertiveness, sociability, emotionality, and conscientiousness. Traits based on ratings may be described as those ways in which individuals behave and differ from each other that are reliably discernible to others. This is sometimes taken as the focal definition of what one wants to know about a person; namely, how others see him. The structure of personality as defined at this level relates to the theoretically unimportant approach of symbolic social interaction. According to the symbolic-interaction theorists, the identity of a person is defined by his perception of the responses of others to him; that is, by how he perceives his value as a social stimulus.

In factor-analytic studies of formal measures of personality (*e.g.*, pencil-and-paper personality inventories or tests) there has been less agreement among different investigators in delineating specific human traits. In part this results from the great variety of tests available, the many different ways of asking questions of the test taker, and of scoring and interpreting test responses. Also, the theoretical ambition of having all the relevant questions about a person's preferences, attitudes, and values measured in any one test is not to be satisfied, if only for practical reasons. Thus, different tests do not necessarily sample the same kinds of behaviour. Additionally, personality-test construction has not been performed by equally sophisticated investigators in all circumstances.

One objective of factor analysis and of related techniques is to reduce the number of dimensions required to account for most of the variation in individual responses to all test items. Thus, a personality inventory with three hundred items may yield evidence for only ten or fifteen personality traits (factors or dimensions) that are relatively distinct (*i.e.*, statistically independent of each other). The traits identified by different investigators often seem to differ. Sometimes these discrepancies may be more apparent than fundamental, however, and may simply result from semantic differences in naming the factor. In other studies the differences seem to indicate basically different personality traits, as revealed when the same set of subjects is used to check two sets of earlier findings.

From the point of view of agreement, however, repeated factor-analytic studies with different personality tests do indicate some traits that emerge with at least a degree of consistency. These have commonly been identified as the dimensions of introversion–extroversion and of social adjustment. Particularly interesting in these findings are the suggested ties to earlier work; for example, Jung's early interest in and emphasis on the introversion–extroversion continuum in accounting for such abnormalities of personality as schizophrenia and the manic-depressive psychosis. Personality inventories based heavily on clinical hunches or intuitions (popular before the advent of more sophisticated test-construction techniques) emphasized concepts of the sort offered by Jung.

Statistical procedures used in the study of personality permit the characteristics of a single individual to be charted over periods of time, yielding evidence as to either the stability or transient nature of some traits. Although the technique is fraught with problems, what is called inverted factor analysis is used to examine the degree to which groups of individuals share the same traits. Thus, individual people take the place of tests or test items in the factor analysis. Investigators who use this technique hope to discover with its help more precise ways of grouping people for such purposes as psychiatric diagnosis.

At present, the scientific concerns with the study of personality tend to de-emphasize reliance on general theories of personality and to place more stress on the study of specific empirical aspects of human behaviour. Hopes for developing a universal theory of personality probably are no more realizable than is the dream of a global theory to account for the functioning of the human organism as a biological entity. Apparently, the theory can be no less complex than the organism itself. What constitutes personality theory at any point in time thus depends on a cumulative mass of information, segments of which may be understood in great detail while others may remain to be discovered.

Personnel Administration

Personnel administration is the management of the people in working organizations. It is also frequently called personnel management, industrial relations, employee relations, and manpower management. It represents a major subsystem in the general management system, in which it refers to the management of human resources, as distinguished from financial or material resources. The term may be used to refer to selected specific functions or activities assigned to specialized personnel officers of departments. It is also used to identify the entire scope of management policies and programs in the recruitment, allocation, leadership, and direction of manpower.

Personnel administration begins with the process of organizing—the process of defining the required quantities of particular personal capabilities. Thereafter, people must be found, recruited, selected, trained or retrained, negotiated with, counselled, led, directed, committed, rewarded, transferred, promoted, and perhaps released or retired. In many of these relations, managers deal with their associates as individuals (the field takes its name in part from this type of relationship). In some working organizations, however, employees are represented by unions, and managers bargain with these associations. Such collective bargaining relationships are generally described as labour relations.

HISTORY

Early practices. The history of personnel jobs is one of persistent job enlargement. Today's personnel departments and activities bear little resemblance to earlier personnel officers and assignments. Responsibilities have expanded and job specifications have changed from low-skill requirements to technical and professional levels of competence.

Early personnel positions

Many early personnel positions were created to implement the policies of paternalistic owners. Those who held these early assignments in England have been described as "welfare workers"; counterparts in the United States have been characterized as "amateur social workers." Expected to convey to rank and file employees the employer's interest in their welfare, early personnel people had to become acquainted with rank and file workers and their personal and family circumstances and to express the employer's sympathy when they faced difficult personal and family problems.

In what was perhaps the most common early development, assignments were expanded to include responsibilities for selection. As this function evolved, personnel workers interviewed applicants "at the gate," and later, in reception rooms. They investigated work histories and experience. Still later, some of them began simple testing programs. Their offices became depositories for personnel records. When unions became common, some personnel officers were expected to prevent them by blacklisting troublemakers. As collective bargaining expanded, some departments handled negotiations and contract administration.

Contemporary practices. All around the world, assignments to personnel departments clearly reflect expanding industrialization and accompanying social and political developments. Developing nations have faced the problem of adapting their agricultural labour forces to industrial employment. Specialized personnel officers have been expected to reorient workers and to enforce safety and security programs. In the economic development process, public policy has turned toward objectives of "full employment," shorter working days and weeks, higher real wages, equal employment opportunity, and increased economic security. Technological change has created new skill requirements and reduced employment for "raw," unskilled labour. Lead times between decisions to hire and actual employment have become longer. Geographic boundaries of labour markets have broadened as labour mobility has increased.

As skill shortages created new demands for manpower planning and training, rising levels of citizen education and sophistication complicated the employer's problem of gaining commitment. More sophisticated employees sought promises of new satisfactions in their work. Problems in employment behaviour attracted growing attention from the rejuvenated behavioral sciences. New theories of human behaviour suggested new approaches in manipulation and direction. Managers recognized the need for new patterns and styles of leadership and new structures of working organizations.

Utilization of human resources

Today's personnel assignments have emerged in managerial reactions to industrialization. In modern industrial economies, the manager's responsibilities for human resources require a complex mixture of programs. In less industrialized nations, on the other hand, programs emphasize recruitment, reorientation, and employment security, as political leaders seek to gain commitment to industrial jobs. Labour movements may emerge in these nations as protests against the regimen and control of mass employment and are likely to be considerably more explosive than are the older unions of more "mature" economies. New unions may be oriented more strongly toward political action than toward collective bargaining.

Government regulation. Governments in the developing nations, sensitive to worker fears of mass unemployment and of health hazards, usually try to provide extensive benefit programs. Personnel managers may enforce limitations on working hours, ensure approved working environments, and administer a variety of supplementary benefits. In India, for example, employment of an employee welfare officer with such responsibilities is required by law in firms with more than 500 employees. In contrast, in the more mature, industrialized nations, assignments to personnel departments are much broader and more varied. Many current discussions refer to the personnel "system," implying a scope as broad as the total of interacting variables that influence employment behaviour.

Personnel associations. Personnel workers have created numerous local, national, and international associations. They sponsor periodic meetings and conferences and publish journals that report on research, experience, and the opinions of practitioners. They include the European Association for Personnel Management, the Institute of Personnel Management in England, the American Society for Personnel Administration, the Society for Personnel Administration, and the Industrial Relations Research Association in the United States and Canada. Training and safety officers and wage and salary administrators have created more specialized associations (for example, the American Society for Training and Development and the American Compensation Association).

PERSONNEL DEPARTMENTS

Responsibilities. Current practice shows wide variation in the range of responsibilities assigned to personnel or industrial relations departments. Organizations with 100 or more employees generally provide some such specialized services. The average "personnel ratio" is about 0.50, meaning one full-time professional or technical personnel worker for each 200 employees. In larger organizations, personnel departments usually include a variety of personnel specialists.

Major areas of responsibility

Major areas of personnel department responsibilities include: (1) organizing—devising and revising organizational structures of authority and functional responsibility and facilitating two-way, reciprocal, vertical, and horizontal communication; (2) planning—forecasting personnel requirements in terms of numbers and special qualifications, scheduling inputs, and anticipating the need for appropriate managerial policies and programs; (3) staffing or manning—analyzing jobs, developing job descriptions and specifications, appraising and maintaining an inventory of available capabilities, recruiting, selecting, placing, transferring, demoting, promoting, and thus assuring qualified manpower when and where it is needed; (4) training and development—assisting team members in their continuing personal growth, from pre-employment, preparatory job training to executive development programs; (5) collective bargaining—negotiating agreements and following through in day-to-day administration; (6) rewarding—providing financial and nonfinancial incentives for individual commitment and contribution; (7) general administration—developing appropriate styles and patterns of leadership throughout the organization; (8) audit, review, and research—evaluating current performance and procedures in order to facilitate control and improve future practice.

Individual personnel departments may be assigned varying degrees of responsibility in a few, many, or all of these areas. In areas assigned to them, personnel departments exercise various levels of authority. Some officers and departments create policy and make major decisions and determinations. Some study and recommend policy and create and direct appropriate programs. The personnel vice president may be a member of the executive cabinet; he may be expected to assume leadership in and responsibility for all manpower management policy and programs. Other personnel departments are essentially "staff" or advisory; their activities are restricted to recommending, consulting, and providing such specified technical and professional services as are requested by operating managers. Such a department, for example, may provide the "legwork" of recruiting or of interviewing or testing. All important decisions may be reserved to line managers. In this latter type of assignment, personnel departments provide "staff services" for management. Among the most common examples, the personnel staff (when, as, and if requested and authorized by operating managers) analyzes jobs and prepares job specifications, visits sources of potential employees, conducts preliminary screening interviews, administers tests, supervises rating or appraisal programs, counsels employees, conducts training and development programs, negotiates agreements, monitors grievance settlements, maintains safety and accident control programs, administers employee benefits and services, prepares forecasts of future manpower requirements, recommends changes in organizational structures, supervises formal in-house communication, conducts employee attitude and morale surveys, and supplies other related services, sometimes including public relations.

Staffing policies and programs. Among the earliest and most persistent of assignments to personnel officers is that of finding and choosing people to fill present or future jobs. These staffing programs are built around several steps or stages, including: (1) manpower planning—forecasting manpower requirements and creating necessary

policies and programs for filling openings as they appear; (2) job analysis—providing information for job specifications that identify required skills, competence, and potential capabilities for each job; (3) recruitment—identifying likely sources of potential candidates who are informed of opportunities and encouraged to apply; (4) selection—using interviews, tests, references, and other sources of relevant information to identify candidates to be offered employment; (5) placement and induction—introducing newly selected employees to working colleagues and conditions and explaining task assignments.

Current policy objectives

Manpower planning. The simplest form of staffing policy proposes to find and hire whatever manpower is needed when it is needed. Current policy in private firms and public agencies frequently emphasizes these objectives, but more often more complex staffing is required. Public policy may insist on equal employment opportunities for all. Managers may prefer to hire for a long working career instead of for a single job. They may propose utilization of the highest skills and aptitudes and maximization of employee satisfaction in the job, relating this policy to participant commitment and contribution. Policy may propose preference for employees who are physically handicapped or are available only on a part-time basis. Policy may stress the care and advancement of present employees.

Job analysis. Staffing is designed to fill manpower needs identified in the organizing process, which includes division of labour, specification of tasks to be accomplished, and specification of combinations of tasks in jobs. Thereafter, job analysis spells out these operations, noting the knowledge, skills, and working conditions and jobholder qualifications thus prescribed. It provides the facts for "job descriptions," which systematically summarize this information. "Job specifications" detail the personal qualifications required in such terms as education, minimal scores on tests of knowledge, skill, and aptitudes, experience in the same or related occupations, and other such personal characteristics. "Staffing tables" or "manning tables" summarize quantitative requirements—that is, numbers of jobholders to be employed in each job at specified levels of plant operation. "Time study" may be used to develop job or performance standards for each job.

Recruitment. Sources of acceptable candidates for vacancies may be internal or external. Policy frequently proposes to give priority to internal sources—that is, present employees. That policy, described as "promotion from within," may be implemented by maintaining a "capability inventory" that summarizes the skills, experience, education, and talents of present employees. To fill vacancies, present employees may be promoted—that is, reassigned to jobs with greater responsibilities—or transferred to other jobs at similar levels. Recruitment from within may be guided by a "seniority system" expressing the intention to regard length of service in the organization as a major consideration in promotion or retention. Use of internal sources often places heavy weight on "personnel appraisals" or "ratings," which are periodic evaluations of individual performance or potential by supervisors or peers.

Among the most widely used external sources are "waiting lists" (lists of applicants who have sought employment but have not been hired), unions, schools, public and private employment agencies, executive-search and temporary-help agencies, and professional societies and associations. Search may require extensive lead time for some highly skilled, technical, and professional workers. Recruitment may extend beyond national boundaries. Recruiting programs may encourage nominations by present employees. Employers may advertise in local or distant publications. Recruiters may use brochures describing career and job opportunities. Recruiting teams may be sent to preferred sources. Experienced scouts may visit vocational or secondary schools, universities, or foreign sources.

Selection. Selection separates those offered employment from all others. The objective is to maximize the probability that selected applicants will meet employer specifications and expectations—to hire the best and reject the rest. The selection process has often been described as a series of successive hurdles. Each hurdle presumably pits the qualifications of candidates against one or more requirements called out in job or career specifications. Some programs identify crucial requirements—for example, citizenship, union membership, a credential, or a license—which may be given priority, so that unsuccessful candidates need go no further in the selection process. Among the most widely used screening techniques and devices are the following:

Identifying and measuring capabilities

1. Application blanks, in which applicants provide requested information on such characteristics as age, sex, education, special training, and experience. "Weighted" application blanks include items that can be scored to predict probabilities of success. Practice may require completion in handwriting by the applicant, sometimes designed to permit handwriting analysis.
2. References, the names and addresses of individuals who can provide personal evaluations. Some are essentially character references; others have knowledge of earlier working performance.
3. Physical examinations may be a critical hurdle. In current practice, because of the cost of medical services, these checks may be used only for the most likely candidates.
4. Interviews are the most widely used selective device. Preliminary screening interviews may determine whether or not candidates are admitted to the remainder of the process. Applicants may face a panel or board interview, meeting with a group of supervisors or managers, or they may be interviewed by an individual job supervisor or manager. Selection interviews may be structured or unstructured—that is, carefully preplanned or merely a conversation that follows its own course. Frequently the interviewer will ask certain specific questions. Weaknesses of the interview as a selective device are now widely recognized, but despite these deficiencies, interviews remain a major selective technique, in part because no entirely satisfactory substitute has been found.
5. Observational methods seek to read personality and character from physical traits and appearance. Despite evidence that assumed correlations are dubious and not demonstrable, some employers continue to use phrenology—the examination of head shape; others lean on a more inclusive assessment generally described as character analysis, which infers a wide range of personal traits from individual physique.
6. Tests are essentially small samples of the behaviour and capability of the candidate. Some of them are widely described as paper-and-pencil tests; they require written marks or replies to the questions they raise. Others are essentially performance tests. Major types used in selection include "achievement tests," measuring capability to perform specified tasks (for example, to type with various degrees of speed and accuracy); "aptitude tests," which identify and compare undeveloped as well as developed personal talent or capability (as for example, mechanical, musical, or literary aptitude); "interest tests," which use checklists and required completions to discover areas of major interest to the applicant; and "personality tests," which seek to reveal the whole pattern of basic personal characteristics, including maturity and temperament. Some personality tests are projective—the applicant's interpretations of pictures or inkblots are regarded as evidencing projections of and clues to his personality. Individual firms may develop their own tailor-made test batteries, but many of the most widely used tests are standardized; they have been administered to large numbers and analyzed statistically, thus providing average ranges and norms of scores.

Placement and induction. The process of introducing a new employee to his working colleagues and conditions and explaining his task assignments contains a number of elements: (1) he must have a simple, precise definition of the work to be done and of the conditions surrounding it; (2) he must be assigned specific work to do and be vested with the authority to do it; (3) he must be informed about his relations to others engaged in the en-

terprise; (4) he must be shown how to perform the tasks assigned to him; and (5) he must know the standards and means by which his work is evaluated.

Separation. In any dynamic economy or organization there is bound to be a labour turnover, and there have developed a few business methods of handling the problem (in addition to such governmental methods as unemployment insurance and employment services). The oldest and most common practice is the dismissal notice —an advance notice to the employee, allowing him to remain on the job for a certain length of time while seeking other work.

Company plans that provide dismissal notices usually also offer what is variously called "severance pay," "dismissal compensation," or "separation grant." This payment (which is in addition to any back wages or salary or any vacation pay) is given a worker when his employment is terminated after having served a minimum length of time (usually at least a year); the amount of the payment is geared to the length of service. Most plans grant severance pay for unavoidable—though permanent—layoffs resulting from the elimination of a job category, a plant shutdown, employee disability, or the like. Many plans pay the allowance even to employees discharged for incompetency or similar cause. Few make payments to anyone who voluntarily quits.

Especially in large corporations there has also developed the alternative to dismissal known as the transfer policy. With a knowledge of the situation in each division or subsidiary of the corporation, the personnel department is in a position to anticipate changes in personnel requirements and to transfer surplus workers to other sections requiring additional help.

Changing staffing policy and programs. Questions and concerns about several traditional staffing programs have been widely publicized. Some of the traditional hurdles may be inconsistent with a public policy that proposes equal employment opportunity. Job specifications may be unrealistic, so that artificial barriers interfere with hiring. For example, requirements of secondary school or university graduation or of lengthy experience, and limitations based on sex, colour, and age are frequently questioned, as are abilities to provide a surety bond or a record of no arrests or convictions. Cultural bias in tests and interviews is recognized; new tests and revised procedures seek to ensure "culture-fair" applications. Selection programs may also involve unacceptable invasions of personal privacy, as in use of lie detectors and the investigation of financial histories and credit ratings.

Training and development programs. Helping both managers and workers learn whatever knowledge and skills are required is a widely accepted responsibility in modern manpower management. In-house programs assist individuals in becoming adjusted to and prepared for work. Their behavioral objectives are more satisfactory performance and more satisfying on-the-job experience. Programs concerned with technical skills are described as "training," whereas those that deal with analytical and leadership skills and understanding for supervisory and management jobs are labelled "development."

Improving technical and managerial skills

Several levels of instruction may be distinguished, including: (1) pre-employment training, designed to aid inexperienced workers to make the transition from schools or unemployment into the employed labour force; (2) job training, for specific job requirements of knowledge and skill; (3) supervisor training; (4) manager or executive development; and (5) a variety of special courses tailored to prepare participants for new problems, rapidly changing assignments, transfers to foreign operations, new materials, new processes, and new organizational arrangements. Examples include special training for supervision of minority groups; preparation for retirement; basic reading, writing, and speaking; so-called sensitivity training (in which individuals come together in a kind of group therapy—studying their own adjustments and reactions to group situations); team development courses; and preparation for citizenship.

The range of training and development programs is a function of general manpower policy, organizational resources, and environmental constraints. For some job assignments, management may be forced to offer training courses because no source can provide qualified recruits. Most training and development programs, however, express a typical "buy-or-make" decision: some employers may offer very little training, preferring to purchase required capabilities, whereas other employers may conclude that such programs are less costly than recruiting, assure superior quality, are more dependable, or tend to improve employee commitment.

A policy stressing "investments in people" encourages in-house training and development programs on the assumption that courses pay off by increasing contributions throughout the careers of employees. Training may be related to the learning-curve or unit-cost function, which shows that continued employee experience and improvement in routine operations can result in reductions in unit labour costs.

Training techniques and practices range from lectures and demonstrations to programmed and computer-assisted instruction. Methods include classroom recitation, discussions, role playing, conferences, coaching, understudy arrangements, and apprenticeship. Training may take place on the job, in the shop, or in "vestibule schools," where trainees are under less pressure and do not interfere with ongoing production. Some programs provide impressive special facilities, permitting a multimedia approach with a variety of audiovisual facilities that mobilize all of the individual senses in learning. Some courses may be provided by local schools and colleges, with scholarships and tuition-refund plans to encourage employee participation. Executive development programs may include assignment to one or more of the several hundred university programs.

Commitment and incentive. Many experienced managers regard the task of gaining and holding the interest, commitment, and enthusiasm of their working crews as their most persistent and difficult task. Personnel departments are assigned numerous program responsibilities in this area. Worldwide transition from agricultural to industrialized economies has made historic incentives inappropriate; ancient attitudes of being "born to work" and of accepting orders from owners and masters have lost most of their earlier influence. Industrialized economies are tied to exchange systems; wages become the major rewards for effort and commitment, but managers must also recognize the importance of nonfinancial considerations. Personnel officers manage programs designed to maximize the payoff from both financial and nonfinancial inducements.

Managers seek high levels of individual commitment to the mission and to the goals of the organization. They hope to increase the interest, effort, and contribution of each participant. Commitment policy seeks to attain this objective through suitable reward or incentive systems. Major dependence is placed on exchangeable financial rewards. Recent, more sophisticated policy, however, recognizes employee sensitivity to a wide range of nonfinancial rewards that promise opportunities to satisfy a variety of personal needs. Rewards or commitment theory has thus moved from rather simple to much more complex models. Effort and contribution are assumed to be functions of opportunities for comprehensive personal self-actualization. Commitment levels are a response, not simply to financial rewards, but also to on-the-job promises of such satisfactions as economic security, group membership, status, self-esteem, and self-fulfillment. Some theory further suggests that opportunities for satisfactions in the work itself may be more influential than those offered by the work setting or environment.

Reward and incentive systems

Wages and salaries. Many personnel departments include a subdivision assigned special responsibility for "wage and salary administration" and involving two major types of compensation programs. One type provides direct money payments for participation and contribution. The other type offers deferred, indirect rewards—employee "benefits" and "services." Some immediate rewards are time based. Others are scaled to match measured performance and output; such "incentive wage"

plans vary from simple piece rates to more complicated arrangements that pay for time saved and provide bonuses for superior performance. "Wages" are paid to hourly rated employees; "salaries" are calculated by the month or year. Wage structures may provide "flat rates" (*i.e.*, a single amount) for each job level or classification, or "rate ranges" for "labour grades," with a series of step rates within each range. Adjustments in individual pay may be "merit" increases, or they may be "automatic"—granted at regular intervals, usually each half-year or year. Rates or amounts of pay are subject to a variety of adjustments—for example, compensation for changes in costs of living. Other adjustments match productivity increases, family allowances provide supplements based on numbers of dependents, and sliding scales adjust to match prices of products. Some programs assure guaranteed annual wages. Legal requirements may specify minimum hourly rates.

"Job evaluation" is widely used to establish comparative values of jobs. For professionals, "maturity curves," which relate pay to years of postgraduate experience, may be substituted for job evaluation. Managers use wage and salary surveys to discover current practice in other firms, agencies, and localities. Compensation frequently combines salaries and a variety of deferred payments (including options to buy stock at discounted prices).

Benefits and services

Numerous indirect, deferred payment programs are also widely used. Some benefits may be required by law—for example, those for unemployment, retirement, and work-related accidents and illness. Noncompulsory benefits are created on the initiative of employers or of unions. Benefits may be contributory; potential receivers may or may not make direct contributions. In terms of purposes or objectives, four types of such benefits and services are common: (1) economic security; (2) protection against health hazards; (3) old age and retirement; and (4) special personal assistance, such as legal aid, credit, counselling, recreational and social assistance.

Nonfinancial rewards. Nonfinancial rewards promise satisfactions not available in the market through purchase or exchange. They assume that work itself and the working environment can offer opportunities for satisfying a variety of human needs, and jobs and organizations are structured to provide such satisfactions. All such programs lean heavily on assumptions about the unsatisfied needs and expectations of rewardees. Managers may undertake periodic morale or attitude surveys to appraise individual and group job satisfaction and to identify unsatisfied needs of participants. Special programs encourage listening by supervisors and improved communications from workers to supervisors. Managers may publish house magazines, develop employee handbooks and manuals of standard operating practice, and assign specific responsibility for answering rumours and gossip. Some nonfinancial reward programs approach commitment through job redesign, job restructuring, and job enrichment, the basic concept being one of adapting jobs to the special and changing interests of jobholders. In all such efforts, the persistent problem for managers is that of limited understanding about what variables influence and condition on-the-job interest and effort.

CURRENT TRENDS

Growing manager recognition of the central importance of human resources has, over the present century, broadened the responsibilities of personnel departments to encompass every aspect of manager–worker relationships, from recruitment to retirement. In some current working organizations, this change is symbolized by describing the personnel operations simply as "administration" and giving its officers heavy responsibility for the total administrative style or stance of management. These overall administrative styles may be compared according to the degree of participation afforded workers in solving problems, influencing plans, decisions, and organizational structure, and thus exposing and reducing tensions and conflict. Patterns in total administration may be described in such terms as "authoritarian" or "participative."

Many personnel departments charged with such broad responsibilities are actively promoting programs of organizational or team development, people-centred supervision, group problem solving, supportive management, consultive management, conflict resolution, and organizational renewal. The long-term trend appears to be toward such broader assignments, coupled with "reverse delegation," in which line supervisors and managers accept greater responsibility for such specific programs as personnel appraisals, training crew members, day-to-day communications, compensation, and counselling.

Persuasion

Persuasion, in the sense to be used in this article, refers to the process by which a person's attitudes or behaviour are, without duress, influenced by verbal communications from other people. One's attitudes (*q.v.*) and behaviour are affected by other factors (for example, verbal threats, physical coercion, one's physiological states). Not all verbal communication is directly persuasive; some of it has such effects as informing, entertaining, or deceiving. But persuasion, in which communication and belief intersect, is a particularly pervasive and poignant manifestation of humanity, shown perhaps not at its best but at its most human. Persuasion involves manipulating other people, and for this reason many find the exercise distasteful. Others might argue that without some degree of social control and mutual accommodation, the human community becomes disordered and that persuasion indeed gains moral acceptability when the alternatives are considered. To paraphrase Winston Churchill's evaluation of democracy as a form of government, persuasion is the worst method of social control except for all the others.

Ancient writings on persuasion

So important a process inevitably attracts study from many quarters. Persuasion has been treated as an art, a craft, and a science by the great cultures that have left a substantial historical record. Thinkers from the time of and of the stature of Aristotle and Cicero devoted whole treatises to the topic. In European universities of the Middle Ages it was one of the basic liberal arts to be mastered by any educated man; and from the days of imperial Rome through the Reformation it was raised to a fine art by preachers who used the spoken word to move men to virtue and the Holy Land. In the modern era, persuasion, in the form of advertising, supports a major industry; only education and the military command a greater share of the gross national product.

Analysis of persuasive communication. The process of persuasion can be conveniently analyzed in a preliminary way by distinguishing verbal communication (as cause, or stimulus) from the associated changes in attitudes (as effect, or response).

Components of verbal communication. Alternative schemes for analyzing verbal communications into manageable sets of components often have been presented as questions to be answered. Just as medieval schoolmen suggested such questions as *quis, quid,* and *quando* ("who, what, and when"), so contemporary news reporters are trained to communicate their stories by describing who, what, when, where, why, and how. An American political scientist of the 20th century, Harold Dwight Lasswell, has said that communication is a matter of who says what to whom, how, and with what effect. In the language of the communication engineer, these factors are source, message, channel, receiver, and destination.

Source factors include all of the characteristics of the perceived sender of the communication. The "message" refers to what he says and includes style, content, and organization; "channel" designates the medium (*e.g.*, press, radio) through which the message is communicated; "receiver factors" are the characteristics (*e.g.*, age, sex) of the person to whom the communication is directed. "Destination" indicates the behaviour (*e.g.*, voting) the communication is designed to influence.

Steps in persuasion. Analysis has led to the delineation of a series of successive steps through which a person goes in being persuaded. The communication first is presented; the person pays attention (*q.v.*) to it, and he comprehends its contents (including the basic conclusion being urged and perhaps also the evidence offered in its support). For persuasion to be effected the individual must yield to, or agree with, the point being urged; and, unless only the most immediate impact is of interest, he must retain this new position until opportunity arises to act on it. Finally, if the fruits of the persuasive process are to be reaped, he must carry out the behaviour implied by his new attitudinal position; *e.g.*, he enlists in the army or becomes a Buddhist monk or begins to eat cornflakes for breakfast.

Theories of persuasion. Persuasion research has been undertaken with a great variety of orientation and purpose, and the consequent theoretical diversity, though it gives an untidy appearance, provides a rich set of alternative viewpoints. The theories arose more in ignorance of than in opposition to one another and should be viewed as supplementary rather than contradictory. When there is theoretical conflict, resulting empirical research may provide clarification.

Learning. Some, but by no means all, theorists emphasize a similarity between education and persuasion. They hold that persuasion closely resembles the learning of new information through informative communication. Thus, since repetition in communication will modify learning, they infer that it will have persuasive impact as well; that, for example, principles of verbal learning and conditioning are widely and profitably applied by persuaders (as in the judicious repetition of television advertisements). The learning approach (see LEARNING THEORIES) tends to emphasize attention, comprehension, and retention of the message.

Perception. One's reaction to persuasive communication depends in part on the message and to a considerable extent on the way in which the receiver perceives or interprets it. Words in a newspaper advertisement may take on different persuasive qualities if they are printed in red instead of in black. Perceptual theorists regard persuasion as altering the person's perception of any object of his attitudes (see LEARNING, PERCEPTUAL). Perceptual approaches also rest on evidence that the receiver's preconceptions are at least as important as the message content in determining what will be understood. The approach stresses attention and comprehension.

Functional approaches. While learning and perceptual theorists may stress objective intellectual steps involved in the process of being persuaded, another, functional, approach emphasizes more subjective motivational aspects. It views man as essentially ego-defensive; that is, as an organism with beliefs that function to satisfy his conscious and unconscious personal needs and that may have little to do with the objects toward which his attitudes and actions are directed. Functional theorists say, for example, that one's ethnic prejudice and other forms of social hostility are often manifestations of his underlying personality structure, reflecting his difficulties in dealing with authority. It is held that his childhood hostility toward his father was severely punished and that he represses such tendencies toward authority in later life, tending to keep such feelings in check by idealizing the powerful groups within society and by despising deviant and low-prestige people. His hostility to such outgroups is said to derive more from his own personality structure than from information about the nature of these groups.

The role of prejudice

According to functional theorists, such attitudes are to be changed by helping the person handle his underlying personality problems rather than by informing him about the people he dislikes. Particularly directed toward emotion-laden attitudes, such theories are less relevant to a broad range of persuasive efforts that deal with more objective, less emotional issues and in which unconscious motivation may play a lesser role.

Conflict resolution. Other theories view the person confronted with persuasive communication as being in the harassed role of trying to find some reasonable compromise among many conflicting forces acting on him; *e.g.*, his own desires, his information, and the social pressures put upon him, including this new communication. Those (frequently called congruity, balance, consistency, or dissonance theorists) who stress this conflict-resolution model of man focus on how people weigh these forces in adjusting their attitudes. Some theorists who take this point of departure stress the intellectual aspects of persuasion, while others emphasize emotional considerations.

Information processing. Each of the approaches considered above tends to neglect one or more steps in the process of being persuaded and thus serves to supplement rather than supplant the others. Another more eclectic and inclusive approach, growing out of information-processing theory, is oriented to a consideration of all of the options implied by the communication aspects of source, message, channel, receiver, and destination; and each option is appraised for its persuasive efficacy in terms of presentation, attention, comprehension, yielding, retention, and overt behaviour.

Methods of research. A typical persuasion experiment of the 1970s may begin with a hypothesis about how some communication factor will affect persuasive impact. In connection with a public-health campaign to persuade people to get an annual physical checkup to detect cancer, for example, the working hypothesis may be that a person's intense anxiety about the prevalence and seriousness of cancer will motivate him to seek a diagnostic examination. The researcher may develop this hypothesis further by theorizing that messages designed to arouse high anxiety might be so frightening that they will discourage people from facing the potential "horror" that a medical examination might reveal.

A typical experiment in persuasion

To evaluate such hypotheses, the investigator might design a set of messages in each of which the informational part is the same but each of which could be expected to evoke different levels of anxiety by varying the stress and vividness with which the incidence and seriousness of cancer are described. He would then devise measures (*e.g.*, questionnaires) of how well the communication is understood (comprehension) and of the extent to which people agree with the recommendations (yielding) and intend to get the medical checkup; he may also prepare a measure of retention, hopefully arranging to check if medical examinations are actually obtained (overt behaviour). The researcher then assembles and studies as many matched samples of people as he has versions of the message, one version being presented and evaluated for each group of receivers.

Receivers' responses on the attitude questionnaires and on other instruments are statistically analyzed to discover any relationships between each communication and its persuasive impact. It may be found, for example, that intermediate levels of anxiety are optimal, that communications designed to evoke either very high or very low levels of anxiety are least persuasive. Other studies may focus on how persuasion is affected by such aspects as message complexity, receivers' previous tendency to show chronic worry about health, and so on. Aside from their theoretical value, such experiments may provide specific information that can guide the conduct of practical, large-scale campaigns.

Source factors. *Credibility.* There is evidence to suggest that persons who attempt to persuade others are most likely to be believed if they appear to know the truth and to be motivated to reveal it; that is, their credibility is a function of their perceived expertise and trustworthiness. Perceived expertise on the part of a person who is a message source is found to exert major persuasive impact even

when it is not specific to the issue at hand. It can derive from his general educational attainment or occupational status; for example, those members of juries with relatively high levels of education are likely to be elected foremen and to be especially influential in determining verdicts even if they exhibit only the subtlest kinds of cues to their status. At the same time, it appears that people also tend to be particularly influenced by sources who seem most like themselves, perhaps through some perceived identity of interest. Thus, while the source may gain credibility from his apparent superior knowledgeability, he may lose it if he seems too different from his receivers. In such a situation it can be predicted that people are most influenced by those whom they judge to be somewhat more expert than they are but not a great deal more. Indeed, it is found that children are more influenced by those a few years older than themselves than they are by those who are either their age or very much older.

Aside from having to appear to know enough, one's credibility appears as well to depend on his being perceived as highly motivated to tell the truth as he sees it. People will apparently tend to judge him as less trustworthy if he seems intent on persuading them, or likely to gain from their agreement. In general, however, such suspect motivation appears to entail surprisingly little loss of persuasive impact; in some studies the source actually is found to gain in impact from being explicitly depicted as trying to manipulate the recipient. It would seem that while the tactic of clearly revealing the source's persuasive goal may have a detrimental effect on yielding, it apparently clarifies the purpose of the communication thus facilitating attention, comprehension, and retention. Also, when someone is motivated to ingratiate himself with the source (*e.g.*, a student trying to please a teacher), the clearer the persuasive intent is made the more likely he is to go along.

Attractiveness. The attractiveness of the source to the audience apparently adds to his persuasive impact. This may reflect the extent to which the recipient seeks some satisfying relationship with him; for example, if the source is a greatly admired person, people tend to pursue gratification from identifying with him or from gaining social esteem by appearing to be like him. The source's familiarity and similarity to the receiver also enhance his attractiveness and persuasive impact. Ideological similarity seems particularly potent; thus, people who believe in racial segregation tend to prefer those of other races who share this belief over members of their own ethnic group who endorse racial integration.

Power. There are indications that the recipient is influenced by the power he perceives the source to have over him. In such case the receiver may believe that the source actually can control his rewards and punishments. Some theorists have conjectured that power to reward should add more to persuasive impact than does power to punish, but both have proved to be equally efficacious. There are grounds for believing that the source must be perceived as interested in exerting power in order to obtain the recipient's compliance. Seemingly, one is influenced by the members of his own group to the extent that the fate of all depends on each person's compliance to achieve unanimity. Finally, if power is to be effective, the source seemingly must be able to observe whether or not the individual is complying; thus, sources who derive impact from power to reward and punish show more control over the individual's public action than over his private beliefs.

Reward and punishment

Message factors. *Appeals used.* The cancer campaign noted earlier is an example of the use of fear-appeals in persuasive messages. It was hypothesized that maximum persuasion will occur with an intermediate level of fear arousal and that this optimal level is lower when receivers are chronically anxious. Research has given some corroboration to such hypotheses, though the operation of appeals to fear in persuasive communications is proving to be unexpectedly complex.

Students have been interested in the relative persuasiveness of ethical, emotional, and logical appeals as far back as the ancient Greeks and Romans. Empirical research appears to corroborate the classic notion that all three can be persuasive under given circumstances; but the three kinds of appeals are so interrelated that it is unwise to assume that one can produce purely moral or rational or emotional messages for comparative study.

Stylistic factors have been of perennial interest to such practitioners of persuasion as politicians and salesmen. The question of a dynamic versus a subdued presentation, or of the "hard" versus the "soft" approach in advertising (*q.v.*), for example, has been investigated repeatedly in the laboratory and in the field. It is found that the dynamic delivery tends to reduce the degree of yielding but gains in attention and comprehension. The use of humour in the message can enhance yielding; apparently it puts the recipient in a more pleasant, agreeable state. Even the manifestly extraneous pleasure of eating a snack while listening to a message has been found to increase persuasive impact.

Information included. The most studied aspect of what is best included or left out of a persuasive message has to do with the opposition's arguments. A number of studies have been made to determine whether persuasive impact is most enhanced by ignoring counterarguments or by mentioning and refuting them. With an initially hostile or highly intelligent audience, it is found efficacious to mention and refute competing views rather than to ignore them; presumably such an audience is already aware of them. By contrast, when recipients are more sympathetic or less intelligent, it appears to be better to ignore one's opponents; it is likely that members of this audience have not yet thought of other views, and their mention (even in refutation) suggests new difficulties to such people. In general, however, refutation is particularly appropriate when the aim is not only to change opinions but also to make them resistant to subsequent efforts by the opposition.

Refuting the opposition

Another well investigated problem relates to whether it is best explicitly to mention the conclusion desired or whether it should be left to be drawn by the receiver himself. Theoretically, persuasive impact might be enhanced if the receiver participates more fully in the communication process and feels that the conclusion is his own. Research data indicate the opposite, however; messages tend to be much more persuasive when specific conclusions are incorporated. It appears to be the case that receivers in most persuasion situations may lack the ability or motivation to make the intended conclusions for themselves.

Organization or sequence. There are indications that the order in which points in a message are presented can change its persuasiveness. To the extent that a communication is likely to be confusing or the issue unclear, for example, it has been found best to offer the conclusion at the outset; this technique seems to provide receiver orientation that enhances attention and comprehension. When the issue is clear but the audience is resistant, it is demonstrably better to put the conclusion at the end of the message. People seem prone to "tune out" and miss a message that indicates opposition to their present views too early.

In two-sided presentations, as in a debate or a jury trial, participants may argue about which side is to make its presentation first. Experimental data indicate the tentative generalization that whether the first or second side is favoured depends on timing. The greater the intervening time between the messages of the opponents, the more the advantage tends to accrue to the one heard last. As the interval between the last message and the time at which the attitude is measured increases, results tend to benefit the first side.

Channel factors. Channel factors refer to the sensory modality or the medium through which any communication is transmitted.

Sensory modality. The relative efficacy of the written versus the spoken word is a problem that arises in connection with persuasion as well as education. Persuasive messages have in general been found to have about the same impact whether they are presented in written or spoken form, but such difference as there may be is in the direc-

tion of a slightly greater impact for the spoken word. Since attention and comprehension of the message contents are usually greater with written presentations, these results indicate that the comprehension advantage of the written word is overridden by a sizably greater yielding to spoken presentations. It has been suggested that the individual may feel in a closer relationship to the source or under more implicit pressure from him when the source is present to deliver his message orally.

Mass media. Various activities in modern society, such as advertising, public relations, and political campaigning, usually involve the investment of vast resources in the use of the mass media to persuade the public to buy a certain product, to love a certain institution, or to vote for a certain candidate. Studies assessing these campaigns have not been successful in demonstrating their persuasive impact, even as regards attitude change, much less changes in actual purchasing or voting behaviour. Advocates of the mass media have suggested various excuses for this lack of demonstrated impact. Some have argued that they do have an impact but that it results from a "two-step" process in which the mass media affect opinion leaders who in turn affect the masses through face-to-face discussion. Others have argued that the mass media may not be effective in changing opinion but do affect the perceived importance of products, candidates, or issues. Still others have said the media are effective but that alternative products and candidates are advertised about equally so that their effects mutually cancel.

Paradoxically, while the media have difficulty in demonstrating that their persuasive communications have the intended effect, there is some evidence that entertainment programs may have considerable unintended effects. It has, for example, been argued that the high amount of violence depicted in entertainment programs has been responsible for an increased level of violence in society. The arguments here are based on laboratory research showing that nonverbal communication in the form of violent behaviour of models evokes subsequent aggressive behaviour of children. The importance of this phenomenon in mass media presentations in the natural environment has yet to be demonstrated but is currently receiving considerable research attention.

Direct contact. The contact between the recipient and the attitude object in a persuasion situation is only indirect, being mediated through the communication. It thus invites comparison, as regards attitudinal effect, with direct contact between the believer and the object. This topic has been studied most fully in connection with attitudes of racial hostility and with how they are affected by racial integration. An optimistic "to know them is to love them" hypothesis leads to the prediction that when hostile groups of people are brought into direct contact so that they can interact and learn about one another, they should develop more positive mutual attitudes. But the limited results of research suggest that the situation is rather more complex. It may be that there is some small tendency for integration to produce more positive attitudes, but it would also appear that the stronger effect of integration is to multiply pre-existing attitudes so that those with initially favourable attitudes become more favourable while the initially hostile become increasingly hostile. It would seem that man can derive information from interpersonal contacts to bolster whatever initial preconceptions he might have had.

Available research findings appear to specify those conditions under which contact between hostile groups is most likely to result in the development of favourable attitudes. There is, for example, evidence to indicate that this is likely to happen to the extent that the interaction involves two groups on equal status levels, requires the participants to work for a mutually desirable goal, allows them to experience success and discover shared attitudes, and is continued over an extended period of time.

In general, work on channel factors in persuasion has been somewhat neglected over the past several decades. For one thing, the factors involved, while often of practical interest, have little theoretical relevance and so offer little intellectual stimulation to scholars. Also, investigation of these factors often requires research in society at large, while most recent work has been done in the laboratory. It may, however, be the case that the pendulum is swinging back to correct this neglect of channel factors.

Receiver factors. Considerable effort has been extended to discover what kinds of people (receivers) are most readily persuadable.

Demographic characteristics. Among adults, it appears that females generally are more persuadable than males, though the difference is less clear in early childhood years, suggesting that the differences are learned rather than innate. There also seems to be a tendency for the individual's personality characteristics to predict persuadability to a greater extent in males than in females. Perhaps this means that in the social role assigned to him, the man's own proclivities are left to determine his degree of susceptibility while outside factors tend to impose the level of susceptibility in the female regardless of her personal predilections.

Chronological age is another demographic variable that has received considerable attention. Studies indicate that one's persuadability tends to increase during the first five or six years of life, presumably through a growing ability to attend to and to understand the persuasive message, and then perhaps falls slightly before it levels off during the adolescent period for the remainder of the active life span. Persuadability manifests less clear-cut relationships to other demographic variables such as ethnic origin, social class, and regional residence.

Individual differences in ability and personality. When theoretical analysis focusses on the phenomenon of yielding to persuasion, it frequently leads to predictions that the more intelligent person will be more resistant to persuasion (in view of his high critical ability, self-esteem, and willingness to hold deviant attitudes). But when it is considered that he first must understand and remember the persuasive message if he is to be influenced, the more intelligent person may be expected to be more vulnerable to persuasion. Indeed, empirical findings are as complex as these two logically tenable approaches would suggest. In situations that require relatively simple understandings, people with undistinguished intelligence tend to be most responsive to persuasion. When the situation is more demanding of attention and comprehension, high intelligence tends to be associated with persuadability. In general, people at intermediate levels of intelligence appear most persuadable, with those who are very low in intelligence being resistant as a result of poor reception and those of very high intelligence being less likely to yield.

Persuadability of disturbed persons

The relationship of psychiatric disturbance to persuadability is similarly complicated. Those who exhibit minor neurotic signs seem more susceptible to influence in many situations, plausibly as a result of low self-esteem and a greater proneness to yield. Seriously disturbed people (*e.g.*, psychotics) seem to be more difficult to persuade, presumably as a result of their low attention and comprehension; indeed, even with the simple repetitive messages used to induce hypnosis (*q.v.*), schizophrenics are notoriously resistant as compared with more normal people.

In studies of personality characteristics, such as anxiety and self-esteem, people who exhibit moderate degrees of a given trait tend to be more susceptible to influence than are those who are very high or low. The evidence suggests that there may be two opposed underlying factors pushing the relationship in opposite directions. The person who is chronically anxious, for example, seems to have a low self-image that prompts him to yield, yet it appears that his preoccupation with his anxiety tends to interfere with attention, comprehension, and retention. At any rate, the typical research finding is that those who suffer intermediate levels of anxiety are the most vulnerable.

Destination factors. Destination factors refer to the specific, observable activity at which the persuasive communication is aimed—for example, verbalized changes of attitude toward a politician, or overt behaviour in purchasing a particular brand of breakfast food.

Verbalized attitude versus overt behaviour. Research findings with regard to verbalized changes of attitude are

often quite different from those that emerge from studies of gross behavioral response. To some extent this can be understood by assuming greater difficulty in changing behaviour than in changing attitude. Thus, a public-health campaign designed to persuade individuals to give up smoking leads to more who *say* they intend to comply than who actually do. But the disparity is more complicated than that. Often there seems to be more change in gross behaviour than in attitude; among American prisoners of war in North Korea, for example, indoctrination led to substantial alterations in gross behaviour (*e.g.*, participation in propaganda broadcasts), while underlying attitudes apparently were little affected.

It is generally supposed that one's attitudes should be altered if his behaviour is to change. Yet, in other studies it has been found that behaviour often changes first, and attitudes only later. Religious missionaries, for example, may encourage potential converts first to "bend the knee" in the expectation that true faith will follow.

Immediate and delayed impact. It is more convenient to measure immediate changes of attitude than it is to assess long-term effects, although the latter may be of primary interest.

Even as the message tends to be forgotten with the passage of time, there is a general tendency in the long run for a change of attitude produced by persuasive communication to dissipate. The rate of such decay varies widely; depending on conditions, different studies have shown that about half of an originally produced attitude change may decay in anywhere from one week to six months after original exposure to the communication. The rate can be shown to depend on the characteristics of the original message and those of the recipient, as well as other factors.

Delayed-action effects

In many studies of persuasion, a delayed-action effect has seemed to develop over a period of a few days or weeks after receipt of the communication. Delayed-action effects are likely to be observed when the communication initially appears untrustworthy (*e.g.*, is attributed to a suspect source) or when the message is complex or subtle or when its arguments are perceived to hedge to some degree. A major difference between simply forgetting the contents of a message and decay of induced attitude change is the prevalence of delayed-action effects in persuasion.

Inducing resistance to persuasion. Techniques have also been sought by which to make people more resistant to persuasion. Such efforts rest on a most diverse set of approaches, some of the more productive of which are presented below.

Prior commitment. One effective means of making a person more resistant to subsequent persuasive attack appears to be to commit him in advance to his initial belief by having him publicly announce it or simply privately consider it in some formal or effortful way. Indeed, the latter seems to be as effective as the former in making the person resist subsequent attacks on the belief. Commitment becomes even firmer when the person is led to make irreversible decisions and to take action on the basis of his initial belief. With such commitment he tends not only to resist changing his attitude but actively to recruit others in support of his own viewpoint.

Anchoring. A person's belief can apparently be made resistant by anchoring it to other aspects of his life. It may be anchored, for example, to other people or groups who are significant to him, by providing him with firmer information than he already has that they endorse the belief. A belief can be anchored to the individual's values or moral principles by showing him that his adherence to it leads to the attainment of goals he seeks and the avoidance of outcomes that he holds undesirable. Or the belief may be anchored to other beliefs since, as the person becomes more aware of such interrelations, he tends to resist change in any given belief that he perceives would require major readjustments throughout his system of attitudes.

Personality reconstruction. Fundamental alterations in personality might be produced to make one more resistant on all issues. One such approach that has been explored is to increase the general level of hostility, but such efforts have been found to create new problems and do not seem generally effective. Instead, the more hostile person tends to be more resistant to messages that argue for benign and tolerant positions and more receptive to those that argue for punitive stands.

Enhancing the subject's self-esteem

A more attractive approach, which also promises to be more effective, is to raise the person's general level of self-esteem. It has been found that the higher the individual's self-esteem the less prone he will be to pressure. On the other hand, to the extent that enhanced self-esteem also increases attention and comprehension of persuasive messages, this approach could actually add to persuadability. If the person is manipulated in the direction of heightened anxiety, yielding should increase but message reception should decrease. With complex relations such as these, the use of personality restructuring to enhance resistance to persuasion could be hazardous. Under these circumstances it can be difficult to predict whether manipulating a given personality characteristic will increase or decrease persuadability.

Evasion training. People protect themselves against being persuaded by avoiding exposure to positions with which they do not agree or by distorting disagreeable contents or by repressing such dissonant material as they do learn. While these tendencies may seem to be unhealthy, they nevertheless can be used to develop resistance to persuasion. A person can be trained to detect persuasive communications aimed against his belief and quickly to bring into play selective avoidance mechanisms.

Inoculation. Metaphorically akin to smallpox immunization, inoculation against being persuaded has been a heavily studied mode of producing resistance. In this approach a person may be pre-exposed to a weakened dose of attacking arguments sufficient to stimulate his defenses without overcoming them. The method assumes that people typically live in an overprotected ideological environment that leaves belief intensity at a level analogous to the health of a laboratory animal reared in a germ-free environment. Such animals prove most vulnerable when suddenly exposed to germs. By analogy, to protect the individual he is first exposed to weakened arguments that give him motivation and practice in summoning up arguments to bolster his belief in the face of later, massive attack.

Empirical work has shown the approach to be successful. Considerable resistance had indeed been developed through exposure to weakened counterarguments. As in the case of biological inoculation, resistance to subsequent persuasive attack requires time to develop, building up to a maximum over a few days after exposure, after which it decays slowly. The analogy to smallpox holds in other aspects of persuasion as well, including the strength of the pre-exposure and its similarity to the attacking material.

Conclusion. Persuasion has been a major research topic in the social and behavioral sciences during recent years. This research has been directed toward testing old insights accumulated over many centuries of theorizing about the persuasion process and also has revealed new relationships. The number of investigations shows no sign of diminishing, and it is likely that coming decades will show similar progress. Since manipulation of attitudes and behaviour obviously threatens the autonomy of the individual, it is fortunate that study continues to be devoted to ways of producing resistance as well as compliance to persuasive communication.

BIBLIOGRAPHY. A succinct yet comprehensive survey of empirical findings and theories regarding persuasion may be found in W.J. MCGUIRE, "The Nature of Attitudes and Attitude Change," in G. LINDZEY and E. ARONSON (eds.), *Handbook of Social Psychology*, 2nd ed., vol. 3 (1969). Major experimental studies of persuasion are reprinted in R. ROSNOW and E.J. ROBINSON (eds.), *Experiments in Persuasion* (1967); in M. JAHODA and N. WARREN (eds.), *Attitudes* (1966); and in A.G. GREENWALD, T.C. BROCK, and T.M. OSTROM (eds.), *Psychological Foundations of Attitudes* (1968). Theoretical analyses are found in C.A. INSKO, *Theories of Attitude Change* (1967); and in C.A. KIESLER, B.E. COLLINS, and N. MILLER,

Attitude Change (1969). The role of personality factors in persuadability is described in W.J. MCGUIRE, "Personality and Susceptibility to Social Influence," in E.F. BORGATTA and W.W. LAMBERT (eds.), *Handbook of Personality Theory and Research* (1968). Practical applications are discussed in D.J. BEM, *Beliefs, Attitudes, and Human Affairs* (1970); and in P.G. ZIMBARDO and E. EBBESEN, *Influencing Attitudes and Changing Behavior* (1969).

Peru

A republic bordering the Pacific Ocean, straddling the Andes mountains, and containing the headwaters of the Amazon River, Peru is the third largest nation in South America after Brazil and Argentina. Its name is derived from a Quechua Indian word implying land of abundance, a reference to the economic plenitude produced by the highly organized agricultural technology of the Inca civilization that ruled the region for centuries. The nation's vast natural resources, many of them virtually untapped, long have been exploited by foreign companies and a handful of wealthy Peruvian families. Since 1968, however, a revolutionary government has pressed toward nationalization of industry and of resource development in an attempt to gain greater economic freedom and to improve the living standards and income of the nation's approximately 14,000,000 people.

An overview of the nation

With Ecuador to the north, Bolivia to the southeast, and Chile to the south, all or most of Peru's borders run across the high Andes, whereas the borders with Colombia to the north and Brazil to the east run through lower ranges or tropical forests. In the past, lengthy disputes over certain of these boundaries, some resulting from inexact geographical knowledge, have produced open warfare with Ecuador and Chile, but since a protocol signed in Rio de Janeiro in 1942, only a few landmarks along the Ecuadorian border have remained unsettled. The 496,224 square miles (1,285,216 square kilometres) of Peru, equal to the combined area of Great Britain, France, and Spain, is supplemented by the 238,417 square miles (617,500 square kilometres) of territorial waters, reaching 200 miles (320 kilometres) into the Pacific, that it claims.

Peru is a tropical country, with its northern tip nearly touching the Equator. A great diversity of climate, of way of life, and of economic activity is brought about, however, by the high altitude of much of the country and by the prevailing southwest winds that sweep in from the cold Humboldt, or Peru, Current in the Pacific. The immense difficulties of travel have long impeded national unity. Iquitos on the upper Amazon lies only about 600 miles from Lima, the capital, but before the airplane, travellers between the cities were forced to choose between arduous mountaineering or a 7,000-mile trip that included the Amazon, the Atlantic, the Isthmus of Panama, and the Pacific. The latter was the more frequent route. (For information on related topics, see the articles PERU, HISTORY OF; LIMA; ANDES MOUNTAIN RANGES; and TITICACA, LAKE.)

THE NATURAL AND HUMAN LANDSCAPE

Geographical regions. According to Spanish tradition, Peru comprises three major areas: a narrow belt of arid desert along most of the Pacific; the steep and complex Andes system, or highlands; and the wet, densely forested Montaña, or selva, on the lower eastern slopes of the Andes. The divisions made by the pre-Hispanic peoples, however, are both more complex and in greater agreement with modern geographical principles.

The Chala region, or coastal plain. Bordering the sea and rising to about 1,500 feet (500 metres) above sea level, the Chala is a region of arid plains formed by marine abrasion or fluvial action on old mountain systems and fractured or eroded sedimentary rock. Although it receives less rain than the Sahara, it is the population and economic centre of Peru. Every few decades, the Chala's delicate balance of wind, water, and plant and animal life is disastrously upset by the inundation of the desert coast in great quantities of rain. This sudden visitation, called El Niño (The Child), generally occurs in December. The resulting floods devastate both the natural and human landscapes; the fish leave the coast for months, damaging the fishing industry, and the birds, lacking their customary food, die, littering the beaches by the thousands. The plains are irrigated at intervals by irregularly flowing rivers that produce cultivable oases and woods. In northern and central areas, sandy deserts predominate, whereas rough hills may reach to the ocean in the south.

Coastal climate

The Yunga regions: the Inter-Andean Valley. A maritime Yunga ("jungle valley") lies on the western slope of the Andes, rising from about 1,000 to 7,500 feet above sea level, whereas the fluvial Yunga on the eastern slopes lies at altitudes of about 3,200 to 7,500 feet. These are regions of narrow, enclosed valleys at the bottom of rocky canyons. A hot climate produces a high incidence of yaws, malaria, and goitre among the scanty population. Despite frequent downpours and accompanying mud avalanches, water for agriculture is scarce.

The Quechua, or temperate, region. The principal cities of the Inca Empire—on or near the sites of such present-day cities as Cuzco, Cajamarca, Tarma, and Jauja—were built in this rolling landscape, which is from 7,500 to 11,500 feet in altitude. The region is heavily populated because of the moderate climate, and the rich volcanic soils are cultivable for vegetable and tree-fruit crops.

The Suni, or high-barren, region. The high, rough terrain of the Suni rises from about 11,500 to 13,000 feet and has numerous cliffs, escarpments, and other natural obstacles. The climate is cold, frosts frequent, and soils thin, limiting crops to a few leafy and tuberous varieties. Species of eucalyptus are among the several trees adapted to life in this environment.

The Puna region: the Altiplano, or High Andes. Rising from about 13,000 to 15,700 feet, the Puna is characterized by vast tablelands open to blazing sun and constant winds. The cold climate has wide daily fluctuations in temperature, but varieties of potato and fruit can be grown to about 14,000 feet, the upper limit of human habitation in Peru. Lacking in natural forestation, it is a world of forage grasses for the llama, alpaca, vicuña, and guanaco.

The Janca, or high cordilleran, region. Above 15,700 feet, at the nucleus of the Andean system, the Janca comprises a succession of craggy and snow-covered volcanic cones or shafts. Nighttime temperatures are below freezing throughout the year, and no spontaneous vegetation occurs. Human settlement is ephemeral.

The Rupa-Rupa, or high-forest, region. Descending from the eastern fluvial Yunga to about 1,300 feet, the Rupa-Rupa comprises a succession of valleys, ridges, and plains related to Andean and eastern Peruvian earth-fault systems. Its climate is warm, with cool evenings, and its rough and rolling relief is covered with trees and pastures that are kept green throughout the year by heavy annual precipitation of more than 157 inches. Livestock raising and plantation agriculture are widespread, and large forest reserves contain a great variety of woods.

The eastern forests

The Omagua, Amazonian, or low-forest region. The Amazon River and its affluents wander through the huge plain of the Omagua, creating meanders, lakes, marshes, and other formations. Soils are rich in alluvial and organic deposits. The climate is warm, the precipitation more than 118 inches, and flooding is frequent. In its woods and waters live thousands of tropical, terrestrial, and aquatic species, including colourful ornamental fish. The heavy forestation is commercially important for its rubber, chicle, and rosewood, and a rudimentary agriculture is pursued by primitive tribes on the shifting stream banks and higher locations.

Drainage. Fifty-four rivers empty into the Pacific from the Andes. Of these, only the Río Tumbes is navigable. Only 20 percent of the flow is utilized by agriculture. The Amazon, with the largest volume flow of any river in the world, rises in Peru as the Río Ucayali. It is navigable, as are its seven principal affluents. In the south, four rivers cross the Collao Plateau to empty into Lake Titica-

ca, which is shared with Bolivia and is—at 12,500 feet (3,810 metres) in altitude and 3,205 square miles (8,300 square kilometres) in size—the world's highest navigable body of water.

Patterns of human settlement. The nature of Peruvian life, whether urban or rural, varies by physiographic region. The greater degree of commonality exists, however, in relation to population densities.

Rural Peru. In the coastal desert, populated areas along wagon roads and bridle paths usually have a single, unpaved street. Their one-story houses are built of such light materials as *quincha*, a sticks-and-clay compound, dictated by the danger of earthquakes. The settlements lack services; in some places, the houses have wells and small groves of tropical and subtropical fruit trees.

Going upward, settlements are located at distances of a day's foot or horseback journey—about nine miles—taking advantage of crossroads, river mouths, or high ground. In the warm Yungas, houses generally have one story, the front of which faces the interior of the property. They are separated from one another by groves of fruit trees. Kitchens and bread ovens are set apart. Roofless, circular enclosures sometimes guard the livestock. In the temperate Quechua and the cold Suni regions houses have walls of solid adobe, of adobe bricks, or of stones mortared with clay. Of the usual two stories, the first is for living, the second for storing crops. Corrals hold the livestock and sheds the kindling, whereas kitchens have special devices for fattening guinea pigs. In the very cold Punas, houses are either made similarly or are of straw or sod; kitchens are attached to the house to provide heat. The small crop fields are protected by enclosures, or by stone walls, as are the pens for llamas, alpacas, and other animals.

In both the high and low eastern forests, houses are placed among the cultivated fields close to communications routes and to sources of drinking water—although water may be captured from zinc roofs. The houses are built with bases of termite- and fungi-resistant woods and with palm-leaf roofs that are replaced frequently. In flood areas, houses are raised on supports. Kitchens are always at a distance to avoid fires. Rafts and canoes are moored on the banks of navigable lakes and rivers.

In all of the regions, the old landed estates, or haciendas, are characterized by their large buildings, solid and well protected. Construction varies with the particular activity of the hacienda. There are no logging haciendas, but establishments for fishing have been organized recently.

Urban Peru. Lima (*q.v.*), with more than 3,000,000 inhabitants, is Peru's administrative, commercial, and cultural centre.

The Peruvian cities

Since World War II, glass and steel have come to form striking contrasts with the sprawling slums, or *barriadas*, of the Indians who have left their mountains to seek a better life.

Arequipa, about 60 miles east of the southern coast, lies at the foot of El Misti volcano, presumably inactive. Originally an Inca city, Arequipa is sometimes called the White City because it is constructed almost entirely of white volcanic rock. The principal population centre of the northern Andes is Cajamarca, a sleepy town where an Inca king gave the Spanish conquistador Francisco Pizarro piles of gold and silver for his freedom but was then executed. To the south, Cerro de Pasco, the nation's mining centre, is, at 14,300 feet, one of the world's highest cities. Huancayo, a farming centre, is famous for its colourful Sunday fairs, during which Indians from the countryside sell a variety of products, including figurines, llama-wool blankets, and the high-domed hats worn by Indian women everywhere in the Andes.

The principal Andean centre, however, is the ancient city of Cuzco, once the capital of the Inca Empire. Tourists from around the world visit Inca remains in Cuzco and environs as well as the many Spanish colonial churches, often regarded as the finest in the Western Hemisphere. The Inca past is apparent in many places. Inca walls topped by Spanish-style houses stand along several streets. The base of the Temple of the Sun, portions of which were plated in gold, was used as the foundation for the Church of Santo Domingo, which stands

on the main plaza. The most monumental Inca ruins are those of the fortress of Sacsahuamán, consisting of a gigantic three-tiered stone wall built of monoliths as large as 18 feet in length and weighing 300 tons.

The bygone world of Spanish colonial power is evident in the tile-roofed buildings, museums, and churches of Cuzco. Among the most impressive is the cathedral (*c.* 1550), the only building that survived the earthquake of 1650. Other churches are celebrated for their 17th-century Baroque facades, in the mestizo style, which is an exuberant mixture of Indian and European motifs.

The major city of eastern Peru is Iquitos, which was a small jungle outpost on the upper Amazon until the rubber boom of the 1880s. Since the boom ended, lumber has been the major product. Among other major centres are Talara, a city amid the northern desert serving the petroleum industry; and Ica, another desert enclave and a viticulture centre. Huánuco is a university city at the gateway to the forests, whereas Ayacucho is famous for its temples and colonial mansions.

THE PEOPLES OF PERU

Pre-Hispanic groups. Diverse groups of indigenous Indians occupied the various natural regions during the pre-Hispanic millennium. The inhabitants of the coast were and are still called Chalacos. Farmers of the oases and of the deserts and skilled fishermen, they spoke languages, such as Sec, Quignam, and Pescadora, that today have disappeared. The Yunkachus, or Mapayungas, who inhabited the Yungas, were fruit and coca growers and spoke a variety of languages. Some were identical to the languages of the coast, for which reason all acquired the generic designation Yunga languages. The Quechua of the temperate highlands were expert agriculturalists who bestowed their name on a race, a culture, and a language. The Quechua spoke, and still speak, the Runa-Shimi language. In the Suni lived the Shucuy, a guinea-pig raiser, forester, and dehydrator of food products, who spoke Runa-Shimi and Cauqui. The Jatire, or Jamilli, of the Puna was a herder and grower who still speaks Runa-Shimi and Aymara. The Chuncho, inhabiting the high forests, was a hunter and gatherer; his numerous languages and dialects evidence a diverse linguistic heritage. In the low-forest region lived the Omagua, navigator of the big rivers, fisherman, gatherer, and eventual farmer. He spoke and still speaks languages related to those of the Chunchos.

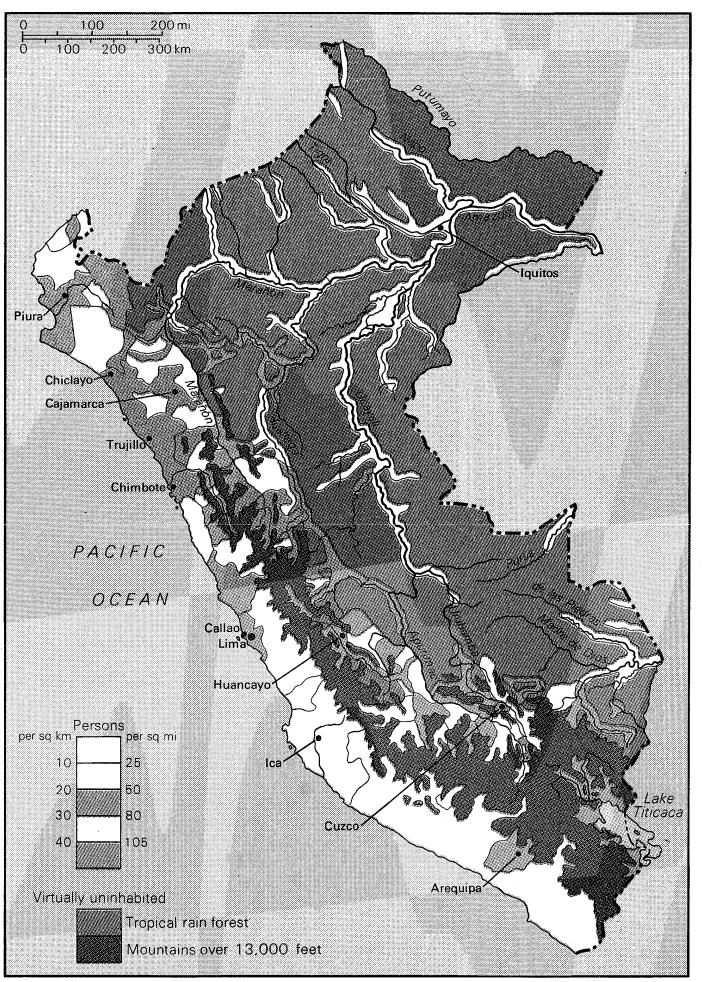
The Peruvian Indians

Development of ethnic diversity. The Spanish conquerors settled in the coastal deserts and oases and in the cities that they established in the cold and temperate zones on the ruins of the cities that formerly had belonged to the indigenous peoples—*e.g.*, Cuzco, Cajamarca, Arequipa, Huaraz, Huánuco, Tarma, Huancavelica, and Ayacucho. They were a prototypical dominating group, masters in every area: politics, religion, and economics. They brought their European culture and transmitted their white skin, Spanish language, and Catholic religion to their descendants, who have become greatly mixed, however. Although they have received infusions from new groups of Europeans, there is currently no hereditarily pure white group in the Spanish tradition.

With the Spaniards, blacks came as slaves. Following the revolution and prohibition of slavery, Chinese were imported as farm labourers, and new groups of Spaniards, Nordic whites, and Japanese arrived. A complete absence of racial prejudice has permitted these diverse racial and ethnic groups to intermarry and produce various new racial types: mestizo, the mixture of white with Indian; mulatto, white with black; injerto, white with Chinese or Japanese; zambo, black with Indian; and chinocholo, black with Chinese or Japanese. More varied mixtures in succeeding generations have led to numerous additional distinctions. Joined together in the Peru of today, they comprise a complex mosaic of racial intermingling.

Differences in life-styles and attitudes are pronounced. Peruvians of Spanish descent and the mestizos live mainly along the coast and own the lion's share of the nation's wealth. The Indians of the mountains make up half of the population and live in extreme poverty in one of the world's harshest environments. Despite frequent attempts to improve their lot, they remain both indifferent to, and outside of, the large affairs of the country.

Contrasts of life-styles



Typically, the small group of white people who are part of the ruling class live in urban homes or rural haciendas, and share a widespread belief in the Indians as shiftless and lazy. Mestizo culture is a blend of Indian and European ways known as *criollo*.

The Indian population, about 70 percent of the mountain people, has been a submerged element since the Spanish conquest. Living apart from the mestizos and Europeans, they shepherd their llama herds and work tiny plots of land to eke out a subsistence living. On the coast, they lived under near-feudal conditions, as tenant farmers on the large estates or as day labourers and sharecroppers. Like their Inca ancestors, the overwhelming number of Indians read neither their own nor another language.

Religion. Ancient Peru had various fetishistic, polytheistic, and pantheistic religions. The most important god was Viracocha—lord, creator, and father of men. The sun, the lightning, and the moon were worshipped. Each traditional culture raised great temples to honour its local divinity.

The Spanish indoctrinated the Indians and spread the Catholic religion, built hundreds of sumptuous churches, and held fiestas for patron saints in every village. The people were not strict in their practices, however, and Protestant sects have proliferated. The Indians have adapted many Catholic events in the light of the older practices to produce a rich diversity in religious practice.

Demography. Carbon-dated remains found in Ayacucho place the length of man's stay in Peru at 18,000 years. Under the Incas, the population reached 12,000,000, but in the first 50 years of Spanish domination, nearly

Population density of Peru.

10,000,000 Indians perished. The 1793 census showed 1,076,000 inhabitants; the 1940 census, more than 7,000,000; that for 1961, more than 9,900,000. During the five-year period 1965–70, the number of live births per 1,000 inhabitants was 43.5, the death rate, 12.3, giving a rate of natural increase of 31.2 and an estimated population in the early 1970s of about 14,000,000. These figures include an estimated 100,000 persons of the Amazon jungles living in Stone Age conditions.

The population structure is pyramidal. In 1966, about 55 percent of Peruvians were 19 years of age and under, whereas those over 60 years of age represented only 5 percent. Only about 31 percent were in an economically active age bracket in 1970. Between 1940 and 1971 there was a great increase in the urban population to more than 50 percent.

The population of Peru is doubling by natural increase every 25 years. Peru is considered large and empty, though new agricultural lands are being opened by irrigation works and by the building of roads to the eastern forests. The population is moving down from the highlands to the lowlands adjacent to the sea and to the Amazonian rivers, and the urban areas are growing while the cold countryside is gradually being depopulated.

THE NATIONAL ECONOMY

Economic overview

Peru is the world's leading fishing country, the prime exporter of fish meal, the foremost producer of bismuth, the third largest producer of silver, the fifth largest copper producer, and the sole producer of alpaca wool and of the fertilizer known as guano. It contributes the world's finest wool, vicuña, and the natural food most complete in nutrients, quinoa, a leafy vegetable eaten like spinach.

Serious economic problems persist, however, in several areas. A shortage of investment capital is paralleled by a loss of university-trained technicians to offers of higher salaries abroad. Extensive destruction of highways and other physical properties occurs each year from earthquakes, slides, and other geological disasters. The limited agricultural areas are failing to meet the needs of a rapidly expanding population, resulting in continually rising imports and in attempts to alter both the nation's planting and eating habits. The nationalization of the petroleum and other industries since 1968 has been directed toward remedying these and other economic deficiencies.

Economic resources and utilization. *Mining.* Copper, iron, phosphorus, and manganese exist in huge quantities of high-yield ores. Gold and silver are found extensively, as are other rare metals. In all, more than 40 metallic elements and compounds are commercially exploitable. Petroleum and natural-gas fields of the northern desert and continental shelf supply fuel along with the huge carboniferous belts producing peats and various coals and the great stores of sugar-cane waste, or bagasse.

In spite of this potential wealth, exploitation has varied greatly with foreign investment, price fluctuations on the world markets, lack of roads, a scarcity of adequate installations, and, in some cases, the exhaustion of deposits. Modern mining legislation and the intensification of mining operations are based on the expectation of greater importance in the world market. An investment of more than $1,225,000,000 has been calculated for the period 1968–81. Most of this is designated to achieve a greater copper and phosphate production.

Biological resources. Between 1968 and 1970, farmlands increased nearly 20 percent, to about 7,000,000 acres (3,000,000 hectares). The principal crops are cotton, sugarcane, rice, cereals, coffee, tea, and fruits. The decline in the production of guano, an organic fertilizer of unique quality, has meant a serious reverse for agriculture, for it has not yet been adequately replaced by the chemical fertilizers.

Agriculture and fishing

An insufficient area under cultivation has caused increasing importation of foodstuffs, which now account for nearly 20 percent of total imports. Peru is in the process of changing its national diet away from the former staples—corn, potatoes, cassava, sweet potatoes, quinoa, and llama—but as yet it must import much of the wheat, beef and other livestock, and dairy products. Meeting these new requirements has become Peru's most urgent problem.

The fishing industry, developed within recent decades, is based on the enormous schools of anchovy. Prudence limits the catch, however, to about 13,000,000 tons per year. Current technology does not permit total recovery of all the oil extracted during fish-meal production, nor is it possible to take due advantage of full nutritional potentiality in the catch. Fishing for human consumption is still insignificant, and the country is in the anomalous position of exporting proteins via the fish meal while lacking them in the popular diet.

Many of Peru's hundreds of land and water animals have disappeared, including the chinchilla, the puna ostrich, and the mountain turkey; others are in danger, such as the guanay, whose droppings are the valuable guano; the fur-bearing vicuña and guanaco; and the pirarucu, an important food fish. Recent conservationist measures prohibit the hunting of about 50 species and fix guidelines for the export of such wild animals as ornamental fish, monkeys, crocodiles, iguanas, otters (nutria), jaguars, and the manatee or sea cow. Strict, closed seasons are observed in the fishing of anchovy, river prawn, and trout. The hunting of vicuña and chinchilla, whose repopulation is being attempted, is prohibited. Artificial hatcheries for river prawn and *paiche* have been built.

Flora and fauna

More than half of Peru is covered with natural hardwood and softwood forests. Species most worked commercially include cedar, mahogany, and walnut. Paper production from softwoods is relatively recent, and newly introduced techniques in pressed wood and veneering have given rise to an important industry.

Electrical power. The hydroelectric potentiality in Peru is great, especially on the Amazon and its tributaries; but until 1968, only 2 percent of this had been harnessed. Several plants were projected for the early 1970s, and it was anticipated that interconnections could be affected between the several operating plants, both thermal and hydroelectric. Nearly half of the nation's production and demand are in Lima Department, though mining activities are the biggest single user of power. In the early 1970s, public and private ownership remained about equal.

Manufacturing. Government plans for the period 1970–75 call for industry to increase its share of gross

national product from 20.7 to 26.5 percent. To utilize the nation's natural resources to achieve self-sustained growth, a particular push was given to such basic industries as chemical and steel refining and production. Companies remaining in private hands were to pass gradually into the public sector, as were the housing, educational, clothing, and food industries. The goal of various new laws was to make industrial profits benefit the masses.

Foreign commerce. During 1968, Peru had a favourable balance of trade amounting to $240,000,000. A decline in imports was due to a monetary devaluation in 1967, to a customs surcharge, and to import restrictions. Exports increased due to greater sales of fish meal, copper, silver, sugar, and coffee. More recently, lower sales of fishmeal and a drop in mineral prices, aggravated by strikes among the mine workers, have injured foreign commerce. The availability of dollars has decreased, but large loans as well as purchases and investments have been obtained from socialist countries.

Economic administration. *Current policies.* The financing of investment in works and studies for 1970 amounted to nearly 10,000,000,000 soles (38.70 soles = $1 U.S.; 93.27 soles = £1 U.K. on May 1, 1971). Seventy percent of these sums was covered by the treasury and its own resources, the remainder by loans from foreign and international monetary agencies. The government's goal has been to raise the gross national product by a higher figure than was achieved in 1970 and to lower drastically the unemployment and underemployment figures. Heavy investments were made in fishing research and in state enterprises in iron and steel, electricity, and mining. Construction was begun on the copper and zinc refineries and reconstruction of the areas destroyed by earthquake in 1970 was undertaken. In housing, the government planned to strengthen housing cooperatives and to control the current process of urbanization.

Planning and investment

The public and private sectors. Private enterprise continued its heavy investment in the Peruvian economy in the early 1970s, with manufacturing and construction receiving about 10,000,000,000 and 13,000,000,000 soles, respectively. Mining received about 4,000,000,000, whereas agriculture, fishing, and power investment was about one-half that figure. The heaviest governmental expenditures—more than 20,000,000,000 soles—were for operations, but billions were poured into the same sectors of the economy as well as into transportation and communications, housing and education. At present, numerous firms and governments are interested in investing in Peruvian petroleum, copper, phosphates, irrigation, and metallurgy.

Taxation. Taking 1960 as the base year, the index of direct taxes rose more than 50 percent by 1966, and the indirect tax index rose by nearly 250 percent. First place went to the stamp tax, which in that year accounted for more than one-third of tax revenue. Personal income taxes are at a maximum of more than 50 percent, and luxury items are heavily taxed.

Labour. The Confederación de Trabajadores del Perú unites blue- and white-collar workers, most notably in the bus transportation, sugar, mining, banking, and teaching forces. There is also a dissident labour federation of Communists. Legislation since 1968 has created agricultural cooperatives and some industrial organizations that may in the long run decrease the power of the established unions. Strikes are subject to mediation among labour, management, and government. Recent legislation requires biennial collective work agreements.

Transportation. Peru's transportation system faces the challenge of the Andes and of the complex Amazon River system. The only really integrated systems are the roads and the airlines, for the railroads have not succeeded in forming a connecting network, and maritime traffic is primarily dependent on calls from world shipping lines. The 31,103 miles of roadway—asphalted, macadamized and metalled, or unpaved but drivable—cross the country from north to south, form the penetration roads that run west and east, or link the small villages to close up the road network. Among the longitudinal roads are the Pan American Highway, which crosses the country from Ecuador to Chile, and the macadamized Carretera Longitudinal de la Sierra, which will unite Ecuador with Bolivia. The principal penetration roads uniting the seacoast with the ports on the Amazonian rivers follow Chiclayo–Jaén–Nazareth, Lima–Pucallpa, Pisco–Teresita, and Mollendo–Puerto Maldonado routes. The Piura–Moyobamba–Yurimaguas will soon enter into service.

The major Peruvian railroad, the Ferrocarril Central, is the world's highest rail line, rising from the coast at Callao to cross the continental divide at 15,806 feet. It connects with the line from Cerro de Pasco, making it of great importance to the mining industry. Begun in the 1860s, it passes through 66 tunnels and over 59 bridges during its 215-mile course. A longer southern line, the Ferrocarriles del Sur, serves Cuzco, Arequipa, and other cities; much of its traffic originates in Bolivia.

Callao is the largest of Peru's numerous maritime, river, and lake ports. Chimbote is the world's largest fishing port. Iquitos, 2,300 miles up the Amazon, is a characteristic river port, with inadequate dock facilities, and unreachable by larger boats in the dry season.

The rough terrain compels the use of the airplane, yet makes it more difficult. Commercial aviation was founded in 1928, and four domestic lines currently operate in addition to APSA, an international carrier. There are also military aid and assistance services. An international airport in Callao is the most important of the more than 150 airports in the country.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. Since October 1968, Peru has been ruled by a revolutionary government of the armed forces, which has suspended the constitution, dissolved the Congress, reorganized the judiciary, and placed Gen. Juan Velasco Alvarado in the presidency. The present Peruvian regime has been concerned with increasing the nation's economic self-sufficiency. Principal measures of the new government include nationalization of petroleum (without excluding the possibility of granting new concessions); an agricultural reform law that terminated the old landed estates; a water law that converted all water into state property; a mining law to stimulate foreign investment; an industries law to strengthen national industry; and the nationalization of the bank.

The revolutionary government

Prior to the coup d'etat in 1968, Peru was nominally a democratic republic but one in which the great majority of the economic and political power in fact was wielded by a minute percentage of the population. The president and the members of the bicameral Congress were elected for six-year terms, and the Supreme Court of Justice was elected by the Congress. Local government was divided among municipalities by 23 departments, 1 constitutional province, 149 provinces, and 1,672 districts. Voting was compulsory for all adult citizens except the military, who also could not hold office. The majority political party was the Alianza Popular Revolucionaria Americana (APRA), founded in 1924 by Víctor Raúl Haya de la Torre.

Armed forces. Theoretically, all Peruvian males between 20 and 25 years of age are subject to two years of military duty, but the law has been poorly observed. The regular army, navy, and air force, though small, have modern equipment, most of it from the United States and France. The military also does road-construction work.

Social conditions. The oligarchy that long ruled Peru was severely disrupted by the 1968 coup. The haciendas have been given over to cooperatives of former employees, whereas workers were granted access to ownership of factories through the Industrial Community (Comunidad Industrial). The majority of Peruvians continue to earn less than $1 a day, however, and the country suffers from inflation. Sanitation is a major problem; most cities lack adequate sewerage, lighting, and paving.

Education. The revolutionary government has undertaken major reforms in education to strengthen the roles of the people in the restructuring of society and the increase of national self-sufficiency. Among the means is an ongoing drive against illiteracy, which in 1940 had held about 60 percent of the nation in its grip.

Education is free and compulsory for all children between six and 15, though outside urban centres—and often inside—this is difficult to enforce. In the mid-1960s, primary and secondary curricula were under review with the help of United Nations Educational, Scientific, and Cultural Organization (UNESCO), and teachers were being prepared for bilingual work in the mountains and the Montaña. Twenty-one national universities are supported by the state, and 12 other institutions are private. The University of San Marcos, in Lima, is the oldest university in South America, having been founded in 1551.

Health and housing. Infant and young-child mortality long was a major scourge of Peru, and it is one of the major concerns of government. Numerous public agencies are involved in national health and insurance work, including the military. With only about 6,500 doctors and 4,000 nurses, however, the nation faced a difficult road to adequate service for all age levels.

Peru is about 1,000,000 housing units short, especially in the *barriadas* but also in the countryside. An earthquake in May 1970 further aggravated the problem by destroying 10 percent of the housing units in the country and 200 towns and villages. Private construction has been aided by a system of mutual aid, and the state is building large developments.

CULTURAL LIFE AND INSTITUTIONS

The complex ethnic and cultural miscegenation of Peru presents an entwining of aboriginal pantheism, Spanish mysticism, and African religious practices that erupts into song, literature, textile art, engraved gourds, gold- and silverworking, and a bounteous cuisine.

Archaeological remains

The ancient culture of Peru perhaps is best known not only in its Spanish–Inca cities but also in such remains as Machu Picchu, a "lost city" of the Incas discovered in 1911 on an 8,000-foot-high mountain 50 miles from Cuzco. The most extraordinary ruin in the Americas, Machu Picchu comprises five square miles of terraced construction, 3,000 steps connecting its many levels, and a multitude of small houses built of unmortared stone.

The dryness of the central and southern coasts has preserved the remains of a long succession of pre-Inca peoples, about whom little is known except for their exquisitely decorated jugs and bowls and embroidered mantles. The Mochica people detailed every aspect of their lives, including erotic practices, on their jugs.

Folk culture. Peruvian folk culture is deeply tinged with inheritances from the ancestral races. In both towns and countryside notable examples of pre-Hispanic and *mestizo* lore abound in myths, song, superstitions, and dances representing a historical synthesis. An impressive system of learning based on the course of the seasons and of agricultural cycles includes mastery of the medicinal qualities of plants. The leaves of the coca plant are chewed by nearly all Indians to produce a narcotic effect. Intricately carved figures and elaborate horned, toothed, and tufted masks are popular with tourists and collectors. Ceramics often represent a blend of Catholic and Indian symbolism.

Literature, music, and the visual arts

Westernized arts. The arts long have occupied positions of esteem among Peru's educated minority. Since the late 19th century, most writers have felt a ceaseless duty to analyze their society. Ricardo Palma (died 1919) was among the first to utilize Peruvian themes. The poet José Santos Chocano (died 1934) was one of the first to write sympathetically about the Incas. The *pensador* (intellectual) Manuel González Prada (died 1919) founded a literary circle to encourage writers alienated by the nation's cultural dichotomies. *Aves sin nido* (1889; *Birds Without a Nest*, Eng. trans., 1904) by Clorinda Matto de Turner, a member of Prada's group, was the first of many books whose authors exposed the conditions of Indian life. César Vallejo is often regarded as Peru's finest poet; he died (1938) in poverty in Paris.

Valle-Riestra's *Ollanta* and Vicente Stea's *Sinfonía autóctona* (*Aboriginal Symphony*) were the basic musical works of 19th-century Peru. Later, Luís Duncker Lavalle incorporated Peruvian motifs into Western forms. Other users of folk materials include Daniel Alomía Robles, notably in his "Hymn to the Sun" and *The Condor Passes.*

Painting reached its zenith with the famous Cuzco school during the 17th and 18th centuries. Most of the thousands of paintings and sculptures are anonymous; the works show resemblances both to Byzantine and to Asian forms. Modern Peruvian art has followed an abstract course, notably in the work of the painter Fernando de Szyszlo and the sculptor Joaquín Roca Rey.

Architecture. The ancient Peruvians were great builders of houses, temples, palaces, fortresses, roads, and canals, adapting their architecture to the landscape. The oldest colonial work is the Cathedral of Lima, and the most important architectural jewel is the Convent and Church of San Francisco of Lima. Modern architecture has been characterized by the so-called neo-Peruvian, or Peruvian Baroque, and, recently, by the introduction of concrete and steel structures.

Communications. Some of Peru's daily newspapers, such as *El Peruano* and *El Comercio,* are among the oldest in America. Others of the more than 500 publications include popular magazines and the organs of specialized institutions in the arts and sciences. More than 200 radio stations blanket the entire country. Lima has seven television channels, whereas Arequipa, Huancayo, Trujillo, and Piura have one each.

Prospects. Peru's 1,000 years of cultural tradition are in the process of radical change. In a land of vast mineral wealth, grave shortages continue in many aspects of human life. Problems in internal communications, housing, health, and illiteracy are being tackled vigorously, and attempts are being made to draw the mass of workers and peasants more closely into the mainstream of national life. Few Peruvians pretend that the processes of change will be easy or quick.

BIBLIOGRAPHY

General works: A complete picture of Peru is found in the *Atlas histórico, geográfico y de paisajes peruanos* (1970), published by the President's National Planning Institute; other comprehensive studies include D.A. ROBINSON, *Peru in Four Dimensions* (1964); GEORGE PENDLE, *The Land and People of Peru* (1966); R.J. OWENS, *Peru* (1963); PRESTON E. JAMES, *Latin America,* 3rd ed., pp. 160–203 (1959).

Physical geography: Boundaries, dimensions, relief, and other features are treated in the analytical work of the MILITARY GEOGRAPHIC INSTITUTE, *La carta nacional* (1945–71), as well as in ISAIAH BOWMAN, *The Andes of Southern Peru* (1916); CARLOS PENAHERRERA DEL AGUILA, *Geografía general del Perú,* vol. 1, *Aspectos físicos* (1969); G.R. JOHNSON and R.R. PLATT, *Peru from the Air* (1930), aerial photographs; oceanography and marine biology are dealt with by ERWIN SCHWEIGGER, *El litoral peruano,* 2nd ed. (1964); and by ZACARIAS POPOVICI, *El Pacífico peruano* (1970); other works on the subject are OLIVIER DOLLFUS, *Les Andes centrales du Pérou et leurs piémonts* (1965); and CLAUDE COLLIN DELAVAUD, *Les Régions côtières du Pérou septentrional* (1968); geological works include GUSTAV STEINMANN, *Geologie von Perú* (1929); A. ALBERCA CEVALLOS, *Los minerales en el Perú* (1970); LEONIDAS CASTRO BASTOS, *Anotaciones geológicas y petrológicas sobre las ocho regiones naturales* (1967); JUAN DE LA CRUZ LOPEZ, *Algunas observaciones sobre las unidades morfológicas en las ochos regiones naturales del Perú* (1967); the lands of Peru are treated in CARLOS J. ZAMORA, *Suelos del Perú y capacidad de uso de los suelos* (1970); a detailed analysis of the natural regions of Peru and the principal types of its vegetation are found in JAVIER PULGAR-VIDAL, *Geografía del Perú: las ocho regiones naturales* (1967) and in his *Análisis geográfico sobre las ocho regiones naturales del Perú* (1960); also valuable are JOSEPH A. TOSI, JR., *Zonas de vida natural en el Perú* (1960); and AUGUST WEBERBAUER, *El mundo vegetal de los Andes peruanos,* new ed. (1945).

People: The life of the Peruvian population is dealt with in JULIO C. TELLO, *Origen y desarrollo de las civilizaciones prehistóricas andinas* (1942); EFRAIN ORBEGOSO RODRIGUEZ, *Geografía humana del Perú* (1968) and *Migraciones en el Perú* (1970); AVENCIO VILLAREJO, *Así es la selva,* 2nd ed. (1953), and *La selva y el hombre* (1959); JOHN P. GILLIN, *Moche: A Peruvian Coastal Community* (1947); HARRY TSCHOPIK, *Highland Communities of Central Peru: A Regional Survey* (1947); BERNARD MISHKIN, "The Contemporary Quechua," in JULIAN H. STEWARD (ed.), *Handbook of South American Indians,* vol. 2 (1946); JOSE MATOS MAR, "The 'Barriadas' of Lima: An Example of Integration into Urban

Life," in PHILIP M. HAUSER (ed.), *Urbanization in Latin America* (1961); birth and death rates, ethnic composition, and demographic trends are treated in numerous works published between 1964 and 1971 by the NATIONAL PLANNING INSTITUTE OF PERU.

Economics: A realistic picture of the economic situation in Peru is provided by the ACCION PARA EL DESARROLLO (Developmental Action Committee), *Memorandum sobre la situación económica nacional* (1970); economic information in English is found in D.R. KILTY, *Planning for Development in Peru* (1967); and FERNANDO BELAUNDE-TERRY, *Peru's Own Conquest* (1965); a systematic study of the economic geography of Peru is provided in EMILIO ROMERO, *Geografía económica del Perú*, 3rd ed. (1953), and economic history in his *Historia económica del Perú* (1971).

Social and political life: Excellent analyses are found in VICTOR RAUL HAYA DE LA TORRE, *El antimperialismo y el Apra* (1936); HARRY KANTOR, *The Ideology and Program of the Peruvian Aprista Movement* (1953); FRANCOIS BOURRICAUD, *Pouvoir et société dans le Pérou contemporain* (1967; Eng. trans., *Power and Society in Contemporary Peru*, 1970); and J.C. CAREY, *Peru and the United States, 1900–1962* (1964).

Culture: LUIS C. LUMBRERAS, *Panorama de la arqueología peruana* (1970); JORGE GUILLERMO LLOSA, *La cultura peruana en el siglo XX* (1963); LUIS ALBERTO SANCHEZ, *Panorama cultural del Perú* (1968); AUGUSTO TAMAYO VARGAS, *La literatura en el Perú* (1968); JUAN MANUEL UGARTE ELESPURU, *Problema y posibilidad de la pintura actual* (1968); HECTOR VERLARDE, *La arquitectura peruana del siglo XX* (1963).

(J.P.-V.)

Peru, History of

Before its conquest from the Incas by the Spaniards under Francisco Pizarro in 1531–33, Peru had been the home of advanced Indian civilizations for more than a thousand years (see ANDEAN CIVILIZATION, HISTORY OF).

Spain consolidated its control over Peru, and the region remained under Spanish rule for nearly 300 years (see LATIN AMERICA AND THE CARIBBEAN, COLONIAL). In the early 19th century, despite moves toward independence by other Spanish colonies, Peru remained loyal to Spain because of the conservatism of its aristocracy, the presence of many Spaniards in the region, the concentration of Spanish military power in Lima, and the effectiveness of Spanish officials in Peru in suppressing uprisings. Independence was imposed on it primarily by outsiders.

Peru from 1824 to 1930. The Venezuelan general Antonio José de Sucre's victory over Spanish forces at Ayacucho in the south central Peruvian Andes in 1824 brought independence to Peru. The end of Spanish rule did not, however, provide a solution to the many political, social, and economic problems facing the country. The transition from a colonial dependency to a modern state proved difficult and was still incomplete in the 1970s.

The caudillos

Struggle for power. At the outset of Peru's national existence, military leaders (*caudillos*) who had gained prominence in the struggle for independence sought to seize power. The departure of Simón Bolívar, the South American liberator whose army had been essential in freeing the country, removed a stabilizing influence. The aims of the caudillos were furthered by the absence of a tradition of self-government, by the prevalence of a feudal society of creoles and Indians, and by the reluctance of civilians to assume political responsibility. Despite military influences, a liberal constitution was adopted in 1828. This did not prevent Gen. Agustín Gamarra a year later from becoming head of the government by illegal means. His position was successfully challenged in 1835 by another self-seeking caudillo, Gen. Felipe Salaverry.

Peruvian-Bolivian confederation. The ambitions of Gamarra and Salaverry were thwarted by Andrés Santa Cruz, an intelligent military commander of Spanish-Indian descent, who proposed a confederation of Peru and Bolivia. For three years Santa Cruz, though born in La Paz, obtained the backing of influential groups in Peru and maintained the political union. But his hopes were shattered at the Battle of Yungay in 1839 by a joint force of nationalist-minded Peruvians and of Chileans fearing a threat to the balance of power in the Pacific.

Establishment of order. During the initial period of statehood in Peru, liberal and conservative parties with ill-defined programs emerged. Their rivalry enhanced the political instability of the country.

Growth under Ramón Castilla

Gen. Ramón Castilla assumed the presidency in 1845. Castilla dominated the political scene from 1845 to 1851 and from 1855 to 1862, in spite of his mestizo (racially mixed) background. His greatest accomplishment for the promotion of national wealth was the exploitation of the guano deposits along the coast and offshore islands. Taxes on this industry, which was controlled by foreign corporations, furnished the principal source of government revenue for several decades. Castilla appealed to liberals by abolishing the payment of tribute by Indians and by emancipating the Negro slaves. Landowners on the coastal plantations, however, were permitted to import thousands of Chinese coolies in order to have a sufficient labour supply. As an additional concession to the liberals, Castilla established a system of state education at the primary and secondary levels. Owing to his influence, an assembly in 1860 adopted a constitution that lasted into the 1900s.

National setbacks

The Spanish invasion (1864–69). In the second half of the 19th century, Peru's history was characterized by many setbacks. In 1864 Spain dispatched a naval force to the Pacific, ostensibly to protect the rights of Basque immigrants, but in reality to re-establish domination over its former colony. In 1869, after meeting with the determined opposition of Peru and Chile, Spain withdrew and recognized Peru's independence for the first time, but the conflict was a heavy drain on Peru's treasury.

The Meiggs railway project. Dissatisfaction with military rule resulted in 1871 in the formation of the Civilian Party, representing an oligarchy of landowners and merchants. This party, headed by Manuel Pardo (president, 1872–76), approved a costly program of internal development, which included the construction of railroads across the Andes by Henry Meiggs, an unscrupulous U.S. entrepreneur. Corruption and fraud on the part of government officials and contractors characterized the work. Although it decreased the isolation of the Peruvian interior, it increased enormously the national debt.

The War of the Pacific (1879–84). Another untoward event was the War of the Pacific with Chile, 1879–84, caused mainly by rivalry over the exploitation of the rich nitrate beds in the Atacama desert then in Peru, now between Chile and Peru. Chile's superior resources and military discipline brought overwhelming defeat to Peru and its ally Bolivia.

At the Battle of Iquique (then in Peru, now in Chile), on May 21, 1879, the Peruvians suffered the loss of their best warship, the "Independencia." The eventual surrender of control of the sea permitted a Chilean army to land on the Peruvian coast. On January 17, 1881, Chilean forces captured the capital, Lima. Looting and pillage followed, with the destruction of the National Library, which had over 58,000 volumes. According to the terms of the Treaty of Ancón (October 20, 1883), Peru turned over to Chile full possession of the province of Tarapacá (now in northern Chile) and the administration for ten years of the provinces of Tacna and Arica, after which a plebiscite was to determine their future sovereignty.

The Peruvian Corporation. Expenditures for the war, and the consequent loss of revenue from the nitrate fields, created the possibility of imminent bankruptcy. To avert this disaster, the Civilian regime accepted in 1889 a plan proposed by the bondholders for handling the debt. The Peruvian Corporation, representing the creditors, with headquarters in London, was to control the railroads for 66 years, to mine up to 3,000,000 tons of guano, and to receive 33 annual payments of £80,000 each. The plan worked satisfactorily to the benefit of both parties.

Peaceful civilian rule

Social reforms and economic development. The decline in national prestige created an atmosphere conducive to political change. The Democratic Party was formed, and in 1895, under the leadership of Nicolás de Piérola, it won the presidential election. Having a broad, popular base, it championed direct suffrage and the restoration of municipal elections. Public education was fostered, but schools for the children of the poor were lacking in both urban and rural areas.

An orderly political scene, marked by rivalry between the Democratic and Civilian groups, accelerated economic development. There was an increase in the production of minerals, notably copper, and of such agricultural commodities as cotton, sugar, and wool. In the mining of copper, U.S. capital acquired important interests, founding the Cerro de Pasco Corporation in the central Peruvian highlands. Small factories designed for the domestic market appeared in the cities. Railroad construction, halted in the 1880s, was resumed, stimulating trade.

The presidencies of Augusto Leguía (1908–12; 1919–30). In 1908 Augusto Leguía, chief spokesman for the Civilians, assumed the presidency; a former minister of the treasury, he was closely identified with business groups. By selling guano to owners of the large coastal estates the government expanded indirectly the production of sugar and cotton—thenceforth important props for the economy.

Leguía's second period in office was generally less successful. By advocating social reform and the modernization of the country, he appealed strongly to many sectors, including the newly formed Socialist Party, but he permanently undermined the Civilian and Democratic parties. Eventually, his leadership rested on a popular basis. In line with his theme of progressiveness, Peru received a new constitution in 1920 to replace the one of 1860. The new charter authorized the state to limit property rights; to build hospitals, clinics, and asylums; and to provide free primary education; Article 58 protected the communal lands of the Indians from sale and seizure.

The administration's economic policies achieved a temporary prosperity. An expensive program of public works aided a number of cities and communities, especially Lima, the capital. Irrigation projects opened up 100,000 acres along the coast. To provide technicians, the government founded a National Agricultural School in Lima. Foreign investments were encouraged. In 1924 the International Petroleum Company, a subsidiary of the U.S.-owned Standard Oil Company of New Jersey, acquired the oil fields of La Brea-Pariñas, near Talara on the northern coast, from the London and Pacific Petroleum Company, and built a refinery to supply the nation with oil and gasoline; the nature of the British company's exploitation of the concessions raised the question of the legality of the purchase. To finance its policies, the Peruvian government resorted to large loans from U.S. banks.

Indianism

The period of the 1920s witnessed a significant development of Indianism. The government's failure to implement Article 58 of the constitution made the issue a critical one. Peruvian intellectuals created a vogue of Inca history, tradition, and archaeology; the Indian, they argued, should enjoy equality in society hitherto denied him. While a majority of thinkers urged gradual reforms, some favoured radical means to achieve this goal. This latter group found support in the ideology of the Mexican Revolution of 1910; one of these was José Carlos Mariátegui, the founder of the Peruvian Communist Party.

Formation of the Aprista movement. The Alianza Popular Revolucionaria Americana (APRA), known as the "Aprista movement," was formed in 1924 in Mexico City by Víctor Raúl Haya de la Torre, an intellectual then in exile. Internationally, it expressed the ideals of the unity of American Indians and the elimination of U.S. imperialism. Nationally, it proclaimed the need to end the exploitation of the Peruvian masses through the institution of a planned economy and the nationalization of foreign-owned enterprises. Its anticapitalist and anti-imperialist stand appealed to intellectuals, to the Indians, and to the lower middle class. Many teachers and students participated in the movement, and the University of San Marcos became a stronghold of radicalism.

Peru since 1930. By 1930 Leguía had experienced a definite loss in popularity. Final settlement of the long-standing Tacna-Arica dispute with Chile, by which Peru ceded the province of Arica, angered the extreme nationalists. The world depression, resulting in a serious decline in exports and a curtailment of loans from U.S. bankers, cost Leguía the support of the commercial and financial groups. Finally, the establishment of a repressive dictatorship alienated the liberals. In 1930 a military junta headed by Gen. Luis Sánchez Cerro, a mestizo, engineered Leguía's overthrow.

The presidencies of Luis Sánchez Cerro and Oscar Benavides (1931–39). Politically, the era of military domination in the 1930s was one of the most strife-torn in Peru's history. In 1931 Sánchez Cerro obtained the presidency over the Aprista candidate Haya de la Torre. In 1933 a new constitution set up a presidential parliamentary system with a strong executive to be chosen for a five year term.

Aprista opposition

Sánchez Cerro had to deal both with strong political opposition and with the effects of the depression. APRA claimed that the 1931 election was fraudulent and instigated a campaign to discredit the regime. The threat from the left led to the emergence of a Fascist group, whose chief exponent was the conservative historian José de la Riva Agüero. Sánchez Cerro's efforts to win over the Indians by a promise of agrarian reform were futile. In July 1932 Apristas organized an uprising in Trujillo, along the northern coast. During their withdrawal the revolutionaries shot hostages, including officers and enlisted men; the army retaliated with wholesale executions. Sánchez Cerro was assassinated by an Aprista in 1933. These incidents created an enduring enmity between the military establishment and APRA.

Sánchez Cerro's successor was Gen. Oscar Benavides (1933–39), who restored confidence in the economy. Benavides settled a dangerous boundary controversy with Colombia that had erupted into open fighting in 1932. The scene of the dispute was the port of Leticia on the upper Amazon and a finger of land giving access to the river, both of which had been ceded to Colombia in a treaty of 1922. To avoid full-scale war, Benavides disclaimed the acts of invading Peruvians and returned the territory to Colombia.

Benavides reduced the strength of the APRA, now claiming a majority of the middle and lower sector of the population, by outlawing the party, by a relentless persecution of its leaders, and by the adoption of social assistance projects. In the presidential election of 1939 the Apristas backed Benavides' choice—Manuel Prado, a banker and member of an aristocratic family of Lima.

The first presidency of Manuel Prado (1939–45). During World War II Peru cooperated with the United States. Prado authorized Allied use of airfields and ports and arranged to sell them petroleum, cotton, and minerals. In 1942 Peru severed diplomatic relations with the Axis powers, and in 1945 it declared war against them. During the war Peru succeeded, with U.S. backing, in getting a favourable settlement of a boundary dispute with Ecuador, which recognized Peru's sovereignty over a stretch of territory along the Marañon River (an Amazon headwater) and over the town of Zarumilla.

Alignment with the United States

Gains by the Apristas. World War II not only brought economic prosperity but also hope for real democracy. Prado, swayed by public opinion, approved the presidential candidacy in 1945 of José Bustamante, a lawyer from Arequipa with liberal leanings, who represented a coalition of middle- and upper-class elements. APRA, again a legal party, obtained a majority of seats in the lower house and half the seats in the senate. Because of Haya de la Torre's secret acquiescence in Bustamante's selection, APRA believed that many of its policies would be accepted. But Bustamante generally followed an independent course, and the Apristas withdrew their collaboration. After Apristas staged an abortive insurrection in Callao, near Lima, the president outlawed the party.

The dictatorship of Manuel Odría (1948–56). In October 1948 Gen. Manuel Odría seized power in the capital, protesting the president's lack of firmness in dealing with the radicals; Odría served as president until 1956. Extreme measures were taken to suppress the Apristas. Haya de la Torre found refuge in the Colombian embassy, where he stayed five years before leaving Peru.

From 1948 to 1956 Peru had an authoritarian regime. Political stability allowed the revival of prosperity, which had been hurt by a postwar recession. The Korean conflict of the early 1950s augmented foreign trade because

of heavy U.S. demand for Peruvian minerals. A friendly policy toward foreign capital prompted investments on a large scale. To appeal to the lower classes, Odría advocated medical and social assistance; but these proved to be illusory. Some progress was made, however, in the establishment of primary and secondary schools. Lavish expenditures in the capital, marked by official graft, and the ending of the Korean War led to the adoption of inflationary policies by the treasury.

Prado's second term (1956–62). In the election of 1956, Manuel Prado, who was supported by Odría, won a second term. Prado defeated Fernando Belaúnde-Terry, a U.S.-educated architect and a descendant of a prominent Peruvian family, who captivated intellectuals, students, and professional groups by advocating thorough social and economic reforms. A surprising feature of the election was the decline of APRA, some of whose members joined Belaúnde's National Front Party.

Decline of APRA

By currying favour with the Apristas, again a legal body, Prado avoided disorders. He countered the financial crisis inherited from Odría by appointing as minister of the treasury Pedro Beltrán, director of the conservative Lima newspaper *La Prensa,* whose orthodox policies contributed to a 4½ percent annual increase in the gross national product. Aiding the economy was the expansion of the fishing industry based on the Peruvian Current; by 1966 Peru was foremost in the world in anchovy and fishmeal products. Beltrán's measures did not, however, lessen the pressure from the landless Indians and the underpaid urban proletariat.

The presidency of Fernando Belaúnde-Terry (1963–68). With political tension at a high level in 1962, none of the presidential candidates of the three leading parties received the necessary one-third vote for election. Haya de la Torre had a slight plurality, followed closely by Belaúnde-Terry and Odría. The election went to the congress for a decision, but the military, fearing an alliance between the conservatives and the Apristas that might have given the latter a strong influence, stepped in and seized the government. A new election called in 1963 by the junta permitted Belaúnde's party, now called "Popular Action," to be victorious.

Reforms of Belaúnde

Belaúnde promised practical solutions to the country's economic and social problems, especially the high rate of population increase (in 1966 Peru had an estimated population of 12,000,000, three-fourths of whom had a subnormal standard of living). An agrarian act of 1964 provided for more effective use of the land, with expropriation of unused or misused agricultural properties; by 1966 more than 500,000 acres had been distributed to the peons. To enhance living conditions and the dignity of the Indians, the government organized community development projects; Indians were encouraged to colonize land in the foothills east of the Andes. Irrigation schemes were instituted for arid areas on the coast, and a network of roads was planned for the interior. Education was promoted with the establishment of new universities and with attacks on illiteracy—by 1961 down to 40 percent. Excessive outlays for these projects provoked a financial crisis.

Military rule. On October 3, 1968, the military reasserted its power and forced the resignation of Belaúnde on the pretext of his unduly moderate position toward the International Petroleum Company. Behind this, however, was a fear of APRA acquiring power in the forthcoming elections. The junta, headed by Juan Velasco Alvarado, jailed opposing politicians and suspended constitutional liberties. On October 9 the government expropriated the holdings of the International Petroleum Company, declaring that the company owed $690,500,000 for exploitation of illegal concessions. This further strained relations with the U.S., already affected by seizures of U.S. fishing craft in a 200-mile limit claimed by Peru as national waters and by the purchase of supersonic jet fighters from France. The U.S. State Department protested but refrained from cutting off foreign aid. As a gesture of independence Peru opened diplomatic relations with the Communist Bloc nations.

In 1969 the junta embarked on a vigorous program of economic nationalism. Velasco, while denouncing Marxism, proclaimed his intent "to combine public and private ownership of the economy." This policy would affect U.S. capital investments totalling $600,000,000, which had contributed to the economic growth of the country. In 13 months, three basic reform measures were enacted; the Agrarian Law (June 24, 1969); the Mining Law (April 14, 1970); and the Industrial Law (July 30, 1970). Accordingly, the government seized on August 22, 1969, the Paramonga chemical and paper complex of W.R. Grace & Company, the largest U.S. interest in Peru next to that of Standard Oil, and many foreign and domestic owned plantations on the coast. It sought also to control essential industries and public services through outright ownership and by "Peruvianization"—insistence that a majority of the stock of a foreign company be held by nationals. The success of the government's program depended on the continued support of the Indian masses and of the growing middle sectors and on the exercise of managerial ability. The occurrence on May 31, 1970, in the northeastern Andean region and in the adjoining coastal strip, of the worst Latin American earthquake in the 20th century partly jeopardized the financial stability of the regime. Loss of life was estimated at 50,000, with property damage in the hundreds of millions of dollars.

Economic nationalism

Perugino

Of all the Italian Renaissance painters of the late 15th century, Perugino, an artist from the province of Umbria, was one of the most significant. The compositional clarity, sense of spaciousness, and economy of formal elements in his works were to become some of the distinguishing aesthetic principles of the High Renaissance

style of the early 16th century. Perugino is also important for his influential role as the teacher of the famous painter Raphael, whose paintings are regarded as the quintessence of High Renaissance art.

"Vision of St. Bernard," wood panel by Perugino, *c.* 1491–94. In the Alte Pinakothek, Munich. 1.73 × 1.70 m.

Born about 1450 at Città della Pieve, Italy, Pietro di Cristoforo Vannucci became known as Perugino, derived from the Umbrian city of Perugia located near his birthplace. Nothing is known for certain of his early training, but he may have been a pupil of Fiorenzo di Lorenzo (*c.* 1440-1525), a minor painter in Perugia, and of the renowned Umbrian Piero della Francesca (*c.* 1420–92) in Arezzo, in which case he would have been a fellow pupil of one of his most famous contemporaries, Luca Signorelli. The two men were acquainted, and an occasional influence from Signorelli is visible in Perugino's work, notably in the direction of an increased hardness of drawing (*e.g.*, "Crucifixion and Saints," *c.* 1480–1500; Uffizi, Florence). In Florence, where he is first recorded in 1472, he almost certainly worked in the shop of the important painter and sculptor Andrea del Verrocchio, where the young Leonardo da Vinci was apprenticed.

Early work

The first certain work by Perugino is a "Saint Sebastian," at Cerqueto, near Perugia. This fresco, or mural painted on plaster with water-dissolved pigments, dates from 1478 and is typical of Perugino's style. He must have attained a considerable reputation by this time, since he probably worked for Pope Sixtus IV in Rome, 1478–79, on frescoes now lost. Sixtus IV also employed him to paint a number of the frescoes in the Sistine Chapel in the Vatican Palace. Completed between 1481 and 1482, three narrative scenes behind the altar were destroyed by Michelangelo in 1535–36 in order to use the space for his fresco of the "Last Judgment." Of the scenes completely by Perugino's own hand, only the fresco "Giving of the Keys to St. Peter" has survived. The simple and lucid arrangement of the composition reveals the centre of narrative action unlike the frescoes in the same series by the Florentine painter Sandro Botticelli, which, in comparison, appear overcrowded and confused in their narrative focus. After completing his work in the Sistine Chapel, Perugino returned to Florence, where he was commissioned to work in the Palazzo della Signoria. In 1491 he was invited to sit on the committee concerned with finishing the Florence Cathedral.

Summit of artistic career

From approximately 1490 to 1500 Perugino was at his most productive and at the artistic summit of his career. Among the finest of his works executed during this time are the "Vision of St. Bernard," the "Madonna and Saints," the "Pietà," and the fresco of the "Crucifixion" for the Florentine convent of Sta. Maria Maddalena dei Pazzi. These works are characterized by ample sculpturesque figures gracefully posed in simple Renaissance architectural settings, which act as a frame to the images and the narrative. The harmonious space is tightly controlled in the foreground and middle ground, while the background effect is conversely one of infinite space. During this period he painted his best known portrait, a likeness of "Francesco delle Opere." Perugino must have been well acquainted with the late 15th-century portraiture of Flanders, since the influence of the Flemish painter Hans Memling is unmistakable.

Commissioned by the guild of bankers of Perugia, Perugino painted a fresco cycle in their Sala dell'Udienza that is believed to have been completed during or shortly after 1500, the date that appears opposite Perugino's self-portrait in one of the scenes. The importance of these frescoes lies less in their artistic merit than in the fact that the young Raphael, Perugino's pupil around 1500, probably was an assistant learning the technique of fresco painting. An allegorical figure of Fortitude from this series is often attributed to Raphael.

Creative decline

After 1500, Perugino's art began to decline, and he frequently repeated his earlier compositions in a routine manner. Giorgio Vasari, a 16th-century biographer and artist, wrote that the critical Florentines began to lampoon him, and Perugino replied that they had once praised his work, and, if he now gave the same designs, they had no right to blame him. It is certainly true that the "Combat of Love and Chastity" (Louvre, Paris) was commissioned in 1503 by Isabella d'Este and was delivered only in 1505, after a great many letters had passed between all concerned, at which time Isabella expressed herself as satisfied but only moderately so. In fact, Perugino left Florence about 1505 and began to work principally for the less critical public of Umbria. In 1508 he made a temporary comeback by painting roundels on the ceiling of the Stanza dell'Incendio in the Vatican. The commission for the frescoes on the walls of the room went to his pupil Raphael, who, in the few years after leaving Perugino's studio, proved himself the greater artist. One of Perugino's last commissions was the completion in 1521 of some frescoes in S. Severo, Perugia, which had been begun by Raphael. He was still painting in February or March 1523, when he died of the plague at Fontignano, near Perugia. The fresco of the "Nativity," in the National Gallery, London, comes from Fontignano and is generally supposed to be Perugino's last work.

MAJOR WORKS

"St. Sebastian" (1478; Cerqueto, Italy); "Giving of the Keys to St. Peter" (1481–82; Vatican, Sistine Chapel, Rome); "Crucifixion" (*c.* 1485; National Gallery, Washington D.C.); "Vision of St. Bernard" (*c.* 1491–94; Alte Pinakothek, Munich); "Adoration of the Child, Crucifixion, and Saints" (1491; Villa Torlonia, formerly Albani, Rome); "Madonna and Saints" (1493; Uffizi, Florence); "Madonna and Saints" (1493; Kunsthistorisches Museum, Vienna); "Crucifixion" (1493–96; Convent of Sta. Maria Maddalena dei Pazzi); "Francesco delle Opere" (1494; Uffizi, Florence); "Pietà" (*c.* 1494–95; Uffizi, Florence); "Virgin in Glory with Saints" (*c.* 1495–96; Pinacoteca Nazionale, Bologna); "Agony in the Garden" (1495; Galleria Palatina, Florence); Altarpiece (1497; Church of Sta. Maria Nuova, Fano, Italy); "Ascension" (1496–98; Musée Municipal des Beaux-Arts, Lyons), panels belonging to this painting in museums at Nantes and Rouen; "Annunciation" (1498; Church of Sta. Maria Nuova, Fano, Italy); "Archangel Michael, The Virgin Adoring the Child, Archangel Raphael with Tobias" (*c.* 1499; National Gallery, London); "Biagio Milanesi" (1500; Uffizi, Florence); "The Monk Baldassare" (1500; Uffizi, Florence); "Prophets, Heroes, Sibyls, and Sages, the Transfiguration and the Adoration of the Shepherds" (*c.* 1497–1500; Sala dell'Udienza, Collegio del Cambio, Perugia); "St. Sebastian" (1500–08; Hermitage, Leningrad); "Resurrection" (*c.* 1501; Vatican Gallery, Rome); "Adoration of the Shepherds" (1501; Galleria

Nazionale dell'Umbria, Perugia); "Crucifixion and Saints" (1502–06; Church of S. Agostino, Siena); "Marriage of the Virgin" (1503–04; Musée de l'Hôtel de Ville, Caen, France); "Combat of Love and Chastity" (1505; Louvre, Paris); "Deposition" (1505–07; Uffizi, Florence); "Assumption" (1506; Uffizi, Florence); "Ascension" (*c.* 1509; Cathedral, San Sepolcro); Altarpiece (before 1517; Galleria Nazionale dell'Umbria, Perugia); "Adoration of the Magi" (1521; Church of Sta. Maria delle Lacrime, Trevi, Italy); "Nativity" (1522; National Gallery, London).

BIBLIOGRAPHY. The most complete documentation on Perugino is in FIORENZO CANUTI, *Il Perugino*, 2 vol. (1931); but there is a useful modern monograph by E. CAMESASCA, *Tutta la pittura del Perugino* (1959). See also the lengthy article by FRANCESCO SANTI in the *Encyclopedia of World Art*, vol. 11, col. 265–271 (1966); and FREDERICK HARTT, *A History of Italian Renaissance Art* (1969).

Pestalozzi, Johann Heinrich

Johann Heinrich Pestalozzi, Swiss educational reformer, was among the first to recognize the social problems of the industrial age and to stress the need for better popular education. Believing that every man, even the lowest, has inherent powers capable of development and has equal rights to be educated, he devised a teaching method aimed at strengthening the child's own faculties to make him proficient and secure, able to help himself and others. His "method" became widely accepted and gave impetus to teacher training. Most of his principles have been absorbed into modern elementary education.

Pestalozzi, lithograph after a drawing by G.A. Hippius, 1818. In the Pestalozzianum, Zürich.

Pestalozzi was born in Zürich on January 12, 1746. He was influenced by the political conditions of his country and by the educational ideas of Jean-Jacques Rousseau; he abandoned the study of theology to go "back to Nature." In 1769 he took up agriculture on neglected land near the River Aare—the Neuhof. When this enterprise collapsed in 1774, he took poor children into his house, making them work by spinning and weaving and learn simultaneously to become self-supporting. This project also failed materially, although Pestalozzi had gained valuable experience. He continued to take an active interest in Swiss politics.

As practical realization of his ideas was denied him, he turned to writing. *The Evening Hour of a Hermit* (1780) outlines his fundamental theory that education must be "according to nature" and that security in the home is the foundation of man's happiness. His novel *Leonard and Gertrude* (1781–87), written for "the people," was a literary success as the first realistic representation of rural life in German. It describes how an ideal woman exposes corrupt practices and, by her well-ordered homelife, sets a model for the village school and the larger community. The important role of the mother in early education is a recurrent theme in Pestalozzi's writings.

Life at Neuhof

For 30 years Pestalozzi lived in isolation on his Neuhof estate, writing profusely on educational, political, and economic topics, indicating ways of improving the lot of the poor. His proposals were ignored by his own countrymen, and he became increasingly despondent. He would have accepted the post of educational adviser anywhere in Europe had it been forthcoming. His main philosophical treatise, *Meine Nachforschungen über den Gang der Natur* (1797; "My Inquiries into the Course of Nature in the Development of Mankind"), reflects his personal disappointment but expresses his unshakable belief in the resources of human nature and his conviction that man himself is responsible for his moral and intellectual state. Thus, Pestalozzi was convinced, education should develop man's innate faculties to think for himself.

Pestalozzi's chance to act came after the French Revolution, when he was over 50 years old. The French-imposed Helvetian Republic in Switzerland invited him to organize higher education, but he preferred to begin at the beginning. He collected scores of destitute war orphans and cared for them almost single-handedly, attempting to create a family atmosphere and to restore their moral qualities. These few exhausting months in Stans (1799) were, according to Pestalozzi's own account, the happiest days of his life.

From 1800 to 1804 he directed an educational establishment in Burgdorf and from 1805 until 1825 a boarding school at Yverdon, near Neuchâtel. Both schools relied for funds on fee-paying pupils, though some poor children were taken in; and these institutes served as experimental bases for proving his method in its three branches —intellectual, moral, and physical, the latter including vocational and civic training. They also were to finance his life's "dream," an industrial (*i.e.*, poor) school. The Yverdon Institute became world famous, drawing pupils from all over Europe as well as many foreign visitors. Some visiting educators—*e.g.*, Friedrich Froebel, J.F. Herbart, and Carl Ritter—were so impressed that they stayed on to study the method and later introduced it into their own teaching.

The Yverdon Institute

While dedicated assistants carried on the teaching, Pestalozzi remained the institute's heart and soul and continued to work out his method. *Wie Gertrud ihre Kinder lehrt* (1801; *How Gertrude Teaches Her Children*, 1894) contains the main principles of intellectual education: that the child's innate faculties should be evolved, that he should learn how to think, proceeding gradually from observation to comprehension to form clear ideas. Although the teaching method is treated in greater detail, Pestalozzi considered moral education pre-eminent.

The family spirit prevailing in Yverdon was shattered in later years by a progressively severe dispute among the teachers for first place by Pestalozzi's side. The longed-for poor school, established by means of the proceeds from publication of his collected works, existed for only two years. The Yverdon Institute lost its fame and its pupils to Pestalozzi's great distress. His efforts at reconciliation were in vain. With a few pupils he retreated to Neuhof in 1825, sad but convinced that his ideas would prevail in the end. His *Schwanengesang* (1826; "Swan Song") culminated in the maxim "Life itself educates." He died on February 17, 1827.

Pestalozzi was an odd-looking man but an impressive personality, highly esteemed by his contemporaries. His concept of education embraced politics, economics, and philosophy, and the influence of his "method" was immense.

BIBLIOGRAPHY. JOHANN HEINRICH PESTALOZZI, *Sämtliche Werke und Briefe* (1927– and 1946–), is the scholarly critical edition in German of Pestalozzi's complete works (26 vol.) and letters (12 vol.), the majority of which was hitherto unknown. KATE SILBER, *Pestalozzi: The Man and His Work*, 2nd ed. (1965), containing a select bibliography of texts and literature, is the only comprehensive account of Pestalozzi's life and personality and interpretation of his writings in English. FRIEDRICH DELEKAT, *Johann Heinrich Pestalozzi*, 3rd ed. (1968), is a most recent excellent study on Pestalozzi in German.

(K.Si.)

Pest Control

When man hunted animals and foraged for food he shared the natural resources with other organisms in the community. As man's culture developed and his population rose, he made ever-increasing demands on these resources. In order to satisfy these increasing demands, man has modified his environment with little regard for the biological consequences of his actions.

One result of changing the environment has been a great increase in the number of species that are now recognized as competitors of man. These competitors are usually referred to as pests. The definition of pest is, of course, subjective. An ecologist would not necessarily consider several leaf-eating catepillars on a plant as pests, whereas a gardener who cultivated the plant might very well do so. And only one bat, rat, or mouse is enough to qualify as a household pest. As the term will be used in this article, however, a pest is an animal or plant that occurs in such abundance as to present a distinct threat, economically or medically, to man or his interests. This article is concerned mainly with animal pests; for plant pests see WEED CONTROL.

A pest defined

Natural communities have always contained organisms that were economically significant; locusts, for example, have plagued man throughout history, and grain from Stone Age locations has been found infected with bunt and ergot diseases. Most species that became pests, however, did so because of environmental modification, occasionally from natural causes but usually from the activities of man.

In order to appreciate some of the methods devised to combat pests, it is instructive to consider how advancing technology has increased the number of harmful insect species. The change from natural vegetation to large areas of single-crop (monoculture) agriculture has three consequences. First, given a more uniform plant cover, some plant-eating species increase to large populations. Second, uniform vegetation is easily invaded by attacking pests. Third, the introduction of new crops over large areas results in the transfer of previously harmless insects from scattered native plants to the new and abundant sources of food. Cultural practices such as fertilization, irrigation, and the use of selected varieties as crops enhance still further the ability of pest species to increase rapidly in abundance. Additional reasons for the increase in the number of pest problems include the increasingly higher standards of crop production, and the occurrence of unintended effects in some pest control programs.

Pests are found throughout the plant and animal kingdoms. Weeds are often strong competitors of crop plants. Micro-organisms such as fungi, bacteria, and viruses are here considered with the pests even though they are usually thought of as agents of disease. Most animal pests are invertebrates, among them protozoa, flatworms, nematodes, snails, slugs, insects, and mites. Among the vertebrates, rabbits, elk, deer, and many kinds of rodents are sometimes injurious to crops. Because weeds, plant diseases, and arthropods (insects and mites) constitute the chief threats to the welfare of man, the development of pest control has been directed mostly toward restricting the abundance of these forms.

In spite of the immense efforts expended in controlling pests, their significance for man appears to be increasing. Pesticides have contributed toward the evolution of pests that are increasingly difficult to control and have often caused the replacement of one species of pest by another. Toxic materials have polluted biotic communities throughout the world. As a result the effects of these materials on living organisms has become a matter of major concern.

This article discusses various means, both artificial and natural, that can be used to combat man's competitors and draws attention to their merits and deficiencies.

BACKGROUND

The extent of pest damage. Although the number of species that inhabit the earth is very large, the number that are serious pests is remarkably small, less than 1%, most of which are insects. In spite of the small number of pest species, the losses attributable to insects and mites, plant diseases, and weeds are substantial. One recent estimate of annual worldwide crop loss, expressed as a percentage of the market value of the crop, puts the loss from insect damage at 13.8%, from diseases at 11.6%, and from weeds at 9.5%. The annual regional losses, in percentage of crop market value, are estimated as follows: North and Central America, 28.7%; South America, 33%; Europe, 25%; Africa, 41.6%; Asia, 43.3%; Oceania, 27.9%; U.S.S.R. and China, 29.7%. Annual losses, in millions of tons, for various crops are estimated as follows: cereals, 506; potatoes, 129; sugar beets and sugar cane, 636; vegetables, 78; fruit crops, 56; oil crops, 42; and fibre crops and natural rubber, 8. Added to these losses are the costs of pest control programs.

Economic impact of pests

Insects are also serious pests because some of them play an essential role in the transmission of disease. Each year millions of lives, particularly in the tropics, are threatened by insect-borne diseases. Malaria and yellow fever are transmitted by mosquitoes, plague by fleas, typhus by the human louse, sleeping sickness by tsetse flies, Chagas' disease by blood-sucking bugs, and leishmaniasis by sandflies. Other diseases may be spread by insects accidentally as a result of their habits.

Pest control programs. Pest control began to receive attention in the 18th century, and it has become increasingly important since then. As control programs were developed, they tended to fall primarily into two somewhat mutually exclusive categories: chemical and biological. Physical or mechanical methods, including sticky barriers, heat killing (for storage pests), and flooding (for ground pests), were also developed. Because of their limited utility and short-term effectiveness, they have been superseded largely by chemical and biological methods.

The chemical, or pesticide, approach to pest control probably began with the use of poisonous plant compounds—ground tobacco was used in France to kill aphids about 1763. Other natural products such as nicotine, rotenone, petroleum, kerosene, creosote, and turpentine were used in the 19th century. Inorganic compounds such as Paris green, lime sulfur, Bordeaux mixture, hydrogen cyanide, and lead arsenate were also introduced in the 1800s.

With the appearance of the synthetic organic compounds during World War II, a dramatic change occurred in pest control. Some organic compounds, such as the dinitrophenols, had been used earlier, but the discovery of the insecticidal properties of DDT (dichloro-diphenyl-trichloroethane) and of BHC (benzene hexachloride) made the concept of pest-free crops possible. Research in the 1930s on plant hormones and related compounds led to the development of the selective herbicide 2,4-D (2,4-dichlorophenoxyacetic acid) and this became commercially available about the same time as DDT. Following the appearance of these new synthetic organic compounds, a whole new series of pesticides—insecticides, fungicides, herbicides, and plant growth regulators—was introduced.

Although the ancient Chinese used predacious ants to control foliage-feeding insects, the control of pests by biological means appears to have been initiated in the Western world with the importation of the Indian Mynah bird into Mauritius in 1762 to control the red locust. Control of bedbugs by predatory agents was recommended in 1776. A number of other projects in biological control were carried out in the 1800s, but the modern era in this phase of pest control began in 1888 with the importation into California of the vedalia beetle (*Rodolia cardinalis*) to control the cottony-cushion scale (*Icerya purchasi*). This beetle, imported from Australia, saved the citrus-fruit industry.

Beginnings of biological control

The use of plants resistant to insects was suggested about 1788 as a means of controlling the Hessian fly, a pest of wheat. The classic example of this approach was the control of phylloxera, aphid-like insects that attacked the root stocks of the European wine grape and almost ruined the European wine industry. The solution lay in grafting the European wine grape onto resistant American stocks. The effort, about 1900, to control the lantana shrub in Hawaii

Table 1: Categories of Chemical Pesticides

class	type	example
Insecticides	stomach poisons	
	arsenicals	lead arsenate, Paris green, calcium arsenate
	fluorine compounds	sodium fluoride, cryolite
	contact poisons (natural)	
	plant extracts	pyrethrum, nicotine, rotenone
	hydrocarbons	oil
	(synthetic)	
	chlorinated hydrocarbons	DDT, BHC, lindane, Chlorobenzilate, methoxychlor, and cyclodienes including aldrin, dieldrin, chlordane, heptachlor, endrin, toxaphene
	organophosphates	parathion, malathion, Diazinon, naled, methyl parathion, dichlorvos
	carbamates	carbamyl, methomyl, carbofuran
	hormone mimics	farnesol, sesquiterpenes
	fumigants	hydrogen cyanide, naphthalene, nicotine
	for stored products	methyl bromide
	for soil	chloropicrin, dichloropropane
	systemic poisons	
	plant	demeton, oxydemetonmethyl, dimethoate, phorate, some carbamates
	animal	ronnel
Miticides		Kelthane, Aramite, dicofol
Repellents		dimethyl phthalate, deet
Chemosterilants	alkylating agents	apholate
	antimetabolites	aminopterin
	miscellaneous	triazine herbicides
Antibiotics		streptomycin
Fungicides	inorganic	lime sulfur, Bordeaux mixture, copper sulfate, copper oxide, sulfur, mercuric chloride, cadmium chloride
	organic mercury compounds	phenylmercuric acetate
	dithiocarbamates	ferbam, nabam, maneb, thiram
	chlorine based compounds	folpet, chloranil, dichloran, dichlone
Herbicides	inorganic compounds	sodium arsenite
	metal-organic compounds	cacodylic acid
	carboxylic aromatic	2,4-D; 2,4,5-T; dicamba; endothall; naptalam
	aliphatic acid compounds	dalapon
	heterocyclic nitrogen derivatives	atrazine
	aliphatic organic nitrogen compounds	diuron, barban
Rodenticides	inorganic	thallium sulfate, arsenic trioxide, arsenic sulfide
	botanicals	strychnine
	anticoagulants	coumafuryl, coumafene
	fluorides	sodium fluoroacetate

by introducing an insect appears to have been the first attempt to control weeds biologically. The use of microorganisms to destroy insect pests began in the late 1800s and early 1900s.

With the appearance of the synthetic organic insecticides, however, emphasis was placed on chemical control, and biological means fell into neglect. The extensive use of powerful chemical agents soon resulted in a number of serious ecological problems. Consequently, current pest control practice minimizes the use of pesticides and combines them with biological methods in an approach called integrated control.

CHEMICAL PEST CONTROL

All pesticides act alike in blocking some metabolic process. They differ, however, in composition, potency, mode of action, speed of effect, dosage required, and stage of pest against which they may be used. They are often classified according to the type of organism they are principally intended to control; hence the terms rodenticide, insecticide, acaricide (against mites), nematicide (against roundworms), herbicide (against plants), fungicide, etc. See Table 1.

The chief categories of chemical pesticides. *Insecticides.* Insecticides can be classified on the basis of their chemistry, toxicological action, or principal method of penetration. The method of penetration scheme allows insecticides to be listed as stomach poisons, contact poisons, fumigants, or systemics. The distinction between these latter categories is somewhat arbitrary and a given compound may fall into two or more of them.

Stomach poisons are used against insects with biting mouthparts, such as caterpillars, and are toxic only if ingested. The inorganics, such as the arsenic compounds, are thought to be general protoplasmic poisons, and the fluorine compounds are believed to interfere with enzymes associated with cellular oxidation. This group of compounds has gradually been replaced by the synthetic organic insecticides, which are generally less dangerous to mammals.

Contact poisons penetrate the skin of the pest and are used against those arthropods, such as aphids, that pierce the surface of a plant and suck out juices. The contact insecticides are composed of two main groups: naturally occurring and synthetic organic.

Naturally occurring contact insecticides are nicotine, developed from tobacco; pyrethrum, from flowers of *Chrysanthemum cinerariaefolium*; rotenone, from roots of *Derris* species and related plants; and oils, from petroleum. Although these compounds are originally derived mainly from plant extracts, the toxic agents of some of them (*e.g.*, pyrethrins) have been synthesized. Natural in-

secticides are usually short-lived on plants and cannot provide protection against prolonged invasions. They are effective, however, provided they hit the pests directly. Except for pyrethrum, they have been largely replaced by the newer synthetic organic insecticides.

Synthetic contact insecticides

The main synthetic groups are chlorinated hydrocarbons, organic phosphates (organophosphates), carbamates, and the insect hormones. Other synthetics include thiocyanates, dinitrophenols, sulfonates, sulfides, sulfones, and sulfites.

Chlorinated hydrocarbons were developed following the discovery of the insecticidal properties of DDT. Other examples of this series are BHC, lindane, the cyclodienes, Chlorobenzilate, and methoxychlor. All penetrate the organism readily and are toxic to a wide range of species. Some of these compounds are quite stable and have long residual action; they are, therefore, particularly valuable where protection is required for prolonged periods. In addition to plant protection, they have been of outstanding value in human and animal health fields. Their toxic action is not fully understood but they are known to disrupt the nervous system.

Organophosphates are currently the largest and most versatile class of insecticides. Two widely used compounds in this class are parathion and malathion; others are Diazinon, naled, methyl parathion, and dichlorvos. Usually, they have little residual action and are important, therefore, where residue tolerances limit the choice of insecticides. These compounds are variably hazardous but are generally much more toxic than the chlorinated hydrocarbons. Organophosphates inhibit the enzyme cholinesterase, which is essential in the functioning of the nervous system.

Carbamates form a relatively new group of insecticides that includes such compounds as carbamyl, methomyl, and carbofuran. They are rapidly detoxified and eliminated from animal tissues. Because many of these compounds have a low toxicity to mammals and are selective, they fit well into integrated control programs (see below). The toxicity of the carbamates is thought to arise from a mechanism somewhat similar to that for the organophosphates.

Insect growth hormones have recently been viewed as potential insecticides. Some chemicals, such as the sesquiterpenes and farnesol, have properties similar to such hormones. When they are applied to the target insect at a stage when the natural hormone is absent, they disrupt normal development. These compounds appear to have many advantages, including specificity to particular insect species.

Fumigants such as hydrogen cyanide, naphthalene, nicotine, and methyl bromide are toxic compounds that enter the respiratory system of the pest; they are used mainly for killing insect pests of stored products or nursery stock. Methyl bromide, dichloropropane, and chloropicrin are also used for soil fumigation, principally to control plant parasitic nematodes.

Systemic poisons are absorbed into a plant and later kill sucking insects and mites feeding on it. Absorption into the plant is achieved by spraying the leaves and stems or by applying solutions or granules impregnated with the chemical to the soil, so that intake occurs through the roots. Oxydemetonmethyl, demeton, dimethoate, and phorate are examples of systemic organophosphates. Some carbamates show systemic action. Animal systemics, such as ronnel, are used to control parasites of livestock.

Miticides or acaricides. Because many insecticides also kill mites, the separation of this group of pesticides is somewhat arbitrary. Some compounds, however, such as Aramite and Kelthane are made to be used specifically against mites.

Repellents. Repellents repulse animals rather than kill them. They are used mainly against mosquitoes, blood-sucking flies, and chiggers. Dimethyl phthalate and deet are examples of repellents that are used to protect humans from insect attack. Repellents that can be used for protecting plants from similar insect attacks have not yet been developed.

Chemosterilants. Chemosterilants inhibit reproduction of insect pests rather than killing them directly. Three general types of chemosterilants are usually recognized: alkylating agents (apholate, TEPA, metepa); antimetabolites (aminopterin, amethopterin); and a miscellaneous group of compounds that will induce sterilization but are important primarily for other reasons.

Antibiotics. Although considerable effort has been expended in the development of antibiotics as fungicides and bactericides, they have not been used commercially, largely because they may kill desirable vegetation. Some potential fungicides in this class are streptomycin, cycloheximide, and griseofulvin.

Compounds used as fungicides

Fungicides. Most fungicides are protectants and must be applied before diseases develop although some can arrest the disease if it is already present. Several groups of compounds can be used as fungicides: (1) the inorganics (see Table 1) are still widely used; (2) organic mercury compounds are used for the treatment of seeds, bulbs, and corms; (3) dithiocarbamates can be used as a spray or as a soil drench; (4) chlorine-based compounds are used against a wide range of crop diseases. Systemic fungicides are at an early stage of development and those available are very restricted in use.

Herbicides. Herbicides can be broadly divided into nonselective, which kill all plants, and selective, which kill only certain groups of plants. Herbicides are derived from a wide range of chemical groups: inorganic compounds, metal-organic compounds, carboxylic aromatic compounds, aliphatic acid compounds, heterocyclic nitrogen derivatives, aliphatic organic nitrogen compounds, and others (see WEED CONTROL).

Rodenticides and other vertebrate poisons. Because rodents are probably the chief vertebrate pests, many chemicals have been developed to combat them; however, many rodenticides may be used against other vertebrate pests as well. The highly toxic rodenticides are: (1) the inorganics; (2) the botanicals; (3) the anticoagulants; and (4) the fluorides. The insecticide rotenone is also a potent fish poison. Specific poisons have been developed for certain rats and for the lamprey. Some avicides act as repellents by affecting a few birds, who in turn frighten the others away.

The development, production, and application of chemical pesticides. Although there is a constant demand for new and better pesticides, these are developed only by a time-consuming and costly process. A new chemical is made commercially available for use as an insecticide, for example, by progression through several stages of selection that become increasingly severe and complex. In the laboratory, newly synthesized compounds are tested for biological activity against cultures of standard insect species. They must then be formulated into materials suitable for application as sprays or dusts. Next they must be compared with standard insecticides to establish any unusual properties they may have. Field evaluations are then conducted, first by using small plots and then extensive areas. Finally, if the compound appears promising, a pilot plant is built to provide small amounts for limited testing throughout the area in which the compound is expected to be used. In the meantime, other data must be accumulated relating to residue tolerances, methods of analyzing the compound and its metabolites, and other information required to register the chemical with government agencies. When all requirements for efficiency and safety of the new insecticide have been satisfied and it appears profitable to produce it, a manufacturing plant is constructed and production and marketing are initiated on a major scale.

This process can take from six to eight years. The chance of a compound passing from initial screening to commercial use is very small, as low as 1 in 36,000. The cost of developing a new pesticide may be about $5,000,000, including the cost of those compounds that are rejected.

Pesticide formulations

Pesticides are usually formulated as liquids or solids. In liquid formulations the pesticide may be dissolved in water or in a solvent such as xylene or petroleum oil. In solid formulations the pesticide is prepared as a powder or dust, or as granules. Wettable powders, the most widely used of

the various formulations, consist of the toxicant together with an absorptive carrier such as clay. Dusts are made by mixing the toxicant with a carrier such as a talc, bentonite, or clay. Granular formulations are similar to dusts but they have a larger particle size.

It is necessary to add a number of compounds that, in themselves, are not toxic but that make the toxicant more effective. For example, emulsifiers disperse pesticide solutions insoluble in water, wetting and suspending agents prevent the settling of a wettable powder in water, and stickers improve the retention of spray and dust deposits. Inert carriers aid in obtaining uniform dispersal of small quantities of the active pesticide over large areas. When two pesticides; *e.g.*, an insecticide and a fungicide, are applied together, it is essential that the various additives for each toxicant be compatible. Two toxicants may also act together to produce an effect greater than the sum of each separately.

Applying pesticides

Sprays are applied by hydraulic sprayers or by air-blast sprayers. There are three types of hydraulic sprayers: (1) low-pressure, low-volume sprayers, using pressures up to 100 pounds per square inch, which are suitable for covering plants such as weeds and certain vegetable crops; (2) high-pressure, high-volume sprayers, using pressures of 100–600 pounds per square inch, which are required for thorough coverage of fruit and truck crops; and (3) multipurpose sprayers, which have a relatively wide range of pressures. In air-blast sprayers a blast of air propels the spray and thus large volumes of water are not required. Machines also have been developed to apply the toxicants in a foam. Dusters also use an air stream to carry the pesticide to the plant—particularly to the underside of the leaves. Aerosol fogs and smokes are produced by a pressurized container or by heat-induced volatilization of the pesticides. Aerosol applications are used for treating enclosed spaces and are effective against flying insects. Aircraft, either planes or helicopters, distribute pesticides by using modifications of the low-pressure, low-volume spray, dust, or granular application procedures. For domestic purposes, there is a range of hand-operated sprayers, dusters, and aerosol generators. Animal pesticides may be applied by submerging the animals in solutions held in dipping vats. Soil fumigants are applied by a variety of techniques, each depending on the property of the fumigant being used. Indoor areas may be fumigated with methyl bromide simply by inserting a plastic tube from a cylinder of the gas into the building.

An evaluation of chemical control. *Benefits.* In view of the damage that pests can inflict, it is clear that pesticides are essential for the production of food and fibre. From 1945 to 1965 crop yields have increased by approximately 50 percent, for which pesticides are mainly responsible. Herbicides are estimated to increase yield by 10–15 percent, and fungicides have increased yield by as much as 100 percent. In addition to increasing yield quantitatively, pesticides have increased the quality of crops and the efficiency of crop production and have ensured more stable levels of production.

Insecticides have also been important in improving man's health. They have greatly reduced or eliminated about 30 carriers of disease. Malaria, yellow fever, and typhus have been either eliminated or severely limited in most areas of the world by pesticide use.

Limitations. Although pesticides have proven to be essential in the control of agricultural and medical pests, their extensive use has resulted in a number of serious problems including the development of resistance in pest species, increase in pest abundance, and environmental contamination.

When a formerly susceptible species can no longer be controlled by a pesticide applied at normally recommended rates, it is said to be resistant. Resistance appeared early in the 1900s in scale insects treated with lime sulfur (calcium polysulfides) and hydrogen cyanide, and in 1928 in the codling moth treated with lead arsenate. With the advent of synthetic organic pesticides, resistance increased rapidly; more than 200 species of insects and mites are known to be resistant to some type of insecticide. Rodents, particularly the brown rat and house mouse, have shown resistance to anticoagulants. To oversimplify the situation somewhat, strains that become resistant to one insecticide also may be resistant to a second that has a mode of action similar to the first (cross resistance), or they may become resistant to a number of pesticides with different modes of action when they are exposed to these pesticides simultaneously or in sequence (multiresistance). Resistant strains of a species, for example, the housefly, may arise independently in many areas of the world. Once resistance has developed it tends to persist in the absence of the pesticide for varying periods of time, depending on the type of resistance and the species of pest; this resistance will gradually decline but can be very quickly restored by renewed exposure to the pesticide.

Kinds of resistance

The following may be factors in resistance: body coverings or digestive systems that are not penetrated by poisons, extra fatty tissues that can store pesticides, excretory systems that eliminate pesticides or their toxic metabolites, behaviour patterns that avoid spray deposits, and general vigour. The chief physiological basis of resistance, however, lies in enzymes that detoxify the poisons. In DDT-resistant houseflies, for example, DDT is broken down into nontoxic compounds by an enzyme.

Treatment with wide-spectrum chemicals has often unexpectedly resulted in the rise of surviving populations, which then cause more serious damage than the pest that was eliminated. The majority of pest problems arising from pesticide usage occur from outbreaks of species other than those against which the chemicals were used. In these cases the pesticide eliminates the natural enemies that previously held undesirable species in check. Thus, at times, chemical treatment trades one set of pests for another. This situation arose in the classic case of the control of the cottony-cushion scale (*Icerya purchasi*) by the vedalia beetle (*Rodolia cardinalis*). This predator maintained the pest at a noneconomic status from its introduction in 1888 until about 1947 when the use of DDT on citrus became widespread to control other pests. The vedalia beetle was accidentally eliminated by the DDT, and in its absence the cottony-cushion scale increased to such numbers that complete defoliation occurred in some cases.

In spite of heavy mortality at the time of treatment, use of pesticides sometimes results in a subsequent increase in the density of the pest against which the pesticide was applied. This phenomenon is called flareback, or pest resurgence. Flareback has been recorded for at least 50 species of pests. It can arise for a number of reasons but, in most cases, the pest's natural enemies are eliminated either by the direct effects of the pesticide or by the suppression of the pest itself. In the absence of their natural enemies, the surviving pests can increase their numbers very rapidly.

Pest flareback

Natural enemies of pests can be eliminated from untreated areas if adjacent ones are sprayed. The pesticide sometimes drifts at the time of application so that untreated areas receive dosages often toxic to the natural enemies but not to the pest. Or natural enemies may move through treated areas and become exposed to residual insecticides, thus being "trapped out" and killed.

There are other possible ways in which pesticides may alter the abundance of a species. Although most research shows that the effects of sublethal doses of chemicals are detrimental to pests, such doses appear to have increased the fertility of target species in some instances. Sublethal doses may also reduce the reproduction and development of the natural enemies of pests.

Because pesticides are poisonous compounds, they may adversely affect organisms other than those against which they were originally applied. These hazards to nontarget species or to man can be separated into two classes: the immediate, toxic effects at the time of ingestion or absorption, and the long-term, chronic effects from the gradual assimilation of minute quantities of persistent materials.

Pesticide toxicity varies among the higher animals. Some pesticides, such as the arsenicals, are true biocides, harmful to all living things; many possess varying degrees of

selectivity in insects, birds, and mammals depending on the species and the compound. Some, such as malathion and carbaryl, pose a slight or nonexistent danger to higher terrestrial animals. Pesticides can destroy beneficial insects such as pollinators, as well as pest species. Seeds treated with insecticides have killed birds that consumed them. Some insecticides, such as the organophosphates, are extremely toxic to man and require great care in their manufacture, handling, and application. The ingestion of contaminated food also presents a hazard to man and domestic animals. The protection of food quality is maintained by two means. First, in most countries spray calendars are prepared that indicate the type, amount, and time of application of pesticides for each crop. Second, the maximum permissible amount of residue of each pesticide on various foods has been established in many countries. Some injury to wildlife may occur at the time of application, and incorrect procedures may lead to fatalities among humans, but pesticides cause far fewer direct deaths than many of the other products of advanced technology.

Accumulation of pesticides in the environment poses a much more serious threat to the welfare of man and wildlife. When a pesticide is applied, much of it reaches the soil. Water becomes contaminated from direct application, drift, runoff from treated areas, or waste materials. Minute quantities of pesticides become airborne from volatilization and wind erosion. Many of these chemicals are short-lived or are metabolized by the animals that ingest them. But some are persistent and when applied in large amounts they pervade the environment. The main soil contaminants are arsenic and the chlorinated hydrocarbon insecticides such as DDT, aldrin, dieldrin, heptachlor, and BHC, along with their toxic by-products. The amount that can accumulate is surprisingly large; DDT, for example, has been found in agricultural soils at rates up to 10–100 pounds per acre. Even though they are almost insoluble in water, the persistent organic pesticides are widespread because they are adsorbed to particles of organic matter and become dispersed with them; organic chlorine residues have been found in animal tissues ranging from the Arctic to Antarctic oceans.

Pesticides in food chains

The significance of the persistent pesticides as mortality agents in natural communities is greatly increased because they become associated with food chains. This association has two important consequences. First, some species at the lower end of the chain may be highly susceptible to pesticides and thus the entire chain is destroyed; those species above it lose their food supply. Second, when species at the lower end are resistant, they pass the pesticide to the next species in the chain. This process concentrates the toxicants by a factor of hundreds or perhaps by thousands. Earthworms, being resistant, accumulate DDT without dying but a bird that consumes many such worms may die. Because of the phenomenon of concentration, predators at the top of the food chains are usually the most severely affected.

The usual accumulations of most chlorinated hydrocarbons are harmless to plants and soil micro-organisms, but many organic phosphates, when abundant, reduce plant growth. Minute traces (often measured as parts per thousand million) of chlorinated hydrocarbons can reduce the photosynthesis of marine algae. Marine invertebrates inhabiting coastal waters are particularly susceptible to the organic chlorines; concentrations as low as 0.1 part per thousand million have destroyed mollusks, and other low dosages have killed crabs and shrimp. Many fishes are susceptible to persistent insecticides.

More is known, probably, about the effects of the persistent insecticides on birds than on any other group. Some may die from eating insecticide-treated seeds. Serious population declines or near extinction have been observed in some carnivores at the top of the food chain—the peregrine falcon, bald eagle, osprey, Cooper's hawk, golden eagle, and kestrel. The declines are traceable to a drop in reproduction rather than to the death of adults. Reproductive failures result from delayed breeding, failure to lay eggs, and fragility and breakage of eggs that are laid.

Because the persistent pesticides are so widespread, it is not surprising that they are found in human tissues. The concentration of DDT and its metabolites in fatty tissue varies with person, place, and time. Its average concentration appears to vary from about 4.5 to 8 parts per million for whites and from about 6 to over 16 parts per million for nonwhites. Dieldrin concentrations, on the other hand, are more uniform and much lower (0.04–0.17 parts per million). Lead and arsenic can also accumulate in mammalian tissues; there are 30 atoms of lead for every molecule of DDT circulating in a unit volume of blood.

Because of the clear danger to wildlife and the possible hazard to humans, the use of DDT and other chlorinated hydrocarbons has been restricted by many governments. The amount of DDT used in Canada in 1970, for example, is estimated to be 10 percent of that used in 1967; it is being restricted in the United States, and it has been banned in Sweden. The pattern of legislative restriction continues to change rapidly, however, and a definitive statement cannot be made on this aspect of the pesticide problem.

BIOLOGICAL PEST CONTROL

Although pesticides have proven to be necessary in control programs, they add to the cost of crop production and they give rise to a number of undesirable side effects. Consequently, there has been a renewed interest in previously used nonchemical control methods and in the development of new alternative approaches to pest control in recent years.

The principal methods of biological control. *Cultural control.* Cultural control is concerned with manipulating the environment to make it less favourable for the pests. Because the most vulnerable stage of a pest must be determined, cultural control requires a thorough knowledge of the pest's life history and habits. Some methods are designed to prevent injury to the crop and therefore they must be employed before pest populations become apparent. Others destroy part of the population when the pest is in a susceptible stage of its life cycle. These methods are usually slight modifications in the normal manner of carrying out farming practices. Just as there are many farming practices, there are many cultural methods of control.

Crop rotation

Rotation of plants in cultivated lands or of animals on grazing areas is an important method of limiting pest damage. Crop rotation is the practice of growing a succession of different crops on the same land; it is most effective against pests having limited host range and limited powers of dispersal. Within the rotation there should be some crops that are not suitable for the development of the pest, and the rotation should be sufficiently long so that the pest cannot overwinter for more years than the length of the rotation. Crop rotations can be used to reduce the damage from both insects and disease.

Tillage of the soil at times when crops are not grown will remove weeds, stubble, and volunteer plants that would otherwise provide a reservoir of the pest population and lead to later infestation of newly planted crops. Cultivation will help by either burying pests so deep that they cannot emerge or by bringing them to the surface where they will be destroyed by weather or natural enemies. Clean summer fallowing is often used to reduce plant pests by eliminating their food supply for a season.

Sanitation is an important cultural control method. The destruction of plant refuse often destroys pest populations and so reduces injury to future crops. Many pest populations can develop or overwinter on native vegetation growing on the borders of cultivated fields and later migrate into the cultivated crops. Plowing or burning these areas destroys this source of infestation. A special case arises with alternate host plants. In rust fungi, for example, there is a very complicated life cycle, in which two hosts are necessary. With stem rust of cereals (*Puccinia graminis*) the alternate host is barberry (*Berberis* species) so that the life cycle of this pest may be broken by eradication of the barberry.

Other cultural methods include use of trap crops that are destroyed before the pest can develop, modification of

planting times or spacing, and modification of harvesting techniques.

The use of resistant plant and animal species. Through the normal genetic processes of breeding and selection, man has been able to modify many natural varieties of plants and animals to produce characteristics that he desires—quality of produce, quantity of yield, time of maturing, etc. The same techniques make it possible to develop varieties that also exhibit resistance to attack by pathogens and insects.

There are a number of factors that help plants to avoid attack by fungi. Spores may not find conditions suitable for germination in some plant varieties. If they germinate, they may not be able to secure penetration into the leaf. The pathogen may find growth conditions unsuitable within the host, or the invader's development may result in a response by the host plant to produce structural changes or toxins against the invader.

There are usually three components of resistance to attack by insects: nonpreference, antibiosis, and tolerance. Nonpreference is exhibited by insects that will die before feeding on a plant that otherwise would nourish them. Adults may refuse to oviposit on nonpreferred plant hosts. Nonpreference may also play a role in the resistance of some domestic animals to insects such as flies. Antibiosis is the term used to describe the detrimental effects on an individual pest that result from feeding on a resistant host plant. The results may be death, lowered reproduction, smaller size, or modification of length of life. The tolerance component of resistance operates when the plant withstands populations of the pest that would ordinarily injure a susceptible host. It is found mostly in plants that are attacked by insects with sucking mouthparts, such as aphids, and in which damage results from loss of fluid, or other processes that result in stunted growth.

To develop resistant biotypes of a species, cultures of the pest against which resistance is to be used are maintained. Next, a search for resistance is undertaken by looking for plants or varieties that exhibit little damage under pest attack, compared to common varieties of the species. Because the search for resistance is really a search for genes conferring resistance, it is necessary to prove the genetic basis of the resistant strains by comparing their progeny with standard varieties. Tests for resistance are then carried out in various environments to prove inheritability. When proven resistance is found in combination with other desirable features in a plant, it is then propagated until commercial quantities are available. The whole process may take years to accomplish and is a very complex procedure.

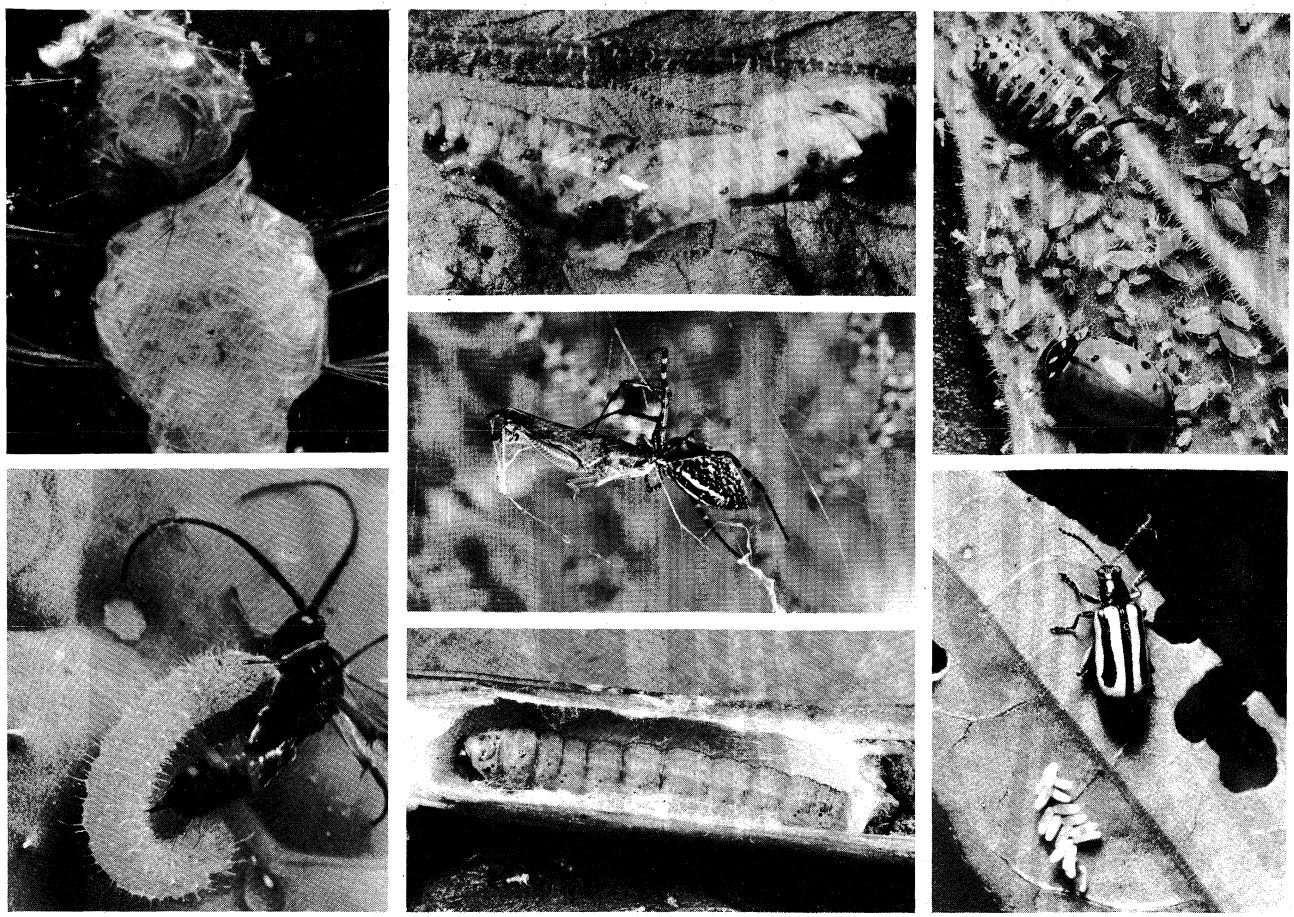
The use of natural enemies. Many pests are species that have been transferred unintentionally to an area from other regions of the world. In their original habitat, they are often harmless, being regulated at low and uneconomic densities by the physical and biotic factors of their environment. Their pest status in the new region might result from the absence of natural enemies that were effective in the original habitat or from the ineffectiveness of native enemies in the new location. An obvious method of pest control consists, therefore, of seeking out the natural enemies of a pest in its original habitat, or in an area similar to the one in which the species is to be controlled, and introducing it into the new area. Attempts are also made to conserve and augment natural enemies to make them more effective. This method of managing natural control is sometimes referred to as biological control. Many types of organisms have been used to combat pests, but the principal ones have been parasites, predators, and pathogens (fungi, bacteria, viruses, protozoa, nematodes), which attack insect and mite pests, and insects, which attack noxious weeds.

Parasites and predators

Insect parasites and predators develop at the expense of the pest population against which they are employed. Insect parasites develop either internally or externally on the host; each successful contact by an ovipositing female usually is sufficient to ensure the death of the individual host and the production of a new parasite in the next generation. Predators, on the other hand, usually consume more than one pest in the course of their development and reproduction. The interactions between natural enemies and the pest population results in self-regulating mechanisms that, when successful from man's point of view, lead to the more or less permanent regulation of the pest population at noneconomic levels of abundance.

Parasites and predators are highly specialized and are especially sensitive to the environmental conditions in which they operate. Probably any natural enemy could regulate pest abundance at low densities if conditions were always ideal. Conditions in the area of introduction, however, are not usually completely identical with the original habitat (where the natural enemy was very effective). The results of this type of biological control are variable: some are completely and permanently successful, some are substantially so, some are partially successful, and the remainder are failures.

When control by parasites and predators is not complete and permanent, it may be possible to make these agents more effective either by conservation or by augmentation. Conservation of already established natural enemies is accomplished by making slight modifications in the environment through the use of suitable insecticides, use of alternate host plants or host insects, diversification of plants and animals, provision of suitable shelters and nesting sites, and adjustment of agricultural practices. Augmentation is necessary when seasonal weather extremes are deleterious to the natural enemies. They can then be recolonized periodically by rearing and releasing them at the proper stage of pest development. They may also be reared in very large numbers, if this can be done cheaply, and used to inundate the area occupied by the pest, just as would be done with a chemical pesticide.



Viruses and bacteria are the most successful and widely used control agents among the more than 1,000 species of micro-organisms found associated with insects. Two important groups of bacteria are the crystalliferous spore-formers and those causing the milky diseases; in the former group, protein crystals toxic to certain insects are formed at the time of spore formation. Like stomach insecticides, both viruses and bacteria must be ingested in order to be effective as pesticides.

In many laboratory studies on competition, one species has been observed to displace and eliminate a second when both were using the same food supply. This same phenomenon can occur in nature. It seems possible, therefore, that man might attempt to eliminate a pest from a given habitat by displacing it with a competitor that, from man's point of view, is relatively harmless. This concept, called competitive displacement, has great potential in a limited number of cases. The larvae of certain blackflies, for example, might be displaced from their aquatic habitats by species that are not so objectionable to man.

Competitive displacement

When crops are grown under intensive cultivation, weeds may be satisfactorily and economically controlled by physical, chemical, and cultural methods. On open rangeland, however, these methods are not practicable, and an alternative method of controlling weeds, particularly those that are imported from another region, is required. Organisms attacking plants can be used to reduce this form of pest to a noneconomic status but not to eradicate it. As with insect pests, the natural enemies of weeds are sought in areas in which they maintain their hosts at noneconomic levels of abundance. The chief natural enemies used for this type of biological control are insects, but other organisms such as mites, vertebrates, microorganisms, and fish (for aquatic weeds) have been used. Insects affect weeds in two ways: either they attack and destroy some vital part of the plant, resulting in its quick or delayed death, or their attack on the plant causes infection by micro-organisms or reduces the weed's competitive advantages over more desirable vegetation.

Probably the most difficult part of a program of managed biological control is deciding what natural enemies are to be used in a particular situation. The identity of the pest must be established precisely, and its enemies that may be scattered throughout the world must be determined.

Biological control of pests.
Microscopic and submicroscopic organisms control the growth of insects by infecting and killing: (top left) the head and thorax of a mosquito larva filled with nematodes; (top centre) the larva of the cabbage looper (*Trichoplusia ni*) killed by a virus. Some insects are predatory or parasitic on others: (top right) adult and larval ladybird beetles feeding on aphids; (centre) a spider eating a grasshopper caught in its web; (bottom left) a wasp (*Apanteles rubecula*) laying eggs in the destructive cabbageworm larva. Insects check the growth of some plants: (bottom centre) the stem-boring caterpillar of the moth *Vogtia malloi* constructing its cocoon in the stem of alligatorweed; (bottom right) the alligatorweed flea beetle (*Agasicles*, adult and eggs) feeding on its leaves.

Once the required species of natural enemies, and the locations from which they are to be collected, have been determined, the organisms are gathered and sent to the country or region where they are to be used. Because there is a great danger of inadvertently releasing unwanted species, the imported material is always handled under strict quarantine conditions. The natural enemies may be held or reared from their hosts when required and then shipped to the area of pest infestation for release at the appropriate stage of pest development. Large-scale propagation requires mass production of the appropriate hosts, which, in turn, demands extensive laboratory facilities, a detailed knowledge of the biology of all species involved, and development of techniques for handling them. Once the natural enemies are released among the pest population, it is necessary to determine whether they have become established and, if so, what effect they exercise in reducing pest damage.

Insect pathogens

Insect pathogens are produced in a number of ways. Because viruses develop only in living tissues, they can be propagated in laboratory reared insects or from infected insects collected in the field. Artificial diets are used in laboratory rearing, where possible, to increase the production efficiency of the host insects and to limit the possibility of competitive diseases developing—one of the main problems in the propagation of insect pathogens. After the viruses are produced, appropriate dosages must be standardized. Some spore-forming bacteria are propagated in living insects, which are later ground up to yield enormous numbers of bacteria. Bacteria produced on an artificial substance are obtained by drying the medium so they can be held in storage until required. Although some fungi need to be propagated on their hosts, most can be produced on artificial media.

One of the many advantages of the spore-forming bacteria and many viruses is that they can be stored without loss of virulence for long periods before use. They can be applied as a spray or extended with carriers and used as a dust. These pathogens may be used in two ways. First, they can be applied to a local infestation and, if the biology of the pest insect is suitable, they will spread throughout the population; this can lead to permanent control. Second, they may be applied like chemical insecticides, for short-term control, particularly if a relatively high level of insect damage can be sustained by the crop.

The selection, importation, propagation, and release of plant-eating insects to control weeds is, in principle, similar to the use of insect parasites and predators to control pest insects. It is important, however, to conduct detailed safety tests before this type of natural enemy is released, to be certain that only the target plant will be damaged.

Sterilization. The sterility technique in pest control causes an insect to bring about the elimination of its own populations. The basic idea is that sexually sterilized insects will mate freely with individuals in the natural population and thus greatly reduce the numbers of fertile eggs laid. To do this, sterile matings must exceed normal matings considerably to ensure continued population decline in successive generations.

Insects may be sterilized by irradiation or by certain

chemicals. The principal ionizing radiations are X-rays and gamma rays. Radiation induces sterility by destroying or inactivating the sex cells (egg or sperm), or by inducing fatal genetic changes (lethal mutations) in those cells. The action of chemosterilants results in either the failure to produce eggs or the death of eggs and sperm after they are produced, or in the induction of dominant lethal mutations.

The sterility principle can be applied in two ways. First, the pest may be reared in very large numbers, sterilized, and released among the natural population. Second, sterility may be induced in natural populations by using chemosterilants, usually in baits, to sterilize males and females in their native habitat. The use of chemosterilants in nature leads to two types of sterility: that of females that consume the chemosterilant and that of normal females that happen to escape sterilization but mate with sterilized males.

Each pest problem must be investigated in great detail before it is decided that the sterile-insect approach is practicable. The rearing of and the induction of sterility in the pest species must not reduce the competitiveness of the sterilized insects. The treated species must be easily and inexpensively reared. The released individuals must not become pests themselves or increase the extent of the damages inflicted by their normal counterparts. Normal females must not be exceptionally prolific.

Attractants. Most insects respond instinctively to numerous stimuli as they develop into adults and reproduce. Stimuli may control movement, feeding, copulation, and egglaying responses of insects. From the point of view of control, however, interest has centred largely on stimuli produced by chemical attractants.

Two important classes of naturally occurring attractants are the pheromones and the food lures. A pheromone is a chemical that is secreted into the external environment by an animal and elicits specific response in another individual of the same species. The sex pheromones (sometimes called sex attractants or sex lures) cause orientation and approach of a sexual partner from a distance. The amount of material required to elicit response is extremely small. Sex pheromones are usually produced by the female insect but may originate with the male. Sex pheromones have been isolated and identified in a number of insects, including the silkworm, gypsy moth, pink bollworm, cabbage looper, and honeybee queen. A second type of pheromone is the aggregation pheromone. The feces and frass produced by male bark beetles that have been feeding on fir trees, for example, contains a volatile attractant that orients flying populations of males and females to the area.

Food lures

Food lures are generally chemical substances emanating from plants, and they have been identified in many instances. Thus floral scents attract insects seeking nectar, essential oils attract plant-eating insects, scavengers respond to decomposition products, and bloodsucking insects respond to animal products when the levels of moisture and carbon dioxide are high.

Even though natural powerful attractants such as the sex pheromones can be isolated from insects, a great amount of labour yields very little. An obvious solution to this problem has been to make some of them synthetically. Methyleugenol for the Oriental fruit fly; anisylacetone and cue-lure for the melon fly; siglure, medlure, and trimedlure for the Mediterranean fruit fly; gyplure for the gypsy moth; and bombykol for the silkworm are examples of synthetic attractants.

The synthetic and food lures may be used in pest control either as a means of detecting insects or as part of a control program. In survey and detection work, a lure specific for one species permits the determination of the range of a new pest and allows insecticides to be applied only where the species is caught. In control programs, traps baited with attractants may be used to bring insects into contact with insecticides, pathogens, or chemosterilants.

Other methods. An important aspect of control is the prevention of entry of a pest species into a country or area where it does not already exist. This is difficult to do in view of the great expansion in commercial traffic; nevertheless, quarantine procedures—*i.e.*, the interception of potential pests by inspection at points of entry—have greatly restricted the spread of noxious insects, diseases, and weeds.

An evaluation of biological control. *Benefits.* The attractiveness of the biological approach to pest control arises from the fact that each individual technique is developed to control one or a few related types of pest. Its use reduces the amount and distribution of pesticides, particularly the persistent ones, in the environment. These methods, therefore, reduce the risk of damage to nontarget organisms and to man, avoid the development of resistant strains of pests, and permit the normal ecological processes to operate much more freely. The cost of pest control may be greatly reduced in those cases in which the biological agents remain effective over a period of years.

The procedures of cultural control are associated often with normal farm practices and can be performed routinely before a pest problem arises. They are, therefore, both effective and inexpensive.

Selective breeding of plant resistance probably has been the most successful of all the biological means of controlling insect and disease damage. For insect pests, effects of resistant crop varieties are both specific and cumulative; resistance need not be complete because its persistence will ensure the elimination of the pest within a few generations. The cost of using resistant varieties is quite small and they can be used along with other measures. This compatibility with other measures permits use of varieties with a relatively low level of resistance that possess some tolerance to attack. The use of a resistant variety of one crop may reduce the population level of the same insect on a second crop. Because of their more normal growth, resistant plants often show an improvement in yield and quality. Strains of alfalfa, cotton, tobacco, beans, potatoes, and tomatoes have been bred successfully for resistance to specific diseases caused by fungi, bacteria, viruses, and nematodes. Resistance to the wheat stem sawfly (*Cephus cinctus*) and to the Hessian fly (*Mayetiola destructor*) has been developed in wheats, and resistance to leafhoppers has been produced in cotton.

More than 100 species of pests are either completely, substantially, or partially controlled by their natural enemies in over 60 countries throughout the world. At least 650 species of insect parasites and predators have been imported into the United States, and about 100 of them have become established and exert some control over about 50 species of pests. In Canada about a dozen species of pests are successfully controlled by this means.

Economic benefits

The economic benefits derived from the use of insect parasites and predators have been substantial. In California the net savings from major projects in biological control have been estimated at $110,000,000 over a 36-year period. The control of the coconut scale (*Aspidiotus destructor*) on the island of Príncipe gave a return over cost of 1,800 percent per annum. Control of the sugarcane borers (*Diatraea* species) gave returns over cost ranging from 200 to 25,000 percent per annum. Use of the vedalia beetle against the cottony-cushion scale in St. Kitts, Nevis, and Montserrat resulted in returns of about 450 percent per annum.

The control of the Japanese beetle by the bacterium *Bacillus popilliae* and of many moths by the crystalliferous bacterium *Bacillus thuringiensis* are examples of the successful use of the bacterial diseases. At least 20 cases involving control of insect pests by viruses have been recorded. Microbial pathogens are usually specific and therefore represent little danger to man, animals, or beneficial insects; and susceptible hosts are very slow to develop resistance.

The classic example of the "rear-and-release" technique, using radiation for sterilization, is the eradication, in the southern areas of the United States, of the screwworm (*Cochliomyia hominivorax*), a parasite of cattle. After eradication, barriers to prevent re-entry of this pest are maintained by periodic releases. More or less extensive field trials on additional species have been conducted; these include the Mediterranean fruit fly (*Ceratitis capita-*

ta), the Oriental fruit fly (*Dacus dorsalis*), the melon fly (*Dacus cucurbitae*), and the codling moth (*Carpocapsa pomonella*). Some limited field experiments have also been conducted using chemicals as the sterilizing agent.

Attractants in traps are used annually to survey for infestations of the Japanese beetle and the gypsy moth. An example of attractant use in a control program is the eradication of the Oriental fruit fly from the Pacific island of Rota; fibreboard squares, saturated with the attractant methyleugenol and the insecticide naled, were distributed in 15 biweekly treatments. The number of males removed from the population was so great that females were unable to reproduce.

Limitations. The great advantage of biological control methods—their specificity—is also a source of weakness. Usually several species of pests attack a given host plant. If biological methods can deal satisfactorily with perhaps three out of five pest species, two pests will still be free of restraint. In this case, it will be necessary to use a pesticide that could have been used initially to control all five species.

Biological methods may be very expensive, especially if they have to be repeated periodically. In the case of resistant varieties, for example, the time required to develop them, if they are not available when a new pest problem arises, may be excessive. For a wheat variety it may require 15–20 years and for alfalfa, 3–5 years. The development of resistant varieties may become an endless process because of the ability of pest species to change into new forms (biotypes) capable of attacking a previously resistant variety. The development of new biotypes appears to occur more rapidly among the pathogens, such as wheat rust, than among the insects.

Limitations of natural enemies

Although insect parasites and predators have been effective against a number of important pests, their use presents some difficulties. Many attempts to use them have been failures: whereas only 95 species of parasites and predators were successfully established in the continental United States between 1875 and 1951, about 390 other species failed to become established. The population dynamics of parasites and predators are dependent on the environment, so that a natural enemy that is effective in one region or during one year may not be in another. Even when successful, the growth of many parasite and predator populations lags behind that of the pest populations, so that damage may be inflicted before the natural enemies can become effective controlling agents. Usually, parasites and predators are more effective against pests attacking perennial plants than against pests of annual plants such as truck crops. Many parasites and predators are themselves attacked by carnivores.

There are also some difficulties attending the use of microbial control methods. The timing of the application must be correct. Usually, the pathogen is effective against only one pest out of all that are present. The pathogen must remain viable between the time of application and its actual contact with the insect pest; in some cases, its viability can be affected by the physical environment. Some pathogens are difficult to produce in large quantities. Even when microbial control methods succeed, other difficulties related to those methods may arise. For example, diseased insects that remain attached to crops are often objectionable.

In the development of pest control methods, the use of chemicals and biotic agents tended to be in conflict with each other. The problems that followed the introduction of the organic pesticides, however, led to the conclusion that both methods must be combined. Integrated control, as this approach is called, was, therefore, originally concerned with developing procedures in which chemicals and natural enemies could be used compatibly.

INTEGRATED PEST CONTROL

The concept of pest management. The term pest management is a summary definition of integrated control practices. Pest management implies both the manipulation of the populations to maintain them at noneconomic levels of abundance and the eradication of a pest species when this is attainable and desirable. Both control strategies are based on a thorough knowledge of the pest's biology and ecology before a control program is undertaken.

In developing an integrated program there are two groups of facts that must be determined in some detail. These are the structure of the agricultural ecosystem and the population densities of the pests below which little economic damage will occur.

Agricultural ecosystems. If pest control depends on manipulation of pest populations, it becomes necessary to develop techniques for analyzing the multitude of factors that influence pest density. The identification of the processes that determine community structure is one of the primary problems of modern ecology. The magnitude of the task may be appreciated from the example of Wytham Woods, where an area of less than two square miles of English countryside contains at least 2,500 species of animals.

Agricultural ecosystems, however, are usually based on one or a few species of plants and so are relatively simple compared with their natural counterparts. This simplicity, of course, is only relative: even with a single crop, alfalfa, about 1,000 species of arthropods have been found in association with it. An agricultural ecosystem comprises all of the organisms in a given farm location, together with the physical environment that prevails there. Usually, precise geographic limitations cannot be placed on the extent of such an ecosystem, but a sufficiently large area must be considered so that all of the biotic elements having an effect on pest density are capable of being evaluated. Thus the area surrounding a group of cultivated fields cannot be ignored, for it may harbour reservoirs of pests and their natural enemies. If some of these species are wide-ranging, their biology may require investigation.

Detailing quantitatively all of the factors that determine the abundance of each species in a simplified agricultural ecosystem is a formidable undertaking. In most agricultural and forestry habitats, however, there are only a few species of insects that are pests and often there is only one of major significance. It is thus possible to consider only one or a few subsystems that affect the target species in a significant manner. Once the major pest has been dealt with, consideration may be turned to other pests if necessary.

Economic thresholds. An integrated program requires a determination of the density of each pest that will result in economic damage to the crop. This is a difficult task because it involves estimating a series of factors, some biological and some economic.

Extent of damage inflicted depends, in part, on the type of pest. Major pests are serious, continuous, and persistent; they dominate control practices because they remain above economically damaging levels of abundance. Few insects in agricultural ecosystems are major pests; of the approximately 100 potential pest species in orchards, for instance, only about five can be considered major. Occasional pests cause damage only at certain places or times; they are suitable objects for integrated control because they permit corrective treatment when necessary rather than continual preventive measures.

Evaluating pest damage

Many biological factors may alter the evaluation of pest density in relation to pest damage. The susceptibility of a given plant to attack can be modified by variation in the physical environment, stage of development of the plant, irrigation, fertilization, and variety of crop. The type of injury that is sustained by the plant is quite important in determining to what extent a pest may be tolerated before economic injury results. Many plants can withstand some loss of leaves, stems, roots, or even fruits before appreciable damage is inflicted. But when pests attack and blemish harvestable crops or are carriers of diseases, even small numbers of them can inflict severe damage.

One important consequence of the concept of an economic threshold of pest damage is the acceptance by growers of noneconomic levels of pest populations in the agricultural ecosystem. The functioning of an integrated control program depends on the presence of at least some pest population as insurance that the natural enemy of

that pest will continue to be maintained. Integrated programs differ in this respect from programs that attempt to eradicate or maintain pests at the minimum densities attainable.

The combination methods of integrated control. Pesticides are, without doubt, the main tools in pest control, and an integrated program attempts to minimize their disruptive effects on the agricultural ecosystem by making them as selective as possible. Unfortunately, pesticides are not very selective, physiologically, among the arthropods, for they usually kill broad groups of organisms—including many species of natural enemies, which are generally more susceptible to pesticides than the pest species themselves.

Selectivity of even the broad-spectrum insecticides may be increased by the manner in which they are used. A limited area of pest infestation can be treated. A degree of selectivity can be achieved by applying pesticides at a time when beneficial insects are elsewhere or are protected. The success of timing can be greatly enhanced through use of pesticides with short residual action. Selectivity can be increased by lowering the dosage of a pesticide; at low dosages, some insecticides can decrease pest abundance but are not detrimental to all of the pest's natural enemies. Systemic insecticides absorbed by the plant and translocated to the leaves are effective against plant feeders such as aphids, mites, and thrips but are not usually harmful to their natural enemies. The use of attractants and seed treatments are means of localizing the distribution of pesticides.

Encouraging natural enemies of pests

Natural enemies should be fostered as much as possible, and the use of selective pesticides, when available, is an important means of accomplishing this. Food for natural enemies has been provided, in some cases, by maintaining an acceptable population level of pests in special plantings of alternate crops that support the pest or other hosts. Thus the supply of natural enemies is maintained and is available when needed. In other cases a host or an alternate host will develop on weeds or cover crops. Strip cutting of alfalfa in California allowed both the pea aphid and its parasite to persist through unfavourable hot, dry, summer periods. Provision of nesting sites also increases the density of beneficial species such as birds and wasps.

In addition to pesticide selectivity and enhancement of natural enemies, other components may be added to an integrated program. Resistant varieties may be used to augment control by natural enemies, which may not be completely effective alone. Insecticides can be combined with microbial agents such as viruses and *Bacillus thuringiensis*; when this can be done, dosages of each agent can be reduced. Chemicals can be combined with attractants to reduce populations yet limit pesticide distribution. The sterile-insect method works best when pest densities are low; an initial application of an insecticide can produce the necessary low densities.

An evaluation of integrated control. *Benefits.* Outstanding examples of successful integrated programs have been developed in three areas of the world.

In Canada control of apple and pear pests was accomplished through use of a modified spray program. At one time, over 80 percent of apple and pear acreage in Nova Scotia was under this type of program. In Quebec apple orchards, a modified spray program gave as clean a crop for approximately half the cost as that obtained with the normal spray program.

In California the spotted alfalfa aphid (*Therioaphis maculata*) was a pest until biological control was augmented by a selective chemical control program. After the successful integration of chemicals and natural enemies, the development of aphid-resistant varieties reduced the status of the aphid to minor proportions.

In the Cañete valley of Peru the production of cotton was seriously threatened while broad-spectrum insecticides were used in the control program. The insecticides were eliminating natural enemies and developing resistance in pest species. In the face of disaster, a series of changes in control programs, including the adoption of arsenates and nicotine sulfate, was made. The new program resulted in the return of many pests to their former harmless state, the diminution of key pest problems, an increase in cotton yields, and reduction of control costs.

Limitations. In spite of the great progress that has been made in developing integrated control programs, the approach has some limitations and is not always possible to apply. Since there are so many variable factors, in any given situation one or more of the central components of integrated control may be invalidated by specific circumstances; for example, natural enemies are not effective in all crops. Or a pest may be so difficult to control as to require a highly toxic broad-spectrum insecticide. Although a pest may be susceptible to low dosages of a highly selective insecticide, residues of this compound may be very dangerous to other organisms, including man, and therefore a more broadly toxic chemical with shorter residual effect must be used. Integrated programs are successful only when supervised by highly qualified specialists, and the techniques employed may sometimes be more costly than normal control programs. When control cannot be obtained, the best solution is to grow crops less susceptible to pest infestation.

Integrated control limitations

PRODUCTION AND CONSUMPTION OF PESTICIDES

The United States produces from 50 to 75 percent of the world's pesticides, an appreciable portion of which is exported. As other countries develop manufacturing facilities, this percentage is expected to decline.

The use of pesticides throughout the world is indicated in Table 2. Pesticides tend to be used against pests attacking the large monocultures; in the early 1970s in the United States about two-thirds of all insecticides, for example, were applied on three crops: cotton, corn, and apples. Although use of DDT in American agriculture is declining, this pesticide is still used extensively in foreign malaria eradication programs.

Table 2: Estimated Quantities of Biocides Used in or Sold to Agriculture, 1967
(active ingredients, in tons)

biocide	U.S.	Canada	Italy	Egypt	India	Japan
Pesticides						
DDT	20,128	842	2,007	2,506	3,165	794
Benzene hexachloride	...	40	4,901	...	25,637	3,468
Aldrin	...	216	4,467	...	337	253
Endrin	43,144	33	37	573	827	140
Organophosphates	54,660	934	4,736	2,390	2,340	2,516

Source: *Production Yearbook*, vol. 22, Food and Agriculture Organization, United Nations, 1967 and 1968.

The production and use of pesticides will, in all probability, increase even more rapidly in the future than it has in the past. In the United States production of synthetic organic pesticides is expected to increase at an annual rate of 15 percent and to reach sales of $3,000,000,000 by 1975. Use of insecticides is expected to at least double by 1975, with sales reaching $600,000,000.

Although some insect parasites and predators, and microbial pathogens such as *Bacillus thuringiensis* are available commercially, the development and execution of biological control programs has, until now, been largely the responsibility of government institutions.

(1968–69), an extensive work on pests and their management, including volumes on weeds, plant diseases, insects, nematodes, and vertebrate pests.

(T.B.)

Pet

Generally, a pet is an animal tamed and kept as a favourite or treated with fondness; however, the range of animals kept by modern man is so wide that the words tamed and fondness must be qualified.

Most pets have been selected from animals that were domesticated early in man's history and have entered into a special, and more or less permanent, relationship with man. They differ from the original forms not only in size, colour, and shape but also in temperament. This inherited capacity to live cooperatively with man may be only potential in some animals, as with horses, which must be individually tamed and trained; others—in particular, the cat—are usually prepared to accept at once their place in the household. In contrast, numerous wild animals are brought into captivity and spend the rest of their lives as captives, some more willingly than others by reason of their temperament or the patience of their masters.

A pet is kept for its own sake and for the pleasure that it gives its owner. For a wide range of higher animals, especially horses, dogs, cats, and primates, this pleasure appears to be mutual. Pet keeping, therefore, is essentially a symbiotic, or mutually beneficial, animal–human relationship. Keeping pets satisfies a deep, universal human need, and pets are found at every cultural level.

ORIGIN AND HISTORY OF PETS

The dog as the first pet

The dog, which became domesticated long before any other species, must have been the first true pet. A working relationship probably formed between early man and the wolves that lived around his settlements and gradually evolved until certain individuals became tame and were then regarded as settlement or household dependents as well as partners in hunting and guarding duties. True domestication slowly followed, and the dog had arrived; later came the deliberate selection of a range of breeds illustrated in many ancient carvings and paintings. In Mesopotamia the giant mastiffs were used in the lion hunt; in Egypt the tomb paintings depict greyhound-like dogs and short-legged terriers resembling those of today. In some periods of history man seems to have had a special affinity for animals; this was markedly true in the 12th dynasty in Egypt (1991–1786 BC) when hyenas and lions were tamed and trained and the cat began to be domesticated. This faculty for keeping animals was gradually lost, to be revived some 200 years later, in the time of Queen Hatshepsut.

Of classical references to pet keeping, two in the Bible are well known. In II Sam. 12 Nathan speaks of a ewe lamb brought up in the family of a poor farmer, a practice that is still common. Because of their scavenging habits, house dogs were not kept by the Jews, but in Mark 7:28 a foreign woman spoke of her little pet dogs that sat under the table.

THE RELATIONSHIP OF PETS TO MAN

Companionship. A wide range of pet–owner relationships is found, the worst of which is little but exploitation. An extreme example of this is the overfed, underexercised dog that has been taught no discipline and whose life contains little of interest or excitement; the selfish owner may keep it alive long after its existence becomes a burden because he or she cannot face losing it. Equally unsatisfactory is a relationship so loose that an animal hardly regards itself as attached to a family, which may feed it but takes little other interest in it.

The emotional relationship between owner and pet is not easy to define, but it seems that most human beings have a latent capacity to seek contact with animals, mostly but not only with furred animals. Modern experience in the pet trade and in zoos suggests that this desire is heightened by living in urban surroundings.

The instructive value of pets

Keeping pets offers the opportunity to teach children the close dependence of privilege on responsibility and also something about sex; the process of mating is soon noticed, followed by such matters as gestation periods and the varied problems involved in the birth and care of young.

Almost by definition, pets kept as companions must also give pleasure and satisfaction. In addition, many animals are kept as personal pets, in the broader sense, to which the description "companion" cannot possibly be given. They are scarcely aware of any relationship with man, for they live in reasonable replicas of their habitats. All invertebrates fall into this class, and, because of their different physiological needs, all fishes and amphibians. This indifference to man is generally true of reptiles as well, but a few snakes, especially captive pythons, appear to seek and enjoy the proximity of humans.

A contrast exists between mammals and birds of domesticated stock and those whose immediate ancestors are truly wild. With the former a more satisfying, complete, and lasting relationship is likely. Such is possible in the latter groups also, but the term companion can be applied properly only to the exceptions. In such cases, which may occur in widely varying groups of mammals and birds, the human, in effect, replaces the mate or, at least, a companion of the same species. Many such animals revert to the wild when they become adult, a pattern particularly true of the large apes. In others, when a mate is accepted, the temperament changes radically, and they can no longer be handled; if the introduction is not made, however, until one or other has long been adult, mate acceptance is unlikely. Moreover, if both animals have been tame, the chance of mating is small and of breeding even less; this is the most likely explanation of the failure to mate many long-term inmates of zoos. The rather vague term humanized is often applied to such animals. From the human side there is some support for this substitute theory; the most extravagant examples of lavish coddling, especially of cats or toy dogs, usually involve unmarried or childless women, often in later life.

Partnership. The relationship between an animal trainer and his animals is a special one, for they form a team to earn money; yet the bond joining them is close, and, although these animals often live in cramped quarters and under artificial conditions, many seem to enjoy a more interesting and satisfying life than the average household pet. This does not constitute an endorsement of all that goes on, especially in the training, but it is clear that most trainers have a deep concern for their animals, which can truly be described as their pets. They are indeed tame animals, whether of wild or domestic stock, in which obedience training has been pursued to an extreme. The training consists largely of noting what individual animals enjoy doing, and developing that habit in an interesting way.

Scientific observation. The margin between keeping pets for their own sake and as objects for serious study is narrow. The wild animals forming the subject of many books often come into human care by accident. The immediate objective, in such instances, is a humanitarian one, providing its own unique satisfaction; this phase is followed by the pleasure of companionship and then the recording of valuable facts about animals hard to observe closely in the wild.

Pets in studies of animal behaviour

It is doubtful whether any animals used solely for scientific study can truly qualify as pets. Many are subjected to observations and experiments and are unaware that they are being studied (in many cases the development of a personal relationship would invalidate the results).

Some aspects of animal behaviour are best studied when the subjects are living free, yet secure and approachable because a special relationship has been built up with the observer. Foremost in this field of ethology is the German zoologist Konrad Lorenz, whose pioneer work is recorded in several popular books (see bibliography). His deep understanding of animal psychology made a family of jackdaws regard him as one of themselves and a flock of greylag geese take him as their leader. Other persons have come to the same terms with wolves, chimpanzees, and gorillas.

KINDS OF PETS AND THEIR NEEDS

Basic requirements. It is important to realize that human standards are not of much use in determining the best way to meet the varied needs of the different pets kept by man. This is best illustrated by mentioning certain basic needs for all kinds of pets. Variety in food is largely an invention of civilized man. For most animals, and also for man in many parts of the world, change comes only with the season. A little variety may be useful in keeping some sensitive higher animals interested in food, but the first requirement is a balanced diet appropriate to each species, adjusted when necessary to individual need or whim. Overfeeding is never good; as with humans, it often results in obesity, lethargy, and shortening of the life-span.

Correct design of pet quarters is usually more important than the total area enclosed. Any group of animals, tame or wild, includes bullies and the bullied; a good plan lets the latter keep safely out of the former's way. Many nocturnal pets find security by day in dark holes that other animals would regard with mistrust, and they may be badly upset if disturbed. A dog's kennel gives him a safe feeling; with his rear protected he can be watchful of the area before him.

Some animals carefully deposit waste products away from their immediate living quarters. Others, however, including lorises and bush babies, put urine on their feet to mark their territory; such an odorous condition is necessary to give a sense of security.

Long walks are desirable for some pet animals, such as dogs, whose makeup has been modified by generations of living with man, but few adult wild animals take exercise for its own sake; they run hard when they must—to kill or avoid being killed.

Proper handling is basic in establishing human–pet relationships; some animals enjoy much physical contact, while others dislike even being touched.

Few pets are kept whose needs are not well known; careful study of these should show whether or not an animal will fit into a particular household. Most pets cannot fend for themselves, even for a weekend, and any decision about keeping an animal must take note of the degree of care it requires.

Household pets. *Dog.* The dog is the most variable domestic animal, with more than 100 breeds, ranging in size from two to four pounds (one to two kilograms) for the Chihuahua to over 200 pounds (100 kilograms) for the St. Bernard and the mastiff. Many crossbred, or mongrel, dogs make delightful pets, but their adult size and shape are often unpredictable, and, contrary to popular belief, they are not necessarily of better temperament than a pedigreed dog. As a general rule, a dog becomes attached to people, a cat to premises (see DOG).

Cat. Partly because of its independent nature and nocturnal wanderings, the cat has comparatively few breeds. Shape and size vary rather little, the differences being mainly in coat length and colour. All cats make good pets, but long-haired breeds should be kept only in homes where they will be groomed daily (see CAT).

Birds. First kept widely in Europe in the 16th century, the canary is still a favourite singing pet. There is much variation of plumage in the show breeds, in which singing is less important. The canary is ideal for a room pet. The wild budgerigar, from Australia, is green, but variants have been selected in many shades and combinations of greens, blues, and yellows, with white and gray. Since they are clean, easily looked after, and cheap to feed, budgerigars (often called parrakeets) make excellent pets, especially for older people living alone. Most individuals of both sexes can be taught to repeat simple phrases. Of the 300 or so parrot species seen in aviaries, the gray parrot of central Africa and the Amazon parrots of South America are the only ones commonly kept as house pets. They are, however, expensive and often noisy, and their powerful beaks make them destructive and capable of severe bites. A member of the starling family, the mynah, is one of the best talking birds. It requires large quantities of soft fruit and may often be messy in its habits.

Other birds kept as house pets include pigeons and doves. There are many varieties of these birds, some of them highly ornamental; they are often kept at liberty, with access to shelter but free to fly in the neighbourhood, where they unfortunately may cause damage.

Poultry and waterfowl are kept primarily for commercial and ornamental purposes, but a few individuals—notably among ducks, geese, and chickens—become unusually tame and are adopted as members of the household.

Vivarium pets. When kept as pets, reptiles and amphibians frequently require special conditions of heat and humidity. For this reason they are best kept in glassed enclosures called vivaria. These animals have no internal temperature regulation and in nature their activity varies with the season. Species of temperate climates can do well at room temperatures and, in the case of some, even outdoors, but they must be allowed to hibernate as winter approaches. The vivaria can be put outdoors in autumn and filled with leaf mold or light soil; when the weather has turned cold, they can be taken in and stored in a cold but frost-free location. Alternatively, early in autumn the animals can be released in suitable places to hibernate.

Tropical snakes, lizards, turtles, frogs, and toads require special treatment. These animals are imported from warm countries, and all are used to being active throughout the year, though not always in the same degree. They need warm quarters at all times, preferably with day and night variation that simulates their native environment. Furthermore, for many people a big difficulty is that snakes, lizards, frogs, and toads eat live animal food. Only experts should keep venomous snakes.

Aquarium pets. Fishes constitute a completely separate section of the pet world, and a worldwide industry exists for catching, breeding, transporting, and supplying stock, as well as for making a great range of equipment and formulating special food. Fishes can be divided into two main groups: cold-water and tropical. Each of these categories may be divided further into freshwater and marine, the largest being the freshwater tropical. Many hundreds of species are available, and there is a rich literature on the subject, with many specialist magazines.

Insect pets. Although enthusiasts in many countries study live insects as a hobby, only a few kinds of insects are of widespread general acceptance as house pets. Stick insects are the easiest to keep; they can be fed privet leaves and do well in simple containers at room temperature. The larvae of silk moths, the semidomesticated form of which yields real silk, can be fed on mulberry or lettuce leaves; they grow to full size before pupating and emerging the following year as silk moths.

It is possible to establish colonies of several kinds of ants in artificial nests in which they can easily be observed under glass.

Hutch pets. Of the common hutch or cage pets, rabbits and guinea pigs perhaps do better when kept in a protected situation out-of-doors, while rats, mice, hamsters, and gerbils thrive under room temperature conditions.

Rabbit. Rabbits are available in many sizes—from the 2½-pound (1-kilogram) Netherland dwarf to the New Zealand and Flemish giant of 12 pounds (5½ kilograms)—and in many colours and patterns, with coats of various lengths and textures. The small and medium sizes are best as pets (the larger are often raised for fur and meat). Rabbits are heavy drinkers and feeders, taking large amounts of roots, leafy shoots, grain products, and hay (modern feeding is based on high protein dried grass pellets and hay).

Guinea pig. There is little variation in size or shape of guinea pigs, but a wide range of colours and three types of coat—short, rosette (Abyssinian), and long (Peruvian). Guinea pigs feed on the same food as rabbits, but not so heavily. They are notably prolific, bearing litter upon litter of young that are fully mobile at birth.

Rat and mouse. Although used mainly in research work, the tame rat, usually white or hooded, makes an excellent and docile pet. It has clean habits and is without a distinctive mousy smell. It tolerates a range of indoor temperatures and is an ideal children's pet that is not easily hurt by handling. Tame mice, domesticated from the house mouse, have certain disadvantages. The adult male's smell is regarded as unpleasant by some. Mice breed rapidly and their small size makes them hard to handle and confine.

Hamster. This small rodent, first tamed from the wild golden variety about 1930, is now available in many colours. The hamster has largely replaced the mouse as a house pet because of its clean habits, lack of odour, and convenient size (six inches long, or about 15 centimetres). Disadvantages are that it is easily injured if dropped and is primarily nocturnal and often bad tempered by day.

Gerbil. Several species of gerbil, mostly from southwestern Asia, became popular pets after having been established as laboratory animals. They are as clean as hamsters and of similar size; however, they are much more active and not as easily handled.

Chinchilla. Originally kept as a fur-producing animal, the chinchilla also makes a charming pet. They enjoy attention, but not all are fond of being picked up and handled.

Paddock pets. This category includes such popular animals as horses and ponies. The high costs of providing for these animals make it increasingly difficult to keep them as personal pets. Space is needed for paddock and stabling, with regular care at all times (see HORSE). In some areas goats are important for their milk and for their wool, and many breeds are kept for show purposes. Some may be suitable as household pets, but they need grazing areas and stabling, with attention twice a day when in milk. The adult male goat is undesirable because of its powerful scent. In farming communities an orphan calf, piglet, or lamb may be adopted by a family, but usually only long enough to rear it safely.

Aviary birds. Many hundreds of species of birds are kept in aviaries, or large enclosures with space for flight. They range from cranes and flamingos to sunbirds and hummingbirds. Jays, magpies, jackdaws, and other members of the crow family are good mimics and make interesting pets. Many are now bred in captivity. The catching of many birds is regulated by governmental agencies.

Wild animals as pets

Unusual mammals. Every year numbers of smaller wild mammals, such as badgers, foxes, otters, hares, and squirrels, are rescued as helpless or wounded young and become hand tamed for varying periods. Only a small minority remain pets all their lives; most of them become difficult to handle after a few months and must be released or sent to the safety of a zoo.

There is much impulse buying of exotic pets; many are offered to zoos after the owners have realized the difficulties of caring for them. The following are some of the most important groups of exotic pets.

Primates. Although apes and monkeys can be kept successfully as house pets, these primates are in general unsuitable for this purpose. With rare exceptions, they cannot be house-trained, they require a great deal of time and attention, and they are potentially dangerous because of their erratic temperament. On the other hand, such primates as bush babies and lorises and other lemurs make interesting pets in warm climates where outside accommodation with some degree of freedom is possible. Their pungent scent, used for marking territory, makes them generally unsuitable as house pets.

Carnivores. Kinkajous, raccoons, coatis, skunks, mongooses, and other small carnivores from many parts of the world are kept in varying numbers, often in large cages, sometimes partly at liberty. Feeding and accommodation are simple, but their temperaments vary widely and only some settle well as pets.

Rodents. Flying squirrels are among the most attractive small rodents. They can do well in pairs in a cage kept indoors. Some enjoy being handled and having occasional freedom of the house so that they may climb and glide.

Jerboas, kangaroo rats, dormice, and other such small rodents make unusual pets and are easy to keep. Because many feed only on seeds and produce dry droppings, they are eminently suitable for keeping indoors.

THE SOURCES OF PETS

Domestic animal sources. Most pets come from domestic stock supplied through breeding and then offered for sale. Small pets going into homes—rodents, budgerigars, etc.—are normally sold through pet shops. The "fancy," or group of enthusiasts interested in a particular pet animal, does most of its business through trade and specialist papers; many dogs and cats are bought and sold in this manner.

Rising costs compel breeders, especially of cats and dogs, to confine themselves to first-class pedigree stock that commands good prices; many buyers go directly to such breeders for their pets. Unfortunately, the standards evolved for some breeds are largely artificial. Attention may be so focussed on details of colour pattern or on small size, for example, that other considerations of temperament and stamina are ignored and the breed may suffer. This has been particularly marked in dog breeding, in which several breeds have declined in quality since World War I.

Native animal sources. Some local animals are deliberately trapped, netted, or taken from the nest. This is especially true of birds, particularly members of the finch and thrush families, that are valued for their song. Most countries now have strict laws that make it illegal to catch birds other than a few regarded as potential pests. The prohibited species may be kept as pets only when "closed ringed"; *i.e.,* when they have been bred in captivity and ringed as nestlings.

Exotic animal sources. A few exotic animals are brought in by returning travellers, but most are obtained through the normal trade channels, which are usually pet stores stocking a wide range of pets and obtaining less common ones on order.

Fishes, amphibians, snakes, invertebrates, etc. are caught by collectors in many parts of the world. Most mammals and birds are found or caught when young, and are much more likely to survive than wild-caught adults; they are also easier and cheaper to ship to markets.

Attempts to limit animal exports

Restrictions are rightly placed on the traffic in animals. The export of certain animals listed in the Red Data Book (list of species in danger of extinction) of the International Union for the Conservation of Nature is totally forbidden; some countries control trading of additional animals and allow export only to approved institutions such as zoos. It will thus become increasingly difficult to import exotic animals, especially mammals and birds, as pets; other classes of animals are less affected. Increasing water pollution, however, could seriously reduce the supply of wild-caught tropical fish.

DISEASES OF PETS AND THEIR HAZARDS TO MAN

Many diseases of pets can be transmitted to humans. Some of these ailments are mild and often pass unnoticed

for what they are; respiratory diseases and skin rashes are among these zoonoses (diseases common to man and other animals).

Cage birds may harbour trachoma, which may damage eye tissue in man, and psittacosis, a viral disease that may be serious in man. Turtles and perhaps other reptilian pets have been implicated as carriers of viruses and fungi that may infect man. Dogs and cats frequently contract respiratory infections from man and in turn can transmit them to man (see also DISEASES OF ANIMALS).

Rabies is one of the most serious animal diseases that can be transmitted to man. It occurs naturally in wild canines such as jackals, foxes, and wolves, and also among the weasels and hyenas. It is widespread in many Asian and European countries where there is always a wild source from which domestic animals may be infected (see INFECTIOUS DISEASES).

External parasites are specific to fairly narrow groups of animals and soon die on other hosts, but some fleas found on cats and dogs may be transferred to man. Suitable insecticides are available to eradicate these pests. Several serious skin diseases are caused by organisms able to live on various pets as well as on man: most important are sarcoptic mange (caused by the mite *Sarcoptes scabei*) and ringworm (caused by the fungus *Microsporum canis*). Among internal parasites, several kinds of parasitic worms of the dog and the cat can be transmitted to man.

Pets obtained from fully reliable sources and well looked after should not endanger human health. Proper care of pets includes sound hygiene, with regular and thorough cleaning of feeding and water bowls, cages or enclosures, and bedding or sleeping area.

Quarantines

It is good practice always to use special bowls for feeding that are kept separate from the utensils used by human members of the household.

PETS IN LAW

Some groups of imported animals are put in quarantine to prevent the spread of serious diseases; in addition, the provision of health certificates from the country of origin may be required. Although details vary with the country and are modified with changing conditions, the most important diseases involving quarantine generally are rabies, foot-and-mouth disease, and psittacosis and other bird diseases.

During outbreaks of some animal diseases, movements within specified areas may be banned and animals such as dogs may be compelled to wear muzzles. Local laws may forbid the keeping of certain types of pets. Animals may be banned from some forms of public transport, and it may be an offense to allow them to run freely on roads or in parks and other public spaces. In many cities, for example, penalties are imposed for the fouling of sidewalks by dogs. In many localities, annual license fees are required for pet animals, especially dogs.

In many countries, societies have been formed that are expressly concerned with the welfare of animals, particularly those in captivity; part of their work may be to help enforce laws that establish minimum standards of care for pets.

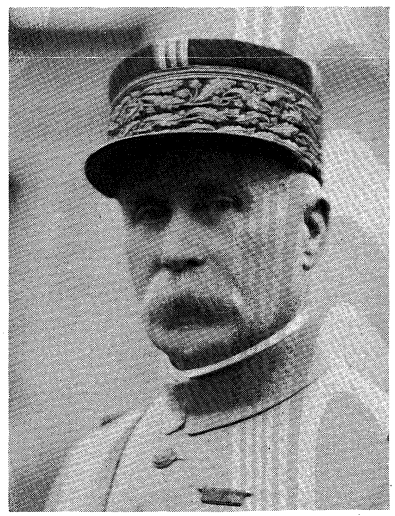
BIBLIOGRAPHY. G.S. CANSDALE, *Animals and Man* (1952), a consideration of all aspects of man's dealings with animals from earliest times, and *Bush Baby Book* (1960), a description of six species of bush babies and other lemuroids kept by the author in Africa and Great Britain, including a chapter on the problems of keeping these animals as house pets; H.F. HEDIGER, *Skizzen zu einer Tierpsychologie im Zoo und in Zirkus* (1954; Eng. trans., *Studies of the Psychology and Behavior of Captive Animals in Zoos and Circuses*, 1955, reprinted 1968), and *Mensch und Tier im Zoo* (1965; Eng. trans., *Man and Animal in the Zoo*, 1969), two books by a foremost animal psychologist that deal mainly with captive animals but also include much information about man's personal relationship to them; G. LOISEL, *Histoire des ménageries de l'antiquité à nos jours*, 3 vol. (1912), published for the Universities Federation for Animal Welfare (UFAW), chiefly valuable for its treatment of rare animals kept in captivity and as pets since ancient Egypt; KONRAD LORENZ, *Er redete mit dem Vieh, den Vögeln und den Fischen*, 6–8th ed. (1952; Eng. trans., *King Solomon's Ring: New Light on Animal Ways*, 1952; reduced photographic reprint, 1961), and *So Kam der Mensch auf den Hund* (1950; Eng. trans., *Man Meets Dog*, 1954), two popular books by a world-famous authority on animal behaviour; J.P. VOLRATH, *Animals in Schools* (1955, later editions), a useful manual in a series published by the UFAW that covers the complete range of house pets other than cats and dogs.

(Ge.C.)

Pétain, Philippe

The victor of Verdun, the hardest fought battle of World War I, the French general Philippe Pétain was first a national hero and, then, 25 years later in World War II, by his equivocal role in dealing with the German victors as chief of state of unoccupied France, an extremely controversial—and poignant—figure in French politics.

Early years



Born into a family of farmers on April 24, 1856, at Cauchy-à-la-Tour in northern France, Pétain, after attending the local village school and a religious secondary school, was admitted to Saint-Cyr, France's principal military academy. As a young second lieutenant in an Alpine regiment, sharing the rough outdoor life of his men, he came to understand the ordinary soldier. The extraordinary popularity he was later to enjoy with the rank and file in World War I is believed to have had its origin there.

His advancement until the outbreak of World War I in 1914—he was 58 when he finally became a general—was slow because as a professor at the War College he had propounded tactical theories opposed to those held by the high command. While the latter favoured the offensive at all costs, Pétain held that a well-organized defensive was sometimes called for and that before any attack the commander must be sure of the superiority of his fire power.

After successively commanding a brigade, a corps, and an army, Pétain in 1916 was charged with stopping the German attack on the fortress city of Verdun. Though the situation was practically hopeless, he masterfully reorganized both the front and the transport systems, made prudent use of the artillery, and was able to inspire in his troops a heroism that became historic. He became a popular hero, and, when serious mutinies erupted in the French Army following the ill-considered offensives of Gen. Robert-Georges Nivelle, then French commander in chief, Pétain was named his successor. He re-established discipline with a minimum of repression by personally explaining his intentions to the soldiers and improving their living conditions. Under him the French armies participated in the victorious offensive of 1918, led by Marshal Ferdinand Foch, generalissimo of the Allied armies. Pétain was made a marshal of France in November 1918 and was subsequently appointed to the highest military offices (vice president of the Supreme War Council and inspector general of the army).

Appointment as commander in chief

EB Inc.

Pétain.

After the German attack of May 1940 in World War II, Paul Reynaud, then head of the government, named Pétain vice premier, and on June 16, at the age of 84, Marshal Pétain was asked to form a new ministry. Seeing the French Army defeated, the "hero of Verdun" asked for an armistice. After it was concluded, the Chamber of Deputies and the Senate, meeting in Vichy, conferred upon him almost absolute powers as "chief of state."

With the German army occupying two-thirds of the country, Pétain believed he could repair the ruin caused by the invasion and the release of the numerous prisoners of war only by cooperating with the Germans. In the southern part of France, left free by the armistice agreement, he set up a paternalistic regime the motto of which was "Work, Family, and Fatherland." Reactionary by temperament and education, he allowed his government to promulgate a law dissolving the Masonic lodges and excluding Jews from certain professions. He was, however, opposed to the policy of close Franco-German collaboration advocated by his prime minister Pierre Laval, whom he dismissed in December 1940, replacing him with Adm. François Darlan. Pétain then attempted to practice a foreign policy of neutrality and delay. He secretly sent an emissary to London, met with the Spanish dictator Francisco Franco, whom he urged to refuse free passage of Hitler's army to North Africa, and maintained a cordial relationship with Adm. William Leahy, the United States ambassador to Vichy until 1942.

Head of Vichy government

When, in April 1942, the Germans forced Pétain to take Laval back as head of the government, he himself withdrew into a purely nominal role. Yet he balked at resigning, convinced that, if he did, Hitler would place all of France directly under German rule. After Allied landings in November 1942 in North Africa, Pétain secretly ordered Admiral Darlan, then in Algeria, to merge the French forces in Africa with those of the Allies. But, at the same time, he published official messages protesting the landing. His double-dealing was to prove his undoing.

In August 1944, after the liberation of Paris by General Charles de Gaulle, Pétain dispatched an emissary to arrange for a peaceful transfer of power. De Gaulle refused to receive the envoy. At the end of August the Germans transferred Pétain from Vichy to Germay. Brought to trial in France for his behaviour after 1940, he was condemned to death in August 1945. His sentence was immediately commuted to solitary confinement for life. He was imprisoned in a fortress on the Île d'Yeu off the Atlantic coast. He died, 95 years old, on July 23, 1951.

BIBLIOGRAPHY. GEORGES BLOND, *Pétain, 1856–1951* (1966), is a recent, definitive biography (in French). On Pétain's long military career prior to 1914, AUGUSTE M.E. LAURE, *Pétain* (1941), while somewhat biassed, furnishes interesting detail. For Pétain's role in World War I, see BERNARD SERRIGNY, *Trente ans avec Pétain* (1959). B.H. LIDDELL HART, *Reputations* (1928); and ALFRED CONQUET, *Autour du maréchal Pétain: Lumières sur l'Histoire* (1963). Interesting familiar details are found in PIERRE BOURGET, *Témoignages inédits sur le Maréchal Pétain* (1960). The first noteworthy attempt at assembling and arranging the documentation on Pétain as chief of state, with a monumental bibliography, was ROBERT ARON, *Histoire de Vichy, 1940–1944* (1954; abridged Eng. trans., *The Vichy Regime, 1940–1944*, 1958). ANDRE BRISSAUD, *La Dernière année de Vichy* (1965), is a well-documented work on this specific period, while his *Pétain à Sigmaringen* (1966), is the most complete book on Pétain's exile and captivity in Germany. Documentation on Pétain's trial may be found in *Le Procès du Maréchal Pétain* (1945); and JACQUES ISORNI, *Souffrances et Mort du Maréchal Pétain* (1951).

(G.Bl.)

Peter the Apostle, Saint

Peter (died *c.* AD 64) was recognized in the early Christian Church as the leader of the disciples of Jesus Christ and by the Roman Catholic Church as the first of its unbroken succession of popes. According to the New Testament, he was designated by Jesus as the "rock" upon which the church would be built, but the meaning of that statement has been the subject of considerable controversy at various times in the history of Christianity up to the present day.

The man and his position among the disciples. The sources of information concerning the life of Peter are limited to the New Testament: the four Gospels, Acts, the letters of Paul, and the two letters that bear the name of Peter. He probably was known originally by the Hebrew name Simeon or the Greek form of that name, Simōn. The former appears only twice in the New Testament; the latter, 49 times. At solemn moments (John 21:15) he was called "Simon, son of John." The Gospel According to John prefers Simon (17 times) or the compound, rarely found elsewhere, of Simon Peter. Though Paul has a distinct preference (eight times out of ten) for the Greek transliteration Kēphas (Latinized as Cephas) of the Aramaic name or title Kepha, meaning "rock," the Gospels and Acts use the Greek translation Petros approximately 150 times. From the Synoptic Gospels (Matt. 8:14) and Paul (I Cor. 9:5), there is indirect evidence that Peter was the son of John and was married, but only later legendary material (*Acts of Nereus and Achilleus; Acts of Philip*) alludes to any children. His family originally came from Bethsaida (John 1:44), but during the period of Jesus' ministry he lived in Capernaum, at the northwest end of the Sea of Galilee, where he and his brother Andrew were in partnership as fishermen with James and John, the sons of Zebedee (Luke 5:10).

Sources of information about Peter

Much can be learned about Peter from the New Testament—either explicitly from the statements made by and about Peter or indirectly from his actions and reactions as revealed in a number of episodes in which he figures prominently. He was at times vacillating and unsure, as in his relations with the church of Antioch when he at first ate with the Gentiles and later refused to do so (Gal. 2:11–14); he could also be resolute (Acts 4:10; 5:1–10). Occasionally he is depicted as rash and hasty (Luke 22:33, etc.) or irritable and capable of great anger (John 18:10). Often he is pictured as gentle but firm and, as in his professions of love to Jesus, capable of great loyalty and love (John 21:15–17).

The New Testament reports that Peter was unlearned in the sense that he was untrained in the Mosaic Law (Acts 4:13), and it is doubtful that he knew Greek. He apparently learned slowly and erred time and time again, but later, when entrusted with responsibility, he demonstrated that he was mature and capable.

The Gospels agree that Peter was called to be a disciple of Jesus at the beginning of his ministry, but when and where the event took place is recorded differently in the several Gospels. Luke (5:1–11) scarcely mentions James and John and omits Andrew while emphasizing the call of Peter. Matthew (4:18–22) and Mark (1:16–20) note the call of the four men and—with Luke—agree that the event took place at the Sea of Galilee. The Gospel According to John places the call in Judaea (1:28) and states that Andrew—who had been a follower of John the Baptist (1:35) and had heard John indicate that Jesus was the Lamb of God—left John and introduced Peter to "the Messiah," who at that time gave him the name (or title) Cephas (*i.e.*, Peter, or "Rock").

The Synoptic Gospels (Matthew, Mark, and Luke) are probably correct in recording that the call to Peter was extended in Galilee when Jesus first began his work in that area. The Gospel According to John is here, as elsewhere, perhaps more theologically than historically motivated; the author of John wishes to stress that Peter recognized Jesus' Messiahship from the beginning and that Jesus had seen Simon as the rock from their first meeting. Several not generally convincing attempts have been made to reconcile the differences between the Synoptics and the Fourth Gospel.

The Synoptic Gospels largely agree in the amount of emphasis each gives to the leadership of Peter among the Twelve Apostles, but there are differences also. For example, in one case Matthew and Luke note that Peter was the speaker in questioning Jesus about a parable, but Mark has attributed these words to the group of disciples (see Matt. 15:15; Luke 8:45; and Mark 7:17). With differing degrees of emphasis, the Synoptic Gospels agree that Peter served as spokesman, the outstanding member of the group, and enjoyed a certain precedence over the

Early prominence

other disciples. Whenever the disciples are listed, Peter is invariably mentioned first (Matt. 10:2–4; Mark 3:16–19; Luke 6:14–16; Acts 1:13; *cf.* only Gal. 2:9). Although it is not certain whether or not this priority is due primarily to reading back into the Gospel narrative Peter's importance in the apostolic church, his forceful personality was surely a factor.

Those not belonging to the immediate followers of Jesus also recognized the authority of Peter, such as when the collectors of the temple tax approached him for information (Matt. 17:24). Again, with characteristic quickness he sought a clarification from Jesus on behalf of the disciples concerning the meaning of a parable (Matt. 15:15) or of a saying (Matt. 18:21). As both an individual and representative of the Twelve Apostles, he made a plea for personal preference in the Kingdom of Heaven as a reward for faithful service (Matt. 19:27, 28).

On several occasions Peter alone is mentioned by name, and others are indicated as merely accompanying him (Mark 1:36; Luke 8:45). Even when the three disciples closest to Jesus (the "pillars"—Peter, James, and John) figure in a particular incident, it is frequently Peter alone who is named. When the three are named, Peter's name invariably appears first (as in Matt. 17:1, 26:37). It was his home in Capernaum that Jesus visited and cured Peter's mother-in-law (Matt. 8:14); it was Peter's boat that Jesus used when he instructed the crowd (Luke 5:3). It was Peter who possessed remarkable insight and displayed his depth of faith in the confession of Christ as the Son of God (Matt. 16:15–18; Mark 8:29; Luke 9:20); and it was Peter who rebuked and in turn was rebuked by Jesus when the Master prophesied that he would suffer and die (Mark 8:32, 33). It was also Peter who manifested the momentary weakness of even the strongest in the denial of his Lord (Matt. 26:69–75; Mark 14:66–72; Luke 22:54–61). Later, however, with greater maturity, he discovered strength and, as he was charged by Jesus (Luke 22:31, 32), effected the strengthening of others. Finally, Peter, who survived his denial, was permitted to be the first witness of the Resurrection (Luke 24:34).

In the Fourth Gospel, the prominence of Peter is challenged in the person of John, the "Beloved Disciple." Though Peter receives mention in John 37 times (out of a total of 109 times in the four Gospels), one-third of the references are found in the appendix (chapter 21), and he appears in only 9 incidents. The Gospel According to John attempts to show the close relationship between John and Jesus while still reserving to Peter the role of representative and spokesman. The fact that Peter is emphasized in John and charged by Jesus to "tend my sheep" and "feed my lambs" (John 21:15, 16) at the same time that the role of the disciples as a whole is being de-emphasized attests to the prestige of Peter in the apostolic church. But throughout the Fourth Gospel Peter is required to share his prominence with John (13:24; 18:15; 19:26, 27, etc.). Among the purposes of chapter 21 in emphasizing Peter may well be an attempt to restore the disciple who denied his Lord to the position he enjoyed in the Synoptic Gospels.

Incidents important in interpretations of Peter. Out of the many incidents in which Peter figures prominently in the Gospels, three should be separately and carefully considered; for each is important, contains problems of interpretation, and is controversial.

Peter's confession of faith

In Mark (8:29) and Luke (9:20), to a question of Jesus concerning his essential identity, about which he pressed the disciples for an opinion, Peter answered for them all that Jesus is the "Messiah" or "God's Messiah." In adjuring them to be silent, Jesus rejected the response as perhaps too partial, too political. In the Matthean version (16:13), expanding upon the narrative in Mark, Peter answered for himself and presumably for the other disciples, "You are the Christ, the Son of the living God." A new dimension of understanding was thus reached, and this heightened awareness of Jesus' divinity was approved by Jesus and occasioned Peter's "ordination."

In what may be a grouping of Petrine material (Matt. 16:18, 19)—the confession, naming, and receiving of authority—Jesus gave to Simon the title of petros ("rock").

> And I tell you, you are Peter, and on this rock I will build my church, and the powers of death shall not prevail against it. I will give you the keys of the kingdom of heaven, and whatever you bind on earth shall be bound in heaven, and whatever you loose on earth shall be loosed in heaven.

Though in the past some authorities have considered that the term rock refers to Jesus himself or to Peter's faith, the consensus of the great majority of scholars today is that the most obvious and traditional understanding should be construed, namely, that rock refers to the person of Peter. In John the title was granted at what may have been their first meeting (1:42). Thus *when* the name was given is open to question, but *that* the name was given by Jesus to Peter seems fairly certain. Matthew continues that upon this rock—that is, upon Peter—the church will be built. The word church in the 1st-century Gospel According to Matthew is to be understood as referring to the community of the faithful rather than to a definite ecclesiastical organization. The passage continues that to this disciple, upon whom the new community is to be founded, will be given the "keys of the kingdom of heaven"; *i.e.*, Peter is to be granted a position of unique authority within the community. But he is to share with his fellow disciples (Matt. 18:18) the authority of "binding" and "loosing" —*i.e.*, controlling admission to the community.

The authenticity of the uniquely Matthean material (Matt. 16:16–19) of this narrative has been and is widely discussed and has been challenged on the bases (1) that verses 16–19 are found only in Matthew or (2) that the inclusion of the word church suggests a level of organization acquired only at a later period. Though these and other arguments against authenticity are given most careful consideration, the general consensus is that at some time—and more likely at the end of his career—these words were spoken by Jesus.

The denial

If Peter's confession demonstrates his faith and insight, his denial that he knew Jesus demonstrates a weakness of will (even if momentary), capability of inaction, and a tendency toward vacillation, but not a loss of faith. Prior to the denial, out of his deep love for Jesus and his overestimation of his own capabilities, he had sought to overrule Jesus' prophecy of his denial and declared that, even if the other disciples deserted Jesus, he would suffer death rather than disown his Lord (Matt. 26:33–35; Mark 14:29–31; Luke 22:31–34; John 13:37–38). As the drama unfolded, Peter fled when Jesus was arrested but did find his way to the palace of the high priest where Jesus had been taken. When confronted in the courtyard

with the danger of admitting having had association with Jesus, he chose to deny (Matt. 26:69–75; Mark 14:66–72; Luke 22:54–61; John 18:15–18, 25–27). The degree of his shame and the depth of his love were revealed when he later realized that the prophecy had been fulfilled, and he wept bitterly (Matt. 26:75; Mark 14:72).

The fact of Peter's denial did not destroy the love and trust that Jesus felt for him. It was to Peter—who had confessed the Sonship of Jesus (Matt. 16:16), who had been commissioned earlier to "lend strength" to his brothers (Luke 22:32), who had hesitated in his resolution at one crucial point (Mark 14:66–72), and who on the morning of the resurrection"ran to the tomb" (Luke 24:12)—that the Resurrected Christ first appeared. The earliest report of Peter's priority as a witness to the Resurrection is found in the letters of Paul (I Cor. 15:5), and this most probably is the intent of Luke (24:34). The initial appearance to Peter in Galilee may have been included in the original ending of Mark.

The silence concerning this important matter of priority in Matthew and John is remarkable. It may be, however, that Matt. 14:27, 28 represents a misplaced post-Resurrection narrative, and John 21 may contain an echo of the tradition preserved by Paul (I Cor. 15:5).

Whether or not Jesus appeared *first* to Peter after the Resurrection, he was a witness, which Peter declared to be a criterion of apostleship (Acts 1:22).

The position of Peter in the Apostolic Church. Given the information supplied by the Gospels, it is not unexpected that Peter should emerge immediately after Jesus' death as the leader of the earliest church. For approximately 15 years after the Resurrection, the figure of Peter dominated the community. He presided over the appointment of Matthias as an Apostle (Acts 1:23–26) to take the place of Judas, who had betrayed Christ and later died. It was Peter who first "raised his voice" and preached at Pentecost, the day when the church came into being (Acts 1:14–39). It was Peter who served as an advocate for the Apostles before the Jewish religious court in Jerusalem (Acts 4:5–22). And it was he who exercised the role of judge in the disciplining of those who erred within the church (Acts 5:1–10).

Peter as leader of the Apostles

Peter led the Twelve Apostles in extending the church "here and there among them all" (Acts 9:32). He went first to the Samaritans (Acts 8:4–17), "who received the Holy Spirit"; in Samaria he encountered the magician and faith healer Simon Magus (the theme of their meeting is developed in apocryphal literature, not included in the Bible); then he went to Lydda, in the plain of Sharon (Acts 9:32–35), where he healed the paralyzed Aeneas; and then at the Mediterranean coastal town of Joppa (Acts 9:36–43) he effected the cure of Tabitha (Dorcas) in the name of Christ.

He went farther north on the Mediterranean coast to Caesarea (Acts 10:1–11:18), where, through the conversion of Cornelius, "a centurion of what was known as the Italian Cohort" (Acts 10:1), Peter introduced Gentiles into the church. According to Jewish requirements, a Gentile convert must first become a Jew through the rite of circumcision and be acceptable as a proselyte. In accepting Cornelius and the others—who may have had some informal connection with the synagogue (Acts 10:1)—and ordering "them to be baptized in the name of Jesus Christ" (Acts 10:48) without submission to the prior rite of circumcision, Peter introduced an innovation that insured the opposition of the Jewish Christians and others. This independent course set by Peter with the blessing of "the Spirit" (Acts 10:10–15) was possibly a factor in Herod's beheading of James (the brother of John) and in the arrest of Peter (Acts 12:2, 3). In prison (*c.* AD 44) Peter was visited by an "angel of the Lord. . . . And the chains fell off his hands," and he made his escape (Acts 12:1–8). He went immediately to "the house of Mary, the mother of John whose other name was Mark" (Acts 12:12). After asking them to report his escape "to James and to the brethren," he "went to another place" (Acts 12:17).

At this point the unchallenged leadership of Peter in Jerusalem came to an end. It is not at all clear where Peter went, but it is not probable that the words to another place refer to a different home in the same general area that would provide temporary refuge. Though there is no internal evidence to suggest any place in particular, he might have travelled to any or none of those places with which tradition has associated his name—perhaps to Antioch of Syria, where he visited later, perhaps to Corinth, perhaps to Rome. Those who would preserve the ancient tradition of the 25-year episcopate of Peter in Rome are particularly confident that the "place" indicated is Rome. Many others, who are certain that he eventually went there, are equally positive that his visit to Rome could not have been this early.

The later work of Peter is not covered in Acts, perhaps because the author of Luke–Acts had planned a third book that would have included such a discussion, but the book was never written or was written and later lost. Perhaps the events would have included unedifying material such as the internal jealousy within the church alluded to in the *First Letter of Clement* 4–6, or perhaps the author died before completion of his work. Whatever momentary glimpses into the period of the later ministry of Peter remain can only be noted in a discussion of his relationship with the two other outstanding Apostles of the time, James and Paul.

Peter and James

Peter was the most prominent figure in the Jerusalem Church up to the time of his departure from Jerusalem after his imprisonment by King Herod and his subsequent release in the New Testament account (Acts 12:1–17). For example, Paul went up to Jerusalem to consult with Peter three years after he had been converted and remained with him for two weeks (Gal. 1:18, 19). When Peter left Jerusalem, however, it appears clear to many New Testament scholars (although unconvincing to others) that he assumed a missionary role while the actual leadership of the church devolved upon James, "the brother of the Lord." This sequence of authority is suggested by Peter's obedience to the wishes of "certain persons who came from James" and hence his ceasing to eat with Gentile Christians at Antioch (Gal. 2:11–14); by a final "summing up" of decisions made in the so-called apostolic Council of Jerusalem (Acts 15:7) by James; and later, when Peter made his departure from the home of the mother of John whose other name was Mark, by the word of explanation or "report" of his whereabouts left primarily for James (Acts 12:17).

Peter and Paul

Paul first met with Peter at Jerusalem three years after his conversion. In the record of this meeting the name of Cephas (Peter) precedes that of James, although Galatians notes that in another meeting 14 years later the name of James precedes that of Cephas (Gal. 2:9). Paul also emphasized an incident involving himself and Peter at Antioch. Apparently, Paul had achieved some success in the difficult matter of welding the Jewish and Gentile Christians of Antioch into one congregation. The Jewish Christians saw the sharing of food with Gentiles as quite alien to their tradition. In the absence of Paul, Peter, perhaps in his capacity as missionary, visited Antioch and ate with the united group. Later, "certain persons came from James" and opposed the united congregation's custom of eating together. In apparent deference to James, Peter "drew back and began to hold aloof," and the Jewish Christians did likewise. The unity of the group had been destroyed. When Paul returned, he upbraided Peter for what he may have considered Peter's vacillation or perhaps even purposeful disruption (Gal. 2:11–14). This incident may have occasioned the Jerusalem Council (AD 49 or 50), in which it was settled that hereafter Paul should be "entrusted with the gospel to the uncircumcised" (Gal. 2:7) and Peter "for the mission to the circumcised" (Gal. 2:8). A late tradition found in Origen's homily on Saint Luke and in the *Clementine Homilies* and *Recognitions* claims that Peter was the first bishop of Antioch, a tradition that may rest upon the early papal lists of the last half of the 2nd century.

In passing, Paul refers to a party of "Cephas" (Peter) in I Corinthians 1:12 that suggests that a group in the church of Corinth was especially devoted to Peter (leading some to assume a residence of Peter in Corinth) and

in I Corinthians 9:5 to Peter as carrying on missionary activity accompanied by his wife. A missionary journey to Asia Minor may be suggested in the First Letter of Peter 1:1.

Except for the possible references to the later residence and martyrdom of the Apostle noted below, there is no further information to be gathered about his life from the pages of the New Testament.

Tradition of Peter in Rome. The problems surrounding the residence, martyrdom, and burial of Peter are among the most complicated and controversial of all those encountered in the study of the New Testament and the early church. The absence of any reference in Acts or Romans to a residence of Peter in Rome gives pause but is not conclusive. If Peter did write I Peter, the mention of "Babylon" in 5:13 is fairly reliable evidence that Peter resided at some time in the capital city. If Peter was not the author of the first epistle that bears his name, the presence of this cryptic reference witnesses at least to a tradition of the late 1st or early 2nd century. An identification of the "Babylon" in I Peter 5:13 with the Babylons of the Euphrates in Mesopotamia or the Nile Delta near Memphis in Egypt must be discarded for lack of evidence, as must the suggestion that it stands for Jerusalem. In that period the first Babylon was "no more than walls"; the second was a military outpost; and for the third there is lacking any convincing evidence that the term was used in this way. "Babylon" is a cryptic term indicating Rome, and it is the understanding utilized in Revelation 14:8; 16:19; 17:5, 6 and in the works of various Jewish seers, such as Baruch 1:1, 4; Esdras 2; and the Sibylline Oracles 5:143, 158.

It may be said that by the end of the 1st century there existed a tradition that Peter had lived in Rome. Further early evidence for the tradition is found in the *Letter to the Romans* by the early-2nd-century bishop of Antioch Ignatius. Later, less trustworthy, evidence exists in the fragment of a work by the 2nd-century bishop of Hierapolis Papias (Eusebius, *Ecclesiastical History*, III. xxxix. 15) and in the *Letter to the Romans* of Dionysius of Corinth (Eusebius, *Ecclesiastical History*, II.xxv.8). Also to be noted are other works: Irenaeus, *Against Heresies*, III. iii. 3; Tertullian, *Against Marcion*, IV. v, *Against the Jews*; the words of the Roman presbyter Gaius (Eusebius, *Ecclesiastical History*, II.xxv. 7); and Clement of Alexandria, *Commentary on I Peter*. It is probable that the tradition of a 25-year episcopate of Peter in Rome is not earlier than the beginning or the middle of the 3rd century. The claims that the church of Rome was founded by Peter or that he served as its first bishop (in the present meaning of the word) are in dispute and rest on evidence that is not earlier than the middle or late 2nd century.

Martyrdom of Peter

Words of John 21:18,19 clearly allude to the death of Peter and are cast into the literary form of prophecy. The author of this chapter is aware of a tradition concerning the martyrdom of Peter when the Apostle was an old man. And there is a possible reference here to crucifixion as the manner of his death. But as to when or where the death took place there is not so much as a hint. It has been forcefully suggested, though rarely supported, that Revelation 11:3–13 contains a cryptic reference to the deaths of both Peter and Paul.

The strongest evidence to support the thesis that Peter was martyred in Rome is to be found in the *Letter to the Corinthians* (*c.* AD 96; 5:1–6:4) of Clement of Rome:

> Peter, who by reason of wicked jealousy, not only once or twice but frequently endured suffering and thus, bearing his witness, went to the glorious place which he merited (5:4) . . . . To these men [Peter and Paul] who lived such holy lives there was joined a great multitude of the elect who by reason of rivalry were victims of many outrages and tortures and who became outstanding examples among us (6:1).

These sources, plus the suggestions and implications of later works, combine to lead many scholars to accept Rome as the location of the martyrdom and the reign of Nero, between AD 64 and 67, as the time. The tradition that he suffered crucifixion in a head-downward position is late and apocryphal. *Why* he was martyred is a question that must still remain unanswered. Perhaps the answer is somehow related to Nero and the great fire of Rome (as implied in I Clement 6:1) or to a refusal to make ritual offering on behalf of the emperor or to one or a number of charges that an unfriendly community might bring against a group, such as the Christians, that it disliked and distrusted. Only later and less trustworthy sources appear to be concerned with the area in Rome where the martyrdom took place, but among these there is virtual agreement in citing the vicinity of the Vatican.

Burial of Peter

As part of the general question of Peter's residence and martyrdom in Rome, debated since the appearance of the *Defensor pacis* of Marsilius of Padua (*c.* 1275–*c.* 1342), the particular question of where Peter was buried has been argued. There is not the slightest hint at a solution in the New Testament. The earliest evidence (*c.* AD 200) is found in a fragment of a work by Gaius (or Caius) witnessing to a tradition at least a generation earlier (*c.* AD 165) that the "trophy" (*i.e.*, *tropaion*, or monument) of Peter was located at the Vatican. Though difficult to interpret, the use of the word trophy indicates that in this period the Vatican area was associated with either the tomb of the Apostle or simply a monument erected in the area of Peter's victory (*i.e.*, his martyrdom).

Some scholars find support for a tradition that the Apostle was buried "Ad Catacumbas" ("at the catacombs" of San Sebastiano) on the Via Appia in an inscription of Damasus (pope, 366–384), composed in such ambiguous terms that it was certain to foster such misinterpretations as are found in the letter of Gregory the Great to Empress Constantina and the notice of Cornelius in the *Liber Pontificalis*. Apart from the aforementioned, later literary tradition is unanimous in indicating the Vatican Hill as the place of burial. See *Peristephanon*, XII, of Prudentius, various notices in the *Liber Pontificalis*, and *The Salzburg Itinerary*. Liturgical sources such as the *Depositio Martyrum*, *Martyrologium Hieronymianum*, though interesting, add nothing to the literary evidence.

Excavations were begun in the late 19th century in order to substantiate the theory that the burial of Peter and Paul was "Ad Catacumbas." After a half century of investigation, it now seems reasonable to concede that a cult of the Apostles existed there about AD 260, though Christian influence may have been exerted as early as AD 200. None of the excavations, however, in all of the areas indicated at various times as the resting place of the apostolic relics, have produced any evidence whatsoever that the bodies of Peter and Paul were either buried there originally or brought there at a later time after earlier burials elsewhere.

In the early 4th century, the emperor Constantine (died AD 337) with considerable difficulty erected a basilica on the Vatican Hill. The difficulty of the task, combined with the comparative ease with which this great church might have been built on level ground only a slight distance to the south, may support the contention that the Emperor was convinced that the relics of Peter rested beneath the small Aedicula (shrine for a small statue) over which he had erected the basilica. The task before the excavators was to determine whether or not the belief of Constantine accorded with the facts or was based merely upon a misunderstanding.

The excavation of this site, which lies far beneath the high altar of the present Church of St. Peter, was begun in 1939. The problems encountered in excavation and interpretation of what has been discovered are extremely complex. There are some scholars who are convinced that a box found in one of the fairly late sidewalls of the Aedicula contains fragments of the remains of the Apostle, fragments which at an earlier time may have rested in the earth beneath the Aedicula. Others are most definitely not convinced. If a grave of the Apostle did exist in the area of the base of the Aedicula, nothing identifiable of that grave remains today. Furthermore, the remains discovered in the box that until comparatively recently rested in the sidewall do not lead necessarily to a more positive conclusion. Archaeological investigation has not solved with any great degree of certainty the question of the location of the tomb of Peter. If it was not in the area of the Aedicula, perhaps the grave rested elsewhere in the

immediate vicinity, or perhaps the body was never recovered for burial at all.

Peter in the apocryphal literature

Later traditions about Peter. Two works attributed to Peter (I and II Peter) are included in the New Testament. In addition to these, there are several apocryphal works that record supposed incidents in the life of the Apostle and contain further teaching. This apocryphal literature is untrustworthy and too late to offer any information that might be considered reliable and independent. The details offered are only important to the extent that they serve to indicate a trend in the development of the tradition. The *Gospel of Peter* supplies details of a post-Resurrection experience of certain disciples, including Peter. The *Gospel of Bartholomew* reports discussions between Mary, the Mother of Christ, and the Apostle. Mary refers to Peter as the "chief" and the "pillar" and "stone hewn out of the rock." In *The Death and Assumption of the Virgin*, Peter is ordained an "archbishop" by Jesus. An appearance of Mary to Peter and John is promised before her assumption into heaven in the *Discourse of Theodosius*.

The *Acts of Peter* includes curious incidents and details not found in the canonical Gospels: Peter's healing of his daughter and then returning her to her infirmity (a similar narrative in the Letter of Paul to Titus may explain the story of the healing of Peter's daughter); a long narrative (chapters 7–32) relating to the conflict between Peter and Simon Magus in Rome that includes discussions and miraculous cures; the "Quo Vadis" ("where are you going?") legend (chapter 35) involving a dialogue between Christ and Peter in Rome; a prophecy of Peter's crucifixion in that city; and the crucifixion, "head downward" (chapter 37). This last detail is noted also in the *Acts of Andrew and Paul*. Further details of teaching and miracles are found in the brief *Acts of Peter and Andrew*. Additional post-Resurrection experiences with Christ are detailed in the *Apocalypse of Peter*.

The alleged stay of Peter in the Mamertine prison in Rome is presented in the Pseudo-Linus text that is little more than a detailed account of the *Martyrdom of Peter*. Material appearing in the *Martyrdom* is elaborated upon in the 6th-century *Acts of Processus and Martinian*. Other legends are contained in a *Latin Passion of Peter and Paul, Acts of Nereus and Achilleus, Preaching of Peter, Slavonic Acts of Peter*, and *Didascalia Apostolorum*, the *Clementine Homilies* and *Recognitions*, etc.

The feasts of St. Peter

Five festivals in the calendar of the Roman Catholic Church involve honour paid to Peter. And in each, the name of Paul is also associated. First chronologically, on January 18, is celebrated the festival of the "Cathedra Petri" at Rome, and on February 22 at Antioch. June 29 marks the festival of Peter and Paul, ranking among the 12 most important celebrations of the Roman Catholic Church. The escape of Peter from his chains is noted in the feast of August 1. Last, the dedications of the basilicas of Peter and Paul, commemorating their construction by the emperor Constantine, are celebrated in the festival of November 18.

Peter I the Great, of Russia

Peter I the Great, tsar of Russia from 1682 and emperor from 1721, was one of his country's greatest statesmen, organizers, and reformers. He was born in Moscow on June 9 (May 30, old style), 1672, the son of Tsar Alexis by his second wife, Natalya Kirillovna Naryshkina. Unlike his half-brothers, sons of his father's first wife, Mariya Ilinichna Miloslavskaya, Peter proved a healthy child, lively and inquisitive. It is probably significant to his development that his mother's former guardian, Artamon Sergeyevich Matveyev, had raised her in an atmosphere open to progressive influences from the West.

Youth and accession. When Alexis died in 1676 Peter was only four years old. His elder half-brother, a sickly youth, then succeeded to the throne as Fyodor III; but, in fact, power fell into the hands of the Miloslavskys, relatives of Fyodor's mother, who deliberately pushed Peter and the Naryshkin circle aside. When Fyodor died childless in 1682, a fierce struggle for power ensued between the Miloslavskys and the Naryshkins: the former wanted to put Fyodor's brother, the delicate and feebleminded Ivan V, on the throne; the Naryshkins stood for the healthy and intelligent Peter. Representatives of the various orders of society, assembled in the Kremlin, declared themselves for Peter, who was then proclaimed tsar; but the Miloslavsky faction exploited a revolt of the Moscow *streltsy*, or musketeers of the sovereign's bodyguard, who killed some of Peter's adherents, including Matveyev. Ivan and Peter were then proclaimed joint tsars; and eventually, because of Ivan's precarious health and Peter's youth, Ivan's 25-year-old sister Sophia was made regent. Clever and influential, Sophia took control of the government; excluded from public affairs, Peter lived with his mother in the village of Preobrazhenskoye, near Moscow, often fearing for his safety. All this left an ineradicable impression on the young tsar and determined his negative attitude toward the *streltsy*.

One result of Sophia's overt exclusion of Peter from the government was that he did not receive the usual educa-

tion of a Russian tsar; he grew up in a free atmosphere instead of being confined within the narrow bounds of a palace. While his first tutor, the former church clerk Nikita Zotov, could give little to satisfy Peter's curiosity, the boy enjoyed noisy outdoor games and took especial interest in military matters, his favourite toys being arms of one sort or another. He also occupied himself with carpentry, joinery, blacksmith's work, and printing.

Boyhood influences

Near Preobrazhenskoye there was a *vemetskaya sloboda* ("colony") where foreigners were allowed to reside. Acquaintance with its inhabitants aroused Peter's interest in the life of other nations, and an English sailboat, found derelict in a shed, whetted his passion for seafaring. Mathematics, fortification, and navigation were the sciences that appealed most strongly to Peter. A model fortress was built for his amusement, and he organized his first "play" troops, from which, in 1687, the Preobrazhensky and Semyonovsky Guards regiments were formed—to become the nucleus of a new Russian Army.

Early in 1689 Natalya Naryshkina arranged Peter's marriage to the beautiful Eudoxia (Yevdokiya Fyodorovna Lopukhina). This was obviously a political act, intended to demonstrate the fact that the 17-year-old Peter was now a grown man, with a right to rule in his own name. The marriage did not last long: Peter soon began to ignore his wife, and in 1698 he relegated her to a convent.

In August 1689 a new revolt of the *streltsy* took place. Sophia and her faction tried to use it to their own advantage for another coup d'état, but events this time turned decisively in Peter's favour. He removed Sophia from power and banished her to the Novodevichy convent, where later in the year, after the suppression of the revolt, she became a nun. Though Ivan V remained nominally joint tsar with Peter, the administration was now largely given over to Peter's kinsmen, the Naryshkins, until Ivan's death in 1696. Peter, meanwhile continuing his military and nautical amusements, sailed the first seaworthy ships to be built in Russia. His games proved to be good training for the tasks ahead.

Peter as sole ruler

External events. At the beginning of Peter's reign, Russia was territorially a huge power, but with no access to the Black Sea, the Caspian, or to the Baltic, and to win such an outlet became the main goal of Peter's foreign policy.

The Azov campaigns (1695–96). The first steps taken in this direction were the campaigns of 1695 and 1696, with the object of capturing Azov from the Crimean Tatar vassals of Turkey. On the one hand, these Azov campaigns could be seen as fulfilling Russia's commitments, undertaken during Sophia's regency, to the anti-Turkish "Holy League" of 1684 (Austria, Poland, and Venice); on the other they were intended to secure the southern frontier against Tatar raids, as well as to approach the Black Sea. The first campaign ended in failure (1695), but this did not discourage Peter: he promptly built a fleet at Voronezh to sail down the Don River and in 1696 Azov was captured. To consolidate this success Taganrog was founded on the northern shore of the Don Estuary, and the building of a large navy was started.

The Grand Embassy (1697–98). Having already sent some young nobles abroad to study nautical matters, Peter, in 1697, went with the so-called Grand Embassy to western Europe. The embassy comprised about 250 people, with the "grand ambassadors" Franz Lefort, F.A. Golovin, and P.B. Voznitsyn at its head. Its chief purposes were to examine the international situation and to strengthen the anti-Turkish coalition, but it was also intended to gather information on the economic and cultural life of Europe. Travelling incognito under the name of Sgt. Pyotr Mikhaylov, Peter familiarized himself with conditions in the advanced countries of the West. For four months he studied shipbuilding, working as a ship's carpenter in the yard of the Dutch East India Company at Saardam; after that he went to Great Britain, where he continued his study of shipbuilding, working in the Royal Navy's dockyard at Deptford, and he also visited factories, arsenals, schools, and museums and even attended a session of Parliament. Meanwhile, the services of foreign experts were engaged for work in Russia.

Familiarization with the West

On the diplomatic side of the Grand Embassy, Peter conducted negotiations with the Dutch and British governments for alliances against Turkey; but the Maritime Powers did not wish to involve themselves with him because they were preoccupied with the problems that were soon to come to a crisis, for them, in the War of the Spanish Succession.

The destruction of the streltsy (1698). From England, Peter went on to Austria; but while he was negotiating in Vienna for a continuance of the anti-Turkish alliance, he received news of a fresh revolt of the *streltsy* in Moscow. In the summer of 1698 he was back in Moscow, where he suppressed the revolt. Hundreds of the *streltsy* were executed, the rest of the rebels were exiled to distant towns, and the corps of the *streltsy* was disbanded.

The Northern War (1700–21). When it became clear that Austria, no less than the Maritime Powers, was preparing to fight for the Spanish Succession and to make peace with Turkey, Peter saw that Russia could not contemplate a war without allies against the Turks, and he abandoned his plans for pushing forward from the Sea of Azov to the Black Sea. By the Russo-Turkish Peace of Constantinople (Istanbul, 1700) he retained possession of Azov. He was now turning his attention to the Baltic instead, following the tradition of his predecessors.

The Swedes occupied Karelia, Ingria, Esthonia, and Livonia and blocked Russia's way to the Baltic coast. To dislodge them, Peter took an active part in forming the great alliance, comprising Russia, Saxony, and Denmark–Norway, which started the Northern War in 1700. This war lasted for 21 years and was Peter's main military enterprise. In planning it and in sustaining it he displayed iron willpower, extraordinary energy, and outstanding gifts of statesmanship, generalship, and diplomacy. Mobilizing all the resources of Russia for the triumph of his cause, constantly keeping himself abreast of events, and actively concerning himself with all important undertakings, often at his personal risk, he could be seen sometimes in a sailor's jacket on a warship, sometimes in an officer's uniform on the battlefield, and sometimes in a labourer's apron and gloves with an axe in a shipyard.

Peter's main military enterprise

The defeat of the Russians at Narva (1700), very early in the war, did not deter Peter and, in fact, he later described it as a blessing: "Necessity drove away sloth and forced me to work night and day." He subsequently took part in the siege that led to the Russian capture of Narva (1704) and in the battles of Lesnaya (1708) and of Poltava (1709). At Poltava, where Charles XII of Sweden suffered a catastrophic defeat, the plan of operations was Peter's own: it was his idea to transform the battlefield by works of his military engineers—the redoubts erected in the path of the Swedish troops to break their combat order, to split them into little groups, and to halt their onslaught. Peter also took part in the naval battle of Gangut (Hanko, or Hangö) in 1714, the first major Russian victory at sea.

The treaties concluded by Russia in the course of the war were made under Peter's personal direction. He also travelled abroad again for diplomatic reasons—*e.g.*, to Pomerania in 1712 and to Denmark, northern Germany, Holland, and France in 1716–17.

In 1703, on the banks of the Neva River, where it flows into the Gulf of Finland, Peter began construction of the city of St. Petersburg (now Leningrad) and established it as the new capital of Russia in 1712. By the Treaty of Nystad (September 10 [August 30, O.S.], 1721) the eastern shores of the Baltic were at last ceded to Russia, Sweden was reduced to a secondary power, and the way was opened for Russian domination over Poland.

In celebration of his triumph, the Senate on November 2 (October 22, O.S.), 1721, changed Peter's title from tsar to that of emperor (imperator) of all the Russias.

The popular revolts (1705–08). The peasant serfs and the poorer urban workers had to bear the greatest hardships in wartime and moreover were intensively exploited in the course of Peter's great work for the modernization and development of Russia (see below *Internal reforms*). Their sufferings, combined with onerous taxation, pro-

Other events during the Northern War

voked a number of revolts, the most important of which were that of Astrakhan (1705–06) and that led by Kondraty Afanasyevich Bulavin in the Don Basin (1707–08). These revolts were cruelly put down.

The Turkish War (1710–13). In the middle of the Northern War, when Peter might have pressed further the advantage won at Poltava, Turkey declared war on Russia. In the summer of 1711 Peter marched against the Turks through Bessarabia into Moldavia, but he was surrounded, with all his forces, on the Prut River. Obliged to sue for peace, he was fortunate to obtain very light terms from the inept Turkish negotiators, who allowed him to retire with no greater sacrifice than the retrocession of Azov. The Turkish government soon decided to renew hostilities; but the Peace of Adrianople (Edirne) was concluded in 1713, leaving Azov to the Turks. From that time on Peter's military effort was concentrated on winning his war against Sweden.

The Tsarevich Alexis and Catherine (to 1718). Peter had a son, the tsarevich Alexis, by his discarded wife Eudoxia. Alexis was his natural heir, but he grew up antipathetic to Peter and receptive to reactionary influences working against Peter's reforms. Peter, meanwhile, had formed a lasting liaison with a low-born woman, the future empress Catherine I, who bore him other children and whom he married in 1712. Pressed finally to mend his ways or to become a monk in renunciation of his hereditary rights (1716), Alexis took refuge in the dominions of the Holy Roman emperor Charles VI, but he was induced to return to Russia in 1718. Thereupon proceedings were brought against him on charges of high treason, and after torture he was condemned to death. He died in prison, presumably by violence, before the formal execution of the sentence.

The Persian campaign (1722–23). Even during the second half of the Northern War, Peter had sent exploratory missions to the East—to the Central Asian steppes in 1714, to the Caspian region in 1715, and to Khiva in 1717. The end of the war left him free to resume a more active policy on his southeastern frontier. In 1722, hearing that the Ottoman Turks would take advantage of Persia's weakness and invade the Caspian region, Peter himself invaded Persian territory. In 1723 Persia ceded the western and southern shores of the Caspian to Russia in return for military aid.

Death. The campaign along the parched shores of the Caspian obviously put a great strain on Peter's health, already undermined by enormous exertions and also by the excesses in which he occasionally indulged himself. In the autumn of 1724, seeing some soldiers in danger of drowning from a ship aground on a sandbank in the Gulf of Finland, he characteristically plunged himself into the icy water to help them. Catching a chill, he became seriously ill in the winter but even so continued to work; indeed, it was at this time that he drew up the instructions for the expedition of Vitus Bering to Kamchatka.

The empire at Peter's death

Peter died in St. Petersburg on February 8 (January 28, O.S.), 1725, leaving an empire that stretched from Arkhangelsk (Archangel) on the White Sea to Mazanderan on the Caspian and from the Baltic Sea to the Pacific Ocean. Though he had in 1722 issued a decree reserving to himself the right to nominate his successor, he did not in fact nominate anyone. His widow Catherine, whom he had crowned as empress in 1724, succeeded him to the temporary exclusion of his grandson, the future Peter II.

Internal reforms. At the beginning of Peter's reign, Russia was backward by comparison with the countries of western Europe. This backwardness inhibited foreign policy and even put Russia's national independence in danger. Peter's aim, therefore, was to overtake the developed countries of western Europe as soon as possible, in order both to promote the national economy and to ensure victory in his wars for access to the seas. Breaking the resistance of the boyars, or members of the ancient landed aristocracy, and of the clergy and severely punishing all other opposition to his projects, he initiated a series of reforms that affected, in the course of 25 years, every field of the national life—administration, industry, commerce, technology, and culture.

The towns. At the beginning of Peter's reign there was already some degree of economic differentiation between the various regions of Russia; and in the towns artisans were establishing small businesses, small-scale production was expanding, and industrial plants and factories were growing up, with both hired workers and serfs employed. There was thus a nascent bourgeoisie, which benefitted considerably from Peter's plans for the development of the national industry and trade. The reform of the urban administration was particularly significant.

Administrative reforms

By a decree of 1699, townspeople (artisans and tradesmen) were released from subjection to the military governors of the provinces and were authorized to elect municipalities of their own, which would be subordinated to the Moscow municipality, or *ratusha*—the council of the great merchant community of the capital. This reform was carried further in 1720, with the establishment of a chief magistracy in St. Petersburg, to which the local town magistracies and the elected municipal officers of the towns (mayors, or *burmistry*; and councillors, or *ratmany*) were subordinated.

All townspeople, meanwhile, were divided between "regulars" and "commons" (inferiors). The regulars were subdivided between two guilds—the first comprising rich merchants and members of the liberal professions (doctors, actors, and artists); the second, artisans (classified according to their vocations) and small tradesmen. A merchant belonged to the first or to the second guild according to the amount of his capital; and those who were also manufacturers had special privileges, coming under the jurisdiction of the College of Manufactures and being exempt from the billeting of troops, from elective rotas of duty, and from military service. The commons were hired labourers, without the privileges of regulars.

Thanks to the reforms, the economic activity and the population of the towns increased. Anyone engaged in trade was legally permitted to settle in a town and to register himself in the appropriate category, and there was a right of "free commerce for people of every rank."

The provinces and the districts. In order to create a more flexible system of control by the central power, Russia was territorially divided in 1708 into eight guberny, or governments, each under a governor appointed by the tsar and vested with administrative, military, and judicial authority. In 1719 these *guberny* were dissolved into 50 *provintsy*, or provinces, which in turn were subdivided into districts. The census of 1722, however, was followed by the substitution of a poll tax for the previous hearth tax; and this provoked a wave of popular discontent, against which Peter decided to distribute the army regiments (released from active service by the Peace of Nystad) in garrisons throughout the country and to make their maintenance obligatory on the local populations. Thus came into being the "regimental districts," which did not coincide with the administrative. The regimental commanders, with their own sphere of jurisdiction and their own requirements, added another layer to the already complex system of local authority.

The central government. In the course of Peter's reign, medieval and obsolescent forms of government gave place to effective autocracy. In 1711 he abolished the *boyarskaya duma*, or boyar council, and established by decree the Senate as the supreme organ of state—to coordinate the action of the various central and local organs, to supervise the collection and expenditure of revenue, and to draft legislation in accordance with his edicts. Martial discipline was extended to civil institutions, and an officer of the guards was always on duty in the Senate. From 1722, moreover, there was a procurator general keeping watch over the daily work of the Senate and its chancellery and acting as "the eye of the sovereign."

When Peter came to power the central departments of state were the *prikazy*, or offices, of which there were about 80, functioning in a confused and fragmented way. To replace most of this outmoded system, Peter in 1718 instituted 9 "colleges" (*kollegy*), or boards, the number of which was by 1722 expanded to 13. Their activities were controlled, on the one hand, by the General Regula-

tion and, on the other, by particular regulations for individual colleges, and indeed there were strict regulations for every branch of the state administration. Crimes against the state came under the jurisdiction of the Preobrazhensky Office, responsible immediately to the tsar.

Europeanization of industry

Industry. A secondary purpose of Peter's Grand Embassy to western Europe in 1697 (see above *The Grand Embassy*) had been to obtain firsthand acquaintance with advanced industrial techniques, and the exigencies of his great war against Sweden, from 1700, made industrial development an urgent matter. In order to provide armaments and to build his navy (Russia had virtually no warships at all), metallurgical and manufacturing industries on a grand scale had to be created; and Peter devoted himself tirelessly to meeting these needs. Large capital investments were made, and numerous privileges were accorded to businessmen and industrialists. These privileges included the right to buy peasant serfs for labour in workshops, with the result that a class of "enlisted" serfs came into existence, living in specified areas and bound to the factories. The methods of other countries were further studied, and foreign experts were invited to Russia. The overall result was satisfactory: the army and the navy were, of course, supplied with their material needs; a great number of manufacturing establishments were founded (mainly with serf labour); the metallurgical industry was so far advanced that by the middle of the 18th century Russia led Europe in this field; and the foreign-trade turnover was increased sevenfold in the course of the reign.

The armed forces. Peter established a regular army on completely modern lines for Russia in the place of the unreliable *streltsy* and the militia of the gentry. While he drew his officers from the nobility, he conscripted peasants and townspeople into the other ranks. Service was for life. The troops were equipped with flintlock firearms and bayonets of Russian make; uniforms were provided; and regular drilling was introduced. For the artillery, obsolete cannons were replaced with new mortars and guns designed by Russian specialists or even by Peter himself (he drew up projects of his own for multicannon warships, fortresses, and ordnance). The Army Regulations of 1716 were particularly important; they required officers to teach their men "how to act in battle," "to know the soldier's business from first principles and not to cling blindly to rules," and to show initiative in the face of the enemy. For the navy, Peter's reign saw the construction, within a few years, of 52 battleships and hundreds of galleys and other craft; thus a powerful Baltic fleet was brought into being. Several special schools prepared their pupils for military or naval service and finally enabled Peter to dispense with foreign experts.

Cultural and educational measures. From January 1, 1700, Peter introduced a new chronology, making the Russian calendar conform to European usage with regard to the year, which in Russia had hitherto been numbered "from the Creation of the World" and had begun on September 1 (he adhered however to the Julian Old Style as opposed to the Gregorian New Style for the days of the month). In 1710 the Old Church Slavonic alphabet was modernized into a secular script.

Peter was the first ruler of Russia to sponsor education on secular lines and to bring an element of state control into that field. Various secular schools were opened; and since too few pupils came from the nobility, the children of soldiers, officials, and churchmen were admitted to them. In many cases, compulsory service to the state was preceded by compulsory education for it. Russians were also permitted to go abroad for their education and indeed were often compelled to do so (at the state's expense). The translation of books from western European languages was actively promoted. The first Russian newspaper, *Vedomosti* ("Records"), appeared in 1703. The Russian Academy of Sciences was instituted in 1724.

Beside his useful measures, Peter often enforced superficial Europeanization rather brutally; for example, when he decreed that beards should be shorn off and Western dress worn. He personally cut the beards of his boyars and the skirts of their long coats (*kaftany*). The Raskolniki (Old Believers) and merchants who insisted on keeping their beards had to pay a special tax, but peasants and the Orthodox clergy were allowed to remain bearded.

Control over church and nobility

The church. In 1721, in order to subject the Orthodox Church of Russia to the state, Peter abolished the Patriarchate of Moscow. Thenceforward the patriach's place as head of the church was taken by a spiritual college, namely the Holy Synod, consisting of representatives of the hierarchy obedient to the tsar's will. A secular official—the *ober-prokuror*, or chief procurator—was appointed by the tsar to supervise the Holy Synod's activities. The Holy Synod ferociously persecuted all dissenters and conducted a censorship of all publications.

Priests officiating in churches were obliged by Peter to deliver sermons and exhortations to make the peasantry "listen to reason" and to teach such prayers to children that everyone would grow up "in fear of God" and in awe of the tsar. The regular clergy were forbidden to allow men under 30 years old or serfs to take vows as monks.

The church was thus transformed into a pillar of the absolutist regime. Partly in the interests of the nobility, the extent of land owned by the church was restricted; Peter disposed of ecclesiastical and monastic property and revenues at his own discretion, for state purposes.

The nobility. Peter's internal policy served to protect the interest of Russia's ruling class—the landowners and the nascent bourgeoisie. The material position of the landed nobility was strengthened considerably under Peter. Almost 100,000 acres of land and 175,000 serfs were allotted to it in the first half of the reign alone. Moreover, a decree of 1714 that instituted succession by primogeniture and so prevented the breaking up of large properties also removed the old distinction between *pomestya* (lands granted by the tsar to the nobility in return for service) and *votchiny* (patrimonial or allodial lands) so that all such property became hereditary.

Moreover, the status of the nobility was modified by Peter's Table of Ranks (1722). This replaced the old system of promotion in the state services, which had been according to ancestry, by one of promotion according to services actually rendered. It classified all functionaries —military, naval, and civilian alike—in 14 categories, the 14th being the lowest and the 1st the highest; and admission to the 8th category conferred hereditary nobility. Factory owners and others who had risen to officer's rank could accede to the nobility, which thus received new blood. The predominance of the boyars ended.

Personality and achievement. Peter was of enormous height, more than six and one-half feet (two metres) tall; he was handsome and of unusual physical strength. Unlike all earlier Russian tsars, whose Byzantine splendours he repudiated, he was very simple in his manners; for example, he enjoyed conversation over a mug of beer with shipwrights and sailors from the foreign ships visiting St. Petersburg. Restless, energetic, and impulsive, he did not like splendid clothes that hindered his movements; often he appeared in worn-out shoes and an old hat, still more often in military or naval uniform. He was fond of merrymaking and knew how to conduct it, though his jokes were frequently crude; and he sometimes drank heavily and forced his guests to do so too. A just man who did not tolerate dishonesty, he was terrible in his anger and could be cruel when he encountered opposition: in such moments only his intimates could soothe him—best of all his beloved second wife, Catherine, whom people frequently asked to intercede with him for them. Sometimes Peter would beat his high officials with his stick, from which even Prince A.D. Menshikov, his closest friend, received many a stroke. One of Peter's great gifts of statesmanship was the ability to pick talented collaborators for the highest appointments, whether from the foremost families of the nobility or from far lower levels of society.

As a ruler, Peter often used the methods of a despotic landlord—the whip and arbitrary rule. He always acted as an autocrat, convinced of the wonder-working power of compulsion by the state. Yet with his insatiable capacity for work he saw himself as the state's servant, and whenever he put himself in a subordinate position he

would perform his duties with the same conscientiousness that he demanded of others. He began his own army service in the lowest rank and required others likewise to master their profession from its elements upward and to expect promotion only for services of real value.

Peter's influence on Russia

Peter's personality left its imprint on the whole history of Russia. A man of original and shrewd intellect, exuberant, courageous, industrious, and iron willed, he could soberly appraise complex and changeable situations so as to uphold consistently the general interests of Russia and his own particular designs. He did not completely bridge the gulf between Russia and the Western countries, but achieved considerable progress in development of the national economy and trade, education, science and culture, and foreign policy. Russia became a great power, without whose concurrence no important European problem could thenceforth be settled. His internal reforms achieved progress to an extent that no earlier innovator could have envisaged (see further RUSSIA AND THE SOVIET UNION, HISTORY OF).

BIBLIOGRAPHY. There are numerous studies in Russian on Peter I and his age. *Письма и бумаги Императора Петра Великаво,* 11 vol. (1887–1962), contains valuable documents on Russian history up to 1711. Other works particularly recommended include: М.М. БОГОСЛОВСКИЙ, *Петр I,* 5 vol. (1940–48), a detailed biography of Peter I until 1700; С.М. СОЛОВЬЕВ, *Публичныя чтения о Петре Великом* (1872), a famous Russian historian on the role of Peter I; И.И. ГОЛИКОВ, *Деяния Петра Великаво,* 30 vol. (1788–97), on his reforms; and Л.А. НИКИФОРОВ, *Русско-английские отношения при Петре I* (1950). Works in English: B.H. SUMNER, *Peter the Great and the Ottoman Empire* (1949, reprinted 1965) and *Peter the Great and the Emergence of Russia* (1950); IAN GREY, *Peter the Great, Emperor of All Russia* (1960). Petrarch

Francesco Petrarch, a scholar, poet, Humanist, and promoter of new ideas, stands between the dying medieval period and the Renaissance, which he ushered in. Although it cannot be claimed that he had much influence on the economic and political forces of his time, the artistic and moral outlook that characterizes the new age can be traced directly to this one man's mind and work. The poet Dante, his older contemporary, belongs entirely to the Middle Ages, and for him the beauty of poetry lay in its *artes*—colours, figures, resonances, verbal and metrical complexities. After Petrarch, beauty was seen to lie in the "classical" virtues of purity, simplicity, and proportion. Morally, Dante was concerned primarily with being theologically right; Petrarch and those who followed him cared for the enrichment of the human mind and conscience.

Education and early poems. Petrarch was a Florentine, but once removed. His father, a lawyer, had been obliged to leave Florence in 1302 and had moved to Arezzo, where Petrarch was born on July 20, 1304. The family eventually moved to Avignon (1312), in the Provence region of southern France, the home of the exiled papal court, at which an Italian lawyer might hope to find employment. Petrarch's first studies were at Carpentras (about 15 miles [24 kilometres] from Avignon itself), and at his father's insistence he was sent to study law at Montpellier (1316) and from there returned to Italy with his younger brother Gherardo to continue these studies at Bologna (1320). But already he was developing what, in a later letter, he described as "an unquenchable thirst for literature." His devotion to it is illustrated by a well-known anecdote: his father, anxious for his son to concentrate on the potentially lucrative study of the law, threw the books that might distract him on the fire; but faced with his son's passionate entreaties he relented sufficiently to rescue copies of Virgil and Cicero.

Earliest surviving poems

Petrarch's earliest surviving poems, on the death of his mother (1318 or 1319; *Epistolae metricae,* i, 7), date from the Montpellier and Bologna period, though like all Petrarch's work they were heavily revised later. Meanwhile, his knowledge and love of the classical authors increased, he made his acquaintance with the new vernacular poetry that was being written, and perhaps he even experimented in it himself.

After his father's death, in 1326, Petrarch was free to abandon his law studies and pursue his own interests. Returning to Avignon, he took minor ecclesiastical orders (which enabled him to hold benefices and canonries without much attendant responsibility or obligation) and entered the household of the influential Cardinal Giovanni Colonna. Petrarch enjoyed life in Avignon, and there is a famous description of him and his brother as dandies in its polished courtly world. But he was also making a name there for his scholarship and the elegance of his culture.

As well as a love of literature, Petrarch also had during his early youth a deep religious faith, a love of virtue, and an unusually deep perception of the transitory nature of human affairs. There now followed the reaction—a period of dissipation—which also coincided with the beginning of his famous chaste love for a woman known now only as Laura. Vain attempts have been made to identify her, but Petrarch himself kept silent about everything concerning her civil status, as though he thought it unimportant. He first saw her in the Church of St. Clare at Avignon on April 6, 1327, and loved her, although she was outside his reach, almost until his death, in 1374. From this love there springs the work for which he is most celebrated, the Italian poems (*Rime*), which he affected to despise as mere trifles in the vulgar tongue but which he collected and revised throughout his life.

Meeting with Laura

Classical studies and career (1330–40). He spent the summer of 1330 at Lombez, a little Gascon town, the bishop of which was an old friend from Bologna, Giacomo Colonna. In 1335 he received a canonry there but continued to reside at Avignon in the service of the Cardinal, with whom he stayed until 1337. Quite apart from his love for Laura, this period was an important one for Petrarch. These were years of ambition and unremitting study (notably in the field of classical Latin). They were also years of travel. In 1333 his journeying took him through France, Flanders, Brabant, and the Rhineland, where he visited men of learning and searched monastic libraries for "lost" classical manuscripts (in Liège he discovered copies of two speeches by Cicero). In Paris he was given a copy of the *Confessions* of St. Augustine by a friend and spiritual confidant, the Augustinian monk Dionigi of Sansepolcro, and he was to use this more and more as the breviary of his spiritual life.

Petrarch's synthesis of the classical tradition and Christianity

These experiences bring Petrarch's mission as a stubborn advocate of the continuity between classical culture and the Christian message more sharply into focus. By making a synthesis of the two seemingly conflicting ideals —regarding the one as the rich promise and the other as its divine fulfillment—he can claim to be the founder and great representative of the movement known as European Humanism. He rejected the sterile argumentation and

endless dialectical subtleties to which medieval Scholasticism had become prey and turned back for values and illumination to the moral weight of the classical world. The list of his books (1333) reveals that Cicero, Virgil, and Horace kept company with St. Augustine and St. Jerome; no Scholastic work is mentioned. In 1337 he visited Rome for the first time, to be stirred among its ruins by the evident grandeur of its past. On returning to Avignon he sought a refuge from its corrupt life—the papacy at this time was wholly absorbed in secular matters—and a few miles to the east found his "fair transalpine solitude" of Vaucluse, which was afterward to become a much-loved place of retreat.

The chronology of Petrach's writings is somewhat complicated by his habit of revising, often very extensively, everything he wrote. (This also means that it is very difficult to perceive the real movement of Petrarch's mind: attitudes properly belonging to his later work often seem to have been anticipated in his earlier writings.) By the time he discovered Vaucluse, however, he had written a good many of the individual poems that he was to include in the *Epistolae metricae* ("66 letters" in Latin hexameter verses) and some of the vernacular *Rime* inspired by his love for Laura. At Vaucluse he began to work on *Africa,* an epic poem on the subject of the Second Punic War, intended to vie with Virgil's *Aeneid* but never completed. He also began work on *De viris illustribus,* intended as a series of biographies of heroes from Roman history (but later modified to include famous men of all time, beginning with Adam, as Petrarch's desire to emphasize the continuity among ideals of the Old Testament, of the classical world, and of Christianity increased).

Moral and literary evolution (1340–46). Meanwhile, his reputation as a scholar was spreading; in September 1340 he received invitations from Paris and Rome to be crowned as poet. He had perhaps sought out this honour, partly from ambition but mainly in order that the rebirth of the cult of poetry after more than 1,000 years might be fittingly celebrated. He had no hesitation in choosing Rome, and accordingly he was crowned on the Capitoline Hill on April 8, 1341, afterward placing his laurel wreath on the tomb of the Apostle in St. Peter's Basilica: again, the symbolic gesture linking the classical tradition with the Christian message.

Poet laureate

From Rome he went to Parma and the nearby solitude of Selvapiana, returning to Avignon in the autumn of 1343. It is generally believed that he went through some kind of moral crisis at this time, rooted in his inability to make his life conform to his religious faith and possibly heightened by his brother's decision to solve his own problems by entering a Carthusian monastery. At any rate, this is a common reading of the *Secretum meum,* written between the autumn of 1342 and the winter of 1343 (later revised). An autobiographical treatise, it consists of three dialogues between Petrarch and St. Augustine in the presence of Truth: he identifies his "secret" as an infirmity of the will that prevents him from achieving a noble life, even while aspiring to it; he accuses himself of all seven deadly sins except envy; he finally convinces himself that his love—even though chaste and directed toward a pure woman—and his desire for glory are sinful. But he declares himself unable to reform. Even so, the work's real conclusion is its most important aspect, one truly Humanistic: for he maintains hope that, even amidst worldly preoccupations and error, even while absorbed in himself and his own affairs, a man might still find a way to God. Thus, Petrarch's spiritual "problem" found a coherent solution, one that can be said to express the Petrarchan vision and the Humanist's religious and moral outlook. It reinforces his experience the year before, when, on climbing Mt. Ventoux in France, he had drawn from his pocket the *Confessions*; his eye fell upon the passage where St. Augustine speaks of men who ". . . go to admire the high mountains and the immensity of the ocean and the course of the heaven . . . and neglect themselves."

It was therefore an evolution—both moral and literary—rather than a "crisis" that made Petrarch decide his love for Laura was love for the creature rather than for the Creator and therefore wrong—proof of his attachment to the world. It was an evolution in his thinking that led him to break through the barriers of his too-exclusive admiration for antiquity and to admit other authoritative voices. It was now, for example, that *De viris* was enlarged to include material from sacred as well as secular history, while in the *De vita solitaria* (1346; later revised and enlarged) he developed the theoretical basis and description of the "solitary life" whereby man enjoys the consolations of nature and study together with those of prayer.

The Petrarchan myth of "solitude"

Break with his past (1346–53). The events of the next few years are fundamental to his biography, both as a man and as a writer. In the first place, he became enthusiastic for the efforts of Cola di Rienzo to revive the Roman republic and restore popular government in Rome—a sympathy that divided him still more sharply from the Avignon court and in 1346 even led to the loss of Cardinal Colonna's friendship. The Plague of 1348, known as the Black Death, saw many friends fall victim, including Laura, who died on April 6, the anniversary of Petrarch's first seeing her. Finally, in the jubilee year of 1350 he made a pilgrimage to Rome and later assigned to this year his renunciation of sensual pleasures.

These are the landmarks of Petrarch's career, but the time in between was filled with diplomatic missions, study, and immense literary activity. In Verona in 1345 he made his great discovery of the letters of Cicero to Atticus, Brutus, and Quintus, which allowed him to penetrate the surface of the great orator and see the man himself. The letters spurred him on to write epistles to the ancient authors whom he loved and to make a collection of his own letters that he had scattered among his friends. These great collections (*Familiarium rerum libri xxiv; Senilium rerum libri*) record not only Petrarch's genius for friendship but also all those shifts in attitude by which he left behind the Middle Ages and prepared for the Renaissance. Toward the end of 1345 he returned again to the peace of Vaucluse and spent two years there, chiefly revising *De vita solitaria* but also developing the theme of solitude in a specifically monastic context, in *De otio religioso*. Between November 1347 and his pilgrimage to Rome in 1350 he was also in Verona, Parma (where the news of Laura's death reached him; he noted it in his copy of Virgil, in order that he might constantly be reminded of the decay of all earthly goods), and Padova. Much of the time was spent in advancing his career in the church; the manoeuvring and animosities this involved resulted in an intense longing for the peace of Vaucluse; not even a visit from his lifelong friend the poet Boccaccio, who offered him a chair to be established under his guidance in the university of Florence, could deflect him. He left Rome in May 1351 for Vaucluse.

Rime. Here he worked on a new plan for the *Rime.* The project was divided into two parts: the *Rime in vita di Laura* ("Poems During Laura's Life") and the *Rime in morte di Laura* ("Poems after Laura's Death"), which he now selected and arranged to illustrate the story of his own spiritual growth. The choice of poems was further governed by an exquisite aesthetic taste and by a preference for an approximately chronological arrangement, from the description of his falling in love to his final invocation to the Virgin; from his "youthful errors" to his realization that "all worldly pleasure is a fleeting dream"; from his love for this world to his final trust in God. The theme of his *Canzoniere* (as the poems are usually known) therefore goes beyond the apparent subject matter, his love for Laura. For the first time in the history of the new poetry, lyrics are held together in a marvellous new tapestry, possessing its own unity (and similar to one that Petrarch was constructing, on the Ciceronian model, from his letters). By selecting all that was most polished and at the same time most vigorous in the lyric tradition of the preceding two centuries and filtering it through his new appreciation of the classics, he not only bequeathed to humanity the most limpid and yet passionate, precise yet suggestive, expression of love and grief, of the ecstasies and sorrows of man, but

The *Rime in vita* and *Rime in morte*

also created with his marvellous sensibility the form and language of the modern lyric, to provide a common stock for lyric poets of the whole of Europe.

He also continued work on the *Metricae,* begun in 1350; he embarked on a polemic against the conservative enemies of his new conception of education, which rejected the prevailing Aristotelianism of the schools and restored the spiritual worth of classical writers—the new studies to be called *litterae humanae,* "humane letters." He also began work on his poem *Trionfi,* a more generalized version of the story of the human soul in its progress from earthly passion toward fulfillment in God (in it, Love is conquered by Chastity, Chastity by Death, Death by Glory, Glory by Time, and Time by Eternity).

Later years (1353–74). But the death of his closest friends, dislike of the newly elected pope, Innocent VI, increasingly bitter relations with the Avignon court, all finally determined Petrarch to leave Provence and settle in Italy. He found rooms in Milan and stayed there for most of the next eight years (in spite of harsh criticisms for accepting hospitality from the Visconti family, enemies of Florence, for whom he carried out a number of important diplomatic missions). During these eight years he also completed the first proper edition of the *Rime,* continued assiduously with the *Familiares,* worked on the *Trionfi,* and set in order many of his earlier writings.

Early in 1361 he went to Padova, hoping to escape the Plague. He remained there until September 1362, when, again a fugitive from the Black Death, he sought shelter in Venice. He was given a house, and in return Petrarch promised to bequeath all his books to the republic. He was joined by his daughter Francesca, and the tranquil happiness of her little family gave him great pleasure. He was visited by his dearest and most famous friends (by the great chancellor Benintendi de' Ravegnani, by Padovan scholars, by Boccaccio, who in 1366 presented him with a long-desired Latin translation of Homer's poems); he was invited to play an honourable part in the life and politics of the city; he worked peacefully but with great concentration at the definitive versions of the *Rime,* the *Familiares,* the *Seniles,* and the *De remediis utriusque fortunae,* a collection of 254 treatises on how to bear with both good fortune and bad. Nevertheless, after receiving an insult from four young men who followed the Arab "naturalist" interpretation of Aristotle's work (they called Petrarch "a good man . . . but illiterate and in fact an idiot" because he believed in Christian doctrines rather than those attributed to Aristotle), Petrarch was induced to move back to Padova in 1367. He remained there until his death, dividing his time from 1370 between Padova and Arquà, in the neighbouring Colli Eugenei (Euganean hills), where he now had a little house. There he wrote the defense of his Humanism against the critical attack from Venice, *De sui ipsius et multorum ignorantia.* He was still in great demand as a diplomat; in 1370 he was called to Rome by Urban V, and he set off eager to see the fulfillment of his great dream of a new Roman papacy, but at Ferrara he was seized by a stroke. Yet he did not stop working; in addition to revision he composed more minor works and added new sections to his *Posteritati,* an autobiographical letter to posterity that was to have formed the conclusion to his *Seniles*; he also composed the final sections of the *Trionfi.*

Petrarch died during the night of July 18–19, 1374, while working in his study at Arquà, and was found the next morning, his head resting on a manuscript of Virgil.

Petrarch's achievement

The hallmark of Petrarch's thought was a deep consciousness of the past as the nutriment of the present. His abiding achievement was to recognize that, if there is a Providence that guides the world, then it has set man at the centre. Petrarch provided a theoretical basis for the enrichment of man's life. But, even more important, the Humanist attitudes of the Italian 15th century that led into the Renaissance would not have been possible without him.

MAJOR WORKS

The chronology of Petrarch's works is difficult to ascertain because the poet habitually and heavily revised everything he wrote. His collected works (*Opera*) were published in 1554 and 1581.

LATIN WORKS: *Epistolae metricae* (he worked on the collection in three phases: 1350, 1357, and 1363; ed. by D. Rossetti, *Poesie minori del Petrarca,* 1831); *Africa* (begun 1338 or 1339; published posthumously 1396; critical edition by N. Festa, 1926); *De viris illustribus* (begun 1338–39; revised 1341–43, and again 1351–53; later replanned with the title *Quorundam virorum illustrium epithoma,* preface by Petrarch, completed by his disciple Lombardo della Seta; ed. by L. Razzolini, 1874–79); *Secretum meum* (1342–43, revised 1353–58; ed. by E. Carrara in *Prose,* 1955); *De vita solitaria* (1346 and later—one addition of 1371; ed. by G. Martellotti in *Prose,* 1955); *De otio religioso* (1347, revised and enlarged 1357; ed. by G. Rotondi, 1958); *Familiarium rerum libri xxiv* (arrangement of the letters begun 1351–53, i-viii; 1359–60, ix-xix; 1363–64, xx-xxiii; 1366, xxiv; critical edition by V. Rossi and U. Bosco, 1933–42); *De remediis utriusque fortunae* (begun 1354; published 1366; Petrarch probably returned to it later); *Senilium rerum libri* (after 1361 to 1374); *Posteritati* (first draft before 1367; additions 1370–72; ed. by E. Carrara and P.G. Ricci in *Prose,* 1955); *De sui ipsius et multorum ignorantia* (written 1367, published 1371; ed. by L.M. Cappelli, 1906).

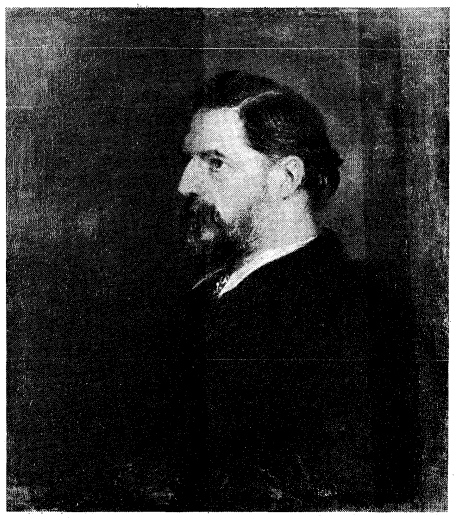
OTHER LATIN WORKS: Prayers (1335–38); *Epistolae sine nomine* (written 1342–58; collected 1359–60; ed. by P. Piur, 1925); *Rerum memorandarum libri* (1343–45; critical edition by G. Billanovich, 1945); *Bucolicum carmen* (1346–48; definitive version 1364; ed. by A. Avena, 1906); *Salmi penitenziali* (1347; ed. by H. Cochin, 1929); *Invectivarum contra medicum quendam libri* iv (1352–55; ed. by P.G. Ricci, 1950); *Invectiva contra quendam magni status hominem sed nullius scientiae aut virtutis* (1355; ed. by P.G. Ricci, 1949); *Itinerarium Syriacum* (*Itinerarium breve de Janua usque ad Jerusalem et Terram Sanctam*) (1358 and later); *Invectiva contra eum qui maledixit Italiae* (1373); *Epistolae variae* (65 letters not included by Petrarch in his collections).

ITALIAN WORKS: *Rerum vulgarium fragmenta* (*Rime in vita di Laura* and *Rime in morte di Laura,* or *Canzoniere*; first edition, 1360; second edition, 1373; definitive edition, preserved in Cod. Vat. Lat. 3195; ed. by G. Contini, 1949; commentaries by G. Carducci and S. Ferrari, 6th edition, 1957; ed. by E. Chiorboli, 1924); *Rime disperse* (or *Estravaganti,* poems not included by Petrarch in his main collection, many of doubtful authenticity, ed. by A. Solerti, 1909); *Trionfi* (begun 1351, revised between 1356–1374, unfinished, published posthumously; critical edition by K. Appel, 1901; to be read in conjunction with *Un inedito petrarchesco,* ed. by R. Weiss, 1950).

BIBLIOGRAPHY. M. FOWLER, *Catalogue of the Petrarch Collection Bequeathed by Willard Fiske* (1916), an exhaustive guide to all the early editions of Petrarch and works concerning him; articles and reviews appear regularly in the journal *Studi petrarcheschi* (1948–).

Editions: Edizione nazionale delle opere di Francesco Petrarca (1926–), includes so far: *Familiares, Africa, Rerum memorandarum libri,* and *De viris illustribus; Rime, Trionfi e Poesie latine,* ed. by F. NERI *et al.* (1951); *Prose,* ed. by G. MARTELLOTTI, E. CARRARA, and P.G. RICCI (1955), the most compendious modern editions of Petrarch.

Selections: J. VIANEY, *Le Pétrarquisme en France au XVI^e siècle* (1909); L. FORSTER, *The Icy Fire: Five Studies in European Petrarchism* (1969); T.G. BERGIN (comp.), *Rhymes: A Selection of Translations* (1955), introductions to the vast theme of imitation and translation of Petrarch in European love poetry; DAVID THOMPSON (ed.), *Petrarch: A Humanist Among Princes* (1971), an anthology of selections from Petrarch's works and letters.



Biographical and critical studies: ABBE DE SADE, *Mémoires pour la vie de François Pétrarque,* 3 vol. (1764–67), the fundamental biography of Petrarch; E.H. WILKINS, *The Making of the Canzoniere and Other Petrarchan Studies* (1951), *Studies in the Life and Works of Petrarch* (1955), *Petrarch's Eight Years in Milan* (1958), *Petrarch's Later Years* (1959), and *Life of Petrarch* (1961), the major American contribution to Petrarch scholarship; PIERRE DE NOLHAC, *Pétrarque et l'humanisme,* 2nd ed., 2 vol. (1907), *Petrarch and the Ancient World* (1907), an abridged version of the great work by de Nolhac; J.H. WHITFIELD, *Petrarch and the Renascence* (1943, reprinted 1966); HANS BARON, *From Petrarch to Leonardo Bruni* (1968); G. BILLANOVICH, *Petrarca letterato* (1947); U. BOSCO, *Francesco Petrarca,* 2nd ed. (1961), the best general Italian presentation of Petrarch; N. SAPEGNO, articles on Petrarch in *Il Trecento,* 3rd ed. (1966); and in vol. 2 of the CECCHI-SAPEGNO *Storia della letteratura italiana* (1965), with copious bibliography.

Petrie, Sir Flinders

Sir Flinders Petrie, a renowned English archaeologist and Egyptologist, made valuable contributions to the techniques and methods of field excavation and invented a method of sequence dating that made possible the reconstruction of history from the remains of ancient cultures.

By courtesy of the National Portrait Gallery, London

Petrie, oil painting by G.F. Watts (1817–1904). In the National Portrait Gallery, London.

Born at Charlton, near Greenwich, London, on June 3, 1853, William Matthew Flinders Petrie was named for his maternal grandfather, Matthew Flinders, British navigator, pioneer hydrographer, and explorer of Australia and Tasmania. A frail child, Petrie was privately educated, early developing archaeological and ethnological interests, particularly in the area of ancient weights and measures, and in Egyptology.

At the age of 24, Petrie wrote *Inductive Metrology, or the Recovery of Ancient Measures from the Monuments*, a work that represented a new approach to archaeological study. Fieldwork done at various locations in Britain, including Stonehenge, enabled him to determine by mathematical computations the unit of measurement for the construction of the monument. His *Stonehenge: Plans, Description, and Theories* was published in 1880, and in that same year he began the surveys and excavation of the Great Pyramid at Giza, which initiated his four decades of exploration in the Middle East.

Excavations and discoveries

During the 1884 excavation of the Temple of Tanis, he found fragments of a colossal statue of Ramses II. In 1885 and 1886, at Naukratis and Daphnae in the Nile Delta, he uncovered painted pottery by which he proved that those sites had been trading colonies for the ancient Greeks. It was this discovery that caused him to believe that history could be reconstructed by a comparison of potsherds (pottery fragments) at various levels of an excavation.

He first applied his principle of sequence dating in Palestine, at Tel Ḥasi, south of Jerusalem. In 1890, in a period of only six weeks, the indefatigable excavator found a series of occupations for which he supplied tentative dates of habitation. His work at the hill site marked the second stratographic study in archaeological history—the first was carried out at Troy by Heinrich Schliemann. The excavations of these two men marked the beginning of the examination of successive levels of a site, rather than the previously practiced method of haphazard digging, which had produced only a jumble of unrelated artifacts. Most of Petrie's contemporaries in archaeology questioned his hypothesis that chronology could be established by potsherds, whether painted or undecorated. But, with the progressive sophistication of the science of archaeology, examination and classification of broken pottery became, as it is now, routine procedure.

He made other important discoveries in the Fayyūm region of Egypt. At Gurob, he found numerous papyri and Aegean pottery that substantiated dates of ancient Greek civilizations, including the Mycenaean. At the Pyramid of Hawara he searched through the tomb of Pharaoh Amenemhet III to discover how grave robbers could have found the tomb's opening and made their way through the labyrinth surrounding the two sarcophagi (stone coffins) that they emptied. He concluded that they must have been given the master plan by an informer. At al-Fayyūm also he made a rich find of 12th-dynasty jewelry (housed at the Metropolitan Museum of New York since 1919). He was delighted by his discovery of the earliest known Egyptian reference to Israel on the stele (a stone slab monument) of Merneptah, pharaoh of ancient Egypt from *c.* 1236–1223 BC.

In 1892 Petrie was made Edwards professor of Egyptology at University College, London, and held the position until 1933, when he became professor emeritus. In 1894, he founded the Egyptian Research Account, which in 1905 became the British School of Archaeology.

Petrie added to the knowledge of the pyramid builders during his exploration of the necropolis of Abydos, holy city of the cult of Osiris, god of the dead. At Tell el-Amarna, he excavated the city of Akhenaten, or Amenhotep IV, ruler of Egypt from 1379–1362 BC, revealing the now-famous painted pavement and other artistic wonders of the Amarna age (14th century BC). Three thousand graves found by Petrie at Naqādah, northeast of Thebes, were identified as those of primitive ancient Egyptians.

Methods and Aims in Archaeology

In 1904, Petrie published *Methods and Aims in Archaeology*, the definitive work of his time, in which he lucidly defined the goals and methodology of his profession along with the more practical aspects of archaeology —details of excavation, including the use of cameras in the field. With uncommon insight, he noted that research results were dependent on the personality of the archaeologist, who, in addition to broad knowledge, had to have insatiable curiosity. His own abundance of that characteristic was never questioned.

Inscriptions Petrie found on the Sinai Peninsula represented an intermediate stage (not later than 1500 BC) of written communication between Egyptian hieroglyphics and the Semitic alphabet. Although he wrote *The Formation of the Alphabet* (1912), language was not Petrie's forte, and he depended on a sixth sense for free translation of inscriptions and for establishing dates through the study of the forms of hieroglyphs.

Petrie was knighted in 1923. Under the auspices of the American School of Research, he excavated in Palestine from 1927 until 1938, when he was 85. In those years, again at Tel Ḥasi, he uncovered the ruins of ten cities. His scientific methods provided the guidelines for all subsequent Palestinian excavations. He died at Jerusalem, July 28, 1942, at the age of 89.

BIBLIOGRAPHY. W.F. ALBRIGHT, *History, Archaeology and Christian Humanism* (1964), in the course of discussing specific contributions to archaeology, evaluates Petrie's work in the development of archaeological method. MARGARET ALICE MURRAY, *The Splendor That Was Egypt*, rev. ed. (1963), is dedicated to her longtime colleague at University College, London, with tribute to the man and the archaeologist. He is given similar recognition in C.L. WOOLLEY, *Dead Towns and Living Men*, rev. ed. (1954). J. LIEBOVITCH, *Ancient Egypt* (1938), a history of the antiquities in the Egyptian Museum, Cairo, illuminates the finds of Petrie and other Egyptologists and is profusely illustrated, including alphabetic signs. KURT W. MAREK (C.W. CERAM, pseud.), *Götter, Gräber, und Gelehrte: Roman der Archäologie* (1963; Eng. trans., *Gods, Graves and Scholars*, 2nd ed. rev., 1967), considers Petrie the outstanding interpreter of discoveries; also contains a chronological table of Egyptian dynasties and a separate bibliography for the section on the pyramids.

(G.J.P.)

Petroleum

Petroleum can be applied as an inclusive term to the complex mixture of hydrocarbons that occurs in the earth in liquid, gaseous, or solid forms. As generally used, however, petroleum is a liquid (crude oil) that is recovered

from some depth within the Earth through boreholes. The liquid and gaseous phases of petroleum occur naturally underground, primarily within the pore spaces of sedimentary rocks, and under normal conditions they migrate freely until stopped by a subsurface obstruction or trap. In its liquid and gaseous forms, petroleum is the most important of the primary fossil fuels that supply the bulk of the world's energy requirements.

History of petroleum usage. The word petroleum (literally "rock oil," from the Greek and Latin words *petra*, "rock" or "stone," and *oleum*, "oil") was first used by the German mineralogist Agricola who described its recovery and refining in a treatise published in 1556. Man's use of petroleum, however, goes back into prehistory. Beginning more than 5,000 years ago, the Sumerians, the Assyrians, and the Babylonians each used the large seepages at Hit on the Euphrates, and similar seepages were known and used in various ways at many places in Mesopotamia and adjacent areas bordering the eastern Mediterranean. The Dead Sea was known in ancient times as Lake Asphaltites (from which is derived the term asphaltum) because of the semisolid petroleum washed up on its shores from underwater seepages.

Because there was a scarcity of natural stone and timber in the lower reaches of the Tigris and Euphrates rivers, the inhabitants of that region used bitumen, or asphalt, for many purposes. Excavations at Susa in Iran and Ur in Iraq reveal that bitumen was mixed with sand and fibrous material for use in construction of watercourses and levees of the extensive irrigation systems of the area and as a mortar for bricks. Bitumen was widely used in the caulking of ships and the building of roads. It was employed to fasten pieces of flint into bone in making sickles and was used in paints and waterproofing baskets and mats, as a cement for mosaic and inlaid work, and in the construction of tools of warfare. It had wide usage in magic and medicine, both as a liniment and a laxative, as well as in fumigation. Artistic and religious objects were carved from bitumen-impregnated sands, and the mining of rock asphalt was an important industry.

The ancient Greeks were familiar with many of the uses of bitumen, but they did not transmit this knowledge to the conquering Romans. The latter had developed excellent mortar from other sources for their building construction. The tars and pitches derived from the cedars of Lebanon, as well as from woods found in many other places in their empire, provided adequate substitutes for the mineral bitumens of the East. Many ancient writers described the natural occurrences of oil and gas seepages in the Middle East, especially in the Baku region of what is now the Soviet Union. Oil and gas from seepages, probably first ignited by lightning, provided the fuel for the "eternal fires" that formed the main centre of the fire-worshiping religion of the ancient Persians.

In China and Burma petroleum was encountered in drilling brine wells. The Chinese are reported to have drilled for salt to a depth of 450 feet (140 metres) about 200 BC and to have ignited and used the associated natural gas to evaporate the brine from these salt wells by the 4th century AD.

Use as an illuminant

Early in the Christian Era the Arabs and Persians developed an interest in crude petroleum and its distillation into illuminants, and, probably as a result of the Arab invasion of Spain, the industrial art of distillation was available in western Europe by the 12th century. The Spanish discovered seepage deposits in Cuba, eastern Mexico, Bolivia, Ecuador, and Peru; Sir Walter Raleigh found the famous pitch seepages of Trinidad; and the Dutch made similar discoveries in Java and Sumatra. All of these explorers used the pitch to caulk their ships. The first explorers of the Great Lakes region found oil seepages near Cuba, New York, and Oil Creek, Pennsylvania, where they reported that the Indians used it for medicinal purposes.

Until the beginning of the 19th century illumination in the United States was little improved over that known by the ancient Greeks and Romans. The increasing development of urban centres, with an accompanying need for better illumination and the growing demand for lubricants, proved only the beginning of new needs for additional sources of oil. Whales were becoming increasingly hard to find, and by the middle of the 19th century kerosine, or coal oil, derived by the distillation of coal, was common in both Europe and America. The rapidly approaching Industrial Revolution required a much cheaper and more convenient source of both lubricants and illuminating oil, and thus the stage was set for completion of the first well specifically drilled for oil. This well, drilled by E.L. Drake in western Pennsylvania and completed in August of 1859 at a depth of 69½ feet (21 metres), opened up the petroleum industry and the closely associated modern industrial age. Within a short time, cheap oil from underground reservoirs was being refined at already existing coal-oil refineries, and the spread of oil field discoveries before the 20th century covered 14 states from New York to California and from Wyoming to Texas. During the same period oil fields were discovered in Europe and the Far East.

World energy consumption. At the outset of the 20th century the Industrial Revolution, characterized by the advent of the automobile, had proceeded so far that the use of refined petroleum for illuminants ceased to be of primary importance, and the oil industry instead became the major supplier of energy.

Although petroleum is an important raw product in the petrochemical industry, its greatest use today is in the manufacture of energy upon which mankind's present and future economy depends. Figure 1 shows that the

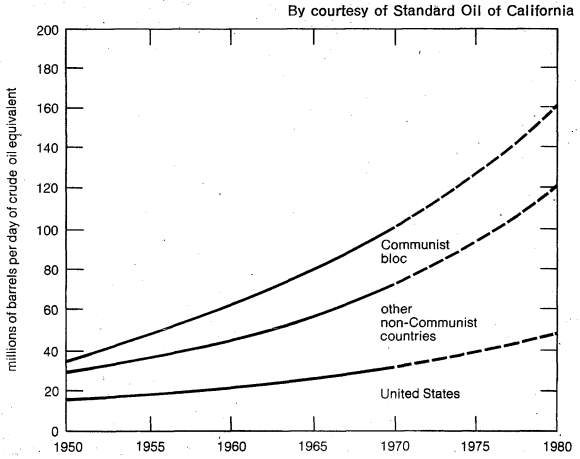

Figure 1: World energy consumption in crude oil equivalent. (Data for China unavailable.)

United States currently uses about 32 percent of the total world energy, the remaining non-Communist countries about 41 percent, and the Communist countries (with the exception of China, for which data are not available) about 27 percent. In 1970 the peoples of the world used the energy equivalent of about 100,000,000 barrels of oil per day, equalling the energy contained in a major or giant oil field, each day of the year. The United States is increasing its energy consumption by about 4 percent per year, other non-Communist countries at almost 6 percent annually, and the Communist countries (again excluding China) are averaging about 5 percent, equal to the worldwide average. Using the 5 percent figure, energy consumption by 1980 will rise to the equivalent of 162,000,000 barrels of oil per day.

Figure 2 shows the world energy consumed each day in terms of hydroelectric power, coal, oil, natural gas, and nuclear power; the energy equivalent is given as millions of barrels of oil. Oil has met the increased demands in world energy best. Use has increased from 11,000,000 barrels daily in 1950 to 46,000,000 barrels in 1970, with a projected use of 80,000,000 barrels per day by 1980. Oil and natural gas together will supply two-thirds of the world energy demand by 1980. Coal consumption shows a small steady increase, but it has failed to hold its relative position in the world energy market. Prior to 1940 coal supplied about 80 percent of Europe's energy demands; today its share is 28 percent. Although coal is still

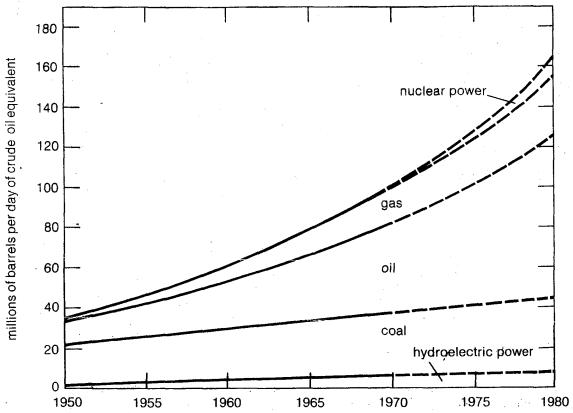

Figure 2: World energy consumption. (Data for China unavailable.)

the predominant fuel for the generation of electricity, the modern demand for reduction of air pollution has forced many users to turn to low-sulfur oil and gas. Hydroelectric power can never become an important competitor in the world energy market; most of the possible generation dam sites are already power committed. Although the development of nuclear power generation is currently behind schedule, by 1980 it may supply about 9 percent of the world's energy.

The growth of consumption of crude oil is shown in Figure 3: the United States, Canada, western Europe, and

Japan are considered in one group; other non-Communist countries are in another; and the Communist countries as a third. The "other non-Communist countries" category represents the comparatively small amounts of oil used in South and Central America, Africa, the Middle East, the Pacific Islands, and non-Communist Asia. In many of these countries the present amounts of energy uses are extremely limited, but the potential energy needs are enormous.

Projected consumption

The projected total consumption of almost 80,000,000 barrels of oil a day by 1980 represents an increase of 5.7 percent per year between 1970 and 1980; this is less than the growth rate for the period between 1960 and 1970. The tremendous increases in demand for energy throughout the world have caused a very critical supply situation. By the beginning of 1970 a total of about 225,000,000,000 barrels of crude oil had been produced by the petroleum industry since the drilling of the Drake well in 1859. From 1970 to 1980, however, the petroleum industry will be called upon to produce almost as much oil as it produced in the previous 110 years. In 1980 oil probably will furnish almost 50 percent of the world's energy, and natural gas will furnish approximately 18 percent.

This article treats the characteristics, origin, and accumulation of petroleum, and its world occurrence and distribution. Type examples of major oil fields are described, and the relation of proved petroleum reserves and probable future discoveries to ever-increasing energy demands is discussed. Further information on allied energy sources is presented in the articles COALS; NATURAL GAS; and OIL SHALES. See also SEDIMENTARY ROCKS; SEDIMENTARY FACIES; and SALT DOMES for additional information on petroleum environments and source rocks; PETROLEUM AND GAS EXTRACTION for methods of exploration and production; and ROCK DEFORMATION for a summary of the geological structures that are involved in many petroleum traps.

CHARACTERISTICS OF PETROLEUM

Physical properties. Petroleum consists of a closely related series of complex hydrocarbon compounds that range from a light gas, methane, to a series of heavy solids. The various mixtures that comprise liquid petroleum or crude oil are separated by distillation under increasing temperatures. The components of the mixture, classified from light to heavy, are the gases, gasolines, kerosine, gas oil, lubricating oil, residual fuel oil, and, finally, asphalt and paraffin.

Colour, consistency, and weight

Because crude oils vary greatly in their chemical compositions, their physical properties such as colour, gravity, and viscosity also vary widely. They are generally greasy or oily to the touch but may vary from a thin liquid with the consistency of gasoline to a thick, viscous black asphalt. In thin layers they range from colourless through all degrees of translucency to opaque, and in reflected light the colours vary from yellow, green, red, through brown, to black. Crude oil is immiscible with water and is lighter than the water; hence, it floats on associated water.

Specific gravity is the ratio of the weight of equal volumes of any material and pure water (considered to be 1). Because the volume of a liquid is affected by both temperature and pressure, the weight of oil is measured at standard conditions of 60° F (16° C) and one atmosphere of pressure. The widely used American Petroleum Institute (API) gravity scale is based on pure water with an arbitrarily assigned API gravity of 10°; oils of progressively lower density have higher values of API gravity. Examples of the relationship of the API gravity scale to the specific gravity of oils through their normal ranges are given below:

specific gravity at 60° F	API degrees
1.0000 (pure water)	10
0.9340	20
0.8762	30
0.8251	40
0.7796	50
0.7389	60

Crude oils that range within 5° of 30° API gravity are the most common and constitute the major portion of the world's production. The specific gravity of crude oil generally tends to decrease with depth of burial, with a corresponding rise in the API gravity. The same phenomenon also may be observed in individual fields with a number of separate reservoirs at varying depths, although there are notable exceptions, as in the great Burgan Field in Kuwait and in a number of fields in the Baku oil province of Russia.

The price of crude oil is ordinarily based on its gravity. The lighter oils command a higher price because they contain a larger amount of the more profitable and easily extracted gasoline hydrocarbons. The colourless or light-coloured crude oils have the highest API gravities, those of medium gravity are often green, and the heavier varieties vary through the darker colours to black.

Because petroleum is always at a temperature above the boiling point of some of its compounds (methane has a boiling point of −164° C [−263° F]), the more volatile constituents are constantly escaping into the atmosphere unless confined. On the other hand, the boiling points of some of the compounds are too high to be normally measured, and it is therefore impossible to determine or refer to a common boiling point for crude oil. For the same reasons, it is impossible to speak of a freezing point

for any particular petroleum, because the individual compounds solidify at different temperatures. The pour point, or the temperature below which crude oil becomes plastic and will not flow, is important and always is determined, however; it ranges from +90° to below −70° F (32° to −57° C).

Viscosity of petroleum is the measurement of the resistance to flow of a certain quantity of oil through a fixed opening at a given temperature and pressure; the greater the viscosity, the longer the time required for flow. The viscosity of petroleum is mainly determined by the amount of dissolved gas it contains and the temperature of the fluid; the more gas in solution and the higher the temperature, the lower the viscosity. The temperature of the earth rises with depth of burial at a rate that varies substantially from place to place; it ranges roughly between 0.5° to 2.2° F per 100 feet, averaging about 1.6° F (0.9° C) per 100 feet. As the oil viscosity decreases with a rise in temperature, the viscosity of the crude oil in the reservoir rock below the surface decreases with depth of burial.

As the depth of burial of the reservoir rock in which petroleum is present increases, so does the pressure exerted on the gas or liquid in the reservoir. This pressure, depending on the depth of burial, may vary from a few hundred pounds to many thousands of pounds per square inch. The amount of gas that can be dissolved in the oil therefore increases with depth of burial, and the volume of the solution (oil and dissolved gas) increases as well, until the oil is saturated with gas (the bubble point). In deep, high-pressure reservoirs, oil may contain 150 times its volume of surface-equivalent dissolved gas. As the oil is brought to the surface from the reservoir, the dissolved gas comes out of solution as the pressure is reduced, and the volume of the reservoir oil decreases to "stock-tank" oil. With the loss of the dissolved gas at the surface the crude oil becomes denser and more viscous.

Crude oil is measured in the United States in barrels of 42 gallons each; the weight per barrel of API 30° gravity oil would be about 306 pounds. In many countries it is measured by the metric ton; for the same gravity oil a metric ton is equal to about 252 imperial gallons, or approximately 7.2 U.S. barrels.

Chemical characteristics. Although petroleum consists basically of compounds of only two elements, carbon and hydrogen, these form a large variety of complex molecular structures. Regardless of physical or chemical variation, however, almost all crude oils will range between 82 and 87 percent carbon by weight and 12 to 15 percent hydrogen. The more viscous asphalts will vary between 80 and 85 percent carbon and 8 to 11 percent hydrogen.

Paraffin, naphthene, and the aromatic series

It is possible to group crude oils into three basic series, paraffin, naphthene, and aromatic. Most petroleums are mixtures of these three series in various and seemingly endless proportions, and no two crude oils from different sources are completely identical. The paraffin series of hydrocarbons, also called the methane (CH_4) series, form the most common hydrocarbons in both crude oils and natural gas. It is a saturated straight-chain series and has a general formula C_nH_{2n+2}, in which C is carbon, H is hydrogen, and n is an integer. The paraffin gases, starting with their most stable and common member—methane, or "swamp gas"—form most of the natural gases, whereas the members of the series that are liquid at normal temperatures but boil between 40° to 200° C (approximately 100° to 400° F) are the major constitutents of gasoline. The paraffin series tend toward the lower densities, or higher API gravities; the residues obtained by refining are paraffin waxes, both plastic and solid.

The naphthene series has the general formula C_nH_{2n} and is a saturated closed-ring series. It contributes an important part of all liquid refinery products but also forms most of the complex residues from the higher boiling-point ranges, and the series is generally heavier (with lower API gravity) for this reason. The residue of the refinery process is an asphalt, and crude oils in which this series predominates are called asphalt-base crudes.

The aromatic series has the general formula C_nH_{2n-6} and is an unsaturated closed-ring series. Its most common member, benzene (C_6H_6), is present in all petroleums, but the aromatics as a series generally comprise only a small percentage of most crude oils.

In addition to the practically infinite mixtures of hydrocarbon compounds that form crude oil, sulfur, nitrogen, and oxygen are generally present in small but often important quantities. Sulfur, which may occur as free sulfur, hydrogen sulfide gas, or organic sulfur compounds, usually varies between 0.1 and 5 percent by weight, but crude oils with less than 0.5 percent sulfur content are rated as "low sulfur," a highly desirable quality in view of the recent reforms in air quality standards. It is now a common practice to remove excess sulfur during refining. The sulfur compounds are heavy, so that the heavier crude oils tend to be higher in sulfur content. Oxygen, generally less than 2 percent by weight, may be present either as free oxygen or, more commonly, as part of heavier hydrocarbon compounds. For this reason, the heavier oils contain the most oxygen. Nitrogen, generally less than 0.1 percent by weight, is present in practically all crude oils, but it may be there as a common part of the dissolved natural gas.

Sodium chloride is also present in most crude oils, and when it exceeds 0.7 percent by weight, it generally is removed, like sulfur. Many metallic elements are found in the ash residue after complete combustion, including most of the elements also found in seawater. They probably are present because of the intimate association between seawater and the organic forms from which petroleum is generated. Among the most common metallic elements in petroleum are vanadium and nickel. These apparently occur in organic combinations in petroleum, just as they do in living organic plants and animals. It has been observed that the vanadium–porphyrin complexes are associated with high-sulfur oils and the nickel–porphyrin complexes with the low-sulfur crudes. Uranium is also found in petroleum, but its relationship to crude oil is still poorly understood.

Metallic elements in petroleum

Crude oil also can contain a small amount of various decay-resistant organic remains, such as siliceous skeletal fragments, wood, spores, resins, coal and lignite, and many other remnants of former life.

ORIGIN OF PETROLEUM

In spite of the common occurrence of both the liquid and gaseous forms of petroleum, and the great amount of scientific research on petroleum that has been carried out by many workers, there remain many unresolved questions regarding its origin. Although it is recognized that the original source of carbon and hydrogen was in the materials that made up the primordial earth, it is generally accepted that these two elements have to pass through an organic phase to be combined into the varying complex molecules recognized as petroleum. There are numerous geochemical and geological reasons for this belief, a few of which may be summarized here:

1. Petroleum commonly is associated with sedimentary rocks, principally those deposited under marine conditions but also including continental sediments; conversely, there is a complete absence of commercial deposits of petroleum where only igneous or metamorphic rocks (formed under great heat and pressure) are present.
2. The optical activity of petroleum (the ability to rotate the plane of polarized light) is almost completely confined to compounds of biogenic origin.
3. Most types of petroleum contain complex hydrocarbon compounds termed porphyrins, formed either from the green colouring matter of plants (chlorophyll) or from the red colouring matter of blood (hemin).
4. Carbon isotope ratios ($^{13}C/^{12}C$) indicate that petroleum may be derived in large part from the lipid (fats and waxes) fractions of organisms.
5. Many petroleum-like hydrocarbons have been found in recent marine sediments as well as in soils in many places throughout the world; these occurrences form a link between present living organisms and the petroleum found in sediments of older geological ages.

Organic source materials. The organic material that is the source of most petroleum has probably been derived

Derivation from plants and animals

from the single-celled planktonic (free-floating) plants, such as diatoms and blue-green algae, and single-celled planktonic animals, such as foraminifera, that live in the aquatic environments of marine water, brackish water, or fresh water. These simple forms were abundant in the seas long before the beginning of the Paleozoic Era, 570,000,000 years ago, and could have formed the source organisms of the petroleum found in the Precambrian and Early Paleozoic rocks; they also may have contributed to much of the petroleum found in younger rocks. In addition, land plants brought into the lakes and seas by rivers apparently have been the source of some crude oils. The larger, more complex forms of sea life—such as corals, mollusks, crustaceans, and shellfish—are neither abundant enough nor are their remains adequately preserved from the sea scavengers to constitute a source for crude oil.

All organic matter can be divided into the classes of proteins (amino acids), carbohydrates (sugars, cellulose), lignin, pigments (including porphyrins), and lipids (fats, fatty acids). All but lignin are present in both living plants and animals; the source material for petroleum is among these five building blocks of living organisms.

The proteins and their amino acids are relatively easily decomposed and probably contribute little to the petroleum source material. The carbohydrates make up the major portion of both plant and animal matter. They are subject to rapid and nearly total degradation but may provide a logical source material for some petroleum. The lignins must definitely be considered as a major contributor to organic deposits of land plants, and although these have contributed largely to lignite and coal deposits, many authorities believe that they may constitute a progenitor of petroleum hydrocarbons as well. The pigments, particularly the porphyrins, are known to form a minor but recognizable source of crude oil.

It is the lipids, however, that may form the chief and primary source of petroleum. Biochemically the lipids (fats and fatty acids) are insoluble in water but are soluble in ether, benzene, or chloroform. Some of the planktonic plants (phytoplanktons) produce and store fatty oils during photosynthesis. Moreover the $^{13}C/^{12}C$ ratios in petroleum closely resemble the ratios found in the lipid fractions of the various phytoplanktons. Because the lipid fraction, which contains the hydrocarbons most closely resembling petroleum, is much more stable than the water-soluble proteins and carbohydrates, it could well be the main building block from which petroleum is constructed.

Living organisms, however, do not generate or synthesize petroleum during their life; further evolution through diagenesis (physical and chemical changes after deposition) of the organic matter over some unknown length of time is required before true petroleum is created.

Importance of rapid burial

Creation of source beds. The preservation of organic materials after the death of their contributors is best obtained by rapid burial within fine-grained, clay-sized sediments along sea margins, particularly in the vicinity of river deltas. These conditions effectively preserve the protopetroleum hydrocarbons for later diagenesis into true petroleum. The same requirements for aquatic but nonmarine environments, as in terrestrial lakes, have also been adequately met in many places in the world in the past, as in the ancient inland-lake deposits of the Uinta Basin of Utah, the Vienna Basin of Europe, and in parts of the eastern and western Venezuela basins.

With the rapid burial of petroleum source material in fine-grained sediments and subsequent shielding of the material from the bottom scavengers of the sea floor, its preservation from immediate and total decay can only occur where anaerobic bacteria are present. This type of bacteria allows the preservation of the material under an oxygen-free (reducing) environment, in contrast to the aerobic bacteria, which require the presence of oxygen to live and which are responsible for complete destruction of organic matter. It is, however, quite doubtful that bacteria can produce petroleum, with the exception of the gas methane, and there is no positive evidence of bacterial action in sediments below depths of a few hundred feet. It appears that the main result of the bacteria is to help create the reducing environment that protects the protopetroleum already developed and allows for the further formation of true petroleum.

Throughout the past, just as today, there have been portions of the seas, as well as areas behind reefs or ridges on the sea floor, where the circulation of waters is essentially restricted and where reducing conditions may prevail. Where the reducing conditions most favourable to the preservation of the organic material are accompanied by the rapid accumulation of fine-grained sediments in an area of rapid subsidence, so that there is a buildup of a substantial thickness of source beds, the most likely conditions prerequisite to the formation of petroleum are encountered.

In addition to the deposition of fine-grained clay-size sediments that are necessary to bury and preserve the organic matter, coarser sands or carbonates also must be present to act as porous carriers or reservoir beds. If porous carrier beds are lacking in a thick shale sequence, any petroleum that may be generated will remain in the source beds and fail to accumulate in commercial quantities. The close association of good reservoir rocks in carbonate reef environments and the nearby source material areas provides the explanation of the importance of reefs in petroleum accumulation.

Evaporites and petroleum

The very common association of evaporite deposits of salt and anhydrite with a sequence of beds that contain oil and gas is probably related to the fact that both evaporites (*q.v.*) and petroleum tend to develop in closed basins, termed silled or barred, when a land or submarine barrier at least partially separates the deeper part of the basin from the open seas. The silled or barred basin is considered by most geologists to be a prerequisite for the deposition of evaporites, but it also forms an excellent sedimentary environment for the accumulation and preservation of the plankton that are concentrated near the surface of the waters and float or are carried across the barrier during life, to be preserved by an anaerobic bottom environment after death.

The total thickness of sediments deposited in individual areas may vary from only a few feet to well over 50,000 feet (15,000 metres), and petroleum occurs today in commercial quantities at depths varying from less than 100 feet (30 metres) to more than 25,000 feet (7,500 metres). Burial thus can create substantial changes in the environment of the original source material. The weight of the overlying sediments, or overburden, increases about one pound for each foot of depth of burial; this results primarily in the continued expulsion of interstitial water contained within the muds and clays and the continued compaction of those sediments with additional burial. The very fact, however, that crude oil of all kinds is found at all depths from just below the surface to below 25,000 feet strongly indicates that direct pressure has no particular effect on the creation of petroleum.

Temperatures of formation

There also are good reasons for believing that most crude oils have never been exposed to temperatures much higher than 212° F (100° C), although in isolated cases oil is commercially produced at temperatures up to 340° F (170° C). Earth temperatures of these higher magnitudes are attainable within reach of the drill only in areas of very high temperature gradients, greatly in excess of those normally encountered. There is no reason to believe that earth temperatures in most of the major oil-producing areas of the world have ever reached anything near the extremes that would be required for conversion of organic material into petroleum, temperatures in excess of 662° F (350° C). It has been suggested that, given the lengths of geologic time available, the formation of petroleum might be accomplished at much lower temperatures than those required in the laboratory to transform the protopetroleum of the recent sea-floor sediments or of kerogen shales into petroleum, although many workers do not accept this premise. It has also been suggested that the presence of catalysts such as acid silicates found in certain clays, some of which are used as catalysts in modern refining, may facilitate the creation of petroleum during geologic time. Opponents of this theory, however,

point to the presence of unconverted oil shales in the oldest rocks as indicating that low temperatures, even given geologic time, cannot create petroleum.

Association of natural gas. Inasmuch as all accumulations of liquid petroleum have gas associated with them, it is assumed by a number of workers that the origin of gas is the same as the origin of oil. A common exception to this assumption is made for methane, which is a product of bacterial decomposition of vegetable matter. Many individual accumulations of gas have no oil associated with them, however, and it may well be that the origin of some gas is different than the origin for the liquid hydrocarbons. For instance, in the great Groningen gas field of The Netherlands, with over 65,000,000,000,000 cubic feet of reserves in Permian rocks (225,000,000 to 280,000,000 years in age), the gas is attributed to the carbonization of the underlying Carboniferous (280,000,000 to 345,000,000 years in age) coal because of the increased temperatures resulting from deep burial. It has also been noted in some areas that hydrocarbon density decreases with increasing depth. At temperatures greater than 350° F (180° C) liquid hydrocarbons probably cannot exist. Depending on the thermal gradient, in some areas liquid hydrocarbons would not exist at depths presently reached by the drill but would be converted into dry gas. In other instances the presence of major gas reserves at shallower depths may be the result of conversion of hydrocarbon liquids to a gaseous phase upon being subjected to temperatures above 350° F, followed by migration of the more freely moving gas into shallower depths under conditions that still allowed it to maintain its gaseous composition.

MIGRATION AND ACCUMULATION

In addition to accepting the organic origin of petroleum, geologists in general accept in one form or another the following history of migration and accumulation of petroleum:

1. The organic matter undergoing diagenesis moves out of the compacting clays under the influence of the expelled water and into more porous and permeable reservoir rocks, such as sandstones or porous carbonates. This initial movement is called primary migration, and, although it certainly occurs, in part, shortly after burial, it may also continue over geologic time.
2. During the period of primary migration or during the subsequent period of retention in the reservoir rock, the change to petroleum occurs. This is followed by a period of collection into a continuous phase, in turn followed by a period of secondary migration, again under the influence of water, through a carrier bed or reservoir rock to a place where further movement is impossible (a trap) and where the petroleum collects into pools or fields.

Character of reservoir rocks. Crude oil in commercial quantities is generally found in reservoirs provided by the pore space in sedimentary rocks; less than 1 percent of the world's oil has been found in fractures in igneous or metamorphic rocks, about 59 percent has been found in the pores between the mineral grains of sandstones, and about 40 percent in the void space present in dolomites or limestones (carbonates).

Porosity and permeability

The two most important characteristics of a reservoir rock are its porosity and its permeability. Porosity is defined as the ratio of the volume of pore space to the total bulk volume of the material expressed in percent. Permeability is the capacity of the rock to transmit fluids through the interconnected pore spaces of a rock; the customary unit of measurement is the millidarcy. Although there often is an apparent close relationship between porosity and permeability, because a highly porous rock may be highly permeable, there is no real relationship between the two; a rock with a high percentage of porosity may be very impermeable because of lack of communication between the individual pores or because of capillary size of the pore spaces.

Reservoir rocks may be divided into two main types: those in which the porosity is primary, or inherent, and existed at the time the rock was first deposited; and secondary, or induced, developed subsequent to deposition by solution, recrystallization, weathering, fracturing, or some other process imposed on the original rock.

The porosity of sandstone reservoirs is mainly primary and varies from 10 to 40 percent, depending for the most part on the original sorting of the sand grains and the amount of cementation that has occurred since burial. Permeabilities in average oil pools generally range from five millidarcies to more than 1,000 millidarcies, and any average greater than 100 millidarcies is considered as good. Figure 4 presents examples of primary porosity in

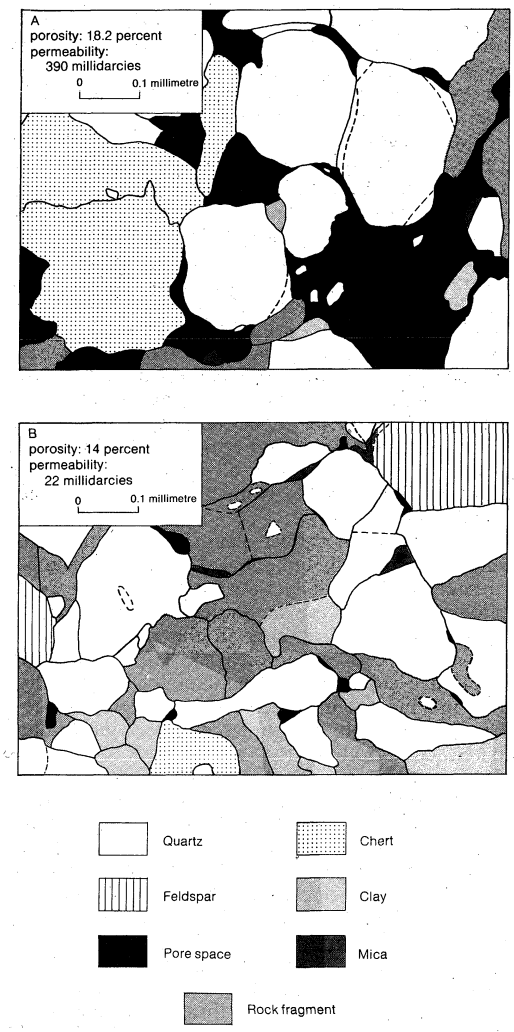

Figure 4: Sections of graywacke reservoir rocks in Alaska, showing (A) excellent reservoir rock and (B) inadequate rock.

a sandstone of an excellent reservoir rock and a poor reservoir rock. The pore spaces are shown in black. Some carbonate sediments may also possess very good primary porosity if the rock is a coquina (consisting principally of shells) or a reef or fragmental limestone.

Secondary, or induced, porosity may develop in a large number of ways after the original deposition of the sediments and is generally more common to carbonate reservoirs than to sandstones. The process of dolomitization of a calcium carbonate rock, a process that involves the substitution of magnesium for calcium during recrystallization, can create a porous and permeable reservoir of major importance in an otherwise dense limestone. Fracturing of carbonate rocks also is of significance. Fracture planes may combine with the initial rock porosity to provide excellent avenues of flow.

The development of secondary porosity by solution, generally involving surface waters that have become acid through the decay of organic material and the action of soil bacteria at the surface, has created many reservoirs,

both in limestones and dolomites, as the descending percolating waters follow existing pores, joints, and bedding planes through the rock.

Reservoir pressures

The connected pores in all reservoir rocks below the water table are filled with water that may be fresh or saline, except in the relatively small areas occupied by petroleum accumulations. This reservoir water generally contains dissolved hydrocarbon gases in measurable amounts. The water within the reservoir rock exerts a hydrostatic pressure equal to the weight of a column of overlying salt water, which normally is about 0.465 pound per square inch per foot of burial depth. Reservoir pressures may vary from much smaller values to almost that of the weight of the overburden, about one pound per square inch per foot of depth, however.

Primary and secondary migration. Freshly deposited muds have water-filled pore spaces equal to as much as 80 percent of their volume; the addition of only a few hundred feet of overburden will reduce this porosity to a little more than 30 percent, however, and by the time 10,000 feet of overburden is reached the porosity of the resulting shale may be less than 10 percent. The water retained in the muds immediately following deposition is in two forms; it exists in the pore space between the grains and also as an adsorbed film of water molecules around each clay particle. As the weight of the overburden increases, the interstitial water is expelled first, followed by the adsorbed water around the individual particles. The large amounts of water that are expelled provide an escape mechanism for hydrocarbons, which move toward the coarser-grained, more porous sediments in any direction—upward, laterally, or downward—because the pressure gradient is away from the compacting, fine-grained sediments.

The actual form taken by petroleum in its escape with the expelled water is still unknown. It has been held by various researchers that it is transported in water solution, colloidal solution, or as molecular films and is transformed into crude oil only in the pore spaces of supercapillary size in the reservoir rock. There is a strong possibility that a substantial amount of the original hydrocarbons in source beds never does undergo migration into carrier or reservoir beds but remains in its original disseminated condition in the source rock.

The movement of petroleum through reservoir rocks depends first upon its gathering into a continuous phase; the isolated globules must coalesce and form larger masses of oil on which the forces involving buoyancy difference between oil and water can act. Because of the increase in the amount of the gas that may be retained in solution by oil with increased depth and the constant rise in temperature with depth, both of which decrease its viscosity, oil during its migration can possess a mobility greatly exceeding its ability to move at the surface. The many active seeps of petroleum throughout the world attest to the fact that crude oil can migrate vertically; it moves upward through joints and fractures always in the direction of lesser reservoir pressure.

Direction of petroleum migration

In horizontal migration, the propulsive forces that cause the petroleum fluids to move through the water-saturated reservoir rocks are buoyancy, expansion of gas in the oil, and hydrodynamic forces exerted by the reservoir water. Any one of these three mechanisms or combinations operating in concert can move the oil during geological time intervals until it is entrapped or until it reaches the surface. In the case of entrapment any later change of the environment that forms the trap may allow the mobile petroleum to resume its migration. It should be emphasized that oil and gas may move through the reservoir rock in the same direction the water in the reservoir is moving or in a direction opposed to the movement of the water. A high rate of water movement downward toward a lower outlet may actually act as a seal, stagnating and offsetting the upward migration of oil and gas and allowing the accumulation of the petroleum in commercial quantities in areas where no true trap exists. There are a number of instances of oil accumulation where this concept of hydrodynamic entrapment best explains the local situation. It appears probable that a combination of the buoyancy and hydrodynamic forces involved in secondary migration best resolves the complex problem.

Formation of oil and gas pools and fields. The commercial accumulation of oil in a single reservoir is termed a pool. It is possible to have a series of pools in a common reservoir rock, each separated either by faulting or by zones of impermeable intervening rock, as well as a series of pools in a number of different reservoir rocks, all located on the same structure. In the latter case of a series of pools, as well as in the case of a single pool confined to a single reservoir, the area encompassed by the individual structure containing the oil pools is known as an oil field.

A group of oil fields having related origins and a more or less common geologic history constitute a petroleum province. The discovery of an oil province occurs with the initial discovery and development of the first oil pool in an area of regional size.

Petroleum accumulation has been taking place since the earliest part of the Paleozoic Era, about 500,000,000 to 600,000,000 years ago, and it is continuing today. Simply stated, accumulation is the collection of petroleum hydrocarbons that have been trapped and inhibited from further movement. Because both oil and gas have great mobility, however, this period of arrested movement may endure for a geologic period of any duration but can be interrupted any time the bounding forces that create the oil pool change. The change may be artificial, created by man by drilling wells, or natural, when folding or faulting changes the structure of the subsurface.

At one time many geologists believed that the source beds and the reservoir rock were the same, but this theory of accumulation *in situ*, except for very few and minor exceptions, has now generally been discarded. One of the reasons is that, in many oil fields throughout the world, the accumulation into structural traps has taken place many millions of years after the deposition of both the source and reservoir beds, a fact determined by dating the structural deformation that created the traps in the reservoir beds. In other cases the reservoir rock, either nonmarine sandstone or reef limestone, was deposited under conditions inimical to source material preservation; the oil must have accumulated in these reservoirs from areas of substantially different environment. The presence of commercial accumulation of oil in fractured igneous and metamorphic rocks is similarly excellent evidence of migration of oil from its place of origin to a favourable reservoir environment.

Role and types of traps

The accumulation of oil and gas in reservoir rocks is the final step in the formation of an oil pool. The movement of the petroleum into the trap has been along an interface between porous and permeable carrier rock and an overlying impermeable roof; the roof rock, therefore, must be concave at its apex as viewed from below in order to form a trap. When the reservoir water associated with the accumulated oil and gas is under hydrostatic conditions, the oil (and gas, if present) comes to rest in the highest portion of the enclosure, and the contact between the oil and water will be horizontal. A trap, therefore, is an area of low potential energy into which the oil has moved from an area of higher energy. Where there are hydrodynamic gradients the entrapped oil may be moved from the highest point on the structure toward the flank, displaced in the direction of water movement. In these cases, the oil–water contact will be tilted, again in the direction of the water movement. However, the contact between oil and free gas, where present, will be horizontal regardless of whether the water is or is not moving, because the gas–oil contact is determined by the difference in the density of the two materials, neither one of which at their interface is under the influence of moving water. The oil and gas accumulated in the trap will rapidly seek equilibrium determined by the surrounding physical conditions, but any change in those conditions, such as folding, regional tilting, fracturing of the cover rock, or the drilling of oil wells, may result in further movement of the entrapped petroleum to adjust to the areas of lower potential energy.

Structural traps. Structural traps caused by folding occur in an infinite variety of sizes and shapes (no two folds

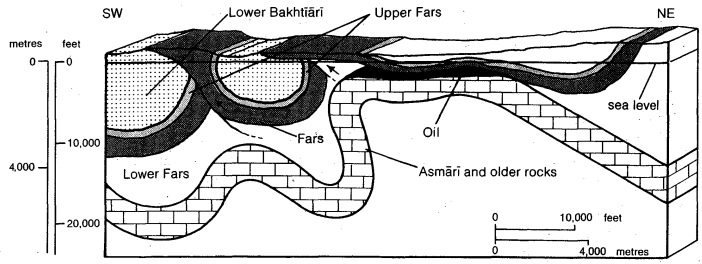

Figure 5: Section through the Masjed Soleymān oil field in Iran.

are ever exactly alike). They may vary from essentially circular in plan view to long narrow folds or anticlines, with the flanks varying from symmetrical through asymmetrical to overturned. Folding can involve a number of reservoir rocks of the same or different types, and oil and gas accumulations frequently occur in a number of these separate but superimposed reservoirs. The folding may be due to compression or tension in the earth's crust, or the structure may result from the initial dip of beds deposited over and around buried hills, or from localized uplifts caused by intrusion of salt or shale plugs (see further SALT DOMES) or igneous intrusions. Many folds may be modified to various degrees by faulting, which may also affect the areas of accumulation of oil or gas. When rocks are folded, the volume of the rock itself is increased by jointing and fracturing; areas of lower potential energy result, toward which oil or gas will move. A good example of this is shown by the cross section through the Masjed Soleymān oil field, Iran (Figure 5). The Asmari limestone, a strong, competent rock unit in which the oil occurs, has been folded and the upper part of the fold contains the oil in a major fracture system.

Effects of folding and faulting

Faulting may form traps in which the fault or faults form one or more of the critical boundaries of the oil reservoir. Because faults may penetrate more than one reservoir rock, there can be a series of petroleum accumulations at various depths, with a single fault creating similar boundaries on different reservoirs. Where faults are curved or cut across low arches or folds, substantial quantities of oil may be entrapped. In certain areas such as the Gulf Coast of Texas and Louisiana, the Niger Delta, the Ganges-Brahmaputra, and the Vienna Basin, much of the seaward thickening takes place across faults that continued to grow during the deposition of the stratigraphic section, and this type of faulting is particularly effective in forming seals in these areas. Figure 6 shows

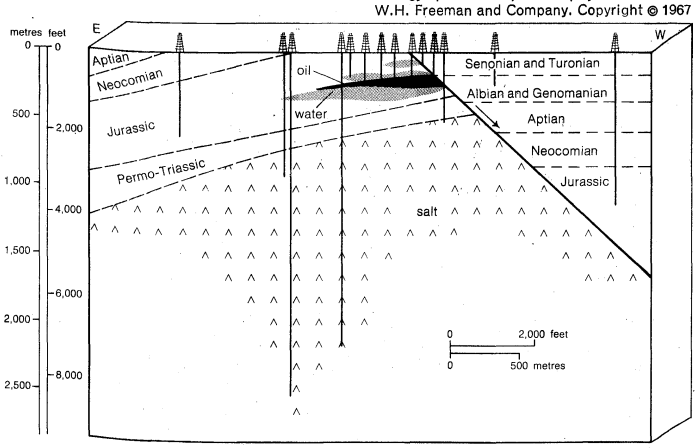

Figure 6: Dossor oil pool in the Emba Province of the Soviet Union. Oil is trapped in a faulted sandstone above the salt mass.

a cross section through the Dossor oil pool in the Emba Province of the U.S.S.R. Production comes from Jurassic sands (136,000,000 to 190,000,000 years in age) that butt against a west-dipping fault plane and younger impermeable beds on the downthrown side of the fault.

Stratigraphic traps. A stratigraphic trap results from a change of depositional environment during the formation of the reservoir or from a change or variation in the reservoir rock that occurred after deposition and diagenesis. The material that forms a porous and permeable reservoir rock changes laterally into impermeable and nonporous formation, so that the effective porosity of the reservoir is limited in areal extent. A lateral change from a porous sandstone into an impermeable shale may result in the creation of a reservoir covering a substantial area. Where a reef limestone grades into an impervious limestone or a shale section or where permeable dolomite changes to an impervious limestone, the stage is set for the development of oil pools. The fact that sand deposition commonly grades both basinward and shoreward into shales means that in many areas there is a concentration of oil pools along the limits of sand deposition, as in the eastern Lake Maracaibo area of Venezuela, the Maikop region along the northwestern Caucasus Mountains in the Soviet Union, and in the Gulf Coast region of Texas and Louisiana.

Shoestring-sand traps (literally, strings of sand that pinch out or lens out) may represent old offshore sandbars or fossil channel-filled stream beds. In either case the porous and permeable sand deposits form long, narrow lenses that may be filled with oil. This type of deposit is very important in many areas, such as eastern Kansas, southern Michigan, Pennsylvania, Oklahoma, and the Maikop oil region of the Soviet Union. A map of the Sallyards shoestring-sand trend in eastern Kansas is shown in Figure 7. On the right, the sand trend is super-

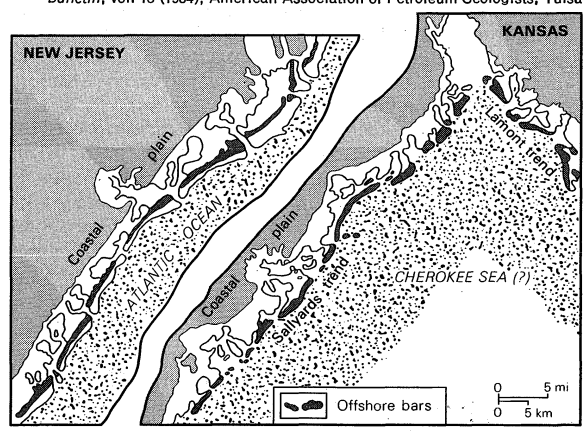

Figure 7: Sallyards shoestring-sand trend in eastern Kansas, superimposed on a hypothetical Cherokee Sea and compared with a portion of the present New Jersey coast.

imposed on a hypothetical map of the Pennsylvania Sea, 300,000,000 years ago, and, on the left, it can be compared with the offshore sandbars of the modern New Jersey coast.

Many great oil pools of the world occur in organic reefs. These reefs are present in all geologic ages from the Cambrian (500,000,000 to 570,000,000 years ago) to the Recent (the last 10,000 years, approximately), and are best referred to as organic reefs rather than coral reefs because corals are not the predominant life-form in many of them. All types of modern reefs are represented in ancient sediments. An ancient barrier reef very similar to present barrier reefs crops out in the Permian Basin of western Texas in the spectacular El Capitan Mountain. This reef is known to extend for at least 400 miles (640 kilometres) and has a thickness of more than 1200 feet (370 metres), with many oil and gas fields found along its buried portion. Most reefs of this type contain backreef, or lagoonal, sediments consisting of limestones, dolomites, shales, and evaporites, whereas the forereef, or basinward side, consists of bedded limestones or shales, which grade into the reef rock through a mixture of reef debris that has fallen from the main reef and accumulated as a talus slope.

Organic reef association

Oil fields associated with organic reefs are common in western Texas and New Mexico in Mississippian and Pennsylvanian rocks (about 280,000,000 to 345,000,000 years in age) and Permian rocks (225,000,000 to 280,000,000 years in age), the great reefs of western Canada in the Upper Devonian (about 350,000,000 years in age), the Middle Cretaceous (about 100,000,000 years in age) reefs of eastern Mexico, and in the Perm Basin reefs west of the Ural Mountains in the U.S.S.R.

An unconformity is a break in the stratigraphic sequence of deposition where the missing beds have been removed by erosion or were never deposited. If an unconformity represents a period of erosion, it is possible that considerable porosity has been developed by solution effected by percolating groundwater. Inasmuch as the reservoir rock may underlie or overlie the unconformity there are a number of ways as well as times in which the oil may migrate into the reservoir rock. In many cases there is good evidence that the source rock that contributed the oil lies above the unconformity and that the oil migrated downward to the porous reservoir rock, crossing the unconformity in its search for a porous and permeable site. The largest petroleum accumulation so far discovered in the contiguous 48 United States, the East Texas pool, is a stratigraphic trap associated with an unconformity where the Woodbine (Cretaceous) producing sand is truncated by a major unconformity and sealed by an impermeable cap rock. This field contained over 6,000,000,000 barrels of recoverable oil.

Other traps. A structural trap may be combined with a stratigraphic trap in any variety of ways, all of which find examples somewhere throughout oil and gas regions. Probably the most common combination is the updip pinch out of porosity, such as a change from porous dolomite to dense limestone or from sandstone to sandy shale on the flanks or across a portion of a subsurface structure, so that only a part of the structure contains commercial accumulation.

Salt domes and diapirs

The intrusion of deep-seated salt masses into overlying rocks may create a great variety of traps both in the intruded sediments and in those draped over the intrusion. Salt domes (*q.v.*) and structures associated with diapiric (piercement) salt masses are known from many places throughout the world. They have been studied most thoroughly in the Hannover Basin of Germany and the Gulf Coast of Louisiana and Texas, where important oil and gas fields occur.

The salt plugs of the Texas and Louisiana coast have come up through sediments from depths of more than 40,000 feet (12,000 metres). There is evidence that they had been moving through most of the Cretaceous (65,000,000 to 136,000,000 years ago) and all of the Tertiary (2,500,000 to 65,000,000 years ago) and that movement of some of them near the coast and under the waters of the Gulf is going on today. The Reitbrook salt dome, Germany, illustrates the prevalent faulting that is associated with salt masses when they breach the overlying sediments (Figure 8).

From A. Levorsen, *Geology of Petroleum* (1956); W.H. Freeman and Co.

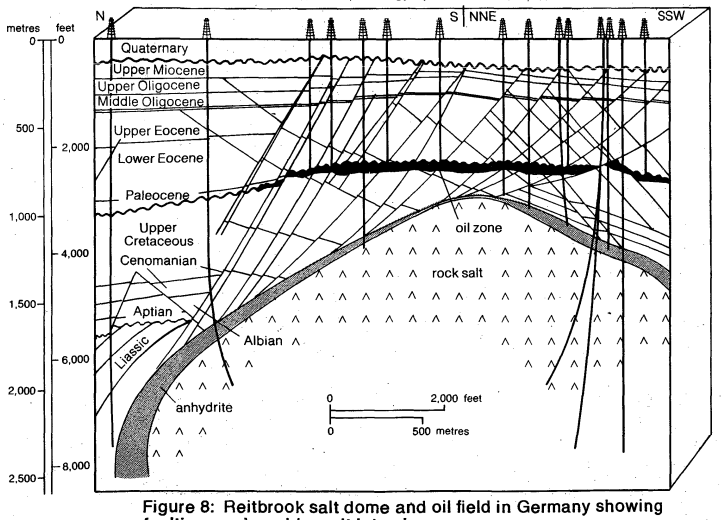

Figure 8: Reitbrook salt dome and oil field in Germany showing faulting produced by salt intrusion.

A hydrodynamic trap may occur where water is in movement through the reservoir rock and where the upward oil and gas migration is stabilized against the movement of the water. Under these conditions, it is possible to find oil and gas accumulations on structures where nothing but movement of the water would inhibit further migration of the oil and gas.

PETROLEUM OCCURRENCE AND DISTRIBUTION

Surface occurrences. Semisolid and solid occurrences of essentially discrete petroleum at the earth's surface are relatively rare, although veins and dikes of asphaltic or paraffinic petroleum residues are known from a number of widely scattered places, such as the Uinta Basin in Utah; South Africa; Trinidad; the Arctic Islands of Canada; Peru; Argentina; and many places in the Middle East. All of these occurrences result from the plastic nature of the incompetent heavy bitumen exuded under the pressure of the overburden along open joints and cracks in the surface rocks. There are also a number of known occurrences of discrete petroleum within small sealed cavities such as those within concretions and geodes, fossil casts, and the natural chambers within corals and ammonites, although the surrounding host rock may be completely barren of hydrocarbons. Liquid petroleum has been found filling small inclusions in both quartz and salt crystals. The origin of the oil found in these unusual occurrences constitutes an unresolved problem.

Lakes, tar pits, and mud volcanoes

Also at the earth's surface are seepages and lakes of bitumen, to a lesser or a greater degree thickened by evaporation. Some of these deposits consist of almost pure heavy oil, but many have substantial amounts of intermixed sand, clay, and other extraneous material. The heavy petroleum in these seepages has risen to the surface from underlying beds along fractures, joints, or faults connected with shallow subsurface folds, fault closures, or diapiric structures that contain residual oil pools. These petroleum lakes or surface seepages may vary in size from only a few yards in diameter through areas covering acres or even square miles, with depths of more than 100 feet. Among the most famous occurrences of this type are the Pitch Lake of Trinidad, the Bermudez pitch lake of eastern Venezuela, the Rancho La Brea Tar Pits of Los Angeles and other seepages in California, the seepages at Hit in Iraq and elsewhere throughout Iran and Saudi Arabia, and in the Baku area on the western shore of the Caspian Sea in the Soviet Union. In the early days of petroleum exploration, many oil fields were found by drilling in the vicinity of oil and gas seepages, although most of today's oil fields have no surface expression of oil or gas leakage nor are oil seepages necessarily related to commercial deposits of petroleum. In addition, many examples of active marine seepages are known throughout the world, among which are those near Santa Barbara, California; Trinidad; the Caspian Sea; and the Louisiana, Texas, and Yucatan portions of the Gulf of Mexico.

In a relatively few areas of the world, mud volcanoes are associated with subsurface accumulations of oil and gas. These surface expressions have no relationship to true volcanism but are mudflows, at times accompanied by oil and gas, that originate from shallow buried beds of unconsolidated clay and shale. The local points of eruption are generally along the crests of buried anticlines, other folds, or fault structures, and the amount of ejected material may be sufficient to build up a group of cones covering several square miles to heights of more than 1,000 feet. The gas escaping from the apex of the subsurface structure no doubt aids the diapiric upwelling of the clay. Commercial oil fields associated with both ancient or active mud volcanoes are found in the Baku region of the Caspian Sea, the island of Trinidad, and Burma, among other places.

Oil sands and tar sands

Sediments containing petroleum in the form of asphalts or thick heavy oil are generally called bituminous sands or bituminous limestones. These occurrences represent

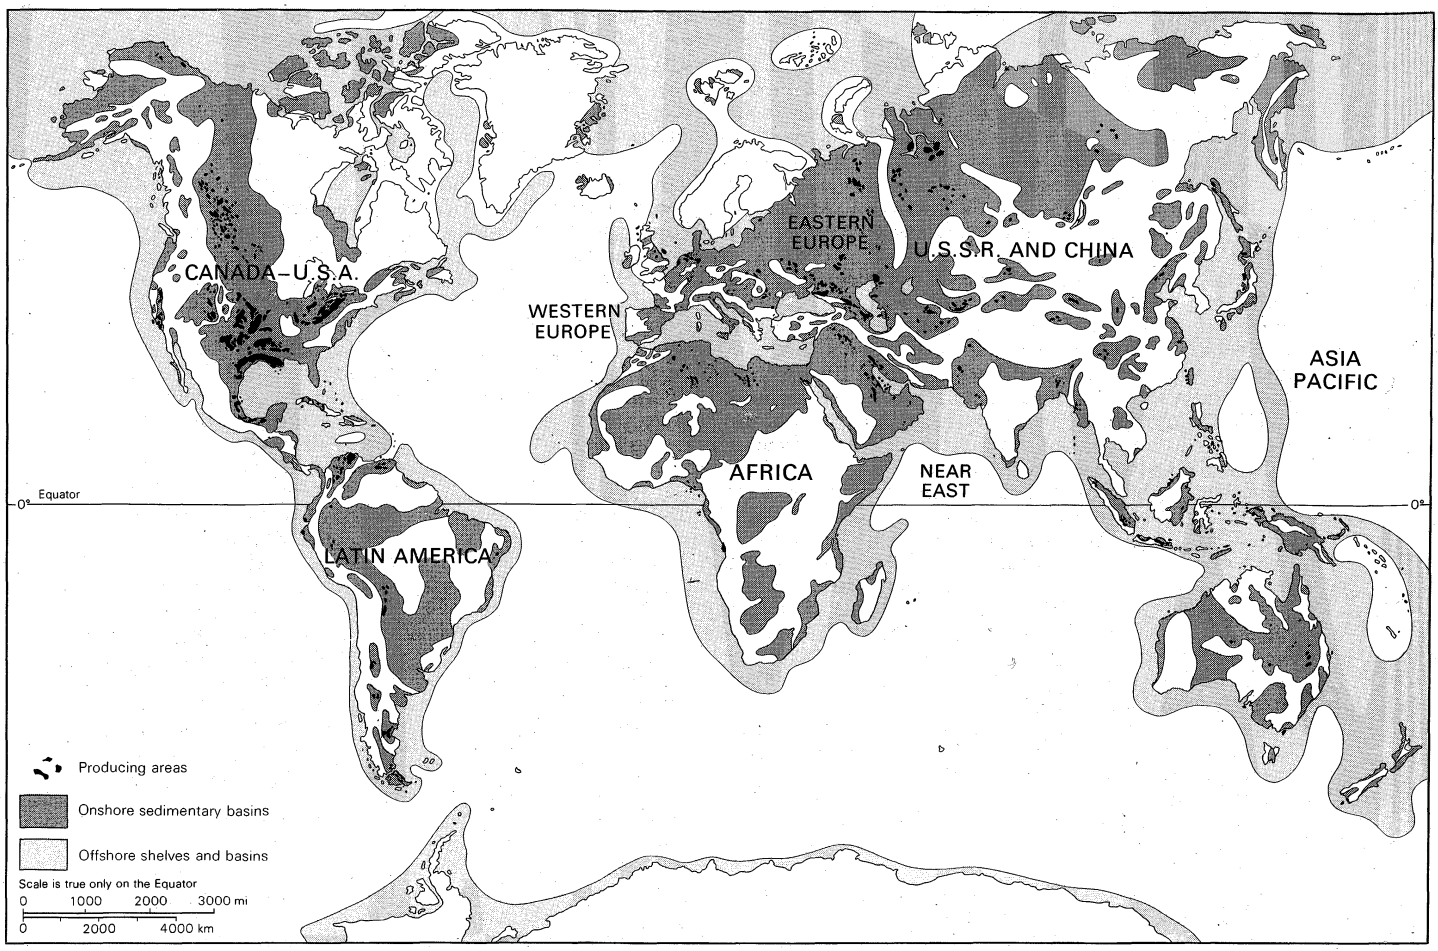

Figure 9: Offshore and onshore sedimentary basins and petroleum-producing areas of the world.
Adapted from "Worldwide offshore activity and sedimentary basins," *Oil and Gas Journal* (November 1970); Petroleum Publishing Co., Tulsa

inspissated, or thickened, deposits that have lost the lighter fractions through evaporation. In southern Oklahoma around the Ouachita and Arbuckle mountains there are many deposits of viscous or semisolid asphalt occurring in rocks ranging from Early Paleozoic to Late Mesozoic (about 100,000,000 to 500,000,000 years ago) in age. The deposits in this area probably represent inspissated oil pools that have been exposed by erosion. One of the largest known deposits of oil in the world, some 300,000,000,000 barrels, is represented by the Athabaska oil sands of Cretaceous age (65,000,000 to 136,000,000 years ago) in Alberta, Canada. Another great area of known tar sands lies just north of the Orinoco River in Venezuela on the southern flank of the Materin Basin, extending 375 miles (600 kilometres) in an east–west direction and from 25 to 50 miles (40 to 80 kilometres) wide. It is estimated that about 700,000,000,000 barrels of oil are locked up in this deposit of Lower Tertiary age (about 60,000,000 years old). A great deal of research has gone into mapping of the potential mining areas and building of pilot plants for the recovery of oil by distillation of the tar sands.

Subsurface occurrences. Until recently exploration for oil involved the search for sedimentary sections or sequences of rocks located on land areas of the continents, and as experience and technology has progressed, this search has probed ever deeper into the earth. It has now included essentially all known accessible geologic basins and prospective areas and has developed about four-fifths of the proved world petroleum reserves. The types of structures in which these reserves have been found are many and varied; no two fields anywhere in the world are exactly alike. The search for new oil and gas fields on the land areas will continue, particularly in the more inaccessible areas such as the Arctic north, the desert areas of North Africa and the Near East, and the jungle areas of the Far East. Fields that are more difficult to find and more expensive to produce will be added to the world's available supply of crude oil, but there is a noticeable downward trend in the land exploration rate throughout the world.

Offshore drilling and exploration

The petroleum industry started developing oil and gas fields located under the waters of the continental shelf off the coast of Louisiana about 20 years ago. This offshore drilling was a logical step from the sea-marsh drilling of the adjoining delta area, where everything pointed toward a continuation of the same sedimentary environments and types of structures that had proved so rewarding on land. It became apparent that the only difference between land and sea drilling was the greatly increased cost of the latter, and this directed attention to similar areas throughout the world. It also became apparent that many of the deep sedimentary basins of the world were located along the margins of existing continents and that in many cases the conditions for the accumulation of oil and gas improved seaward. Major offshore discoveries are currently being developed in the North Sea between England and Norway, in the Bass Straits between Australia and Tasmania, in the Nigerian offshore delta, near the California coast, in the Persian Gulf, and in other areas throughout the world. As the industry enters this virgin field of offshore water bottoms, it can be expected that the early discoveries will be located on the larger, easier to find structures.

For a period of years, water depths up to a few hundred feet were considered to represent the outer limit of oil exploration because of technological problems and cost. When favourable structures were reported to occur out to depths beyond the continental shelf (normally considered about 600 feet [180 metres]) on the much deeper conti-

nental slope and continental rise, the industry began concentrating on the ability to drill in ever deeper water. This has been spurred by testing of the Sigsbee Knolls in the deepest portion of the Gulf of Mexico, in water depths of over 12,000 feet (5,500 metres), where oil was found almost 500 feet (150 metres) below the sea floor in the calcite–gypsum cap rock of a salt dome. Similar diapiric features have been mapped in the Mediterranean Sea, and in the southern Atlantic off the coasts of Africa and Brazil salt domes have been mapped and tested in preliminary fashion.

A map indicating the locations of sedimentary basins and the oil- and gas-producing areas of the world is shown in Figure 9. Also shown on this map are the continental-shelf areas, in many instances the scene of current exploration. More than 60 percent of the world's known oil reserves occur in the small area at the head of and bordering the Persian Gulf; a large proportion of this is stored in a few giant reservoirs, such as Burgan in Kuwait and Ghawar in Saudi Arabia.

Considering the giant oil fields of the world, 8 percent of the oil is found in rocks of the Paleozoic Era (from 225,000,000 to 570,000,000 years in age), 63 percent in rocks of Mesozoic age (from 65,000,000 to 225,000,000 years), and 29 percent in Tertiary and Pleistocene age (from 10,000 to 65,000,000 years ago). If the great Middle East oil reserves were to be excluded from these figures, the youngest geologic period would have the greatest reserve, because most of the Persian Gulf Basin reserves are Mesozoic in age.

Eighty-nine percent of the giant fields of the world are located on anticlines, and only 9 percent are in stratigraphic or partly stratigraphic traps. These figures partly reflect the fact that the more easily found fields are discovered first. As the industry becomes more sophisticated in its search, more of the obscure reservoirs will be found and tested.

Type examples of major fields. *Bay Marchand–Timbalier Bay–Caillou Island.* This salt complex forms a single salt ridge that extends 28 miles (45 kilometres) along the Louisiana coast. The salt of the Late Triassic–Early Jurassic Period (about 190,000,000 years ago) has risen from depths of more than 40,000 feet (12,000 metres) to within 2,000 feet (600 metres) of the surface. The reserves of about 1,700,000,000 barrels are trapped in a multitude of sands ranging in age from Late Miocene to Pleistocene (from about 2,500,000 to 10,000,000 years ago) and in depth from 1,000 to more than 20,000 feet (300 to 6,000 metres). The form of traps associated with the salt uplift include superdomal arching above the salt, truncation of sand reservoirs against the diapiric salt and shale, and traps formed by faulting associated with the uplift.

Prudhoe Bay. This structure in the North Slope Province of Alaska covers an area about 45 by 18 miles (72 by 29 kilometres) and is a broad, anticlinal nose that plunges gently to the northwest. The reservoirs are terminated to the east by truncation against an eastward dipping unconformity. The major oil accumulations occur in very porous quartz sandstone members of the Prudhoe Bay section, mainly Triassic in age (190,000,000 to 225,000,000 years in age). The sands vary in thickness up to 600 feet (180 metres) and lie mainly in the 8,000- to 9,000-foot- (2,400- to 2,700-metre-) depth range. At the present time the field is estimated to contain 9,600,000,000 barrels of recoverable oil and 26,000,000,000,000 cubic feet of gas, making it by far the largest field in North America.

Hassi Messaoud. This oil field, in the eastern portion of the Algerian Sahara Desert and 350 miles (560 kilometres) south of the Mediterranean, produces from a Cambrian (500,000,000 to 570,000,000 years in age) sandstone reservoir that forms a large dome. The depth to the reservoir is about 11,000 feet (3,400 metres), the oil column is about 900 feet (270 metres) thick, and the productive area covers about 500 square miles (1,300 square kilometres). The structure was formed shortly after deposition, but later periods of uplift and erosion exposed the top of the ancient Hassi Messaoud structure, after which 10,000 feet (3,000 metres) of Mesozoic sediments were deposited. Late Silurian (395,000,000 to 430,000,000 years ago) shale zones located on the flanks of the structure are considered to be the primary source beds; if this is so, then the Silurian-generated oil was lost during the pre-Triassic erosion. After the deposition of Tertiary rocks (2,500,000 to 65,000,000 years of age), the Silurian shales would have to yield another generation of hydrocarbons, which migrated downward into the Cambrian reservoir rock. The porosity of the reservoir averages about 8 percent and the permeability ranges from zero to 1,000 millidarcies. There is no gas cap, and the oil is undersaturated. The ultimate recoverable oil is estimated at 5,000,000,000 barrels.

Ghawar. Located about 50 miles (80 kilometres) inland from the western shores of the Persian Gulf in Saudi Arabia, the Ghawar field is a structural accumulation along 140 miles (225 kilometres) of a north–south trending anticline. The productive area covers approximately 900 square miles (2,300 square kilometres) and the vertical oil column is about 1,300 feet (400 metres). The oil–water contact occurs at a depth of about 6,500 feet (2,000 metres) near the middle of the structure, and it dips from the southwest to the northeast. The reservoir, consisting of shallow-water carbonate sediments of Upper Jurassic age (about 150,000,000 years), is sealed by a cap rock of anhydrite evaporites. The reservoir rock varies from sand size to coarser carbonate sediments in which recrystallization and dolomitization is common. The API gravity varies from 32° to 36°, the oil is undersaturated, and there was no initial gas cap. The structure began to grow by Lower Cretaceous time (about 130,000,000 years ago), following the deposition of the reservoir beds, and its growth was probably completed by Miocene time (7,000,000 to 26,000,000 years ago).

It is believed that the source beds for the oil were the same formations that now form the reservoir rock, but that secondary migration into the Ghawar structural area took place during the Upper Cretaceous and Early Tertiary. The Ghawar field is generally recognized as the largest in the world, having a recoverable reserve of about 75,000,000,000 barrels of oil.

Burgan. The structure of this oil field, about 15 miles (24 kilometres) west of the Persian Gulf in the small country of Kuwait, is a large, broad anticlinal fold with a north–south trend. Production is from thick Middle Cretaceous sandstones (about 100,000,000 years old) that were first encountered at about 3,700 feet (1,100 metres); the productive sands comprise 800 feet (240 metres) out of a total of 1,100 feet (340 metres) of section. The development of sandstone reservoirs at Burgan is in striking contrast to most of the oil fields of Saudi Arabia, Iraq, and Iran, in which the reservoir rocks are limestone. The oil is asphaltic in type with a gravity of API 30° and has a high sulfur content of 2 to 2.5 percent. The recoverable reserves of the Burgan oil complex are estimated at about 66,000,000,000 barrels, making it the second largest oil field in the world.

Golden Lane. The Golden Lane fields of Mexico lie just south of Tampico and form a north–south-oriented oval bisected by the coastline and measuring 100 by 40 miles (160 by 64 kilometres). The oil fields, together with some undrilled offshore structures, trace in continuous fashion a Middle Cretaceous (about 100,000,000 years in age) atoll rim that represents an ancient buried reef more than 5,000 feet (1,500 metres) thick. Within the atoll rim, evaporites, calcareous sands, and dolomites were deposited; elsewhere the reservoir rocks are fossiliferous limestones. One of the wells drilled on the western, or land, portion of the atoll produced more than 95,000,000 barrels of oil, probably the world's record from a single well. The depth to the producing section in this area varied from 1,600 to 2,600 feet (500 to 800 metres), and porosities and permeabilities were so high that these fields were rapidly depleted. The marine portion of the atoll was only recently discovered. The whole reef structure was sharply tilted to the southeast during the Early and Middle Tertiary (from 2,500,000 to 65,000,000 years ago), and the hydrocarbons of the reef

probably migrated from southeast to northwest during this period. The group of fields in the western portion of the ancient atoll have produced more than 1,250,000,000 barrels of oil.

Proved world reserves and future provinces. Tabulated below are the estimated proved reserves of crude oil for the world, by country, together with the production during 1970 in barrels per day.

*Estimate. †Incomplete. ‡Withheld by government.
§Including Cabinda.
Source: Figures compiled by *World Oil*, with aid of government agencies, industry associations, oil companies, and other sources.

It has been estimated that an additional 800,000,000,000 to 900,000,000,000 barrels of oil remain to be found in the world, of which about 40 percent will occur within the Communist countries. Although most of this oil and the oil still to be found in the Middle East will be found onshore, most of the potential oil estimated for the rest of the world will be found on the offshore continental shelf and slope, out to water depths of about 2,000 feet (600 metres). Exploratory activity around the world affirms the industry's belief in this statement. The continental shelves range in width from a few to more than 600 miles (950 kilometres), and form between 7 and 8 percent of the total ocean floor. Among the non-Communist countries' largest continental shelf areas are those of the Bering Sea off Alaska, the South China Sea, the Arafura Sea north of Australia, the Sunda shelf of Indonesia, the Atlantic shelf off Argentina, the shelf off northern and eastern Canada and the eastern United States, and the northwestern European shelf.

Of particular interest to explorationists are the marginal semi-enclosed seas, such as the North Sea, the Persian Gulf, the Irish Sea, Hudson Bay, the Gulf of St. Lawrence, the Black Sea, the Caspian Sea, the Red Sea, the Adriatic, and the Balearic Sea, each of which has an adequate sedimentary section and relatively shallow water depth. Their restricted nature favours the accumulation and preservation of the organic source material of petroleum, and favourable reservoirs are to be expected. Their environment is also favourable for evaporite deposition; diapiric salt and shale structures have already been mapped in some of them, and other marginal basins show the continuation of folding trends from the adjacent land areas.

In summary, with the exception of the Soviet Union, China, and the Canadian Arctic Islands, relatively few new petroleum provinces of major importance can be expected to be found on the earth's land areas. The submerged continental margins and inland seas, however, are already the scene of active exploration, and this search will certainly provide a number of major new productive areas during the next 20 years. Whether or not the oil industry can continue to supply the rising world demand for crude oil remains to be seen, however.

BIBLIOGRAPHY. ROBERT H. DOTT and MERRILL J. REYNOLDS (comps.), *Sourcebook for Petroleum Geology* (1969), is an excellent collection of petroleum geology scientific concepts. A.I. LEVORSEN, *Geology of Petroleum* (1954), is the outstanding textbook in its field. WALLACE E. PRATT and DOROTHY GOOD (eds.), *World Geography of Petroleum* (1950); and HAROLD F. WILLIAMSON and ARNOLD R. DAUM, *The American Petroleum Industry: The Age of Illumination, 1859–1899* (1959), contain historical data on oil occurrences and on the development of the petroleum industry. KENNETH K. LANDES, *Petroleum Geology*, 2nd ed. (1959); GRAHAM B. MOODY (ed.), *Petroleum Exploration Handbook* (1961); and JOHN D. HAUN and L.W. LEROY (eds.), *Subsurface Geology in Petroleum Exploration* (1958), are sources of information on theories of origin and accumulation of petroleum as well as practical applications of scientific knowledge to petroleum problems. The AMERICAN ASSOCIATION OF PETROLEUM GEOLOGISTS symposia *Diapirism and Diapirs* (1968), *Fluids in Subsurface Environments* (1965), *Geology of Giant Petroleum Fields* (1970), and *Habitat of Oil* (1958) contain collections of scientific papers in specific areas of petroleum technology. The AMERICAN PETROLEUM INSTITUTE, *Petroleum Facts and Figures*, and the UNITED STATES BUREAU OF MINES, *Minerals Yearbook*, include annual statistical reviews of the petroleum industry. The *American Association of Petroleum Geologists Bulletin* is a monthly scientific journal. *Oil and Gas Journal* (weekly), *World Oil* (14/yr.), and *Offshore* (monthly) are regularly published trade magazines of the petroleum industry.

(G.I.A.)

Petroleum and Gas Extraction

Though petroleum and gas extraction normally involves prospecting, drilling, and production techniques used in the exploitation of petroleum deposits, the transportation and storage of petroleum and gas are also included within the scope of this article.

Nature and occurrence. Petroleum is a naturally occurring hydrocarbon material of animal and vegetable

*Estimated. †Eastern Europe producing oil wells not included in world total.

origin. First formed in deep sedimentary beds, petroleum later migrated to its present position in porous underground rocks. Petroleum occurs as either a liquid, a gas, or a combination of both. Occasional deposits, elevated during the formation of mountain ranges, have been exposed by erosion to form tar (sometimes called pitch) deposits, and some of these have been known and used throughout recorded history. Other near-surface deposits of liquid petroleum seep slowly to the surface through natural fractures and fissures in the overlying rock. Accumulations from these oil seeps, called rock oil, were used commercially in the early 19th century. The vast majority of petroleum deposits, however, lie in natural rock at depths from 500 to 25,000 feet (about 150 to 7,600 metres) below the surface of the ground. The deposits are prevented from migrating upward by intervening layers of dense rock. As a general rule, the deeper deposits have higher internal pressures and contain greater quantities of the gaseous hydrocarbons.

In order to create a petroleum trap or reservoir, a porous rock (one capable of containing liquids), such as sandstone or limestone, must be surrounded on the top and sides by nonporous rock, such as shale. In such an event, either gaseous or liquid petroleum, which is less

dense than the always-present water, may be trapped in the top portion of the porous formation.

Since petroleum reservoirs are the result of an accumulation of liquid or gas in rocks originally containing water, there will always be some water left in the reservoir. Water production often accompanies the production of oil and gas.

History. When it was discovered in the 19th century that rock oil could yield a distilled product (kerosene) suitable for lanterns, sources of this oil were eagerly sought. It is now generally agreed that the first well drilled specifically to find petroleum was that of one Col. Edwin Drake in Titusville, Pennsylvania, in 1859. The success of this well, drilled close to an oil seep, led to further drilling in the same vicinity and soon to exploration elsewhere. The growing demand for petroleum products led quickly to oil wells not only in the United States but in other countries. At the end of 1969, there were almost 600,000 producing oil wells in over 60 different countries (see Table 1). Oil is produced in every continent except Antarctica.

First drilled well

Because of the widespread distribution of petroleum reservoirs, it was possible for new discoveries to be made at a rapid rate through the first half of the 20th century. As one result, there was little incentive for the development of efficient production techniques. Because little use had been found for the natural gas produced along with the crude oil, the gas often was burned at the wells. Such wasteful practices were gradually halted, partly by the increasing difficulty of finding new petroleum reservoirs and partly by the increased uses found for natural gas. New engineering methods led to an economically optimum recovery from each reservoir. These methods often were based on the injection of some less expensive fluid, such as water, to force additional petroleum into the producing wells.

As the value of the petroleum produced reached impressive proportions, governmental agencies in every producing area sought to prevent wasteful exploitation.

PROSPECTING AND EXPLORATION

Drake's original well was drilled close to a known surface seepage of crude oil, and for many years such seepages were the only reliable indicators of the presence of oil. As demand grew, however, new methods were devised for exploring the petroleum potential of underground rock formations. There are now three major exploration methods: (1) surface feature mapping, (2) seismograph observations, and (3) earth gravity surveys. But there is still no accurate way to predict the actual presence of underground petroleum deposits. Exploration methods carried out on the surface can only indicate the presence or absence of underground formations that are favourable for petroleum accumulation.

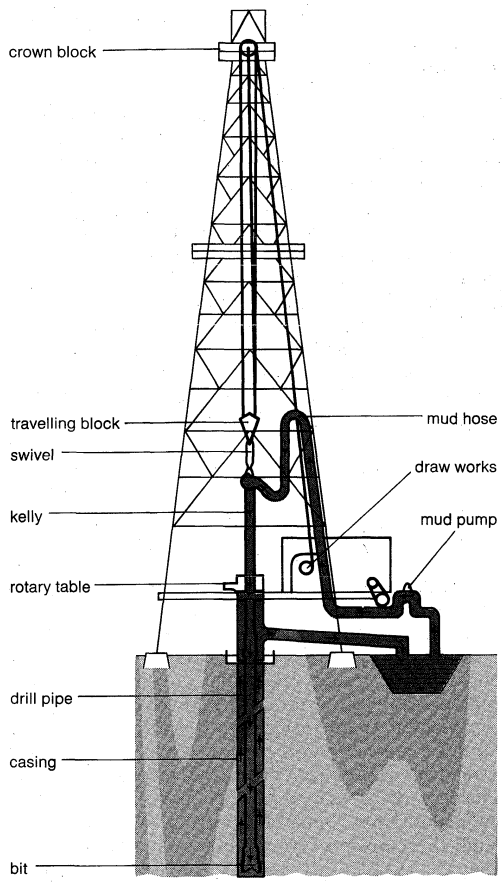
Surface methods. A seepage of crude oil sometimes appears as a tarlike deposit in a low area such as the oil springs at Baku, on the Caspian Sea, described by Marco Polo. More often, it can be seen as a thin skim of oil on small creeks that pass through the seepage area. This latter phenomenon was responsible for the naming of Oil Creek (a place in Pennsylvania), where Drake's well was drilled. Such seepages of natural gas cannot usually be seen, though instruments can detect natural gas concentrations in air down to less than one part in 100,000. Exploration methods have been used in which air samples from areas immediately over or under the ground surface are tested. Such samples taken from a wide area can yield a map of gas concentration points. A similar method has been used to test for traces of petroleum gases dissolved in seawater in the hope that undersea seepages could be thus detected. These geochemical prospecting methods are not applicable to the large majority of underground reservoirs that do not have leakage to the surface.

Oil Creek

A second class of surface prospecting methods is based on surface indications of underground rock formations. In some cases, subsurface folds and faults in rock formations are repeated in the surface features. Also, underground salt domes (*q.v.*) may announce their presence by a low bulge in an otherwise flat ground surface. Since these features usually produce possible petroleum traps, drilling in the area may be productive.

Seismographic methods. Most folds and faults in subsurface rocks are not apparent at the ground surface. Seismic methods that have been useful for mapping such underground formations involve the transmission and echo-producing properties of rock in a manner similar to underwater sonar methods. Sound waves travel at differing velocities depending on the types of rock formations and are reflected at interfaces between different types of rock. The sound wave source is usually a small explosion in a shallow drilled hole. Microphones are placed at various distances and in various directions from the source to record the arrival times of the echoes. This procedure is repeated at intervals over a large area. An experienced seismologist can then interpret the records to map the underground formation contours. Possible locations for petroleum accumulations may then be located for drilling.

Gravity meter surveys. The gravity meter has become a primary exploration tool. Although gravity at the earth's surface is very nearly a constant, it is slightly greater where large rock formations lie closest to the surface. The gravity field, therefore, increases over the tops of anticlinal (downward-inclined) folds and other similar subsurface anomalies. A salt dome results in lowered gravity because salt is less dense than other rocks. Gravity surveys are usually carried out from the air. A sensitive instrument, the gravity meter, is suspended on a cable below the aircraft, while the recording devices are operated from inside. As the aircraft is flown over an area on a precise grid pattern, a map showing the gravity strengths is prepared from the recordings. These maps can show the presence of such possible accumulation spots as anticlinal folds, fault blocks, and salt domes, even though there are no surface indications of such. The gravity meter survey is faster and less expensive than the seismic method. It can locate only large rock features that exist relatively close to the surface, however, and is generally used as a preliminary survey tool to locate areas in which seismic work may profitably be concentrated.



DRILLING AND COMPLETING WELLS

Early wells were drilled with impact-type tools in a method called cable-tool drilling, in which a chisel-like bit was suspended from a cable to a lever at the surface, and an up-and-down motion of the lever caused the bit to pound the bottom of the hole and chip away the rock. Such drilling had to be interrupted periodically to allow loose rock chips to be removed with a basket-like device on the cable. Also, the well had to be free of liquids during the drilling process so that the bit could effectively remove rock. These necessarily dry holes allowed oil and gas to flow to the surface in large quantities as soon as a producing formation was penetrated. This created the image of a "gusher" as a successful well. Often, a large amount of oil was wasted before the well could be capped and brought under control.

Cable-tool drilling

Rotary drilling. During the last 40 years, rotary drilling has become the preferred method for penetrating underground formations (see illustration). In this method, a special tool—the drill bit—rotates while bearing down on the bottom of the well, thus gouging and chipping its way downward. Probably the greatest advantage of rotary drilling over cable tooling is that the well bore is kept full of liquid during drilling. A weighted fluid (called drilling mud) in the bore hole serves two important purposes: by its hydrostatic pressure, it prevents the entry of formation fluids into the well, thus preventing "blowouts" and "gushers." In addition, the drilling mud carries the crushed rock to the surface, so that the drilling is continuous until the bit wears out.

The drill bit is connected to the surface equipment through a drill pipe, a heavy-walled tubing through which the drilling mud is fed to the bottom of the bore hole. In most cases, the drill pipe also transmits the rotary motion from a turntable at the surface to the bit at the bottom of the hole. The top piece of the drill pipe is

Rotary drilling rig.
By courtesy of the American Petroleum Institute

a tube of square or octagonal cross section called the kelly, which passes through a square or octagonal hole in the turntable. At the bottom end of the drill pipe are extra-heavy sections called drill collars that serve to concentrate the weight on the rotating bit. The drilling mud leaves the drill pipe in such a way that it washes the loose rock from the bottom and carries it to the surface. Drilling mud is carefully formulated to assure correct weight and viscosity characteristics for its required tasks. After screening to remove the rock chips, the returning mud is held in open pits to be recirculated through the well. The mud is picked up by piston pumps and forced through a swivel joint into the top of the drill pipe.

The characteristic tall derrick contains the hoisting equipment that is used to raise and lower the drill pipe into the well. The drill bit wears quickly and requires frequent replacement, making it necessary to pull the entire drill string from the well and stack it at one side of the derrick. Joints of drill pipe are usually 30 feet (nine metres) long. Sections of two or three such joints are separated and stacked vertically while the bit is being changed. Drilling mud is left in the bore hole during this time to prevent excessive flow of fluids into the well.

Such rotary drilling techniques as those described have made it possible for wells to be drilled to depths of more than 25,000 feet (7,600 metres). Wells have been drilled in both coastal waters and in the open sea. In relatively shallow waters (less than 200 feet or 60 metres), the wells are usually drilled from platforms that rest on the bottom; the drilling platform is constructed above the highest expected waves. In deeper waters and for exploratory work, drilling is done from a floating vessel that is kept in place by a combination of anchors and motors. Since the fixed platforms are quite expensive, many (20 or more) wells are often drilled from the same platform. Yet for most efficient coverage, the wells must enter the producing formation with more than 1,000 feet (300 metres) between them. Thus, each well except one has to be drilled in a precise slantwise direction. This directional drilling is achieved with a tool called a whipstock, which causes the drill bit to veer slightly in the desired direction. The whipstock is used at intervals until the total desired angular deviation is reached. Sharp bends in the bore hole must be avoided because the rather rigid drill pipe has to bend through the deviation while rotating.

Use of a floating vessel

A recent variation in rotary drilling has involved introducing a fluid-powered turbine at the bottom of the bore hole to produce the rotary motion of the bit. In this method, the drill pipe does not rotate but is used to regulate the weight on the bit and to carry the drilling mud that turns the turbine. In the early 1960s the Turbodrill was used extensively in eastern Europe.

Well logging and drill-stem testing. After the bore hole has penetrated the possibly productive formations, these formations must be tested to determine if expensive completion procedures should be used. The first evaluation is usually made by well-logging methods, in which the logging tool is lowered past the formations while response signals are relayed to operators on the surface. Often these tools make use of the difference in electrical conductivities of rock, water, and petroleum to detect possible oil or gas accumulations. Other logging tools depend on difference in absorption of atomic particles. With well-logging tools, the exact depths of possibly productive formations are determined. Only a production test, however, can establish the potential productivity of a well.

The production test normally used is the so-called drill-stem test, in which the bore hole is sealed above and below the formation to be tested, with only the drill pipe open to the formation. The drill pipe is then emptied of the drilling mud so that the formation fluid may enter. When enough time has passed, the openings into the drill pipe are closed, and the pipe containing the formation fluid is brought to the surface for analysis. If there is gas present, the gas may flow from the top of the drill pipe during the test.

Well completion. If the preliminary tests show that one or more of the formations in the bore hole will be commercially productive, the well must be prepared for the continuous production of the oil or gas. First, a large outside pipe, or casing, slightly smaller in diameter than the drill hole, is inserted to the full depth of the well. A cement slurry is forced between the outside of the casing and the inside surface of the drill hole. When set, this cement forms a seal so that fluids cannot pass from one portion of the well to the other through the bore hole. The casing is usually about nine inches (23 centimetres) in diameter. It creates a permanent well through which the productive formations may be reached. After the casing is in place, a production string of smaller (about three inches, or eight centimetres, in diameter) tubing is extended from the surface to the productive formation with a packing device to seal the productive interval from the rest of the well. If multiple productive formations are found, as many as four production strings of tubing may be hung in the same cased well. If a pump is needed to lift oil to the surface, it is placed on the bottom of the production string.

Since the casing is sealed against the productive formation, openings must be made to allow the oil or gas to enter the well. A down-hole perforator uses an explosive to shoot holes through the casing and cement and into the formation. The perforator tool is lowered through the tubing on a wire line. When it is in the correct position, the charges are fired electrically from the surface. Such perforating will be sufficient if the formation is quite productive. If not, an inert fluid may be injected into the formation at pressures high enough to fracture the rock around the well and thus open more flow passages for the petroleum. In early times, nitroglycerin was exploded in the well bore for the same purpose. An acid that dissolves rock may be used in place of the inert fluid.

Christmas tree valves

When the subsurface equipment is in place, a network of valves (called a Christmas tree) is installed on the surface, arranged so that flow from the well may be regulated and measured and so that tools to perform subsurface work may be introduced through the tubing. Christmas

trees may be very simple, such as those found on a low-pressure well that must be pumped, or they may be very complex, as in the case of a high-pressure well with multiple producing strings.

Artificial lift. Many oil wells do not have a formation pressure high enough to push the oil (which weighs about six pounds per gallon, or 0.7 kilogram per litre) to the surface. In these cases, some artificial method for lifting the oil to the surface must be installed. The most common installation involves a motor and "walking beam" (like a seesaw) on the surface that operates the pump on the bottom of the production string. A chain of solid metal rods connects the beam and the pump. Another method, called gas lift, uses the buoyancy of a bubble of gas in the tubing to push the oil to the surface. A third type of artificial lift forces some of the produced oil down the well at high pressure to operate a pump at the bottom of the well. Even though an oilfield may have enough pressure to produce naturally at first, artificial lift will usually be required in the later stages of production. Gas wells that produce little or no liquid do not need artificial lift devices.

Surface equipment. Water often flows into the well along with oil and gas. Surface equipment separates the water from the petroleum and separates the oil and the gas for storage and transportation. Also, the production from a number of wells must be gathered at a central point for distribution. A settling tank is usually used to separate the water, although either heat or chemical treatment may be necessary to break down emulsions. Gas is separated from the oil by allowing the produced stream to pass through a series of pressure-reducing valves and removing the liberated gas to storage. The remaining crude oil is kept at normal pressures in cylindrical tanks after being brought through pipelines from the individual wells. Gas is usually piped directly to a central processing plant (called a gasoline plant) where remaining liquids are removed before it is fed to the consumer pipeline.

RECOVERY OF OIL AND GAS

As indicated above, both oil and gas reservoirs usually start with a formation pressure that forces fluid into the well and sometimes to the surface. With artificial lift, reservoir fluids may be produced as long as enough reservoir pressure remains to cause the fluids to flow into the well. Since a decline in reservoir pressure invariably accompanies fluid production, a point is reached at which commercial quantities of oil or gas no longer flow into the well. In natural gas reservoirs, this does not usually occur until most of the gas is recovered. In nearly all crude-oil fields, however, less than one-third of the oil originally present can be produced using only the reservoir pressure.

Secondary recovery of oil. When a large part of the crude oil cannot be recovered simply by allowing the original reservoir pressure to furnish the driving energy, a method for supplying extra energy must be found. Usually, an injected fluid such as water or gas replaces the produced oil and thus maintains the reservoir pressure. When this procedure substantially increases the potential production of oil, it is called secondary recovery. When gas alone is used as the injected fluid, it is usually put into the top of the reservoir where gas normally collects to form a gas cap. The effective use of this type of secondary recovery is restricted to reservoirs that have a high flow potential so that gravity allows the oil to drain to the lower part of the formation where it may be produced. In such a situation, gas injection can be a very effective recovery method. When gravity segregation of the gas and oil cannot occur, however, or when little vertical relief exists in the formation, only a small increase over the natural pressure decline production is realized.

Water flooding

Another even more widely used secondary recovery method is water flooding. Water, after treatment to remove certain impurities, is injected through some of the wells. In moving through the formation, it pushes oil toward the remaining production wells. The wells to be used for water injection are usually spaced evenly among the producing wells so that the oil has the shortest possible paths to follow. Water has been an effective injection fluid and is not dependent upon gravity segregation. A water-flooding project often increases the oil recovery to at least twice that obtained by pressure decline methods. The major exception is oil reservoirs that are connected to an active subsurface water source and are thus subjected to water flooding without injection.

Although water flooding greatly increases the recovery of oil from a particular reservoir, it leaves one-fourth to one-third of the oil behind, and several other methods have been tried in efforts to achieve even better oil recovery. One such method uses a quantity of fluid, such as alcohol or liquefied carbon dioxide, ahead of the injected water to decrease the quantity of oil bypassed by the water. On occasion the injected water is made more viscous by the addition of jellying agents, which help to increase the reservoir volume invaded by water. Still another method requires that a small amount of liquid hydrocarbon, such as propane, be placed ahead of a gas injection to help push the oil ahead of the gas.

Several recent methods for secondary recovery involve the application of heat to the reservoir to make the oil more flowable. These methods are best suited for reservoirs that contain viscous crude oil. In one of them (in situ combustion), a portion of the oil in the formation is burned by igniting the oil around the well and then forcing air through the formation to push the burning region out into the reservoir. The heat thus generated makes the oil more flowable. In a successful project, about ten times as much oil is recovered as is burned. In another heat method, steam is injected into the reservoir; the heat liberated by the condensation decreases the viscosity of the crude oil. The heated oil is often produced from the same well into which the steam was injected. Several cycles of such injection and production may be used on a single well.

Gas cycling. Natural gas reservoirs often contain appreciable quantities of liquid hydrocarbons held in the gaseous state. Since these liquids are liquefied petroleum gases (LPG) such as propane and butane, they are important sources of both fuel and chemical feedstocks. If the pressure in such a reservoir is allowed to decline during gas production, these liquids will condense in the reservoir and become nonrecoverable. To prevent this decline in pressure, a quantity of the produced gas from which the liquids have been removed is put back into the reservoir. This process, called gas cycling, is continued until the optimum quantity of liquids has been removed. The reservoir pressure is then allowed to decline during the production of the nearly dry gas. In effect, this process defers the use of the reinjected natural gas until after the liquids have been produced.

Overall, the production of oil and gas has become an exacting engineering job. Since new oilfields are not being discovered at a rate high enough to supply the steadily increasing demand for products (see Table 2), fields already discovered must be used more efficiently.

TRANSPORTATION AND STORAGE

Petroleum is transported by every conceivable means. Among the major transportation methods are pipelines for overland movement and barge or tanker for water shipment. When a pipeline can be constructed, it is nearly always the most economical means of transportation.

Pipeline sizes

Pipeline diameters vary from the two-inch (five-centimetre) lines that are used in well-gathering systems to 48-inch (120-centimetre) lines for carrying petroleum from producing areas to large consumer centres. The pipelines, normally placed underground, are welded into continuous lengths. Since a major problem is corrosion of the metal pipe, the lines are coated with protective materials such as asphalted felt. Pumping stations are located periodically along the pipeline to help move the petroleum over long distances.

Although barges are used in inland waters, the overseas shipment of petroleum and products is made in specially constructed ships (tankers). For crude-oil transportation, these tankers vary in capacity from 100,000 barrels to 1,000,000 barrels or more. Several tanker ships have been

*Revised.

converted for the shipment of liquefied natural gas. This type of gas transport will undoubtedly open new markets to the natural gas industry.

Nonvolatile crude oil and its products are most often stored in cylindrical tanks set above ground. These storage tanks may be as large as 100 feet (30 metres) in diameter and 30 feet (nine metres) tall. Smaller versions are used to store crude oil at the reservoirs. Highly volatile hydrocarbons such as the liquefied petroleum gases are stored in spherical or nearly spherical tanks. Natural gas is the most difficult product to store. Liquefication requires either high pressures or extremely low temperatures. Probably the most successful storage technique is the use of an underground reservoir much like the original reservoir. The storage reservoir must have nonporous rock over and around it to prohibit the escape of the gas into nearby formations. Another relatively recent method is the storage of liquefied natural gas in underground caverns. It is believed that the low temperatures will freeze the moisture in the surrounding soil and thus prevent the escape of the gas.

Petroleum Refining

Crude oil as it is found in nature consists of complex mixtures of compounds containing hydrogen and carbon (hydrocarbons). In the petroleum refining process, useful products, such as gasoline, motor oil, and petrochemicals, are manufactured from crude oil which in general is unsuitable for direct use.

History. Petroleum refining began in the United States and Russia in the second half of the 19th century, following the discovery in 1859 of "rock oil" in Pennsylvania. In the earliest refineries, simple stills separated crude oil into impure gasoline, kerosene, lubricating oil, and fuel oil fractions. Kerosene, or lamp oil, was the principal marketable product. To improve its odour and appearance the kerosene was treated chemically with caustic soda or sulfuric acid.

The earliest automobile fuel was composed of those fractions of crude oil that were too light to be included in kerosene. Before the invention of the automobile this fraction had been virtually unsalable; as demand for it rose, refiners increased production and improved quality. Methods for the continuous distillation of crude oil were introduced.

After World War I a major improvement in refining came with development of the cracking process, consisting of heating surplus heavier oils under pressure and thereby cracking, or splitting, their large molecules into the smaller ones that form the lighter, more valuable fractions. After appropriate chemical treatment, gasoline manufactured by cracking performed better in automobile engines than gasoline derived from straight distillation.

During the 1930s and World War II, sophisticated refining processes involving the use of catalysts led to further improvements in the quality of fuels and increased their supply. These improved processes, including catalytic cracking, polymerization, alkylation, and isomerization (see below), permitted the petroleum industry to meet the high-performance demands of combat aircraft and, after the war, to supply the increasing quantities required by commercial aviation.

The 1950s and 1960s brought a large-scale demand for jet fuel and for high-quality lubricating oils. Catalytic reforming was established as the leading process for upgrading automotive motor gasolines for use in the higher compression engines. Hydrocracking, accomplished by the addition of hydrogen during refining, also improved the crude-oil fractions.

Classification and types of crude oils. The various hydrocarbon compounds that are mixed together in crude oil have different boiling points, but apart from the lightest, the differences between the boiling points of neighbouring members in the rising scale of molecular weight are so small (only fractions of a degree) that they cannot be separated by ordinary distillation. Fortunately, sep-

arating is not usually necessary; most common petroleum products consist of mixtures of compounds whose boiling points fall within a specified range.

Typical boiling ranges are: motor gasoline 75°–300° F (25°–150° C), kerosene 300°–450° F (150°–230° C), diesel oils 450°–650° F (230°–340° C), and fuel oils above 650° F. In practice, however, there are many different grades of each product with different boiling-point specifications.

Crude oil composition

Crude oils vary widely in boiling range and composition. Figure 1 shows the proportions of the products obtained by distillation of six typical crude oils, ranging

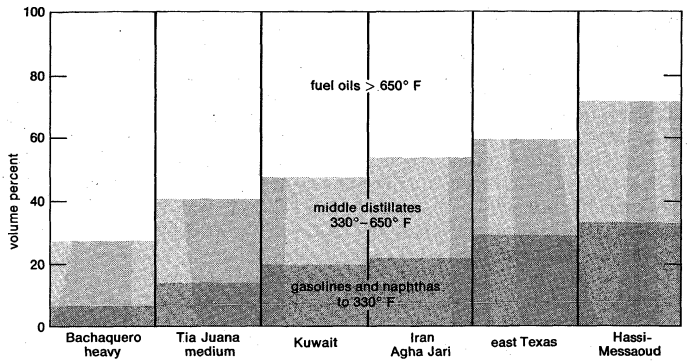

Figure 1: Proportions of the products obtained by distillation of six crude oils.

from West Venezuelan Bachaquero Heavy crude to the light Algerian crude Hassi-Messaoud. The percentage of lighter products (gasoline and naphtha) increases to the right of the chart. Middle distillates (which include kerosene and gas oil) also increase, while fuel-oil content diminishes.

Four main types of hydrocarbons are present in crude oil: normal paraffins, isoparaffins, cycloparaffins (also called naphthenes), and aromatics. Some crude oils, such as Pennsylvanian, consist mainly of paraffins. Others, such as the heavy Mexican and Venezuelan crudes, are predominantly naphthenic and are rich in asphalt (a high boiling semisolid material). Wax is usually, but not always, associated with paraffin-base crudes. The U.S. Bureau of Mines classifies crude oils as paraffin base, naphthene base, or mixed base by determining the properties of key fractions distilled from the oil.

In addition to the hydrocarbons, compounds of sulfur, nitrogen, and oxygen are present in small amounts in crude oil. These are harmful unless removed. Also, there are usually traces of vanadium, nickel, chlorine, and arsenic.

SEPARATION INTO COMPONENTS

The primary refinery process is fractional distillation, which may be followed by other physical separation methods, such as solvent extraction, in which superior lubricating stocks are extracted by means of a solvent, usually furfural obtained from oat hulls.

Fractional distillation. Modern petroleum distillation units operate continuously over long periods of time and are large compared with those that carry out the same process in other industries. Units with 100,000-barrel-per-day capacities are commonplace, and units of over 200,000 barrels per day are now in operation. The American barrel is the most widely used unit in the oil industry and comprises 42 U.S. gallons, or 35 imperial gallons (about 160 litres).

Figure 2 shows the principles of operation of a fractional distillation unit. Crude oil is pumped at a constant rate through steel alloy tubes in a furnace, fired by gas or oil, and heated to a temperature between 600° and 700° F (315°–370° C), depending on the type of crude oil and the end products desired. A mixture of vapour and unvaporized oil passes from the furnace into the fractionating column, a vertical cylindrical tower as much as 150 feet (45 metres) high, provided with 30 or 40 perforated fractionating trays spaced at regular intervals. The bubble-cap tray is the commonest type used, but the sieve tray (less expensive, but with a narrower operating range) is sometimes employed. It consists of a simple perforated plate with small holes about $\frac{3}{16}$ to $\frac{1}{4}$ inch in diameter.

The oil vapours rise up through the column and are condensed to a liquid in a water-cooled condenser at the top. A small amount of gas remains uncondensed; this is piped away to the refinery fuel-gas system. A pressure control valve on this line maintains fractionating-column pressure at the required figure, usually near atmospheric pressure.

Reflux

Part of the condensed liquid, called reflux, is pumped back into the top of the column and runs down from tray to tray, contacting the rising vapours as they pass through the slots in the bubble caps. The liquid progressively absorbs heavier constituents from the vapours and in turn loses its lighter components. Condensation and re-evaporation take place on each tray. Eventually, an equilibrium is reached in which there is a continuous gradation of temperature and of oil properties throughout the column, with the lightest constituent on the top tray and the heaviest at the bottom. The use of reflux and a column of this type distinguishes fractional distillation from simple distillation.

In the column shown in Figure 2, fractions called sidestreams are withdrawn at several points. These products have properties intermediate from the top and base of the column. Typical boiling ranges for various products are as follows: light gasoline (overhead) 75°–200° F (25°–95° C); naphtha (no. 1 sidestream) 200°–300° F (95°–150° C); kerosene (no. 2 sidestream) 300°–450° F (150°–230° C); and gas oil (no. 3 sidestream) 450°–650° F (230°–340° C).

In practice, the boiling ranges of these products can be varied within wide limits according to requirements. This is accomplished either by selecting different drawoff points in the column or by varying the quantity of oil withdrawn and has the effect of changing the equilibrium concentration of the liquid on the tray concerned.

The degree of fractionation, or sharpness of separation between hydrocarbons, depends on the number of trays and their efficiency in achieving equilibrium between vapour and liquid. It also depends on the reflux ratio; *i.e.*, the volume of liquid pumped back divided by the volume of overhead product. Reflux ratios in crude oil distillation columns are usually between 1:1 and 3:1.

Unvaporized oil entering the column (Figure 2) flows downward over another set of trays in the lower part of

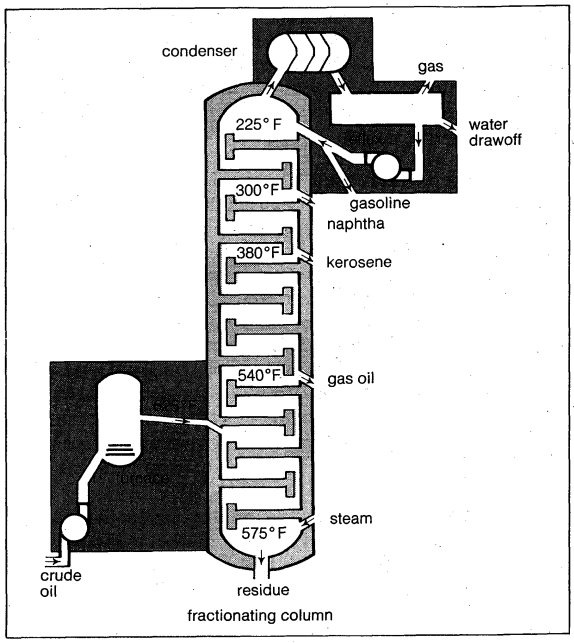

Figure 2: General operating principles of a fractional distillation unit (see text).

Treatment of unvaporized oil

the column called stripping trays, which remove any light constituents remaining in the liquid. To assist in this, steam is injected at the bottom of the column. The residue that passes from the base of the fractionating column is suitable for blending into fuel oils. Alternatively, it may be distilled a second time under vacuum conditions and further quantities of distillate recovered for use as a starting material for manufacturing lubricating oil or as feedstock for catalytic cracking.

Vacuum distillation. The principles of vacuum distillation resemble those of fractional distillation, and, except that larger diameter columns are used to maintain comparable vapour velocities at the reduced pressures, the equipment is also similar. The vacuum is produced by steam ejectors in vacuum distillation. Components that are less volatile can be distilled without raising the temperature to the range at which cracking occurs, as it would at atmospheric pressure. Firing conditions in the furnace are adjusted so that the oil temperature does not exceed about 750° F (400° C). The residue after vacuum distillation is asphalt, or bitumen.

Superfractionation. Superfractionation is an extension of fractional distillation employing columns with a much larger number of trays (*e.g.*, 100) and reflux ratios exceeding 5:1. With such equipment it is possible to obtain fractions containing only a few hydrocarbons or even to separate pure compounds. By this method, isopentane of over 90 percent purity is produced for aviation gasoline; isohexane and isoheptane concentrates are also prepared for the same purpose. These isoparaffins have much higher octane numbers than the corresponding normal paraffins.

Other methods. *Absorption and stripping.* Absorption and stripping are processes used to obtain valuable light products such as propane/propylene and butane/butylene from the gasoline vapours that pass out of the top of the fractionating tower. In the absorption process, gasoline vapours are bubbled through an absorption oil such as kerosene or heavy naphtha in equipment resembling a fractionating column. The light products dissolve in the oil while dry gases such as hydrogen, methane, ethane, and ethylene pass through undissolved. Absorption is more effective under pressures of about 100–150 pounds per square inch than it is at atmospheric pressure.

The light products are separated from the absorption oil in the stripping process. The solution of absorption oil and light products is boiled by steam and passes to a stripping column, where the light product vapours pass upward and are recovered by condensation by water-cooling under pressure. The unvaporized oil passes from the base of the column for reuse.

Solvent extraction. Solvent-extraction processes are used primarily for the removal of constituents that would have an adverse effect on the performance of the product in use. The quality of kerosene is improved by the extraction of aromatic compounds that burn with a smoky flame (these compounds can be used to advantage in tractor fuels).

Another important operation is the removal of heavy aromatic compounds from lubricating oils. Removal improves the viscosity–temperature relationship of the oil, extending the temperature range over which satisfactory lubrication is obtained. The usual solvents for extraction of lubricating oil are furfural and phenol. Other solvents are dichloroethyl ether, nitrobenzene, and a mixture of liquid propane and cresylic acid.

Adsorption. Certain highly porous, solid materials have the ability to select and adsorb specific types of molecules, thus separating them from other types. Silica gel is used in this way to separate aromatics from other hydrocarbons, and activated charcoal is used to remove liquid components from gases.

Adsorption is thus somewhat analogous to the process of absorption with an oil, although the principles are different. Layers of the absorbed material only a few molecules thick are formed on the extensive interior surface of the adsorbent; this interior surface may amount to several acres per pound of material.

Recent years have brought new developments in the use of adsorbents of a very selective nature called molecular sieves. Molecular sieves are produced by the dehydration of naturally occurring or synthetic zeolites (crystalline alkali-metal aluminosilicates). The dehydration leaves intercrystalline cavities that have pore openings of definite size, depending upon the alkali metal of the zeolite. Under adsorptive conditions normal paraffin molecules can enter the crystalline lattice and be selectively retained, whereas the other molecules are excluded This principle is used commercially for the removal of normal paraffins from gasoline fuels, thus increasing their octane number. The use of molecular sieves has also been extended to the separation of hydrocarbons of higher molecular weight.

Molecular sieves

Thermal diffusion. When a mixture of hydrocarbons is passed through a narrow gap, of the order of $\frac{1}{100}$ inch, between hot and cold surfaces, some of the constituents concentrate near the hot surface and others near the cold. The phenomenon, known as thermal diffusion, is not clearly understood, but it is believed that separation occurs as a result of differences in the shapes of the molecules. Though this process has been applied in the laboratory as an analytical tool, it is unlikely to find much use in industry as the thermodynamic efficiency is low.

Crystallization. The crystallization of wax from lubricating oil fractions is essential to make the oils suitable for use. A solvent, (for example, a mixture of benzene and methyl ethyl ketone) is first added to the oil and the solution chilled to about −5° F (−20° C). The function of the benzene is to keep the oil in solution and maintain its fluidity at low temperatures, whereas the methyl ethyl ketone acts as a wax precipitant. Rotary filters are used to filter off the wax crystals on a specially woven canvas cloth stretched over a perforated cylindrical drum. A vacuum, maintained within the drum, sucks the oil into it. The wax crystals are removed from the cloth by metal scrapers, after washing with solvent to remove traces of oil. The solvents are later distilled from the oil and reused.

ALTERATIONS OF MOLECULAR STRUCTURE

The separation processes described above are based on differences in physical properties of the components of crude oil. By chemically changing their molecular structure, it is possible to convert less valuable hydrocarbon compounds into those in demand.

The first of these conversion processes is cracking, or thermal decomposition of long-chain hydrocarbon molecules into shorter molecules with lower boiling points. For example, a paraffin molecule such as dodecane ($C_{12}H_{26}$) has such poor "antiknock" properties that it cannot be used in a modern automobile engine, but under intense heat it breaks down into shorter molecules such as paraffins (C_6H_{14};C_7H_{16}) or olefins (C_6H_{12};C_5H_{10}), which are suitable for motor fuels. The chemical reactions that take place in a cracking operation are complex.

The product derived from a cracking process is, in effect, a synthetic crude oil. Desired gasoline fractions must be separated by distillation.

Thermal cracking and reforming. The earliest cracking techniques are typified by processes in which kerosene or gas oil materials were converted by heating to temperatures between 850° and 1000° F (450°–540° C) at pressures of 250 to 500 pounds per square inch. This process produced gasolines of about 70 octane number (low by modern standards).

Visbreaking, another thermal cracking process, reduces viscosity of heavy crude oil residues to make them more suitable for inclusion in fuel oils.

The steam cracking process, by which ethylene and other olefins are made from naphtha, differs from thermal cracking in that it is carried out at low pressures and higher temperatures.

Thermal reforming, a modification of the thermal cracking process, reforms or alters the properties of low-grade components such as naphthas by converting the molecules into those of higher octane number. Pressures used are somewhat higher than in cracking. At temperatures from 950° to 1,050° F, it is possible to obtain gasolines with octane numbers of 70–80 from components of less than 40.

Catalytic cracking. The development of catalytic cracking was one of the major achievements of the petroleum industry. Enormous catalytic cracking plants dominate the skylines of modern oil refineries and operate continuously for years on end. The catalytic cracking of gas oil is one of the most important processes for manufacture of gasoline.

Use of a catalyst (a material that assists a chemical reaction but does not take part in it) in the cracking reaction increases the yield of improved quality products under much less severe operating conditions than in thermal cracking. Typical temperatures used are from 850° to 950° F at much lower pressures of 10 to 20 pounds per square inch. At first natural or synthetic clays were used as catalysts. A typical synthetic clay contains 12.5 percent alumina and 87.5 percent silica. In the last few years zeolitic or molecular sieve-base catalysts have been introduced. These give greater gasoline yields while reducing the formation of gas and coke.

Cracking may be accomplished either with a "fixed bed" of catalyst, with a "moving bed" of granular catalyst, or with a "fluid" catalyst, which is a finely divided solid having properties analogous to a liquid when agitated by air or oil vapours.

Fluid catalytic cracking process

The fluid catalytic cracking process may be examined as an example. Figure 3 shows the principles of operation of a fluid catalytic cracking unit.

From *Hydrocarbon Processing* (September, 1968)

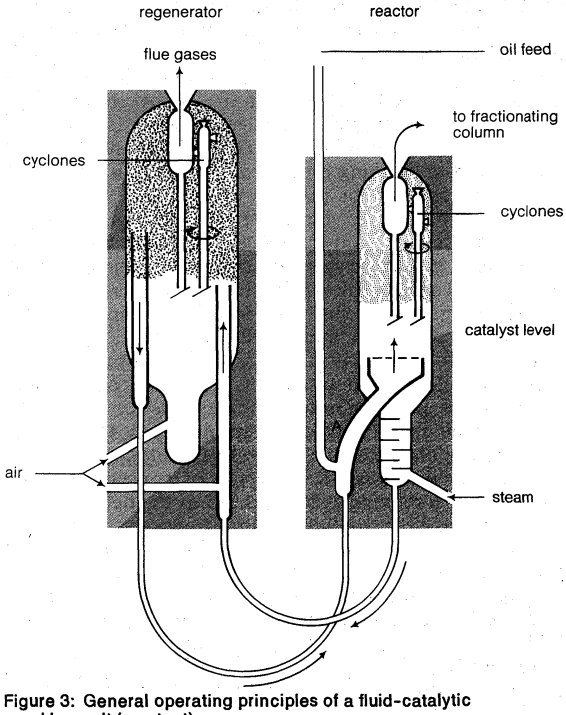

Figure 3: General operating principles of a fluid-catalytic cracking unit (see text).

In this arrangement a reactor and a regenerator vessel are located side by side. The oil is vaporized when it meets the hot catalyst at point A. The vapours force the catalyst up into the reactor, which (because its cross section is larger in area) allows the catalyst to settle into a bed whose depth can be varied to regulate the reaction time. The oil vapours maintain the bed of catalyst in a turbulent condition, thus effecting the close contact between vapours and catalyst necessary for cracking.

As the cracking reactions proceed, carbon is deposited on the catalyst particles. Since these deposits impair its efficiency, catalyst is continuously withdrawn from the base of the reactor and regenerated in the other vessel by burning off the carbon with a current of air. This also heats up the catalyst to the required reaction temperature.

Product vapours pass out of the top of the reactor through separators using centrifugal force, called cyclone separators, where the catalyst is removed and dropped back into the reactor bed. Similar cyclones recover catalyst from the flue gases that emerge from the top of the regenerator. A small amount of fresh catalyst is added to the system from time to time to maintain the activity and a similar amount withdrawn.

The products are fractionated in a distillation column. The yield of gasoline is in the region of 40–60 percent of the gas oil feed.

Catalytic reforming. This process uses catalysts to mold molecular structure into desirable forms without the formation of unwanted heavy products and coke. As in thermal reforming, a naphtha-type material is used as the feedstock, but the reactions are carried out in the presence of hydrogen, which inhibits the formation of unstable unsaturates that polymerize into high-boiling compounds.

Use of platinum, chlorine, and fluorine

Most catalytic reforming processes use platinum as the active catalyst. It is distributed on the surface of aluminum oxide as a carrier. Small amounts of chlorine and fluorine act as catalyst promoters. In spite of the high cost of platinum, the process is feasible because of the long life of the catalyst and the high quality and yield of the products obtained. This process has almost entirely replaced thermal reforming.

Other important reactions include the breaking down of long-chain hydrocarbon molecules into smaller saturated chains and the formation of isoparaffins, made up of branched-chain molecules. Formation of ring compounds, or cyclization, of paraffins into naphthenes also takes place and naphthenes are in turn dehydrogenated into aromatic compounds. The desirable end products are isoparaffins and aromatics, both with high octane numbers.

Commercially available processes include platforming, powerforming, ultraforming, and catalytic reforming. In a typical platforming unit, the naphtha charge mixed with hydrogen (the mixture is about five molecules of hydrogen to one of hydrocarbon) is heated to a temperature normally in the range of 455°–535° C. This gaseous mixture passes downward through the pellets of catalyst contained in three reactors in series. Operating pressures vary from 200 to 800 pounds per square inch. Because heat is absorbed in the reforming reactions, the mixture is reheated in intermediate heaters between the reactors.

After leaving the third reactor, the liquid product is condensed, separated, and passed to the stabilizer column, where hydrocarbon gases produced in the reactions are removed. The catalytic reformate product is then available for blending into motor gasoline without further treatment. The hydrogen leaving the products separator is returned to the reactors by the compressor.

Operating conditions are set to obtain the required octane number, usually between 90 and 100. At the higher levels, reduced yields are obtained. Octane numbers can be raised by the addition of between 1.5 and 3 millilitres of tetraethyl lead per U.S. gallon (3.8 litres). In some countries, legislation is proposed to limit the amount of tetraethyl addition to motor gasolines as an antipollution measure. Such restrictions will tend to increase the use of catalytic reforming, an important process for production of high-octane components.

Polymerization. Gaseous hydrocarbons produced in thermal and catalytic cracking processes may be used for refinery fuel, or they may be converted into more valuable products by various methods such as polymerization. In polymerization, the hydrocarbon molecules are induced to combine, or polymerize, into molecules of two or more times the molecular weight, forming a material that performs well as a motor fuel. Early commercial processes used 65 percent sulfuric acid as catalyst but were soon superseded by processes using catalysts of phosphoric acid on kieselguhr or the phosphates of copper and cadmium. High pressures, of the order of 400 to 1,200 pounds per square inch are required at temperatures from 350° to 450° F.

The polymer gasolines derived from petroleum fractions containing propylene and butylene have octane numbers above 90, and with the addition of tetraethyl lead, above 100.

Alkylation. The alkylation reaction also achieves a longer chain molecule by the combination of two small-

er molecules, one being an olefin and the other an isoparaffin (usually isobutane). During World War II, alkylation became the main process for the manufacture of isooctane, which made possible the production of large quantities of aviation gasoline.

Sulfuric acid alkylation. Concentrated sulfuric acid (98 percent) is used as the catalyst, and the process is carried out in reaction vessels of mild steel, as corrosion of this material with concentrated acid is relatively low. The reaction must be carried out at low temperatures, 35° to 45° F (2° to 7° C). Refrigeration is necessary because heat is generated by the reaction.

The octane numbers of alkylates produced range from 89 to 95. For aviation fuel, butylene fractions are usually used as feedstocks. After the addition of tetraethyl lead, octane numbers of over 100 are attainable. The sulfuric acid alkylation process was announced in 1938 and is still extensively used for production of aviation gasoline and high-octane motor gasoline.

Hydrofluoric acid alkylation. Hydrofluoric acid is used as the catalyst in this variant of the alkylation process. The chemical reactions are similar, but it is possible to use higher temperatures (between 24° and 46° C), thus avoiding the need for refrigeration. Recovery of the hydrofluoric acid is simple and it can be accomplished by distillation. Stringent safety precautions must be exercised when using this highly corrosive and toxic substance.

Isomerization. The demand for aviation gasoline became so great during World War II and after that the quantities of isobutane available for alkylation feedstock were insufficient. The deficiency was remedied by isomerization (changing molecular structure) of the more abundant normal butane into isobutane. The isomerization catalyst is aluminum chloride supported on alumina, promoted by hydrogen chloride gas.

Commercial processes have also been developed for isomerization of normal pentane and normal hexane to the corresponding isoparaffins. Here, the catalyst is usually of the platinum type. The reactions are carried out in the presence of hydrogen, as in catalytic reforming. Hydrogen is neither made nor consumed but is used to inhibit undesirable side reactions. The objective of these processes is to convert low-octane-number pentane and hexane feedstocks into high-octane-number gasoline-blending components or into highly pure isopentane or neohexane (2,2, dimethylbutane). In the latter case the isomerization product is purified by molecular sieve extraction followed by distillation. Application of this process is increasing and will be more valuable if limitations are placed on the use of tetraethyl lead in gasolines.

Hydrogenation and hydrocracking. One of the most far-reaching developments since World War II has been the use of hydrogen in refining, in part as the result of the availability of hydrogen as a by-product of catalytic reforming. But refining with hydrogen is now becoming so popular that hydrogen-manufacturing plants are being built.

One of the earliest applications was the conversion of octenes (eight-carbon-atom olefins) produced by polymerization into isooctane for manufacture of aviation gasoline, but the alkylation process has since rendered this obsolete. Today, two main types of hydrogenation exist; hydrotreatment and hydrocracking. Hydrotreatment is used to remove impurities such as sulfur, nitrogen, and oxygen (see below *Purification processes*).

Advantages of hydrocracking

Although capital costs are high, the flexibility of hydrocracking is such that it promises to become the most effective process available to the refiner for extending the use of the barrel of crude oil. This process can be used for producing gasoline or middle distillates from heavy gas oils, for converting residues into lighter oils, or for producing liquefied petroleum gases from straight-run naphthas. By cracking these in the presence of hydrogen and a catalyst, valuable products are obtained without simultaneous formation of coke and large quantities of gas. The activity of the catalyst can be maintained for long periods. Continuous regeneration is not necessary, as it is in catalytic cracking.

In the United States, the main objective has been to increase gasoline production, particularly from heavy crudes. In the Eastern Hemisphere there has been a trend to install units designed for middle-distillate production, to augment the supplies of heating oils; but in Europe, gasoline-producing units are being erected, releasing naphtha (petrochemical feedstock) for catalytic reforming.

Hydrocracking is accomplished at lower temperatures than catalytic cracking—*e.g.*, at 500° to 800° F—but at much higher pressures—1,000 to 2,000 pounds per square inch. The design and manufacture of the large, thick-walled vessels for operation under these conditions has been a considerable engineering achievement.

The catalysts used vary widely. The cracking reactions are induced by materials of the silica–alumina type. Hydrogenation catalysts such as nickel, tungsten oxide, platinum, or palladium are incorporated. Molecular sieve-type catalysts with a hydrogenation constituent are also being used.

PURIFICATION PROCESSES

Before petroleum products are marketed, certain impurities must be removed or made less obnoxious. The most common impurities are sulfur compounds, which, apart from their evil odour, are technically undesirable. In motor and aviation gasolines these compounds reduce the effectiveness of the antiknock tetraethyl lead; in diesel oils, they cause corrosion in the engine. Finally, there is increasing need in many countries to limit sulfur content of fuel oils to reduce atmospheric pollution.

Common impurities

Most crude oils contain small amounts of hydrogen sulfide; this is increased by the breakdown of heavier sulfur compounds during distillation. Though the bulk of the hydrogen sulfide passes off in the overhead gases, some remains dissolved in the gasoline. It is easily removed by alkaline solutions. The light distillates and products from cracking processes also contain more complex sulfur compounds that are not removed so readily. The most common of these are the mercaptans, which have a particularly unpleasant smell. Other undesirable constituents include oxygenated compounds such as alkyl phenols and naphthenic acids, nitrogen bases, gums and gum-forming constituents, and unstable compounds that can lead to colour formation in the product.

Processes for the purification of petroleum products are described below. Product quality is assessed by standard test methods. In addition to chemical tests for impurities, they include many physical tests designed to measure performance characteristics against relevant specifications.

Sulfuric acid treatment. The use of concentrated sulfuric acid as a refining agent is as old as the petroleum industry. It has been applied to almost every type of product. Though still important, its use has declined in recent years, following the introduction of solvent extraction and catalytic processes using hydrogen. Sulfuric acid removes sulfur compounds by solution. It also polymerizes highly reactive hydrocarbons and neutralizes nitrogen bases. Asphaltic constituents and easily oxidizable compounds are also removed.

Sulfuric acid treatment improves the colour of cracked gasolines and inhibits the formation of gum in storage. Sulfuric acid is particularly valuable for refining special boiling-point solvents and white spirits when a very low sulfur content is required. In the past it was extensively used for treatment of lubricating oils. The introduction of more modern processes, such as solvent extraction, has displaced it except for special purposes.

A serious inconvenience associated with acid treatment is the need to dispose of the acid tars that are formed as waste. An acid recovery plant is required to regenerate the sulfuric acid for reuse, both to economize in acid consumption and to prevent pollution. Most modern refineries have adopted catalytic refining processes to avoid these problems. Another disadvantage is the slight loss of useful product in acid treatment, since there is some polymerization to high-boiling compounds. These compounds are eliminated by redistillation of the product.

Sweetening. Sweetening processes convert evil-smelling and corrosive mercaptans into relatively innocuous disulfides. Mercaptans are slightly acidic compounds. Their

acidity decreases as the number of carbon atoms increases. Examples are methyl mercaptan, ethyl mercaptan, and propyl mercaptan. The lighter ones are partially removed by alkali treatment, but in sweetening reactions they are oxidized. Catalysts assist oxidation. In what is known as the doctor process of oxidation, the catalyst is a solution of sodium plumbite, made by dissolving lead oxide in caustic soda. This inexpensive process was very popular until recently, but the necessity of adding elemental sulfur to make the reactions proceed causes an increase in the total sulfur content of the oil. The doctor process is consequently being superseded by processes in which there are no undesirable side reactions and no increase in total sulfur content. One such is the copper chloride process, in which the catalyst is a suspension, or slurry, of copper chloride and fuller's earth. It is applicable to both gasolines and kerosenes. The oil is heated and then brought into contact with the slurry while being agitated by a stream of air or oxygen that oxidizes the mercaptans to disulfides. The slurry is then allowed to settle and is separated for reuse. The heater raises the temperature to a point that will keep the water formed in the reaction dissolved in the oil, so that the catalyst slurry remains at the right degree of hydration. After sweetening, the oil is water washed to remove any traces of catalyst and dried by a salt filter.

The copper chloride process

Mercaptan extraction. Simple sweetening is adequate for many purposes and is widely used, but other methods must be adopted if actual removal of sulfur compounds is required. One of these methods is mercaptan extraction. When certain chemicals called solutizers, such as potassium isobutyrate and sodium cresylate, are added to caustic soda solution, the solubility of the higher mercaptans is increased and they can be extracted from the oil. The oil is first pretreated with caustic soda to remove traces of hydrogen sulfide and alkyl phenols and then brought into contact with the solutizer solution, either in a packed column or other mixing device. The mixture is allowed to settle and the product pumped away to storage, via a water washer.

Regeneration of the solution containing sodium mercaptides can be accomplished by heating or by oxidation with air in the presence of a catalyst. In the latter case the regenerated solution is washed with an oil to remove the disulfides that are formed before being recycled to the extraction stage.

Clay treatment. Some natural clays, activated by roasting or by treatment with steam or acids, have been used for many years in the industry for removing traces of impurities. The phenomenon is similar to that described under the adsorption separation process; the clays retain the larger long-chain molecules within their highly porous structure.

Clay treatment is occasionally used to remove gum and gum-forming materials from thermally cracked and thermally reformed gasolines in the vapour phase. A more economic procedure, however, is to add small quantities of inhibitors, synthetic anti-oxidants, to the gasoline. These prevent, or greatly retard, gum formation.

Final purification of lubricating oils by clay treatment is in general use. Resins and highly coloured bodies remaining after solvent extraction are removed, and a pleasing appearance is given to the oil. The treatment may be by contact—that is, the clay is added to the oil, the mixture heated, and the clay filtered off—or by percolation, in which the heated oil is allowed to flow through a large bed of active adsorbent.

The spent clay is usually discarded, although there are processes in which the clay is regenerated by roasting. Disposal of spent clay presents a problem to refineries. Newer hydrofinishing processes are available in which mild hydrogenation achieves results similar to treatment by clay.

Hydrogen treatment. A major application of the hydrogen treatment is in the removal of sulfur compounds of all types. Hydrogen treatment can be applied to a wide range of products. The processes are known as hydrofining or hydrodesulfurization. In them, the oil is mixed with hydrogen and vaporized before passing over a catalyst such as tungsten, nickel, or a mixture of cobalt and molybdenum oxides, supported on an alumina base. Mild operating temperatures are used—*e.g.*, between 500° and 800° F—and pressures between 200 and 1,000 pounds per square inch.

The sulfur in the oil is converted to hydrogen sulfide, which is eliminated from the circulating hydrogen by absorption in a solution such as diethanolamine, which can then be heated to remove the hydrogen sulfide and reused. The hydrogen sulfide recovered is useful for manufacturing elemental sulfur of high purity.

Hydrotreatment processes are used primarily for sulfur removal from gasolines, naphthas, kerosenes, and gas oils. There is no breakdown of hydrocarbons and so the oils are virtually unchanged, except for the purification.

Molecular sieves. Molecular sieves are also used to purify petroleum products since they have a strong affinity for polar compounds such as water, carbon dioxide, hydrogen sulfide, and mercaptans.

Usually sieves with a pore size of 13 Angstrom units (13 $\times 10^{-8}$ centimetres) are used. These are prepared by the dehydration of a sodium aluminosilicate (zeolite). Fixed beds of adsorbent are used. The petroleum product is passed through for a predetermined period, depending on the amount of impurity to be removed. The adsorbed contaminants may then be eliminated from the sieves by purging with a gas stream at temperatures between 400° and 600° F. The cycle is then repeated.

PETROLEUM PRODUCTS AND THEIR USES

Gases. Refinery gas has a heating value similar to natural gas and is used to enrich supplies. It is used as a starting material for petrochemical industries. It is also converted into liquefied petroleum gas (LPG), a convenient fuel for domestic and light industrial use.

Refinery gas

Gasolines. *Motor gasoline.* A good motor gasoline must possess three characteristics. (1) The fuel must burn smoothly in the engine without detonating, called knocking. A common performance characteristic is the octane number, an expression of the engine performance of a gasoline when compared with two standard test fuels, normal heptane and isooctane. Normal heptane, a fuel of poor quality (*i.e.*, very prone to "knocking"), is assigned a value of 0 and isooctane, of very high quality, 100. Thus, when a motor gasoline is given an octane number of 90, it means that its test performance in a standard engine is equivalent to that of a mixture of 90 parts by volume of isooctane and 10 parts of normal heptane. There are two methods for carrying out the test: the Research Method, under mild conditions of temperature and running speed (120° F and 600 revolutions per minute), and the Motor Method, under more severe conditions (300° F and 900 revolutions per minute). In commercial practice, Research Method ratings are usually quoted. Motor gasolines are blended to required octane number (90 to 100 for most modern cars) from the components whose manufacture is described above. A small amount of tetraethyl lead (TEL) is usually added. (2) A good motor gasoline must start the car easily in cold weather. (3) The fuel system must not become vapour locked when temperatures are high. Volatility and vapour pressure define these latter two requirements quantitatively.

Octane number

Aviation gasoline. Piston-type aircraft engines are extremely fastidious in their demands on fuel quality. Knocking cannot be tolerated without risk of serious mechanical failure; this is true whether a weak mixture is being used, as under cruising conditions, or whether an enriched mixture is being used, as during takeoff or under maximum power.

Antiknock ratings of aviation gasolines are therefore determined under both conditions. The methods used, known respectively as the F3 and F4 methods, can rate fuels with octane numbers above 100. Aviation fuels are designated by quoting both figures. Thus a 100/130-grade fuel has an F3 rating of 100 and an F4 rating of 130. Because of the low temperatures in flight at high altitudes, a maximum freezing point of −60° C (−76° F) is specified to ensure that the fuel remains fluid.

Kerosene. Though its use as an illuminant has greatly diminished, kerosene still finds considerable use throughout the world in cooking and space heating. Newer uses are as fuel for tractors and as a turbine fuel for jet and turboprop aircraft.

Burning oil. Kerosene used as a burning oil must not give a smoky flame and there must be a minimum of charring of the wick or formation of "bloom" on lamp glasses. Standard laboratory procedures test these properties by burning the oil in special lamps. All kerosene fuels must satisfy minimum flash-point specifications, 120° F (49° C), to limit fire hazard in storage and handling.

Jet fuels. Jet fuels must burn cleanly in the aircraft engine combustion chambers. The first fuel used was a kerosene, and this type fuel still finds considerable use in civil aircraft. For military purposes, however, and to increase availability, it was necessary to extend the boiling range to include both gasolines and kerosenes.

As with aviation gasolines, freezing point is important and the fuels are freed of suspended water that might cause blockage of the fuel system with ice particles.

Gas oils and diesel oils. The main use of gas oils is to power the diesel engines in trucks, buses, railway engines, and similar vehicles. In a diesel engine, combustion is induced by the heat of compression of the air in the cylinder caused by the moving piston. Detonation, which leads to knocking in a gasoline engine, is a necessity for diesel fuel. A good diesel fuel starts to burn at several places in the cylinder soon after the oil is injected as a mist. Once the flame is started, any further fuel entering the cylinder ignites at once (see also DIESEL ENGINE).

Straight-chain hydrocarbons make the best diesel fuels. In order to have a standard reference scale, the oil is matched against blends of cetane (normal hexadecane) and alpha methylnaphthalene, the latter of which gives a very poor engine performance. High-quality diesel fuels have cetane numbers around 50, equivalent to a blend containing 50 percent cetane and 50 percent alpha methylnaphthalene.

For the slower diesel engines used in ships and in stationary engines on land, it is possible to cut deeper into the crude oil than with high-speed diesel fuels. The heavier, more viscous grades of oil are heated to permit easy pumping and to give the correct viscosity at the fuel injectors for good combustion.

Fuel oils. Fuel oil, or furnace oil, consists largely of residues from crude oil distillation. These are blended with other suitable fractions to obtain the required viscosity, the basis on which fuel oils are sold. About 70 percent of these oils are used to generate steam in power stations, ships' boilers, and industrial boilers. Their calorific value ranges from about 19,000 British thermal units per pound (Btu/lb), for the lightest fuels, to about 18,300 Btu/lb for the heaviest. (The British thermal unit is the amount of heat required to raise the temperature of one pound of water one degree Fahrenheit.) Calorific value depends on the carbon:hydrogen ratio of the fuel and also on its sulfur content, which may vary from about 1 to 4 percent, according to the source of the crude oil. The combustion properties of fuel oils of high sulfur content are satisfactory if the flue gases do not impinge on cool surfaces, which could lead to corrosion by the condensation of acidic sulfur trioxide.

With increasing attention being given to air pollution, some highly industrialized countries propose to reduce the concentration of sulfur oxides in the atmosphere by limiting the sulfur content of fuels burned. In the early 1970s the oil industry was avoiding the cost of desulfurizing this product by processing mixtures of low and high sulfur crude oils.

Fuel oils derived from waxy crudes can solidify under storage conditions; it is usual, therefore, to specify a pour point for the oil. This point (the lowest temperature at which the oil still flows) varies from about 35° F for the lighter fuel oils to about 70° F for the heavier. The heavier oils are usually heated in storage and in use. A pumpability test, measuring the viscosity–temperature relationships of the oil, gives a good indication of its performance in actual use.

Pumpability test

Lubricating oils. At one time the suitability of petroleum fractions for use as lubricants depended entirely on the sources of the crude oils from which they were prepared. Those from Pennsylvanian crudes were recognized as having very superior properties, being largely paraffinic in nature. But with the advent of solvent extraction the choice of suitable crude oils has been considerably extended.

Viscosity is the basic property by which lubricating oils are classified. Requirements vary from the thin oil needed for the high-speed spindles of textile machinery to the viscous, tacky compositions applied to open gears or wire ropes. Between these extremes is a range of products, many highly refined, with special characteristics (see also LUBRICATION).

Automobile oils represent a large proportion of those manufactured. In the U.S., the Society of Automotive Engineers established a system of SAE numbers to indicate the viscosity at a particular temperature, 0° F (−18° C). Oils in common use have SAE numbers varying from 5 to 50.

When ordinary mineral oils having satisfactory fluidity at low temperatures are used over an extended temperature range, excessive thinning occurs at the high temperatures. To correct this, multigrade oils incorporating synthetic long-chain polymers have been developed. These have much more satisfactory viscosity–temperature relationships. Thus an oil designated SAE 10W/40 has the viscosity of an SAE 10W oil at 0° F (−18° C), and of an SAE 40 oil at 210° F (99° C). Such an oil will help start an engine in winter (hence the suffix W) and will lubricate well under running conditions in summer. Other additives that improve the performance of lubricating oils are anti-oxidants and detergents, which maintain engine cleanliness by keeping fine carbon particles in suspension in the oil.

Gear oils. In gear lubrication the oil separates metal surfaces, reducing friction and wear. Extreme pressures develop in some gears, notably those in the rear axles of cars; special additives are incorporated to prevent freezing together (seizing) of the metal surfaces. The oils contain sulfur compounds that form a resistant film on the surfaces, preventing actual metal-to-metal contact. Such compounds are known as extreme pressure (EP) additives.

Greases. Greases are lubricating oils to which thickeners, or gelling agents, are added. Soaps of aluminum, calcium, lithium, and sodium are commonly used, while more recently nonsoap thickeners (*e.g.*, carbon, silica, and polyethylene) have been employed.

Other petroleum products. Highly purified distillate fuels are used in pottery kilns, for glass manufacture, and many other purposes, including the baking of bread. Metallurgical operations employing petroleum products include the smelting of ores, forging, and alloy melting.

White spirits are used as thinners for paints and varnishes and for dry cleaning. They are highly purified to avoid unpleasant odours. Similar materials are used in the rubber industry and for the extraction of vegetable oils.

Waxes and petroleum jellies are familiar products. Asphaltic bitumen is the earliest known petroleum product, having been used by the pre-Babylonian inhabitants of the Euphrates valley before 2500 BC. Today it is widely used for the construction of roads and airfields. Specialized uses of bitumen include the manufacture of roofing felts, waterproof papers, pipeline coatings, and electrical insulation.

Asphaltic bitumen

Carbon black was previously made by the incomplete combustion of natural gas. Today it is manufactured by decomposing liquid hydrocarbon fractions; it is compounded with rubber in tire manufacture and is a constituent of printing inks and lacquers.

Petroleum chemicals. By definition, petroleum chemicals are simply chemicals that happen to be made from a starting material obtained from petroleum. They are, in almost every case, virtually identical with the same product from other sources, such as coal and coke or fermentation processes.

Olefins. The thermal cracking process in refineries, as

it developed from 1910 onwards, aimed at increasing the quantity and improving the quality of gasoline. As a by-product of this process, gases were produced that included a significant proportion of lower molecular weight olefins, particularly propylene and *n*-butylenes (olefins are unsaturated compounds of carbon and hydrogen and are chemically very reactive). Commercial production of chemicals from this source dates from 1919. Today catalytic cracking is a valuable source of propylene and *n*-butylenes but not a very good one of ethylene, a most important petroleum chemical.

It is important to differentiate between the current practices of the U.S. and most of the rest of the world in producing olefins. In the U.S., propylene and *n*-butylenes are produced from refinery catalytic cracking. Ethylene is largely produced in the U.S. by cracking ethane extracted from natural gas. In Europe, Japan, and other major centres of petroleum chemical production, catalytic cracking is a less important refinery operation, and appropriate supplies of natural gas are not readily available. As a result, Europeans (now also Japanese) generally crack a liquid hydrocarbon fraction in the gasoline range (light or heavy naphtha). In a single operation this yields a whole range of olefins, notably ethylene, propylene, the *n*-butylenes, and butadiene.

Cracking plants are usually situated adjacent to a refinery from which they derive the fractions used as feedstock and to which they return liquid cracking product.

Petroleum chemical plant complexes

Plants that consume these various olefins are clustered around the cracker. Among typical plant complexes in Europe are ICI at Wilton, England; Shell at Carrington, England; BP Chemicals at Grangemouth, Scotland; Shell and Naphtachimie near Marseilles, France; Shell, Dow, Gulf, ICI, and other companies near Rotterdam, The Netherlands; Shell/BASF at Wesseling, Germany; and BP/Bayer at Dormagen, Germany. Similar major industrial sites are characteristic of the Japanese petroleum chemical industry (for example at Yokkaichi and Tokuyama).

Petroleum has become the favoured source of organic chemicals. Over 80 percent of the world's organic chemicals are now made from petroleum; and the proportion is expected to rise to about 98 percent within the next 15 years.

Inorganic chemicals. Various inorganic chemicals are also made from petroleum, some, particularly ammonia and sulfur, in large quantities. Ammonia production requires hydrogen from a hydrocarbon source. Traditionally, this hydrogen was produced from a coke and steam reaction, but today most ammonia is synthesized from liquid petroleum fractions, natural gas, or refinery gases. It has been pointed out that sulfur is an unwanted impurity in many petroleum products. In the process of eliminating it from oil products, it is ultimately recoverable either as elemental sulfur or as sulfuric acid. Though various inorganic chemicals manufactured from petroleum represent a substantial tonnage, the total is still only a modest proportion of the world production of such chemicals.

Aromatic compounds. The aromatic compounds, prominent in the refinery process of catalytic reforming, are major sources of petroleum chemical products as well as the lower olefins mentioned above. In the traditional chemical industry, aromatics such as benzene, toluene, and the xylenes were made from coal during the course of coal carbonization in making coke or town gas. Today a much larger volume of these compounds is made in petroleum refineries by catalytic reforming. A further source of supply now increasingly used in Europe is the aromatic-rich liquid fraction produced in the cracking of naphtha to make ethylene and other olefins.

Polymers. A highly significant proportion of products made from these basic chemicals are the plastics, synthetic rubbers, and synthetic fibres known as high polymers because their molecules are the high-molecular-weight compounds made up of the repeated structural units that have combined chemically, or polymerized. In plastics the four major products are polyethylene, polyvinyl chloride, and polystyrene, all made from the simple structural unit, or monomer, ethylene, and polypropylene made from the monomer propylene. Major raw materials for synthetic rubbers include butadiene, ethylene, benzene, and propylene.

Among synthetic fibres, nylon still represents the largest tonnage; in it, the most important raw material is benzene. The second major synthetic fibre is represented by the polyesters, which are a combination of ethylene glycol (made from ethylene) and terephthalic acid (made from one of the xylenes). The third major synthetic fibre is represented by the acrylics, in which the major raw material is the propylene derivative acrylonitrile (see also FIBRES, MAN-MADE).

By-products. Petroleum chemicals have advanced from the original concept of by-product usage and represent a large investment of money and technology. An additional group of products, however, that represent a direct by-product of oil-refining operations, the naphthenic acids, can be abstracted for use in paint dryers and other derivatives. Naphthasulfonates recovered in sulfuric acid refining of oil products serve as emulsifying agents. Many cresylic acid products can be recovered as by-products.

Table 1: World Refining Capacities (1969)

country or area	barrels per calendar day (000)	percent share	percent average annual increase 1964–69
U.S.	11,960	25.6	3.8
Canada	1,210	2.6	3.5

REFINERY PLANT AND FACILITIES

Refining facilities. Integration of the separate processing plants in a modern refinery has resulted in economies of services, intermediate tankage, and manpower. The simplest refinery contains a distillation unit, catalytic reformer, and various treatment units. Small refineries of this type supply local markets in many parts of the world. With such units, it is possible to produce motor gasolines

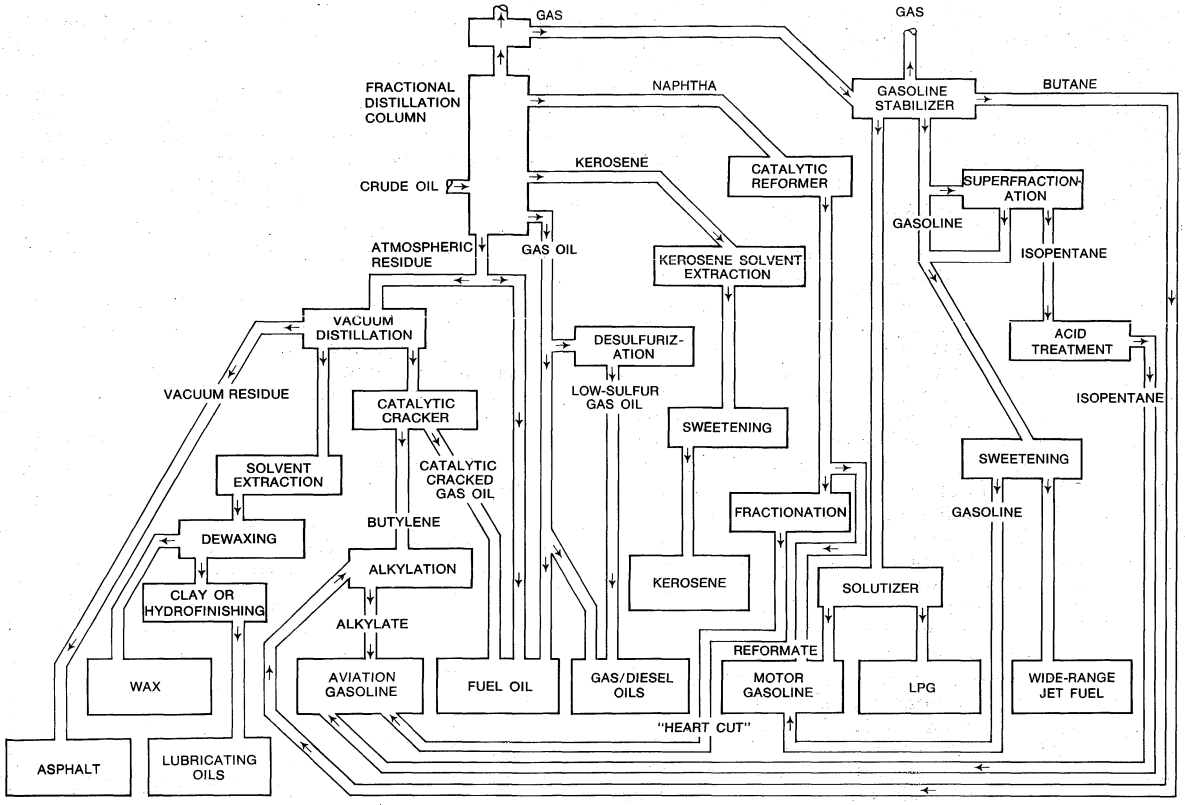

Figure 4: Generalized flow chart of the refinery process.

of different octane numbers, lamp kerosene, jet fuel, gas and diesel oil, and residual fuels. There may also be a plant for recovery of propane and butane.

In deciding which process to use, refinery managers analyze the market for residual fuel oil, which may amount to 40 or 50 percent of the crude oil processed. In some countries of the Eastern Hemisphere this fuel oil is easily marketed. But in the U.S. and Canada, where large quantities of gasoline are required, less fuel oil is used because natural gas is available within reach of consuming areas. Cracking plants, usually catalytic, together with vacuum-distillation units to produce fractions for use as feedstock, solve this problem. The production of gasolines can then be further augmented by polymerization or alkylation, superfractionation, and possibly by hydrocracking.

Effect of marketing research on processing

With further additions of plant it is possible to build a fully integrated, comprehensive refinery by stages, including solvent extraction (of kerosene), hydrodesulfurization, lubricating-oil plant (propane de-asphalting, solvent extraction, dewaxing, and clay treatment or hydrofining), and plant for the production of asphalt, wax, sulfur, and special products. The chart in Figure 4 shows how these plants are interrelated.

Tankage. The manufacturing units form only part of a refinery, though the most important one. A large proportion of the cost, and the area covered, is taken up by tankage, handling facilities, etc.

The storage capacity allocated to crude oil may be minimal if the refinery is connected to the oilfields by pipeline. When crude oil has to be imported, however, sufficient tankage is provided to enable continuous refinery operation while still allowing for the irregular arrival of tankers. Scheduling of tanker movements is important in integrated oil operations, particularly with the very large tankers (up to 250,000 tons and more) now in service.

Finished products require much more tankage in terms of storage capacity than crude oil. Provision is made for short-term variations in the sales of refinery products to avoid frequent alterations in the refinery process units. Nonvolatile products such as diesel oils and fuel oils are stored in large diameter cylindrical tanks with low-pitched conical roofs. Tanks with floating roofs are used to reduce evaporation losses in gasolines and other volatile products, including crude oils. The roof, which resembles a pontoon, moves up and down inside the tank, thus eliminating the air space that could contain a considerable proportion of petroleum vapour. Fire hazards are also reduced by the use of floating roof tanks.

For liquefied petroleum gases, pressure vessels (usually spherical) are used. Alternatively, these materials may be stored in suitable geological formations underground, such as cavities in salt domes. Large refrigerated tanks are a recent development. In these, the liquefied gas is stored at normal pressure but at reduced temperatures.

Bulk transportation. The supertankers have sharply cut the cost of transporting crude oil, making it practical to locate refineries near areas of consumption rather than adjacent to oilfields. Deepwater ports have been built to receive these large tankers, particularly in Europe, which obtains most of its supplies from the Middle East and Africa. Examples are Rotterdam, Gothenburg, Le Havre, Foss near Marseilles, and Milford Haven in the United Kingdom. Groups of refineries have been constructed near these ports or connected to them by pipeline.

If pipelines are not practical or economic, water transport is the first choice for petroleum products. Full-size tankers or smaller coastal vessels, with capacities of 15,000 barrels or less, distribute the different grades of oil to depots situated on the coastline.

Countries having networks of canals and navigable rivers afford many opportunities for using barges, a very cheap method of transportation. On the Mississippi, barges of over 5,000-tons (37,000-barrels) capacity are in use; the Rhine and the Seine are also suitable for large barges. Many canals, however, can only accommodate 200-ton barges (1,500 barrels). Each barge is divided into separate calibrated compartments so that more than one type of product can be carried on a voyage; pumps are fitted for the discharge of the cargo.

Transport by rail tank car is still widely used. The cars normally have capacities of up to 50 tons (390 barrels), but there is a trend to larger sizes.

The final stage of delivery to the majority of customers is by the familiar road tank trucks, whose carrying capacity is about 150 to 200 barrels.

Table 2: World Oil Consumption (1969)

country or area	barrels per day (000)	percent share	percent average annual increase 1964–69
U.S.	13,810	32	5.0
Canada	1,440	3	6.0

Pipelines and pumping stations. *Pipelines.* Development of crude-oil trunk lines began in the United States in the early years of the 20th century when refineries in the populous eastern area had insufficient supplies from convenient oilfields. Pipelines were used for the transportation of crude oil in the United States in the late 19th century, supplying refineries in the general areas of the known oilfields. After 1900 there was a rapid development of crude-oil trunk lines following the discoveries of oil in Texas, Kansas, and Oklahoma. These fields were used to supplement the declining production of the eastern oilfields. By 1940 more than 85 percent of the crude oil supplied to eastern refineries came from west of the Mississippi river. In 1970 there were more than 200,000 miles of pipeline in operation in North America, of which 70,000 miles are crude oil trunk lines and a similar amount smaller feeder lines in the oilfield areas. A major pipeline project was planned for the 1970s to bring crude oil from the newly discovered fields on the North Slope of Alaska. Europe also has several crude oil pipelines supplying inland refineries. In the Middle East, large pipelines have been built for transporting crude oil from the oilfields in Iraq and Saudi Arabia to deepwater export terminals in the eastern Mediterranean.

Crude oil and product pipelines

More and more large pipelines are coming into operation to pump batches of different products successively down the line, since it is possible to do this without intermingling them. The "Big Inch" line, completed in 1943 to transport crude oil from Texas and Louisiana to refineries in the eastern United States, was converted for carrying gas from Texas to New Jersey, a distance of 1,475 miles (2,375 kilometres). In 1964, it was replaced by the world's largest products line, which can transport 1,000,000 barrels per day of products from Houston, Texas, to New Jersey. In Europe, the first product line was the TRAPIL line from the lower Seine region to Paris, completed in 1953. This and other such lines on the Continent and in the United Kingdom enable inland refineries to dispose of products economically when the local market pattern does not match the proportions manufactured.

Centrifugal pumps are almost invariably used for mainline pumping, and with long lines the capacity can be increased by installing booster stations at intermediate points along the line. In recent years, many of these have been designed for unattended operation, the starting of pumps and the opening or closing of valves being carried out by automatic sequence control initiated by signals sent over telephone lines or by radio or by instruments responding to line pressure at the unattended pump station.

Service plant and facilities. Refineries today contain much equipment for servicing refinery operations. This includes the plant for steam generation and in some cases electric power, water treatment, effluent systems, and antipollution facilities. This equipment is essential for the operation of the industry within the community. One of the advantages of the self-contained refinery is its flexibility regarding surplus products; usually gas and heavy residue can be used for the generation of steam and power and for combustion in the oil-plant furnaces.

Table 3: Demand for Major Products (1969)
(000 barrels per day)

BIBLIOGRAPHY. The literature on petroleum refining is extensive; each of the publications listed gives further references for study. W.L. NELSON, *Petroleum Refinery Engineering*, 4th ed. (1958), an authoritative textbook on all aspects of the industry; R.J. HENGSTEBECK, *Petroleum Processing* (1959), a highly readable account; A.E. DUNSTAN *et al.* (eds.), *The Science of Petroleum*, 6 vol. (1938–53), an encyclopaedic work prepared by worldwide authorities; W.A. GRUSE and D.R. STEVENS, *Chemical Technology of Petroleum*, 3rd ed. (1960); INSTITUTE OF PETROLEUM, *Modern Petroleum Technology*, 3rd ed. (1962); THE BRITISH PETROLEUM COMPANY LTD., *Our Industry Petroleum*, 4th ed. (1970); and SHELL INTERNATIONAL PETROLEUM COMPANY LTD., *The Petroleum Handbook*, 5th ed. (1966). A valuable reference work is the *Refining Processes Handbook* (pub. at two-yearly intervals by the journal *Hydrocarbon Processing*), containing current technical details and flow diagrams of commercial processes available to the petroleum refiner.

Books treating specific aspects of petroleum refining include: C.S. ROBINSON and E.R. GILLILAND, *Elements of Fractional Distillation*, 4th ed. rev. (1950); and V.A. KALICHEVSKY and K.A. KOBE, *Petroleum Refining with Chemicals* (1956). K.A. KOBE and J.J. MCKETTA, JR. (eds.), *Advances in Petroleum Chemistry and Refining*, 10 vol. (1958–65), contains articles useful for more detailed insight into specific topics.

The utilization of petroleum products is treated in the following works: H. ABRAHAM, *Asphalts and Allied Substances*, 5th ed., 2 vol. (1945); L.C. DENNY, L.L. LUXON, and B.E. HALL, *The Handbook of Butane-Propane Gases*, 4th ed. (1962); W. FRANCIS, *Fuels and Fuel Technology* (1965); V.B. GUTHRIE (ed.), *Petroleum Products Handbook* (1960); and H.H. ZUIDEMA, *The Performance of Lubricating Oils* (1952). The manufacture and utilization of chemicals derived from petroleum is extensively discussed in R.F. GOLDSTEIN and A.L. WADDAMS, *The Petroleum Chemicals Industry*, 3rd ed. (1967). The transportation of petroleum is treated in the publication of the ORGANIZATION FOR ECONOMIC CO-OPERATION AND DEVELOPMENT, *Pipelines in the United States and Europe and their Legal and Regulatory Aspects* (1969).

Techniques in petroleum refining are advancing continuously; accounts of recent developments appear regularly in these technical journals: *Hydrocarbon Processing—Petroleum Refiner, Oil and Gas Journal, Industrial and Engineering Chemistry, Petroleum Engineer, Petroleum Press Service, The Petroleum Times,* and *World Petroleum Report.*

(J.E.C./A.L.W.)

Petronius Arbiter

The reputed author of the *Satyricon,* the first European novel, Petronius Arbiter was a close friend of the sybarit-

ic Roman emperor Nero. Described by the historian Tacitus as a complex man who, although possessing serious talents, devoted almost his entire life to the pursuit of pleasure, Petronius in the *Satyricon* presented a consummately hedonistic approach toward life that was common to his age.

The most complete and the most authentic account of Petronius' life appears in Tacitus' *Annals*, an account that may be supplemented, with caution, from other sources. It is probable that Petronius' correct name was Titus Petronius Niger. From his high position in Roman society, it may be assumed that he was wealthy; he belonged to a noble family and was therefore, by Roman standards, a man from whom solid achievements might have been expected. Tacitus' account, however, shows that he belonged to a class of pleasure-seekers attacked by the Stoic philosopher Seneca, men who "turned night into day"; where others won reputation by effort, Petronius did so by idleness. On the rare occasions, however, when he was appointed to official positions, he showed himself energetic and fully equal to public responsibilities. He is known to have served as governor of the Asian province of Bithynia and later in his career, probably in AD 62 or 63, to have held the high office of consul, or first magistrate of Rome.

Associate of Nero as "director of elegance"

After his term as consul, Petronius was received by Nero into his most intimate circle as his "director of elegance" (*arbiter elegantiae*), whose word on all matters of taste was law. It is from this title that the epithet "Arbiter" was attached to his name. Petronius' association with Nero fell within the Emperor's later years, when he had embarked on a career of reckless extravagance that shocked public opinion almost more than the actual crimes of which he was guilty. A chance remark by the biographer Plutarch suggests that Petronius in particular encouraged Nero's spendthrift schemes. That Nero, who may be discerned through the accounts of Tacitus and the historian Suetonius as a man with some artistic talent and independent pretensions to taste, should have chosen the stylish Petronius as his aesthetic adviser is some evidence of his discrimination. What Petronius thought of his patron may be indicated by his treatment of the rich vulgarian Trimalchio in the *Satyricon*. Trimalchio is a composite figure, but there are detailed correspondences between him and Nero that cannot, given the contemporary nature of the work, be accidental and that strongly suggest that Petronius was sneering at the Emperor.

Petronius' death

Tacitus records that Nero's friendship ultimately brought on Petronius the enmity of the commander of the Emperor's guard, Tigellinus, who in AD 66 denounced him as having been implicated in a conspiracy of the previous year to assassinate Nero and place a rival on the imperial throne. Petronius, though innocent, was arrested at Cumae in southern Italy; he did not wait for the inevitable sentence but made his own preparations for death. Slitting his veins and then bandaging them again in order to delay his death, he passed the remaining hours of his life conversing with his friends on trivial topics, listening to light music and poetry, rewarding or punishing his slaves, feasting, and finally sleeping "so that his death, though forced upon him, should seem natural." In a special codicil to his will, instead of the customary legacies to the Emperor and his favourites for the protection of the accused person's dependents, he composed a detailed catalog of Nero's sexual perversions, even going so far as to include a list of the Emperor's partners. When it was completed Petronius dispatched this scurrilous catalog, under his seal, to the Emperor, afterward destroying the seal he had used in order to ensure that it could not be used to incriminate others.

The *Satyricon*

The independence and the sometimes cynical opportunism of Petronius revealed in Tacitus' account are in keeping with the general character of the *Satyricon*. That Petronius did in fact write the book that is transmitted under his name is generally accepted by scholars, though the attribution rests mainly on circumstantial arguments. What insights it allows into the character and views of its author is another and a debatable question. The *Satyricon* is a comic, picaresque novel, related to several ancient literary genres. In style it ranges between the highly realistic and the self-consciously literary, and its form is episodic.

As with most works of creative literature, it is hazardous to attempt to identify any of the views expressed in it as those of the author, even when in his role of satirist he appears to address himself directly to the reader, especially since much of the work consists of fragments that have come down to us out of context. The verses in which the writer defends what he calls his "work of fresh candour" recall Tacitus' comment that Petronius' dissolute sayings and doings impressed his contemporaries "by their appearance of candour." Similarly the persistent hostility toward the more austere kinds of philosophy, which sometimes takes the form of parodies of Seneca or of commonplaces that he particularly favoured, reminds the reader of Tacitus' description of Petronius' "anti-philosophical" deathbed and of his rejection of disquisitions on the immortality of the soul in favour of light entertainment. The poem quoted above ends with an appeal to the authority of the philosopher Epicurus for pleasure to be the guiding principle of life; but in the *Satyricon* as a whole it is impossible to detect any consistent philosophical or moral position, Epicurean or other. Insofar as any moral attitude at all is perceptible, it is a trivial and debased brand of hedonism, which in this book is typical of the age and the culture from which the work sprang. The aim of the *Satyricon* was evidently above all to entertain by portraying certain aspects of contemporary society; modern readers who find the portrayal satirical in any deep and consistent sense are responding to the portrayal of corruption itself rather than to the author's views and intentions.

Considered as a portrait of society, the book is of immense value: superficial details of the speech, behaviour, appearance, and surroundings of the characters are exactly observed and vividly communicated. Of any real interest in human beings, comparable with that displayed by a great social satirist such as Charles Dickens, there is little or no sign. The wealth of specific allusions to persons and events of Nero's time shows that the work was aimed at a contemporary audience, and certain features suggest that the audience in fact consisted of Nero and his courtiers. The realistic descriptions of low life recall the Emperor's relish for slumming expeditions; and the combination of literary sophistication with polished obscenity is consistent with the wish to titillate the jaded palates of a debauched court.

If Petronius' book has a message, it is aesthetic rather than moral. The emphasis throughout the account of Trimalchio's dinner party, the longest and most elaborate episode in the work as it has survived, is on the contrast between taste and tastelessness. Stylistically, too, the *Satyricon* is what Tacitus' account of the author would lead one to expect. The language of the narrative and the educated speakers is pure, easy, and elegant, and the wit of the best comic passages is brilliant; but the general impression, even when allowance is made for the fragmentary state of the text, is that of a book written quickly and somewhat carelessly by a writer who would not take the necessary trouble to discipline his astonishing powers of invention. In his book, as in his life, Petronius achieved fame by indolence.

MAJOR WORKS

The *Satyricon* (1st century AD; *The Satyricon of Titus Petronius Arbiter*, "Loeb Series," 1913; "Penguin Classics Series," 1965), containing the episode of the "Cena Trimalchionis" (*Dinner at Trimalchio's*, 1925 and 1950) and the anecdote known as the *Widow of Ephesus*.

BIBLIOGRAPHY. The ancient sources for Petronius' life are TACITUS, *Annals xvi.* 18–19; PLINY THE ELDER, *Natural History* xxxvii. 20; and PLUTARCH, *Moralia* 60 d-e. On the identification with T. Petronius Niger, see K.F.C. ROSE, "The Author of the Satyricon," *Latomus*, 20:821–825; (1961); further discussion of the problems of identification and authorship, with bibliographies of the older literature, is in J.P. SULLIVAN, *The Satyricon of Petronius: A Literary Study* (1968); and P.G. WALSH, *The Roman Novel* (1970). There are biographical reconstructions by the Polish novelist,

H. SIENKIEWICZ in his *Quo Vadis* (1896), a highly idealized portrait; and by G. BAGNANI in his *Arbiter of Elegance: A Study of the Life and Works of C. Petronius* (1954), relying heavily on conjecture. The attempt of O. RAITH, in his *Petronius ein Epikureer* (1963), to demonstrate that Petronius was a professed Epicurean has met with general dissent.

(E.J.Ke.)

Pharmaceuticals, Production of

The World Health Organization (WHO) defines a drug or pharmaceutical preparation as

> any substance or mixture of substances manufactured, sold, offered for sale, or represented for use in . . . the diagnosis, treatment, mitigation, or prevention of disease, abnormal physical state or the symptoms thereof in man or animal; [and for use in] . . . restoring, correcting, or modifying organic functions in man or animal.

The same organization defines a pharmaceutical specialty as "a simple or compound drug ready for use, and placed on the market under a special name or in a characteristic form."

The modern pharmaceutical industry began in the 19th century with the discovery of highly active medicinal compounds that could most efficiently be manufactured on a large scale. As these compounds replaced herbal medicines of earlier times, the occurrence and severity of such diseases as pernicious anemia, rheumatic fever, typhoid fever, lobar pneumonia, poliomyelitis, syphilis, and tuberculosis were greatly reduced. Pharmaceutical industry research has greatly aided medical progress; of the 66 most valuable drugs introduced since aspirin in 1899, 57 were discovered and then produced in industrial laboratories.

History. The earliest records of medicinal plants and minerals are those of the ancient Chinese, Hindu, and Mediterranean civilizations. In 2735 BC, the Chinese emperor Shen Nung wrote an herbal in which he described the antifever capabilities of a substance known as Ch'ang Shang, since shown to contain antimalarial alkaloids. The school of alchemy that flourished in Alexandria in the 2nd century BC could prepare white lead (lead carbonate) from litharge, arsenic from realgar (arsenic disulfide), and mercury by roasting cinnabar (mercuric sulfide) in a current of air. It is recorded in *De materia medica*, a book of the 1st century BC, that verdigris (basic cupric acetate) and cupric sulfate were prescribed as medicinal agents. Remarkably, cupric sulfate is still used in medicine today.

Many crude drugs still used now, such as ipecacuanha root (ipecac), were known and employed by the ancients. The Egyptians treated constipation with senna pods and castor oil and employed caraway and peppermint to relieve indigestion. The Greek physician Galen (*c.* AD 130–*c.* 200) included hyoscyamus, opium, squill (a plant drug used as an expectorant, cardiac stimulant, and diuretic), and viper toxin among other drugs in his apothecary shop. He also insisted on purity in drugs; *i.e.*, the right variety and age of the botanical specimens.

Pharmaceutical practice improved markedly in the 16th and 17th centuries. In 1546 the first pharmacopoeia, or collected list of drugs and medicinal chemicals with directions for making preparations from them, appeared in Nuremberg (Nürnberg, West Germany). Previous to this time, medical preparations had varied in concentration and even in constituents. Other pharmacopoeias followed, in Basel (1561), Augsburg (1564), and London (1618). Despite its name, the *London Pharmacopoeia* was mandatory for the whole of England and thus was the first example of a national pharmacopoeia.

The first apothecaries

In 1617 the Society of Apothecaries, London, was founded, marking the emergence of pharmacy as a distinct profession. The separation of apothecaries from grocers was authorized by King James I; only a member of the society could keep an apothecary's shop and make or sell pharmaceutical preparations. In 1841 the Pharmaceutical Society of Great Britain, London, was founded, placing the education and training of the pharmacist upon a proper scientific basis. Today, pharmaceutical practice and education are carefully supervised throughout the world.

Known as "Hoffman's drops," ether was first employed as an anesthetic in 1842; chloroform followed soon afterward in 1847. Alkaloid compounds were also isolated from plant sources during this period. Narcotine was obtained from opium by a French pharmacist in 1803 and was followed by morphine in 1806, emetine and strychnine (around 1817), brucine and piperine (1819), colchicine and quinine (1820), nicotine (1828), atropine (1833), cocaine (1860), and physostigmine (1867). Isolation of these potent compounds was a milestone in pharmaceutical progress for three reasons. First, accurate doses could now be administered; this had been impossible previously with crude drugs of unknown and variable composition. Second, toxic effects due to impurities in crude drugs could now be eliminated if pure compounds were used; and third, knowledge of the chemical structure of these drugs led to attempts at laboratory synthesis, which led in turn to discovery of valuable related compounds.

Joseph Lister, in England, opened the modern era of antiseptic surgery in 1865 when he used phenol (carbolic acid) to prevent infections. In 1869 the soporific properties of chloral hydrate, the first synthetic hypnotic (sleep-producing drug), were discovered. In 1874 it was found that organic nitrites relax the blood vessels, and, in 1875, salts of salicylic acid were introduced as remedies for fever. The year 1879 witnessed the introduction of saccharin, still in use today as a sweetening agent for diabetic patients. The simple compound acetanilide, introduced in 1886, was one of the first analgesic–antipyretic drugs (*i.e.*, reducing both pain and fever) to be used but was later replaced by the less toxic phenacetin in 1887, by aspirin in 1899, and all of these to some extent by paracetamol in 1956. The hypnotic sulfonal (sulfonmethane) was discovered about 1888, followed a few years later by barbital; this latter led to a whole series of barbiturates of which phenobarbital is the best known.

Cocaine was the only known potent local anesthetic until about 1900, when the much simpler compound benzocaine was introduced. The closely related local anesthetic procaine followed early in the 20th century.

In 1909 arsphenamine, highly effective against syphilis, was introduced. Since arsphenamine is both insoluble in water and unstable, further work led to neoarsphenamine in 1912, a soluble derivative. Many other synthetic drugs followed, among which was the hormone progesterone, synthesized in 1934. Some thousands of similar compounds have since been prepared, some of which are used as oral contraceptives.

The sulfa drugs and antibiotics

In 1935 it was discovered that sulfanilamide (Prontosil) stopped the growth of bacteria. Over 6,000 derivatives of sulfanilamide—the sulfonamides, or sulfa drugs—were prepared and tested for their antibacterial properties. Today, the sulfonamides have partially been superseded by antibiotics, of which the first was penicillin, first isolated in 1941. In 1959, 6-aminopenicillanic acid was isolated for the first time; this led to production of many semisynthetic penicillins such as ampicillin, carbenicillin, cloxacillin, methicillin, oxacillin, and phenethicillin. Also used as antibiotics are compounds known as cephalosporins, the first of which was isolated in 1961.

Classification of pharmaceutical products. Drugs may be classified in one of three ways: by chemical group (*e.g.*, alkaloids, mentioned above); pharmacologically (*i.e.*, by the way they work in the body); and according to their therapeutic uses. Pharmacological and therapeutic classifications show considerable divergence, as drugs that act upon the body in different ways may bring about the same desired therapeutic result. Furthermore, classification by therapeutic usage is complicated by the fact that a drug may be used to combat more than one ailment. The antimalarial compound primaquine, for example, may also be employed to relieve arthritis. Some familiar drugs classified by therapeutic use include aspirin, an analgesic, or pain-killer; benzocaine, a local anesthetic; magnesium carbonate, an antacid; charcoal, an antiflatulent (preventing production of flatulent gases); penicillin, used against syphilis; calcium lactate, a calcium supplement; hexachlorophene, a deodorant; phenol-

phthalein, a laxative; levulose, a nutrient; cascara sagrada, a purgative; phenobarbital, a sedative; and thiamine hydrochloride, a vitamin. See also articles on major groups of drugs, such as ANESTHETIC; ANTISEPTIC AND GERMICIDE; CHEMOTHERAPEUTIC DRUGS; HORMONE; TRANQUILLIZER; and VITAMIN.

PRODUCTION OF PHARMACEUTICALS

Raw materials and their purity. Pharmaceutical raw materials may be plant, animal, or other biologic products; inorganic elements and compounds; or organic compounds. If the raw material is "official"—that is, if it is the subject of a monograph in a pharmacopoeia or national formulary—then the minimum acceptable degree of chemical purity is specified. Very often, however, because some raw materials at specified levels may begin to decompose after a time, purification far exceeds these minimum requirements. If extra purification is inconvenient, a preservative may be added. If the raw material is not the subject of an official monograph, then physical or chemical specifications or both are drawn up by the manufacturer in accordance with the pharmaceutical requirements of the finished product, on lines similar to the official monographs.

Crude drugs. The term crude drug is usually applied to plant or animal organs or whole organisms or exudations of these, either in the fresh state or dried and either ground or unground. Some crude drugs such as acacia, belladonna, and starch are official; for these, rigid specifications are available. Plant-derived crude drugs may come from cultivated sources or may be collected in the wild. Cultivation and collection are carefully planned to obtain drugs with the highest possible therapeutic activity or content of active constituents. The harvested drug plant must then be cleaned to remove matter such as sand and dirt. Next, unwanted plants or plant parts are carefully removed. Some crude drugs, such as belladonna, undergo curing, a process that consists either of slow drying or sweating, during which enzymes bring about chemical changes whereby the content of active ingredient is increased. Alternatively, as with cascara sagrada, the drug is carefully stored for a year, during which time unwanted constituents slowly decompose. The final stage in crude-drug production consists of drying, accomplished in air or with artificial heat. Drying aids preservation, stops various chemical reactions that might weaken or destroy the substance, facilitates subsequent grinding, and reduces weight and bulk. Drugs containing volatile constituents are dried at temperatures near freezing. After drying, some drugs (such as belladonna and ipecac) are reduced to a fine powder.

Drying the drug

Inorganic elements and compounds. Production methods for inorganic elements and compounds are not always the same as those for industrial chemicals, since purification is usually carried to a much higher level. Industrial zinc oxide, for example, may contain as much as 10 percent of impurities, including small quantities of lead. The pharmaceutical substance, by contrast, must contain at least 99 percent zinc oxide and no lead. For this reason, industrial zinc oxide is manufactured by combustion of zinc in air, whereas pharmacopoeial zinc oxide is produced from zinc sulfate.

Organic compounds. Organic compounds used as pharmaceuticals are either extracted from natural sources or prepared by chemical synthesis (various methods are described below). Physical specifications used in purity control of inorganic and organic pharmaceuticals include particle size, colour, odour, solubility, homogeneity, and freedom from particulate impurities. Some common chemical specifications are melting point, boiling point, density, viscosity, and freedom from impurities.

Preparation from natural sources. *The alkaloids.* As mentioned above, the first pure pharmaceuticals isolated from natural sources were the alkaloids. Though the methods adopted for their extraction from plants vary in detail, all are based on three general characteristics of these compounds. First, most alkaloids are only slightly soluble in water but readily soluble in certain organic solvents such as benzene, chloroform, ether, and light petroleum. Second, alkaloids combine with acids to form salts that are usually freely soluble in water but only slightly so in organic solvents. Third, alkaloids are liberated from their salts by alkalies.

Application of these general principles can be seen in the following generalized outline of extraction methods. The crude drug, ground to a suitable state of subdivision, is mixed with water, a water-soluble alkali such as lime, and some organic solvent that does not mix with water. The mixture separates into two layers: one contains water, lime, and impurities and is discarded; the other contains the alkaloid dissolved in the organic solvent. Fresh water and dilute acid are now added to the mixture. Again there are two layers, but the acid has caused the alkaloids to pass from the organic layer into the aqueous layer. The aqueous layer is now separated, and the alkaloidal salt or salts may be crystallized out by cooling or concentrating the solution. The process described above is used to obtain quinine sulfate from cinchona bark.

Extraction of alkaloids

Glycosides. Glycosides such as digoxin are another important group of drugs obtained from plants. Generally, the glycoside is extracted from the crude drug with alcohol. Adding basic lead acetate to the alcoholic extract causes the impurities to fall to the bottom. After being poured through a filter, the alcoholic extract is concentrated, and the glycosides may crystallize out. Often, however, concentration of the extract is not sufficient to cause crystallization, and more complicated procedures must be employed.

Volatile, or essential, oils. Volatile, or essential, oils, also obtained from plants, may be extracted by distillation, steam distillation, expression, or by extraction with fats or organic solvents. In steam distillation, the most common method, the crude drug—either fresh or dried—is used in powder form. Water is mixed with the powder, serving the double purpose of preventing decomposition of plant material by excessive heat and of facilitating volatilization of the essential oil. The powder–water mixture is usually placed in a basket through which the steam penetrates. The distillate consists of a water–oil mixture; the oil forms a separate layer, which is run off. Anise, cinnamon, clove, coriander, fennel, and peppermint oils are all obtained by this method, as is the pharmaceutical substance camphor from camphor wood.

Fixed or fatty oils cannot be obtained by distillation, but only by expression or extraction. Castor, olive, and sesame oil, for example, are all obtained by expression. Cod-liver and halibut-liver oils, rich sources of vitamins A and D, are both extracted by passing steam into tanks containing the livers suspended in water, until the temperature reaches 70–80° C (158°–176° F). The tissues disintegrate, and the oils float to the surface and are skimmed or centrifuged off.

Obtaining cod-liver oil

Insulin. Other drugs of animal origin primarily include glandular extracts containing hormones, such as thyroid and parathyroid, and purified hormones, such as insulin, obtained from the pancreas of a pig, sheep, or ox. For insulin production, the pancreas must either be absolutely fresh or frozen immediately after removal from the animal. Otherwise, enzymes will cause decomposition of the insulin. The glands are minced and immediately stirred with cold acidified alcohol, which both extracts the insulin and prevents its destruction by the enzyme trypsin. The gland residue is separated by centrifugation and further extracted with more acidified alcohol. The final alcoholic extract is passed through filter presses to remove the remaining fine particles of meat. The extract is now made sufficiently basic to cause precipitation of the inert proteins and allow their removal. Next, the extract is acidified again, and the alcohol is removed as quickly and with as little heat as possible. When the concentrated extract is cooled, fat separates and is filtered off. The crude insulin is then precipitated by adding common salt and is purified by repeated crystallization. For medical practice, insulin is almost always made up in the form of a solution for injection.

Antibiotics. Antibiotics are an extremely important group of drugs isolated from natural sources. Penicillin

was originally produced by growing the *Penicillium notatum* mold in small containers; the mycelium, or vegetative portion, formed a mat on the surface of the medium that contained the penicillin in solution. The process was difficult to operate and required a large labour force to inoculate and harvest the containers.

Deep culture of penicillin

Penicillin production was revolutionized by the discovery that a strain of *Penicillium chrysogenum* mold (isolated from an overripe cantaloupe) would produce high yields when grown in deep culture. The growth of a mold is aerobic (it requires air), and in surface culture the growth and consequent production of antibiotic is limited by the rate at which air can diffuse into the medium. In submerged or deep culture, the mold is grown in large tanks supplied with a continuous flow of sterile air.

Though the medium used in fermentation varies for the particular antibiotic being produced, all contain a source of carbon (which may be lactose or glucose); nitrogen (in the form of ammonium salts); and trace elements (such as phosphorus, sulfur, magnesium, iron, zinc, and copper). If phenylacetic acid is added, the mold will utilize it and produce benzylpenicillin (penicillin G), whereas, if phenoxyacetic acid is added, phenoxymethylpenicillin (penicillin V) is obtained. In addition, corn-steep liquor may be added for penicillin production, and soybean meal and dried distiller's residues for streptomycin; these help increase the yield of product. (Corn-steep liquor is prepared by steeping cleaned corn grain in water for about 40 hours at about 48° C [118° F]; the liquor is drawn off and evaporated at reduced pressure to a suitable concentration—about 55 percent solids. Corn-steep liquor stimulates penicillin formation due to certain amino acids, minerals, and precursors that it contains.) Before use the medium—as well as the fermenter and associated equipment—is steam sterilized, as bacterial contamination can destroy the antibiotic.

A large volume of concentrated, actively growing fungal suspension is required for the main fermenting tanks, to keep the fermentation time to a minimum. This is obtained in three stages. First, the selected culture is transferred from cold storage to a culture medium (agar) to produce an initial inoculum. This inoculum is then cultured in shake flasks to give a suspension. Finally, the suspension is grown in seed tanks in the plant for 24–28 hours to the desired volume and concentration before transfer to the main fermenters. Fermentation is continued for three to five days, during which the vessel is cooled—to keep the temperature between 23–27° C (73–81° F)—and stirred and aerated with sterilized air. The introduction of large volumes of air causes frothing, which is controlled by the addition of antifoams such as lard oil, octadecanol, or silicones. When fermentation is complete, the mycelium is removed on a rotary filter and the penicillin extracted into an organic solvent (such as butyl acetate or methyl isobutyl ketone), after acidification. The free acids of penicillins are generally unstable and are converted into a metal salt by extraction with alkali, followed by freeze-drying of the extract, or by addition of a concentrated solution of a metal salt such as potassium acetate, whereby the potassium salt of the penicillin is precipitated. All products that are to be administered by injection are sterilized by passage through a sterilizing filter, followed by freeze-drying, precipitation, or crystallization under sterile conditions.

Vaccines. Vaccines, viral or bacterial preparations used to induce active immunity, may be divided into three groups: toxoids, bacterial vaccines, and virus vaccines. Toxoids, such as diphtheria and tetanus toxoid, can only be prepared from toxin-producing bacteria. To produce diphtheria toxoid, for example, diphtheria bacilli are cultured under artificial conditions in a suitable broth to produce a fluid rich in toxin. The bacilli are then filtered off, and formaldehyde is added to the crude toxin filtrate, which is incubated for two to three weeks, with the result that the substance is no longer toxic and is called a toxoid. The toxoid is then purified by precipitation with ammonium sulfate and is filtered off. If alum or some other aluminum compound is used to precipitate the toxoid, the product is relatively insoluble and thus more slowly absorbed, thereby possessing increased antigenic (causing the production of antibodies) properties.

Preparation of bacterial vaccines

The first step in the preparation of bacterial vaccines, such as typhoid vaccine, is similar in that an artificial culture of the organism is first prepared. In this case, however, a solid medium is usually used, such as nutrient agar. If a mixed bacterial vaccine is being made, the individual species of organisms are cultured separately and later mixed. The culture is incubated at a suitable temperature for at least 24 hours until sufficient growth has taken place. The bacteria are then collected under aseptic conditions (free from pathogens) by pouring sterile salt solution on the culture and gently shaking or scraping until the micro-organisms have been suspended. If a liquid medium has been used for culture, it is centrifuged, and the bacterial sediment suspended in sterile isotonic saline. In either case, the crude product is shaken to produce a uniform suspension, and the bacterial concentration determined. The suspension is diluted with sterile isotonic saline, and the bacteria killed by a germicide or by heat; finally, a preservative is added.

In the preparation of virus vaccines, such as yellow-fever vaccine, the general principle is similar, with the important exception that most virus vaccines are weakened living virus preparations. The living virus is inoculated into the embryo region of hens' eggs that have been incubated for eight days. After a further six days' incubation, the embryo is removed, homogenized, and the vaccine separated. As these vaccines are unstable, they are freeze-dried and reconstituted at the time of inoculation. Poliomyelitis vaccine is usually prepared from viruses inactivated with formaldehyde. Some virus vaccines, such as measles and rubella, can now be prepared using human cells as the culture medium.

Human blood-plasma fractions. A number of proteins of therapeutic value can be concentrated from human plasma (see BLOOD, HUMAN); these include albumin, immunoglobulins or gamma-globulins that contain antibodies to various viruses, and blood coagulants.

Careful addition of ethanol to protein solutions at temperatures in the range −8° to 0° C (18° to 32° F) causes precipitation without gross damage to molecular structure. The various proteins in plasma have their minimum solubilities at differing acid or base (pH) values and salt concentrations and can be separated from each other by a series of precipitations in which these factors are controlled. Ethanol concentrations, protein concentrations, and temperatures must also be adjusted to precise values. Because protein molecules are unstable, excessive frothing or agitation, local high ethanol concentrations, or local temperature rise (due to the heat of mixing of ethanol and water) must be avoided. Precipitates are separated in refrigerated centrifuges, and the final products are freeze-dried, which removes residual ethanol and makes them more stable for storage and distribution. Albumin and immunoglobulins are sufficiently stable to be redissolved and dispensed in solution.

Difficulties in processing human blood fractions

Processing is complicated for several reasons: proteins, being unstable in heat, can be sterilized only by filtration; large volumes of some products may be given intravenously, thus precluding the use of preservatives; blood coagulant substances are extremely unstable in plasma even at refrigerator temperatures, necessitating their preparation within a few hours after collection of the blood from the donors; and certain diseases, of which blood donors may be carriers, notably serum hepatitis, can be transmitted in the fractions. Albumin is, however, stable enough to withstand heating for ten hours at 60° C or 140° F (which inactivates the hepatitis virus), and heated albumin preparations are now largely replacing whole plasma in transfusion therapy. It has been found that immunoglobulin fractions do not transmit this virus. Control of products includes tests for the presence of micro-organisms, pyrogens, and toxic substances; for pH and salt content; for protein composition; and, where appropriate, for heat stability, antibody activity, or coagulation function.

Steroid hormones. Another important group of pharmaceuticals widely distributed in plants and animals is

the steroid hormones (see also STEROIDS; HORMONE). The plant by-product called diosgenin is by far the most common starting material for the preparation of steroids. It is obtained from whole tubers of wild yams; these are broken up in a hammer mill, and the resultant mash is allowed to ferment for two days. It is then dried in the sun, hydrolyzed with mineral acid, and the diosgenin extracted with an immiscible organic solvent (one that will not mix with water), such as light petroleum or heptane.

The hormone estrone is usually manufactured from pregnant mares' urine, in which it is present almost entirely as the ethereal sulfate. This is hydrolyzed to estrone by acidification of the urine and heating, after previously covering with a layer of immiscible solvent, such as toluene. Estrogens are extracted from the solvent, and the estrone is separated from the other estrogens.

Progesterone was formerly obtained from the ovaries of sows or whales. It is now usually manufactured synthetically by a complex series of chemical reactions from various materials such as stigmasterol (obtained from soybeans) or diosgenin. Testosterone is also manufactured from diosgenin.

Further medicinal steroids, such as ethisterone, methandienone, and methyltestosterone, are obtained from an intermediate of testosterone production.

Sources of cortisone

Cortisone is manufactured from ergosterol, from progesterone (itself obtainable from stigmasterol or from diosgenin), and from other plant by-products, by routes involving both chemical and microbiological transformations. Hydrocortisone, in turn, is produced from cortisone. Deoxycorticosterone is made as the acetate from progesterone.

Vitamins. These were formerly extracted from natural sources, but now the majority are made by synthetic methods. Not only are the synthetic vitamins cheaper and purer, but their production is easier than extraction of natural vitamins.

Preparation by chemical synthesis. Two or more of the methods discussed below are usually involved in the manufacture of any one drug. There are many different possible routes for the production of pharmaceuticals. It is not often that the simplest possible theoretical pathway is the initial choice of the manufacturer; many different methods are chosen by manufacturers depending upon the starting materials and equipment available to them.

Acetylation. This is a special case of acylation, a process in which alcohols, phenols, and primary and secondary amines yield acyl derivatives by displacement of the hydrogen atom of the hydroxy, primary amino, or secondary amino group by an acyl radical. The commonest acyl radical by far is the acetyl radical, CH_3CO-. The usual acetylating agent is acetic anhydride, $(CH_3CO)_2O$, but glacial acetic acid, CH_3COOH, and acetyl chloride, CH_3COCl, are also used. With acetic acid and alcohols or phenols, it is usual to use a dehydrating agent, such as concentrated sulfuric acid or anhydrous sodium acetate, in order to eliminate the water formed in the reaction. With acetyl chloride, a base such as dimethylaniline or pyridine is added to remove hydrogen chloride as it is formed.

Acetylation is often used in drug production since it reduces the toxicity of amines. Thus the drug paracetamol is much less toxic than *p*-aminophenol. Paracetamol is manufactured from *p*-nitrophenol.

Addition. This chemical reaction can only take place with unsaturated compounds, but the addition products vary greatly in nature. The mode of addition, where there are two possibilities, is determined by the structure of the unsaturated compound and the mechanism of addition. (For detailed explanation of this reaction, see CHEMICAL REACTIONS.)

The anesthetic drug halothane is manufactured from trichloroethylene (see below *Dehydrohalogenation*) by an addition reaction with hydrogen chloride. The product is treated with hydrogen fluoride; reaction with bromine then gives halothane.

The manufacture of the anesthetic drug trichloroethylene involves, as a first step, the addition of chlorine to acetylene, followed by dehydrohalogenation.

Alkylation and arylation. Alkylation is a general term for the introduction of an alkyl group into a compound and is more specifically known as methylation, ethylation, propylation, butylation, etc., depending upon the alkyl group inserted. Alkylation of an alcohol or a phenol results in an ether, while alkylation of a thiol gives a sulfide; primary and secondary amines can also be alkylated. The usual alkylating agents are alkyl sulfates and halides. The alcohol, phenol, thiol, or amine is dissolved in sodium hydroxide solution, and dimethyl sulfate, for example, is added to yield the alkylate.

In addition to the above types of compounds, any compound containing "active hydrogen" can be alkylated. Thus, compounds containing a methylene ($-CH_2-$) or a methyne ($=CH-$) group adjacent to a group such as carbonyl ($-CO-$) contain active hydrogen.

The important drug codeine, widely used as a cough suppressant and pain-killer, occurs naturally as an alkaloid in opium, together with morphine. Demand for codeine is such that much of it is manufactured by methylation of morphine. Morphine is dissolved in potassium hydroxide solution, and the solution is treated with methyl iodide to produce codeine.

The well-known constituent of tea and coffee, caffeine, used as a stimulant drug, is produced either from tea wastes or synthetically from the organic chemicals theophylline or theobromine. These three materials are closely related, and methylation of either theophylline or theobromine or a mixture of the two results in the fully methylated caffeine.

Synthesis of barbiturates

The barbiturates, widely used as sedative–hypnotic drugs, provide many examples of alkylation and arylation (introduction of one or more aromatic radicals, such as phenyl or naphthyl, to a molecule). The general method for their synthesis is as follows. Diethyl malonate (a malonic-acid ester, which contains an active methylene group) is treated with an alcoholic solution of sodium ethoxide, and the monosodium derivative produced is converted by reaction with an alkyl halide into an alkylmalonic ester. This is either used as such in the preparation of the barbiturate, or, as is usually required, a second alkyl group, either the same or different, is introduced in the same way. The alkylmalonic or dialkylmalonic ester is then condensed (see below *Condensation and cyclization*) with urea, in the presence of sodium ethoxide, to form the sodium salt of barbituric acid. This is either used as such, since sodium barbiturates are usually very soluble in water, or the free barbituric acid is liberated by acidification. Barbiturates containing aromatic groups (phenobarbital and mephobarbital are the only common examples) must be made by a modified route, because of the relative lack of reactivity of aryl halides. For both these drugs, ethyl phenylacetate is condensed with ethyl oxalate to form ethyl oxalophenylacetate, which, when distilled, decomposes to give diethyl phenylmalonate. Ethylation is then effected to yield diethyl ethylphenylmalonate. For the manufacture of phenobarbital, this ester is condensed with urea as in the scheme above.

Amination. Two important methods of amination (the process of adding an amino ($-NH_2$) group to a compound) are reduction and ammonolysis. There are many reduction methods, but the most common is the reduction of the corresponding nitro compound by means of iron and acid. An example of ammonolysis is the preparation of aniline by heating chlorobenzene with excess aqueous ammonia, in the presence of cuprous oxide, at about 200° C (392° F) under pressure. Amination enters into the synthesis of many pharmaceuticals; a good example is amphetamine. Phenylacetone is treated with ammonia and hydrogen in the presence of a nickel catalyst, and reductive amination takes place, forming amphetamine.

Arsonation. Arsonation applied to aromatic compounds is closely analogous to nitration (see below). For example, *p*-aminophenylarsonic acid (arsanilic acid) is made by heating aniline with concentrated arsenic acid. A method other than arsonation that achieves the same result is Bart's reaction, in which a diazonium salt is coupled with an alkali arsenite, usually in the presence

of a catalyst such as copper powder. Sodium phenylarsonate, for example, can be made from benzenediazonium chloride by Bart's reaction. The drug acetarsol is manufactured from phenol by arsonation followed by nitration, reduction, and acetylation.

Carboxylation. This reaction is best exemplified by the manufacture of salicylic acid, used in external preparations as a skin softener. Dry sodium phenoxide is heated with carbon dioxide, under pressure, at about 130° C (266° F); the resulting sodium salicylate is dissolved in water, and the acid precipitated by acidification with hydrochloric acid. Salicylic acid is used in medicine as the free acid, as its acetyl derivative, aspirin (see below *Esterification*), and as its salts, of which the most important is sodium salicylate, used in the treatment of rheumatism. To obtain the latter product, a weighed amount of salicylic acid is made into a paste with water, and the equivalent quantity of pure sodium bicarbonate is added. The mixture is stirred and warmed until a clear solution is obtained, and this is evaporated to dryness; the sodium salicylate is purified by crystallization from alcohol.

Condensation and cyclization. Condensation is difficult to define, but it involves the linking together of two or more organic molecules (identical or different), with or without the elimination of a simple molecule such as water, ethanol, or a hydrogen halide. Reactions involving condensations that can be defined more precisely, such as esterification, etherification, or polymerization, are usually not described as condensations.

Hexylresorcinol, used for destroying intestinal worms, provides a simple example of a condensation. It is produced by condensing resorcinol with hexanoic acid, in the presence of anhydrous zinc chloride, at about 130° C (266° F). Water is eliminated, and the resulting ketone is reduced by means of zinc amalgam and dilute hydrochloric acid. The sedative meprobamate involves two condensations in its production. Diethyl methyl-*n*-propylmalonate is reduced with lithium aluminum hydride, $LiAlH_4$, to the corresponding dihydric primary alcohol; this is condensed with carbonyl chloride, $COCl_2$, with elimination of hydrogen chloride to give a dichloroformate; condensation of this with ammonia, again with elimination of hydrogen chloride, gives meprobamate. Cyclization is a special case of condensation; internal condensation takes place in one molecule, with resulting formation of a cyclic molecule. The compound *o*-iminodibenzyl, from which the antidepressant drugs desipramine and imipramine are produced, illustrates cyclization. The iminodibenzyl is condensed, in the presence of sodamide, $NaNH_2$, with 1-chloro-3-methylaminopropane to give desipramine or with 1-chloro-3-dimethylaminopropane to give imipramine.

Production of meprobamate

Dehydration. This reaction, as the name indicates, involves the loss of the elements of water. If this takes place internally in a molecule, the result is usually an alkene or a cyclic compound. If dehydration takes place between two molecules (condensation), the product is usually an ether.

Diethyl ether (ordinary ether), used as an anesthetic, is produced by indirect condensation of ethanol. A mixture of concentrated sulfuric acid and ethanol is heated to 140° C (284° F), when ether distills over; more ethanol is run into the mixture at the same rate as the ether distills. The ethanol esterifies with the sulfuric acid to form ethyl hydrogen sulfate. This ester, on heating with ethanol at 140° C, gives ether and sulfuric acid back again.

Vinyl ether is also used as an anesthetic and provides a more complex example of dehydration. Ethylene chlorohydrin with sulfuric acid gives 2,2′-dichlorodiethyl ether, and this is dehydrohalogenated (see below) by means of solid potassium hydroxide to produce divinyl ether.

Dehydrohalogenation. This process may be defined as removal of the elements of hydrogen halides with the resultant formation of an unsaturated bond. It is usually effected by means of a base such as calcium oxide or hydroxide. Examples of its application are the production of the anesthetic trichloroethylene and the drug tetrachloroethylene (used for destroying intestinal worms), both involving the elimination of the elements of hydrogen chloride. Acetylene, readily available and comparatively cheap, is used as the starting material. The reaction with chlorine is dangerously explosive under ordinary conditions, but the reaction can be controlled to give acetylene tetrachloride. This readily yields trichloroethylene. In turn, trichloroethylene takes up one molecule of chlorine to form pentachloroethane, and this, treated in the same way as acetylene tetrachloride, produces tetrachloroethylene.

Esterification. The addition of an acid to an alcohol generally results in esterification; that is, the production of an ester plus water. The reaction is reversible, and the rate of the reverse reaction (see below *Hydrolysis*) will increase as the concentration of water (or ester) increases. Hence, both the anhydrous acid and the anhydrous alcohol are normally used in order to produce good yields. A catalyst such as dry hydrogen chloride speeds up the attainment of equilibrium (but will not affect the point of equilibrium). Concentrated sulfuric acid may be used, but it affects the point of equilibrium since it is a dehydrating agent as well as a catalyst; it may also dehydrate the alcohol and so must not be used in too high a concentration.

Many other catalysts are employed in esterification (or hydrolytic) processes. The acid chloride or anhydride is often used instead of the acid. A simple example is the production of ethyl chloride (an anesthetic) by passing dry hydrogen chloride gas into dehydrated ethanol containing anhydrous zinc chloride.

Acetylsalicylic acid (2-acetoxybenzoic acid, or aspirin) is the most widely used of all synthetic drugs. It is usually manufactured by the action of acetic anhydride on salicylic acid. As aspirin is only slightly soluble in water, it is easily separated by dilution of the reaction mixture with water. It is readily crystallized from aqueous alcohol, benzene, or light petroleum or from mixtures of these or other solvents with glacial acetic acid (to minimize hydrolysis).

Production of acetylsalicylic acid

Halogenation. This may involve reactions of addition, substitution, or replacement of a group of atoms. The catalysts used include halogen carriers such as iron, antimony, or phosphorus, all of which exert two valences as halides. They alternately add on and give up halogen to carry on the reaction. Since the halogens form unstable interhalogen compounds, chlorine, bromine, and iodine can also be used as catalysts. Under suitable conditions, substitution of alkenes with halogens takes place, and not addition. The synthetic oral estrogen, chlorotrianisene, for example, is produced from deoxyanisoin by reaction with 4-methoxyphenyl magnesium bromide, followed by subsequent dehydration and substitutive chlorination with a solution of chlorine in carbon tetrachloride. Gamma benzene hexachloride (gammexane), a delousing agent, is manufactured by the addition (not substitution) of chlorine to benzene. The product is a mixture of four of the nine possible stereoisomers, and the gamma isomer, which is the most active as an insecticide, is separated from the others.

Hydrolysis. This term is applied to reactions wherein water effects a double decomposition with another compound, hydrogen going to one component and hydroxyl to the other:

$$XY + H_2O = HY + XOH$$

The reversal of esterification is an example of hydrolysis. Catalysts that speed up esterification also accelerate hydrolysis; many enzymes will also catalyze hydrolytic reactions.

A pharmaceutical example is the production of propylene glycol. Propene is oxidized and converted by acid-catalyzed hydrolysis to propylene glycol. The pharmaceutical substance called wool alcohol is made by hydrolysis of wool grease.

Inorganic substances. Helium, nitrogen, oxygen, sulfur, and some inorganic compounds still find a place in medical practice. These are prepared by the general methods used in inorganic chemistry; however, they must comply with pharmacopoeial standards of purity, where-

as those used for nonmedical purposes are not usually purified up to these standards.

An example is the manufacture of ferric ammonium citrate, used in iron-deficiency anemias. The first step is preparation of freshly precipitated ferric hydroxide by slow addition, with constant stirring, of a ferric-salt solution (*e.g.*, ferric sulfate) to an alkali solution such as sodium hydroxide:

$$6NaOH + Fe_2(SO_4)_3 = 3Na_2SO_4 + 2Fe(OH)_3.$$

The ferric hydroxide is collected and washed and, without being dried, is stirred with enough citric acid solution to dissolve almost all of it. A slight excess of ammonia solution is then added, and the residual ferric hydroxide filtered off. The clear, reddish-brown filtrate is evaporated to a syrup, a little ammonia being added occasionally to maintain a slight excess. The syrup is painted on glass plates, dried at a temperature below 40° C (104° F), and scraped off as scales. Ferric ammonium citrate is also produced in the form of granules. The medicinal substance is dark red in colour and contains about 21 percent iron. Green ferric ammonium citrate is also made; it contains about 16 percent iron.

Mercuration. This is usually effected by reaction with a solution of mercuric acetate in acetic acid or alcohol; substitution of a hydrogen atom by the acetoxymercuri group, $-HgOCOCH_3$, results. The topical antiseptic acetomeroctol, for example, is prepared by interaction of a complex organic chemical compound with the calculated quantity of mercuric acetate in a 50 percent aqueous ethanolic solution containing 5 percent acetic acid. The mixture is maintained at room temperature for one to two weeks.

Nitration. Medicinal nitro compounds are invariably aromatic carbocyclic or heterocyclic derivatives. These are usually nitrated with a mixture of concentrated sulfuric acid and concentrated or fuming nitric acid (mixed acid). Other nitrating agents include oxides of nitrogen and acetyl nitrate, $CH_3CO_2NO_2$.

Nitrofurantoin is prescribed as a urinary antiseptic and provides an example of nitration. Furfural is reacted with acetyl nitrate, and the resulting triacetate is treated with pyridine to give 5-nitro-2-furaldehyde diacetate. This is condensed (with elimination of acetic acid) with 1-aminohydantoin to yield nitrofurantoin.

Oxidation. This reaction is very widely used in the preparation of chemical compounds. Oxidation may be defined as the loss of electrons or hydrogen or the gain of oxygen; reduction (see below) has the opposite meanings. There are many oxidizing agents available; the choice depends upon the extent to which oxidation is desired. Air, oxygen, ozone, peroxides, chromium trioxide, chlorates, dichromates, permanganates, nitric acid, and sulfuric acid are all common examples. Conversion of the alkaloid nicotine to the vitamin nicotinic acid provides an example of oxidation (see also OXIDATION–REDUCTION REACTIONS).

Oxidizing agents

Polymerization. Polymerization reactions may be broadly divided into addition polymerization and condensation polymerization (polycondensation). The term polymerization strictly refers to addition polymerization but is often used to include all types of polymerization reactions (see also POLYMERS). Addition polymerization may be defined as the joining together of two or more molecules of a compound in such a way that the molecular weight of the polymer produced is a multiple of that of the original compound. Addition polymerization is usually induced either by heat, pressure, or a catalyst or a combination of these.

A pharmaceutical example is the preparation of paraldehyde, used as a sedative drug. A small proportion of concentrated hydrochloric acid is added to acetaldehyde, causing three molecules of the liquid to polymerize to form a molecule of paraldehyde, a saturated heterocyclic system. The reaction involves the mutual saturation of three unsaturated carbonyl groups.

Condensation polymerization involves a similar joining together of molecules, but this time a simple molecule, such as water, is condensed out. Diethylene glycol, for example, can be made by heating glycol with a dehydrating agent. Higher polyethylene glycols can be made similarly, such as polyethylene glycol 400, with a molecular weight of about 400, and polyethylene glycol 4000, with an average molecular weight of about 3,400. These two polymers are employed in the preparation of a water-soluble ointment base.

Reduction. This reaction, the opposite of oxidation, has very wide applications in the production of pharmaceuticals. Examples of reducing agents are aluminum amalgam, hydriodic acid, hydrogen and a catalyst, hypophosphorous acid, lithium aluminum hydride, metal and acid, sodium and alcohol, stannous chloride, and zinc dust and water. Reduction is employed in the synthesis of racemic menthol, an anti-itching agent. It is produced by the catalytic hydrogenation of the aromatic analogue, thymol, or of the saturated ketone, menthone, or of the unsaturated ketone, pulegone.

Sulfation. This consists of direct linkage of a sulfate group to carbon, yielding an acid sulfate, $ROSO_2OH$, or a sulfate, $ROSO_2OR$. The most usual sulfating agents are concentrated sulfuric acid, oleum, sulfur trioxide, chlorosulfonic acid, or sulfamic acid, NH_2SO_3H.

The surface-active agent sodium lauryl sulfate, for example, is produced from commercial lauryl alcohol (mainly dodecanol) by reaction with chlorosulfonic acid. The resulting lauryl hydrogen sulfate is neutralized with sodium hydroxide.

Sulfonation. This consists of direct linkage of the sulfonic-acid group, $-SO_2OH$, or salts thereof, or of the sulfonyl halide group, $-SO_2X$, to a carbon or nitrogen atom. The latter are known as *N*-sulfonates or sulfamates. The same reagents are employed as are used for sulfation, above.

In the production of sulfonamides, the intermediate 4-acetamidobenzenesulfonyl chloride is made from acetanilide and chlorosulfonic acid. Most sulfonamides are made by the condensation of this intermediate with the appropriate primary amine, followed by removal of the acetyl group by alkaline hydrolysis. The hydrolysis is not usually difficult in practice, as the $-CO-NH-$ bond is more easily broken than the $-SO_2-NH-$ linkage. After the alkaline hydrolysis, the sulfonamide is precipitated by neutralization.

Complex chemical conversions. Ascorbic acid (vitamin C) provides an example of a complex synthesis. It is manufactured from D-glucose; this is converted by means of microbiological oxidation to a keto acid, which is catalytically reduced to L-idonic acid. Microbiological oxidation converts this to 2-OXO-L-gulonic acid. The 2-OXO-L-gulonic acid is converted to its methyl ester, which is isomerized and cyclized to L-ascorbic acid.

PREPARATION OF DOSAGE FORMS

Before describing individual types of dosage forms, some consideration of the process of size reduction or comminution is necessary. The degree of comminution varies according to the particular drug and the method of extraction used. Thin leaves and certain substances such as aloes or tolu need no treatment at all. Others may be cut, crushed, broken into small pieces, or sliced thin. Finally, the drug may be powdered or ground to one of five different degrees of fineness. A number of grinding machines are employed for powdering, the most important being the disintegrator, edge-runner mill, ball mill, and end-runner mill.

Process of comminution

Solutions. Many pharmaceuticals are simply solutions of a medicament in water, alcohol, ether, glycerin, or some other solvent. Various flavoured waters (*e.g.*, chloroform or peppermint water) may also be used as solvents. After mixing, many solutions require additional treatment such as sterilization or addition of antimicrobial agents, stabilizers, or buffers.

Spirits are solutions of a volatile substance in alcohol or a mixture of water and alcohol. Elixirs are clear, sweetened hydroalcoholic (alcohol and water solvent) liquids for oral use, usually containing potent or nauseous drugs. Simple elixirs are prepared by solution, while those made from plant drugs are produced by maceration or percola-

tion (described below). Tinctures, solutions of a nonvolatile substance in alcohol or a mixture of water and alcohol, are manufactured by simple solution, maceration, or percolation.

In maceration, the drug, suitably prepared, is placed, together with the extracting solvent (known as the menstruum), in a closed vessel and left for a defined period, usually three to seven days, with occasional shaking. The product is then filtered, the residue on the filter (known as the marc) is pressed to avoid loss, and the mixed filtrates are clarified, either by subsidence (settling out) or filtration.

Percolation

In percolation, the powdered drug is first moistened with the extracting solvent, allowed to stand for a defined period, and then carefully packed in a conical or cylindrical vessel with a perforated false bottom and a tap at the base known as a percolator. Sufficient extracting solvent is added to saturate the drug, and, when liquid begins to drip from the percolator, the tap is closed and sufficient solvent added to form a layer above the drug. Maceration is then allowed to proceed for a defined period (usually 24 hours), followed by slow percolation, more solvent being added as necessary, until the desired volume of percolate is obtained, which is then clarified by subsidence or filtration.

Fluid extracts are solutions, in alcohol, water, ether, or a mixture of these, of the active part of a vegetable drug so prepared that one cubic centimetre of extract has the same strength as one gram of the dry drug. More concentrated than tinctures, fluid extracts are made by percolation or maceration.

Numerous other types of solutions are used in pharmacy, such as collodions (viscous liquids for external application) or liniments (liquids for external application, usually consisting of a drug in oil or soap solution).

Semisolid dosage forms. Ointments are preparations for external use, intended for application directly on the skin or on a surgical dressing. An ointment base is chosen depending upon whether the final product is intended for absorption by the skin or not. Oily- or fatty-base ointments may have hard, soft, or liquid paraffin bases or mixtures of these in such proportions as will render an ointment of suitable consistency. Anhydrous lanolin (wool fat), also included in this group, is particularly suitable whenever a large volume of water or aqueous solution must be incorporated into the ointment, as anhydrous lanolin forms a stable water-in-oil emulsion. Anhydrous lanolin is readily absorbed by the skin and is often mixed with paraffins when both absorption and protection are desired. Emulsifying bases (in which minute globules of fatty substances are suspended) include anhydrous lanolin and hydrophilic petrolatum, which has similar properties. (The solid particles of a hydrophilic substance strongly attract and hold molecules of water.) Other ointment bases are emulsion bases, mixtures of oily substances and water; and water-soluble bases, generally prepared from polymers of ethylene glycol.

When the active medicament in the ointment is a solid, it is powdered as finely as possible, and then incorporated by the principle of geometric dilution (see below *Solid dosage forms*). The ingredients of ointment bases are often mixed together by fusion in a water bath, followed by stirring until cold, the drug being incorporated at a suitable stage. In manufacturing practice, ointments are usually improved by being passed through a roller mill; this ensures uniformity and smoothness. Creams, with the same therapeutic purposes as ointments, are solid or semisolid emulsions of the water-in-oil or oil-in-water type, giving greasy or nongreasy preparations, respectively. Pastes, similar to ointments, are usually stiffer, less greasy, and more absorptive, due to a higher proportion of powdered ingredients, such as calcium carbonate, talc, or zinc oxide. They are made by similar methods but with a glycogelatin, paraffin, or starch basis, or a mixture of these. Jellies used for similar purposes are made with an aqueous gel such as acacia, cellulose derivatives, chondrus, gelatin, gelatinized starch, or tragacanth as a base.

Solid dosage forms. Solid dosages, such as tablets, have many advantages over other types: greater stability, less risk of chemical interreaction between different medicaments, smaller bulk, accurate dosage, and ease of production.

Powders

Powders intended for internal use are usually mixtures of two or more ingredients. If two ingredients are present in unequal quantities, then the lesser ingredient (usually the drug) is mixed with an equal weight of the greater ingredient. Next, the resulting mixture is combined with an equal weight of the greater ingredient in steps until the mixture is complete. This process of geometric dilution (or trituration) is essential in order to produce a homogeneous powder. Powders may be sold in a bulk form or in individual packets. Granules, a dosage form related to powders, are particularly suitable for the preparation of solutions or mixtures of drugs, such as antibiotics, that are unstable in the presence of water. Cachets, occasionally used for administration of powdered drugs with an unpleasant taste, consist of shells made of gelatinized starch paste, the powder being placed inside, and the cachet swallowed. More common today is the hard capsule, in which the powder is enclosed in a shell of hard gelatin. Semiliquid and liquid drugs are often enclosed in a soft capsule with a soft gelatin shell.

Pills. Before the machine-made compressed tablet, pills were a very popular solid dosage form, being prepared at the dispensing bench by the pharmacist. Today pills are rarely prescribed, though some popular types are manufactured by machine. The powdered ingredients are mixed together with a binding agent, such as acacia or tragacanth, and are then made into a plastic mass by incorporation of any liquid drugs and addition of an inert liquid. The resulting mass, known as a pill mass, is then rolled into spheres and coated with talc, gelatin, or sugar.

Tablets. Tablets, by far the most common method of administration of drugs, are only rarely made by compression of the drug alone (*e.g.*, potassium bromide tablets). Usually, the drug is mixed with suitable diluents, such as dextrin, lactose, salt, starch, or synthetic substances, designed to ensure disintegration of the tablet in the body. To prevent sticking in the machine, a lubricant such as liquid paraffin, stearic acid, talc, or a synthetic substance is usually added. Furthermore, it is essential that the tablet machines are fed with the drug mixture in a free-flowing form to ensure complete filling of the molds. To achieve this, the drug mixture is customarily granulated by mechanically forcing pellets of the mixture through a sheet of perforated metal. The granulated mixture is fed into the tablet machine, which feeds the correct dose into a cavity, the mixture then being compressed by means of a punch that fits into the cavity. To be successful, the tablet maker must choose correct diluents and lubricants, prepare suitable granules, and obtain the right degree of compression in the tablet machine. Excessive compression may mean that the tablet will not disintegrate in the body; insufficient compression results in fragile tablets that may break, causing inaccurate dosage.

Tablet coatings

Coatings of various types may be applied to the tablet—to protect the ingredients from deterioration, to hide the taste of certain drugs, to control the release of the drug from the tablet, or to produce a more attractive tablet. For sugarcoatings, a concentrated sucrose syrup containing suspended starch, calcium or magnesium carbonate, or other suitable substance is applied, each successive layer being dried before the application of the next. After the final layer is dried, it is highly polished to give an elegant finish. Sugarcoatings provide both protection and a sweet taste. The chief drawback to sugarcoating is the long time involved. This led to the development of film coating, in which a very thin transparent film, usually a cellulose derivative, is applied. Enteric coating is designed to resist solution in the stomach and to dissolve in the more alkaline intestinal fluid. Many substances have been used for enteric coatings, one of the more recent being cellulose acetate phthalate (cellacephate). In the manufacture of layered tablets, incorporating two or more drugs, a compressed tablet is fed to a second machine where another layer is compressed around it. In this way, drugs normally incompatible may be formulated in the same tablet.

Other solid dosages. Troches, also known as lozenges or pastilles, disintegrate or dissolve in the mouth, slowly releasing the active drug. The base usually consists of a mixture of sugar and gum or gelatin. Lozenges are generally manufactured by compression techniques, while pastilles are fabricated by fusion and the use of molds. Dry extracts are prepared by the methods described above for fluid extracts, followed by evaporation, usually under reduced pressure, either to a pilular consistency or to dryness. Dry extracts are usually granulated by being passed through a sieve and may be used for the preparation of tablets. Suppositories are solid, uniformly medicated masses designed for introduction into the rectum. Various bases are used in their preparation, but theobroma oil is the most common. Solid at room temperature, it melts a few degrees below body temperature. Suppositories are manufactured by the use of molds, together with fusion of the suppository mass or cold compression. Pessaries are suppositories intended for introduction into the vagina, while bougies are designed for insertion into the urethra, nostrils, or ears.

Sterile medicaments. Some drugs cannot be given orally, because they are decomposed by the digestive processes; these drugs must be administered by injection, intravenously, intramuscularly, or subcutaneously (under the skin). It is imperative that such injected solutions be free from micro-organisms or toxic agents; other pharmaceutical preparations that must be sterile include eye drops, eye lotions, eye ointments, implants, powders to be applied to wounds or body cavities, and any solution or preparation to be used in surgical operations, such as surgical dressings, ligatures, and sutures.

Sterilization methods

There are several main methods for preparing sterile products. Steam sterilization is carried out in an enclosed chamber (autoclave). The material is distributed into its final containers, which are sealed to exclude micro-organisms. The containers are then placed in the autoclave and subjected to saturated steam under pressure at a temperature of 121° C (250° F) for 15 minutes. Substances stable in heat may be sterilized at higher temperatures, for which a shorter heating period is sufficient; conversely, lower temperatures require longer sterilization periods.

Pharmaceuticals in which the solvent is not water cannot be sterilized by steam, so dry heat at temperatures of 140° C (284° F) or higher is used, with exposure times ranging from one to four hours. The temperature–time relationship is similar to that for steam sterilization. Another technique is gaseous sterilization, in which the material is exposed to a vapour or gas such as ethylene oxide; this method is much used for foods, biologicals, and medical equipment (*e.g.*, cotton wool, syringes, needles, and tubing). Radiation sterilization generally involves exposure to ultraviolet or gamma radiation or high-energy electrons; its use is limited mainly to the production of sterile medicaments and apparatus on a large scale. The final method, aseptic manipulation, is not actually a sterilization process. Here, the separate ingredients of the pharmaceutical are all available in sterile form and merely require compounding without microbial contamination.

Injections are aqueous or oily solutions, suspensions or emulsions, prepared by normal methods, with special care taken to remove all extraneous particulate matter. Injections must be sterilized by one of the methods given above. Some aqueous injections are not stable and so are prepared at the time of use by adding sterile water to the sterile drug.

Eye drops, eye lotions, and eye ointments are all prepared by general methods, but they must be sterile. The pH value (acid–alkaline content) of eye drops and eye lotions is important; a compromise must be made between the ideal value of 7.4 (almost neutral) and the value of greatest stability or therapeutic activity. Implants or pellets are prepared either by fusion and molding of the drug or by compression of the sterile crystals.

Dispersions. Aerosols were formerly defined as colloidal systems consisting of very finely subdivided liquid or solid particles dispersed in a gas. Today, the term aerosol, in general usage, has become synonymous with a pressurized package. For pharmaceutical purposes aerosols may be divided into two types. Space sprays disperse the medicament as a finely divided spray with particles not exceeding 50 microns (0.05 millimetre, or 0.002 inch) in diameter. Surface-coating aerosols produce a coarse or wet spray and are used to coat surfaces with a residual film. Propellants used in aerosols are of two main types: liquefied gases and compressed gases. The former consist of easily liquefiable gases such as halogenated hydrocarbons. The drug is dissolved in the liquefied gas or in a mixture of the gas and a suitable solvent. When these are sealed into the container, the system separates into a liquid and a vapour phase and soon reaches an equilibrium. The vapour pressure pushes the liquid phase up the standpipe and against the valve. When the valve is opened by pressing down, the liquid phase is expelled into air at atmospheric pressure and immediately vaporizes, leaving an aerosol of the drug. The pressure inside the container is maintained at a constant value as more liquid changes into vapour. When compressed gases are used as the propellant, the pressure falls steadily as the contents of the aerosol are used, and for this reason liquefied gases are used whenever possible. Pharmaceutical aerosols include solutions, suspensions, emulsions, powders, and semisolid preparations. The products include inhalation aerosols, spray-on bandages, creams, and ointments. The application of these latter to wounds and burns is obviously advantageous, as rubbing is eliminated, and the fine film produced promotes rapid absorption. Inhalation aerosols often include a metering valve, so that measured quantities of drug may be administered; these are rapidly replacing old hand sprays.

Aerosols

Sprays, solutions of drugs in aqueous or oily solutions, are applied by means of an atomizer to the mucous membranes of the nose or throat. Oily solutions are no longer considered desirable, and the ideal spray is an aqueous solution isotonic (equal in osmotic pressure) with nasal secretions and of the same pH.

Suspensions

Since some drugs are insoluble in all solvents suitable for medicinal use, they must be administered either as a solid dosage form or as a suspension. Suspensions are chemically more stable than solutions. Apart from aerosols, pharmaceutical suspensions almost always consist of a finely divided solid dispersed in a liquid. The state of subdivision varies from colloidal particles to particles that only slowly subside on standing. Suspensions should not cake on standing, and the solid phase should readily redisperse on shaking; suspensions should pour fairly easily, so the viscosity must not be too high. Gels are special suspensions, namely, those of hydrated drugs in an aqueous medium, in which the particle size is colloidal or nearly colloidal. Lotions, such as calamine lotion, are suspensions for external use only. Magmas and milks are thick, viscous, aqueous suspensions of insoluble inorganic compounds; the particle size is usually larger than in gels. Bentonite magma, for example, is produced by hydration of bentonite, a colloidal hydrated aluminum silicate, and is used as a suspending agent, as, for example, in calamine lotion. Milk (cream) of magnesia, a magnesium hydroxide mixture, is an aqueous suspension of magnesium hydroxide. Mixtures, in the wider sense, are any combination of drugs prescribed and dispensed for internal use but, in the narrow sense, are official mixtures of standard composition. Official mixtures are liquid preparations of one or more solid drugs dissolved or suspended in water; they often contain a thickening or suspending agent such as tragacanth. Thus, most mixtures may be regarded as a special type of suspension.

Mucilages are thick, viscous, aqueous solutions of gums, frequently containing a preservative such as chloroform or benzoic acid. As they are colloidal in nature, they fall between true solutions and suspensions. Acacia and tragacanth mucilages are the best known examples and are used to aid in suspending insoluble solids in liquids.

Emulsions consist of one liquid dispersed in another. Pharmaceutically, they are intended for internal use and consist of small globules dispersed in water. Oil-in-water emulsions will mix with water, whereas water-in-oil

emulsions only mix with oils. However well two immiscible liquids are mixed together, on standing they will separate into two layers. To prevent separation, an emulsifying agent is used. Emulsifying agents can be divided into three groups: finely divided solids such as bentonite and magnesium aluminum silicate; natural emulsifying agents such as cholesterol, gelatin, acacia, methylcellulose, pectin, and tragacanth; and synthetic emulsifying agents such as the anionic sodium lauryl sulfate, the cationic benzalkonium chloride, and the nonionic polyethylene glycol 400 monostearate. A preservative such as chloroform is usually added to emulsions. The production of emulsions depends on the emulsifying agent used. Equipment includes a wide variety of agitators, colloid mills, homogenizers, and ultrasonic devices.

Radioactive dosage forms. A radiopharmaceutical is a medical product incorporating a radioactive isotope. Radiopharmaceuticals are widely used for various diagnostic tests and to a lesser extent as therapeutic agents. Radioactive iodine in the form of sodium iodide has been extensively used in the diagnosis of thyroid disorders. The iodine isotopes used are iodine-131 and iodine-125, orally administered as a sodium iodide solution; the thyroid uptake of radioactive iodine is measured with a measuring instrument placed close to the thyroid gland. Vitamin B_{12} containing cobalt-57, cobalt-58, or cobalt-60 is employed for the diagnosis of pernicious anemia. Chlormerodrin injection containing mercury-203 is used for renal (kidney) scanning and brain scanning.

WORLDWIDE PHARMACEUTICAL PRODUCTION

It is impossible to produce an accurate figure for worldwide pharmaceutical production because published statistics are not available for all countries and because some nations lump pharmaceutical production under the general heading of chemicals. The Table, however, shows pharmaceutical production in selected countries for 1965 through 1970 in millions of dollars. Though the United States is first in world production by a wide margin, several other countries, notably Japan, West Germany, and France, are very important. The highest percent of increase in the 1965 to 1970 period is shown in Japan.

Production of Pharmaceuticals in Selected Countries*

Pharmacological Cults

This article treats the general subject of the religious use of drugs by more or less organized groups, in the past and at the present time. It identifies and lists the main drugs used, and describes their religious functions, purposes, and history. It also considers briefly certain questions raised by the religious use of chemical substances.

NATURE AND SIGNIFICANCE

Though it is a strange idea to the modern religious worshipper, drugs have played an important role in certain religious practices in the history of religions. The ceremonial use of wine and incense in contemporary ritual is most likely a relic of the time when the psychoactive properties of these substances were designed to bring the ancient worshipper into closer touch with supernatural forces. Modern studies of the "hallucinogenic" (productive of hallucinations) or "psychedelic" ("mind-manifesting") drugs have indicated that such drugs in certain individuals under certain conditions release or bring about what they claim to be profound religious experiences of a mystical and transcendental nature. Such experiences involve an immediate subjective experience of ultimate reality or the divine, resulting from the stirring of deeply buried, unconscious, largely nonrational sensitivities. Modern students of pharmacological cults, who have participated in such ceremonies and used the drugs themselves, have often been amazed at the depth of such experiences. R. Gordon Wasson, an eminent researcher in this field, has suggested that the religious impulse itself may have had its origin in such amazement among primitive savages accidentally finding and ingesting psychoactive plants while foraging for food, though this view is not held by most scholars of religion.

The claim that drugs induce religious experience

Whatever the psychological origins of such impulses, they are viewed as religious in nature and have been structured and channelled through cultic forms. Through cultic leaders—such as shamans (spirit-mediums), witch doctors, and medicine men—as well as through tradition, the cults have specified not only how the psychoactive elements should be assimilated but also how they should be gathered and prepared, and also how participants should comport themselves outside of the ceremonies in the practical affairs of living. Western observers of primitive or non-Western cultures, such as missionaries, colonial administrators, travellers, and certain students have often looked on such practices as one might observe the play of children, noting that the primitive societies demonstrate what the observers assume to be superstition and folly. Anthropologists and other scientists, however, who have attempted to participate sympathetically in tribal rituals have reported not only the useful aspects of such practices in primitive society but have also revealed to a wider public information that is of recognized usefulness to science, medicine, religion, and social theory.

The type of drug usually encountered in cultic ceremonies is most generally classifiable as a narcotic. Few of these drugs are true narcotics, however, in the sense of being benumbing. They are usually called hallucinogens when they call attention to reactions similar to hallucinations, or psychedelics, because of their alleged capacity to reveal to the drug-user certain deep-seated truths about himself or to induce transcendental experiences. Most of the psychedelics tend to stimulate the mind rather than to benumb it, though some true narcotics, such as alcohol and opium, both stimulate and stupify the mind at different stages of their physical effect. Most of these drugs come from plants, though newly formed Western cults, composed primarily of

Caucasians in recent times, have made use of the active principles of natural drugs in synthetic form or synthetic analogs of naturally occurring compounds.

TYPES OF DRUGS AND THEIR EFFECTS

Since there are more than 100 plants known to have psychoactive properties, with more being discovered every year, it is impossible to describe all of them here. A few of the major drugs used by cults, however, will be noted. Though these drugs vary greatly in toxicity, there is much overlapping in their effects. Such factors as the personality and expectation of the participants, the setting, the nature of those in charge, and the interpretations of the experiences by various practitioners may have a more significant determining effect on the experiences themselves than the specific properties of the drugs.

At one time or another, such common substances as alcohol, tobacco, coffee, and tea have been used in religious cults for their psychoactive effects, but such use is not common today.

Hemp, mushrooms, cacti, and their derivatives. Probably the most widespread psychedelic plant from which psychedelic properties are derived is Indian hemp, *Cannabis sativa*, which grows all over the world except in very hot and very cold climates. It is used in religious practices in India and Africa (and probably elsewhere) and is also sometimes used illicitly in the United States and Europe. In its most commonly used form, it is known as marijuana, or bhang in India. As hashish, *kif*, or *charas*, it is more concentrated and stronger. But even marijuana is a mild euphoric (the producer of a feeling of well-being) that, on occasion, has been known to induce a profound religious experience. *Tetrahydrocannabinol*, a mixture of related chemicals, contains marihuana's active principle.

Marijuana

Certain mushrooms, of which the best known is *teonanacatl*, "God's flesh," as it was formerly called, are used by cults among the Indians in Latin America, especially in the Sierra Mazateca of Oaxaca province in Mexico. The chief species is *Psilocybe mexicana*, of which the main active principle is *psilocybin*, a fungus-derived (hallucinogenic and organic) compound and a tryptamine recently synthesized, in its chemical composition and activity not unlike LSD (lysergic acid diethylamide-25), a derivative synthesized from the ergot fungus that infects the fruit of rye. The *Amanita muscaria* (fly agaric) mushroom is another psychedelic mushroom that is as yet poorly studied but possibly extremely important since it may possibly be the natural source of the ritual *soma* drink of the ancient Hindus and the Zoroastrians. It is a fungus that grows only in a certain locale, characteristically near birch and pine trees in the cooler temperate climates, and is therefore restricted in its availability. Besides its psychedelic properties it is said both to increase strength and endurance and to be a soporific (sleep-inducing agent). It has the bizarre property of passing through the urine with its psychoactive properties very little diminished and is drunk in this form. This capacity may help in identifying the exact source of *soma*, as will be discussed below.

Plants with somewhat similar psychedelic properties were discovered by Indian tribes of Mexico. The tops of a species of desert cacti known as *Lophophora williamsii*, dried to form the so-called mescal buttons (to be distinguished from the mescal bean, another psychotropic, or mind-expanding, but highly poisonous cultic plant found in the same area) are ingested by widely distributed groups of Indians in Mexico, the U.S., and Canada during night-long ceremonies that have been described and studied by a number of anthropologists. Its chief active principle is an alkaloid called mescaline. Like psilocybin it is reputed, according to cultists, to produce visions and other evidences of a mystical nature such as the direct experience of the unity of all beings, eternity, the holy, the ultimate, and other mystical experiences. Despite claims of missionaries and some government agents that peyote—from the Aztec peyotl ("divine messenger")—is a degenerating and dangerous drug, scientists allegedly have found no evidence of this among the members of the Native American Church, a North American Indian cult that uses peyote in its chief religious ceremony. Worshipped as a god, peyote, like most other psychedelics, is not considered to be addictive and, far from being degenerative, is reputed by cultists and some observers to help promote morale and good behaviour among Indians within this particular cultic framework.

Other psychedelic substances. When the Spanish missionaries came to Mexico in the 16th century they described another psychedelic substance, primarily in derogatory language. The Indians called this substance *ololiuqui* ("round thing" or pellet") and venerated it highly. *Ololiuqui* has been identified as the seeds of the morning glory, mainly of *Rivea corymbosa* and the *Ipomea violacea*. Since the active principles are alkaloids that can be derived from lysergic acid, its properties are closely related to LSD-25. Thus it produces visions and mystical experiences such as are valued in cults using the seeds.

Columbus described the ceremonial snuffing of a powder encountered during one of his voyages to the West Indies. Of the many kinds of snuff, the chief variety was called *yopo*, a powerful psychedelic derived mainly from a tree, Andenanthera (or *Piptadenia peregrina*). This narcotic snuff may be confused with others, as yet not clearly differentiated.

Psychedelic snuffs and drinks

Another psychedelic substance used in South America, especially in the Amazon basin, is a drink variously called *ayahuasca*, *caapi*, and *yajé*, that is produced from the stem bark of the vines *Banisteriopsis cappi* and *Banisteriopsis inebrians*. Natives who use it claim that it has a variety of virtues, including healing powers and producing clairvoyance, among others. This drink has been certified by investigators to produce remarkable visions, often involving the sensation of flying. These visions are thought to be due to the action of *harmine*, a remarkably stable psychedelic compound that the drink contains, or related chemicals.

Other cultic drugs may be mentioned in passing. The *kava* drink, prepared from the roots of the shrub *Piper methysticum*—a variety of the pepper plant—and seemingly more of a hypnotic-narcotic than a psychedelic, is used both secularly and religiously in the South Pacific, especially in Polynesia. *Iboga*, a powerful stimulant and psychedelic derived from the root of *Tabernanthe iboga*, is used by the secret Bwiti cult in the Congo (Brazzaville) and is now said to be making converts much faster than Christianity or Islām there. Coca ("the divine plant of the Incas"), source of the narcotic cocaine, has had both religious and secular use chiefly in Peru. Datura, associated with the jimson weed, is used by both the Huichol tribe in Mexico and by other native peoples in North and South America. Datura is, however, highly toxic and dangerous. A drink prepared from the shrub *Mimosa hostilis* is used religiously in the *ajuca* ceremony of the Jurema cult in eastern Brazil, often participated in by warriors before battle as a source of glorious visions.

GOALS OF PRACTITIONERS

The drugs used by various cults for psychedelic effects were incorporated into the cults for explicit and implicit religious functions and purposes. The effects of the drugs were and are reported to enhance religious experiences similar to those that occur in religious ceremonies or acts practiced among those who do not use drugs. Controlled laboratory experiments and investigations regarding the effects of such drug use that have been performed outside of a culturally determined cultic framework help to make the cults themselves more understandable.

Ecstasy and union with the divine or sacred. The most lofty aim of the cultic use of drugs is the pure delight in what drug users describe as a direct experience of God, ultimate reality, the spirits that preside over one's destiny, or whatever the worshipper may conceive as his object of worship. As a consequence of such worship-experience there may ensue a feeling of

self-transcendence, sometimes through a melting away of the ego boundaries (with consequent loss of sense of self) and even through the terror of death, resulting in a psychological rebirth leading to a feeling of power, freedom, and the release of creative energies. In ritualized form, drugs have been used to enhance the puberty ordeal through which, in certain tribes, a youth is ushered out of the period of childhood and is certified a man. These functions of the drugs as teachers, leading participants through spiritual growth experiences, may be documented by testimonies both of Indian participants and Caucasian members of contemporary Western drug cults.

Drugs as sacraments

As a means of appropriating such experiences, the rites surrounding the assimilation of the drugs become types of sacraments in which the qualities and the gifts of the gods are appropriated, such as when a mushroom is called God's flesh. The visions, self-knowledge, energy, power, and direction reported to be secured from the rite confirm the feeling of the worshipper that he has been in the presence of God or has assimilated some of His powers. Other specific skills and benefits —either of a substantial nature or the products of magical fancy—may be extrapolated from this alleged encounter with the gods, such as sexual attractiveness, skill in hunting, protection in war, or even the ability to transcend war and to love one's enemies, depending in part on the expectations of the cult.

Purification, healing, and divination. Along with the sacramental function of the drug cults there is the concept of purification through drug use. This may take the form of certain ritualistic preparations for the ceremony, the observing of certain taboos for days before it, or as a part of the ceremony itself. Many psychedelic drugs produce nausea and the consequent vomitting may be looked on as a purging of one's faults. In more advanced cults the purification may be seen as the pure and ethical living that should both precede and follow the ceremony. Closely related to the latter may be the devotional function, viewed in the most primitive drug cults as acts of appeasement of the gods for their expected favours, and in the more developed cults as acts directed toward the needs and wishes of the god through the enhancement of the cultic experience itself. The participation in drug taking may also be viewed as an act of devotion in itself.

In some of the more primitive cults the ordinary participant is relegated to a secondary role, for the priest or shaman may be the one who principally ingests the drug and mediates benefits, real or supposed, to the worshipper or suppliant. Such is the case when the shaman mediates the healing function, when the drug is dangerous, or when it is reserved for those with the most prestige. This is also likely to occur when the divination of the answers to important questions are involved; *e.g.*, as whether to set out on a dangerous journey or where to locate lost property.

Divination through use of drugs

Drugs and magic. Sometimes the pharmacological cults do not rise much above the level of witchcraft, and ceremonies involve the expression of the participants' insecurities, anxieties, and hostilities. This is particularly true of cults operating among a marginal, competitive people, as with the *ayahuasca* cult in Iquitos, Peru, a syncretistic cult in which primitive magical beliefs are interwoven with minimal Roman Catholic features. Thus bad luck is looked on as the result of the curse of an envious neighbour. The witch doctor is sought to dispel the curse and, if possible, to return it onto its originator. At other times illness may be interpreted as the result of possession by evil spirits, and the purpose of the ceremony may be exorcism. In all of these cases the vision-producing capacities of the psychedelic drugs, influenced by the assumptions and desires of participants, will be interpreted according to the hopes and fears, prejudices, and suspicions of the participants.

Psychological goals. The literal meaning of the term psychedelic (mind-manifesting) suggests the vast amount of material (feelings, emotions, images, etc.) released by these drugs from the unconscious. This material, related as it is to the psychological needs and past history of the individual, is viewed as both of an uplifting and creative nature and, on the other hand, frightening and destructive. Though these drugs are regarded as dangerous by industrially advanced societies and their medical advisors, cults using such drugs have exhibited durability, and the societies that harbour them apparently show little or no abuse of the drugs, despite open access to the sources of supply. Perhaps these cults are so structured that basic psychological needs are fairly well met and the resulting cultural expressions are directed mainly into creative and constructive ways. Hostilities and anxieties expressed in ritual are sublimated and, therefore, less likely to be acted out. Persons who have taken the drugs maintain that they understand the closeness of feeling that may be engendered among cultic participants and so satisfy that need for comradeship that is one of man's most basic desires, while the excitement of the "trip" (drug experience) may save participants from one of mankind's most pervasive enemies, boredom.

HISTORY OF DRUG USE IN RELIGION

References to the religious use of drugs are scattered through the history of religions, and there is no doubt that the practice is ancient; its origins are lost in pre-history. A Soviet archaeologist has reported presumed ceremonial use of *cannabis* in censers for burning hemp seeds in the frozen 6th to 3rd centuries BC Scythian tombs at Pazarik in the Altai Mountains of Siberia. The ancient Greeks used wine in Dionysian rites, and circumstantial evidence points to the use of a psychedelic substance in the most solemn moments of the secret Eleusinian Mysteries of Hellenistic Greece (*c.* 300 BC–*c.* 300 AD) in the drinking of the *kykeon*—a thick gruel of unknown composition. Both the secular and religious use of the *Amanita muscaria* mushroom in Siberia probably goes back more than 6,000 years, and its cultic use has spread beyond the cool temperate climates where it grows. Evidence of the cultic use of opium in the eastern Mediterranean islands, Greece, and among the Sumerians points to dates as early as 3000 BC, though some of these facts are disputed.

Soma and haoma

One of the pharmacological mysteries is the nature both of *soma*, a sacred drink mentioned in the *Avesta*, the sacred book of the Zoroastrians, and in the Hindu *Ṛg-veda*, and the haoma plant from which it was derived. Its source may be the *Amanita muscaria* mushroom on the basis of Hindu scriptural references to the sacredness of urine drunk as the source of divine insights. But allusions to the twigs and branches of haoma, as with the *barsom* in the Haoma ceremony, suggest other plants, perhaps hemp. It is quite likely, however, that since the mushroom was not available in hot countries, other psychedelic plants may have been substituted until their identity was confused and lost. The mushroom may have been introduced into India by the Aryan invaders from the north, some of whom were from Iran.

There is less evidence for the historical use of drugs in Buddhism or Taoism, though occasionally there is some mention of it. (Some authorities believe that the Buddha may have died from an overdose of psychedelic mushrooms.) In Islām, since Muḥammad prohibited alcohol, there has been much more general use of *Cannabis*. The fanatical sect known as the Assassins, founded by Ḥasan-e Ṣabbāḥ near Baghdad in the 11th century, used hashish. Sensational and fanciful stories, however, told by Marco Polo and others, of the use of hashish to heighten the undoubted homicidal proclivities of the sect, may be untrue.

The use of kava was reported by travellers to the Pacific Islands, notably Fiji, in the 18th century, though its use must go back much farther. The same may be said for the cultic use of drugs like *iboga*, in equatorial Africa, where the discovery of such usage is very recent and where historical records are meagre. Doubtless much remains to be discovered in both of these areas.

Strangely enough, more is known of the history and practices of pharmacological cults, as well as of the varieties of botanical sources of the drugs, in the New World than in the Old. The finding of many little images sculpted in the form of mushrooms in Guatemala almost certainly points to a mushroom cult in the Mayan culture of Central America well before 1000 BC. Columbus reported the use of snuffs, as has been mentioned. The Spanish priest-historian Padre Bernardino de Sahagún reported with disapproval the religious use of mushrooms in Mexico in the 16th century, and there were reports of the widespread use of psychotropic mushrooms during the coronation of the Aztec emperor Montezuma in 1502. Suppressed by the Spaniards, the remnants of these once proud cults remain in the back country of Mexico, particularly in the province of Oaxaca. In 1955 R.G. Wasson and his companions were the first white people invited to eat the sacred mushroom at one of the night ceremonies. Consequent publicity has recently led to an influx of visitors seeking mushrooms and has also attracted the attention of Mexican federal police. Despite this attention, however, the mushroom religion is still a very living one, even though the ceremonies are now carried on less openly.

Spanish reports of about the same era as those covering Mexico allude to cultic use of various drugs in South America. Sahagún also mentioned the religious use of *ololiuqui* and peyote in his reports. The peyote cult continued to be harassed by missionaries and government agents alike toward the end of the 19th century when numerous Indian cults began to come together in an international body comprising Canadian, American, and Mexican Indians. This federation was finally incorporated in the State of Oklahoma in 1918 as the Native American Church. Despite many antipeyote laws, these Indians have steadfastly maintained their right to worship in their own way. They have suffered imprisonment and have fought these laws in the courts. For the most part the courts have upheld this right.

Use of peyote in the Native American Church

PHARMACOLOGICAL CULTS TODAY

Partly because of the recent rise of interest in psychedelic drugs, as well as the accessibility of the peyote religion, the Native American Church has been studied more thoroughly than any other pharmacological cult, mainly by American anthropologists who have written full reports of its practices. Since earlier times it has developed into a syncretic religion, differing from tribe to tribe in minor details and in the degree to which ancient Aztec practices have assimilated Christian elements. The ritual surrounding ingestion of peyote is a highly symbolic night-long ceremony in the charge of an experienced Indian. Whites privileged to attend the service universally speak of its dignity and impressiveness.

Peyote itself is highly venerated and spoken of sometimes as a gift of God, sometimes as a god itself. It is looked on partly as the possessor of magical qualities of protection and healing, and the revealer of hidden knowledge, and partly as a guide that motivates, strengthens, and guides the Indians. There is as much controversy among the Indians themselves over peyote as over LSD among whites. But the cult, claimed by some adherents to number over 300,000 members, seems to be spreading. Contrary to the assertions of missionaries, who find them hard to convert, the peyote Indians, doubtlessly influenced by white religions around them, are reported to be superior to the nonpeyote Indians in achieving their aims of brotherly love, hard work and self-reliance, family responsibility, and abstinence from alchohol.

Because psychedelic drugs, both natural and synthetic, tend to evoke an experience spontaneously recognized by many as religious and therefore of supreme value to the users, small communities of seekers have grown up wherever the drugs are generally used, most recently among whites in large centres of population. Due to what they consider to be harassment by unsympathetic elements in the cities, many such communities have moved to rural or wilderness areas. Often the harassment continues, while emphasis on spontaneity leads to poor organization. Consequently the histories of many of these communities are brief. An example is the League for Spiritual Discovery founded by Timothy Leary in 1966.

League for Spiritual Discovery and Church of the Awakening

A more durable cult is the Church of the Awakening started by two physicians, John and Louisa Aiken, in Socorro, New Mexico, in 1958. Incorporated in that state in 1963, it had a country-wide membership of 400 in 1970. The Aikens administered both peyote and mescaline sacramentally and with complete safety until prohibited by subsequently passed laws. Their application to the U.S. Department of Justice for permission to use peyote religiously was denied.

RELIGIOUS CONSIDERATIONS AND ANALYSES

It is a matter of controversy whether drug-induced religion is true religion or merely psychological phenomena. In a Harvard University doctoral experiment, W.N. Pahnke, M.D., in support of Aldous Huxley, demonstrated (1963) that drugs can induce experiences indistinguishable from certain mystical states, which the American philosopher William James (1842–1910) declared to be the heart of personal religion, partly as the result of a self-experiment with nitrous oxide. R.C. Zaehner, one of the few critics of drug-induced religion to have experimented on himself, claims that drugs may trigger a natural type of mysticism but not a true theological variety. W.T. Stace, on the other hand, acknowledges that the phenomenology of at least some drug experiences has been truly mystical.

Even if one accepts such a personal type of religion as genuine, however, there still remains the question of whether or not it is effective ethically and socially, two important aspects of most religions. This question may be answered variously, depending in part on the practices and beliefs of the particular cult studied and the context within which the drug is taken. According to some of its adherents, the peyote cult seems to have had mostly beneficial effects on its participants, though this has not been the result in some of the drug communes that apparently were hastily assembled for the sole purpose of ingesting drugs. The psychedelics involved in such communes often tend to induce transcendental experiences of unity and the holy that incline the participant toward loving relationships. Without structure, clearly defined aims, and discipline, however, any cult may eventually disintegrate or fall prey to manipulation, and this has been the experience of some drug cults. The cults that have achieved some measure of success often find the initial drug experiences valuable as a means of introducing their followers to a wider world of religious values. After initial use of drugs, the tendency may be either to use the drugs sparingly, or to give them up altogether in favour of the discipline of meditation or some other means of experiencing mystical religion.

Members of the general community tend to disapprove of drug cultists. The average citizen, accustomed to established ecclesiastical norms and forms, often feels vaguely threatened by transcendental or ecstatic expressions of religion. As a result of such critical attitudes pharmacological cults, particularly those in close contact with the larger, more conventional, or more established religious and social groups, are often harassed, legally or otherwise. Furthermore, in Western culture the word drug itself tends to connote danger and degeneracy, particularly among the general public, and even among the ranks of scholars of religion. Though few scholars of religion have had any firsthand experience with drugs, they often adopt a normative approach and tend to write off any veneration of these substances, which drug cultists consider to be sacramental, as magic, superstition, or witchcraft. The worshipper in a drug cult, on the other hand, tends to view drugs as a means of grace.

Nativistic pharmacological cults appear to be growing,

"Hippie" culture

at least in some areas, such as in the case of the Bwiti, or of the peyote religion. Besides such nativistic cults an amorphous movement popularly known as the "hippie" culture, both in the U.S. and elsewhere, has been growing since the middle of the 20th century. Though not acknowledged as a religious movement by the average Western churchgoer, the hippie movement is regarded by some persons as a very dynamic religious movement in terms of its active search for a mystical approach to life and the experience of the divine or sacred through meditation. In this search the hippie movement is influenced, to a great extent, by its use of drugs.

Due to the religious drug-users' demand for the right to practice religion in their own way, a legal crisis has been developing in the U.S. and elsewhere. This legal battle apparently has been won by one group, the Native American Church. Opponents, however, generally claim that to allow anyone to use drugs for such religious purposes is dangerous to society, and that the right to use drugs under such a guise would simply become an occasion for irresponsible indulgence. Many of the drug users, however, have performed what history shows is a characteristic act of those who are deeply committed to any religious ideal or practice—they have defied the law and thus have suffered the consequences.

Pharmacy

Pharmacy is the science and art concerned with the collection, preparation, and standardization of drugs. Its scope includes the cultivation of plants that are used as drugs, the synthesis of chemical compounds of medicinal value, and the analysis and standardization of medicinal agents. The science that embraces all available knowledge of drugs with special reference to the mechanism of their action in the treatment of disease is pharmacology. Obviously this broad science has many subdivisions, such as toxicology (the study of poisons) and therapeutics (the use of drugs in the treatment of disease). According to the foregoing description, pharmacy is one of the subdivisions or specialties of pharmacology. Pharmacists are responsible for the manufacture of the dosage forms of drugs, such as tablets, capsules, and sterile solutions for injection. They compound physicians', dentists', and veterinarians' prescriptions for drugs.

Historical development. The beginnings of pharmacy are ancient. When early man expressed a juice from a succulent leaf to apply to a wound, he was practicing this art. In the Greek legend, Asclepius, the god of the healing art, delegated to Hygieia the duty of compounding his remedies. She was his apothecary or pharmacist. The physician-priests of Egypt were divided into two classes: those who visited the sick and those who remained in the temple and prepared remedies for the patients.

In ancient Greece the art of healing recognized a separation between the duties of the physician and those of the pharmacist. The same separation prevailed among the Roman practitioners. During the Middle Ages in Europe, the separation of the two groups became less distinct, and many physicians undertook the preparation of their own medicines. The Moorish influence in Europe, however, again brought about the practice of separate duties for the pharmacist and physician. The trend toward specialization was later reinforced by a law enacted by the city council of Bruges, Belgium, in 1683, forbidding physicians to prepare medications for their own patients. In France an office of apothecary general in the army was established in the middle of the 18th century. During the same period in America, Benjamin Franklin took an important step in keeping the two professions separated when he appointed an apothecary to the Pennsylvania Hospital.

Ancient and medieval pharmacy

Education in pharmaceutical science. The history of pharmaceutical education has closely followed that of medical education. As the training of the physician underwent changes from the apprenticeship system to formal educational courses, so did the training of the pharmacist. The first college of pharmacy was founded in the United States in 1821 and is now known as the Philadelphia College of Pharmacy and Science. Other institutes and colleges were established soon after in the United States, Great Britain, and continental Europe. Later, many universities organized schools and colleges of pharmacy within their courses of instruction. Colleges of pharmacy as independent organizations or as schools of universities now operate in most developed countries of the world.

The course of instruction leading to a degree in pharmacy (bachelor of science in pharmacy) was extended from four to five years in 1960. The first and frequently the second year of training, embracing general education subjects, are often provided by a school of arts and sciences. Many institutions, in addition, offer graduate courses in pharmacy and cognate sciences leading to the degrees of master of science and doctor of philosophy in pharmacy, pharmacology, or related disciplines. These advanced courses are intended especially for those who are preparing for careers in research, manufacturing, or teaching in the field of pharmacy.

Several schools of pharmacy have now adopted a six-year professional course leading to the degree of doctor of pharmacy. This professional training includes many subjects common to the medical curriculum and involves training on the hospital wards. In this service the professionally trained pharmacist is expected to give advice to the physician in the techniques of administering medication and the possible interaction of drugs in the patient, along with expected side effects.

Since the treatment of the sick with drugs encompasses a wide field of knowledge in the biological and physical sciences, it is obvious that an understanding of these sciences is necessary for adequate pharmaceutical training. The basic five-year curriculum in the colleges of pharmacy of the United States, for example, embraces physics, chemistry, biology, bacteriology, physiology, pharmacology, and many other specialized courses such as dispensing pharmacy. As the pharmacist is engaged in a business as well as a profession, special training is provided in merchandising, accounting, computer techniques, and pharmaceutical jurisprudence. All other countries requiring licenses to practice offer the same basic curriculum with minor variations.

The basic five-year curriculum

Legislation. Before one is permitted to practice pharmacy in those countries in which a license is required, an applicant must be qualified by graduation from a recognized college of pharmacy, meet specific requirements for experience, and pass an examination conducted by a board of pharmacy appointed by the government. The passing of this board examination carries with it the legal right to practice pharmacy. The holder is then designated a registered or licensed pharmacist.

Pharmacy laws generally include the regulations for the practice of pharmacy, the sale of poisons, the dispensing of narcotics, and the labelling and sale of dangerous drugs. The pharmacist sells and dispenses drugs within the provisions of the food and drug laws of the country in

which he practices. These laws recognize the national pharmacopoeia (a treatise on products used in medicine, their purity, dosages, and other pertinent data) as the standard for drugs. The pharmacopoeias of the different nations are compiled and published according to the respective legal national procedures. The World Health Organization of the United Nations published the first volume of the *Pharmacopoea Internationalis* in the early 1950s. Its purpose is to standardize, as far as possible, the medication with drugs throughout the world. There are two volumes and a supplement. This pharmacopoeia is intended to supply standards, strengths, and nomenclature for those countries that have no national pharmacopoeia: volume 1 contains monographs for basic chemicals and drugs of plant origin; volume 2 contains monographs for medicinal agents and specifications for dosage forms.

Organizations. There are numerous national and international organizations of pharmacists. In Britain the Pharmaceutical Society of Great Britain, established in 1841, is typical of the pharmaceutical organizations. In the United States the American Pharmaceutical Association, established in 1852, is a society that embraces all pharmaceutical interests. Among the international societies is the Fédération Internationale Pharmaceutique, founded in 1910 and supported by 48 national societies, for the advancement of the professional and scientific interests of pharmacy on a worldwide basis. The Pan American Pharmaceutical and Biochemical Federation includes the pharmaceutical societies in the various countries in the Western Hemisphere.

International organizations

There are also other international societies in which history, teaching, and the military aspects of pharmacy are given special emphasis.

Research. Pharmaceutical research, conducted mainly in the schools of pharmacy and in the laboratories of the pharmaceutical manufacturing houses, embraces the organic chemical synthesis of new chemical agents for use as drugs and is also concerned with the isolation and purification of plant constituents that might be useful as drugs. Research in pharmacy also includes methods for assay and standardization of medicinal agents. These phases of research in pharmacy are primarily an application of the science of chemistry to drug products, but the pharmacist also engages in research peculiar to the profession. This research involves formulation of dosage forms of medicaments, a study of their palatability, methods of standardization, and their stability. Another facet of pharmaceutical research that has attracted wide medical attention is the problem of the "availability" to the body (bioavailability) of various dosage forms of drugs. Exact methods of determining levels of drugs in blood and organs have revealed that slight changes in the mode of manufacture or the incorporation of a small amount of inert ingredient in a tablet may diminish or completely prevent its absorption from the gastrointestinal tract, thus nullifying the action of the drug. Ingenious methods have been devised to test the bioavailability of pharmaceutical dosage forms. Although these in vitro, or test-tube, methods are useful and indicative, the ultimate test of bioavailability is the response of the patient to dosage form of the drug.

The results of research in pharmacy are usually published in journals, such as the *Journal of Pharmacy and Pharmacology* (London), the *Journal of the American Pharmaceutical Association* and the *Journal of Pharmaceutical Sciences* (Washington), the *American Journal of Pharmacy* and the *American Journal of Hospital Pharmacy* (Philadelphia), and the *Pharmaceutica Acta Helvetiae* (Zürich).

Phase Changes and Equilibria

The existence of a chemical substance, whether element or compound, in different forms or physical states is well-known. Water, for example, is commonly recognized in the forms of solid (ice), liquid, and gas or vapour. Besides these three familiar forms, various others are known. All are called phases of matter. Many substances, for example, in addition to their liquid and vapour phases occur in several solid forms, defined in terms of their crystal structure (*e.g.*, rhombic and monoclinic sulfur, white and violet phosphorus, hexagonal and rhombohedral ice). Less familiar phases of matter include liquid crystals, which have some properties of solids and some properties of liquids, and the supercritical fluid state, which has properties of both gases and liquids.

Varieties of phase forms

GENERAL CONSIDERATIONS

When matter in one form is transformed into another form, a phase change is said to take place. Whether the sample consists of a complicated mixture of many substances or of a single substance, the transformation may be a reversible one. To state the simplest case, in a reversible system, if form *A* is changed into form *B* by raising the temperature, form *B* will be transformed into form *A* by lowering the temperature, assuming that all other factors are constant. If both forms are present, the temperature will determine which form changes into the other. Because the energy of an atom is distributed over a wide spectrum, the whole of a sample of a solid substance, for example, will not be transformed instantly to liquid at the melting point. In fact, while some of the molecules or atoms are changing from solid to liquid, others will be changing from liquid to solid. In any time intervals, the amount of phase *A* changing into phase *B* can be compared to the amount of phase *B* changing into phase *A*, and the proportions can be expressed in terms of the actual number of molecules involved—a quantity that can be calculated by using atomic weights of the elements and actual weights of the substances. It is possible, at a given temperature, to find that both *A* and *B* forms persist indefinitely in a fixed proportion. That is, the rate of change of *A* into *B* equals the rate of change of *B* into *A*, thus creating a system of phases that is in equilibrium. If even the slightest amount of heat is added to the system, the proportions will change until again the rate in one direction equals the rate in the other. Equilibrium is a frequently unwanted condition because it prevents reactions from going to completion and, for example, lowers yields of desired products. Phase changes are of many kinds, and systems in equilibrium are also of various types. The few variable forces that bring about phase changes in any system include temperature, pressure, and concentration of substances.

Phase number. When one substance or a mixture of two or more substances in a given proportion is brought to equilibrium at a specified temperature and pressure, a phase or combination of such phases of matter will result. Such a system, as it is called, is described by enumerating the phases that are present, the composition but not the quantity of each phase, and the temperature and pressure of the system. A phase is defined as a homogeneous, mechanically separable, portion of a system, all parts of the phase being identical in intensive properties; *i.e.*, those qualities that characterize a phase, such as density and refractive index, but do not depend on the actual quantity of phase present. Although a phase must be homogeneous, it need not be continuous: crushed ice, for example, is a single phase since the intensive properties of one piece of ice are indistinguishable from those of every other piece. A system consisting of one substance throughout may have one, two, or three phases, but a complex system may have many liquid and solid phases, but normally only one gas phase because gases mix in all proportions. Thus water, held at 25° C (77° F) under a pressure of one atmosphere, will consist entirely of liq-

Definition of phase

uid water, but if the temperature is raised above 100° C or 212° F (the pressure still being maintained at one atmosphere) it will consist only of vapour. Liquid and vapour phases can coexist only at 100° C when the pressure is one atmosphere. If approximately equal weights of the compound diethyl ether and water are mixed and brought to equilibrium at 25° C (77° F) and one atmosphere, they will not mix completely and two liquid phases will result, one of which is 1.3 percent water while the other is 94 percent water. Similarly, under appropriate conditions, one can form, by mixing common salt (formula NaCl) and water (formula H_2O), a system consisting of four phases: a vapour (H_2O), a liquid (NaCl dissolved in H_2O), and two solids, pure water as ice and a compound of salt and water with twice as many water molecules as salt (formula $NaCl \cdot 2H_2O$). The equilibria in the aforementioned systems are essentially physical, but chemical equilibria are common, as in the system formed from solid calcium carbonate ($CaCO_3$) that, under suitable conditions, partly breaks down into gaseous carbon dioxide (CO_2) and solid calcium oxide (CaO); the system consists of two solid phases—one being calcium carbonate and the other calcium oxide—and one gas phase carbon dioxide, in proportions that remain constant until temperature, pressure, or volume are changed. All such equilibria are included in the term phase equilibria. The study of phase equilibria concerns the problem of determining what phases coexist at equilibrium under what conditions of temperature or pressure for a given combination of substances in given proportion. Equilibrium involving more than one phase is called heterogeneous equilibrium. The number of phases in a system is designated as beta (symbol β).

Distinction between components and substances present

Component number. The number of components, or the order, of the system, is designated as alpha (symbol α). Alpha is not necessarily the same as the number of substances used to form the system but is rather the smallest number of independently variable (explained directly below) substances required to account for the algebraic composition of each and every phase present. In this sense, a system containing only water has only one component, there being no recognition of the presence of molecular species other than water, such as the hydronium ion (H_3O^+) and the hydroxide ion (OH^-), because, although both ions are always present, their concentrations are not independently variable. In the above-mentioned ether–water example, the system has two components, ether and water, because both are independently variable and both are needed to describe the composition of the two phases formed. In the system formed from calcium carbonate, however, even though there are three substances present, there are only two components, calcium oxide and carbon dioxide, because the composition of the $CaCO_3$ phase can be described as 50 percent CaO and 50 percent CO_2, that of the CaO phase as 100 percent CaO, 0 percent CO_2, and that of the gas phase as 0 percent CaO, 100 percent CO_2, these being mole percentages (one mole of a substance is its molecular weight in grams). Other selections of components could be made—*e.g.*, CaO and $CaCO_3$—but these would require negative percentages. In another example, barium sulfate ($BaSO_4$) and sodium carbonate (Na_2CO_3) react when melted together to produce barium carbonate ($BaCO_3$) and sodium sulfate (Na_2SO_4), all solids. Thus, the system involves four substances: $BaSO_4$, Na_2CO_3, $BaCO_3$, and Na_2SO_4, related through the reaction $BaSO_4 + Na_2CO_3 \rightleftharpoons BaCO_3 + Na_2SO_4$, but the system has only three components because the composition of all four can be described in terms of percentages of only three of them. It is, however, not the identity of the components themselves but the actual number of components that is of importance in the discussion immediately below.

The value of alpha corresponding to a given combination of substances can depend on the range of conditions over which it is studied. Thus, a system of oxygen (molecules containing two atoms, O_2) and ozone (molecules containing three atoms of oxygen, O_3) in any proportions has two components under conditions in which neither is converted to the other, but becomes a one-component system when they interact according to the equation $3O_2 \rightleftharpoons 2O_3$. When the reaction is at equilibrium, according to the laws of chemical reaction the concentrations of O_2 and O_3 are no longer independently variable; *i.e.*, one cannot change without the other also changing. A system consisting of solid ammonium chloride (NH_4Cl) in equilibrium with its vapour has one component, even if the vapour dissociates into ammonia (NH_3) and hydrochloric acid (HCl), provided the NH_3 and HCl are present in equal molar quantities. If, however, excess of either NH_3 or HCl is present, alpha will equal two. Systems with alpha (α) = one, two, three, or four are said to be unary, binary, ternary, or quaternary, respectively.

Degrees of freedom. The description of any one system is facilitated by a statement of the number of degrees of freedom, or its variance, symbolized as F, that it possesses. This is the (minimum) number of variables of temperature (symbol T), pressure (symbol P), and concentration that must be fixed in order to define the system—*i.e.*, in order to fix the intensive properties of all the phases. At equilibrium, there is only one pressure variable because all the phases are at the same total pressure; there is only one temperature variable because all the phases are at the same temperature. The maximum number of independent concentration variables for each phase will be $\alpha - 1$ because fixing $\alpha - 1$ concentrations automatically fixes the concentration of the remaining component. In a system containing only water vapour, for example, the properties of the vapour will not be defined until both T and P are fixed, so that F equals two. There is no concentration variable when α equals one. For a system containing liquid water and water vapour in equilibrium, only one of the two variables, T and P, can be fixed arbitrarily—fixing one fixes the other—therefore F equals one. If ice, liquid water, and water vapour are all present, no variables can be fixed arbitrarily—the latter are beyond any control—and therefore $F = 0$. For a system consisting of water vapour and liquid water saturated with solid salt (NaCl), fixing any one of the following will define the system: T, P, concentration of salt in the liquid solution, concentration of water in the liquid solution; F is therefore unity. (The concentrations of NaCl in the H_2O vapour and of H_2O in the solid NaCl are not determinative variables because experimentally none of them is present.)

The variables of a system

Phase rule. The value of F is readily calculated by means of a rigorous thermodynamic equation known as the phase rule, which states that the number of degrees of freedom equals the number of components minus the number of phases, plus two, or $F = \alpha - \beta + 2$. Systems for which F equals zero, one, two, or three are invariant, univariant, bivariant, and trivariant, respectively.

The phase rule was derived by a U.S. physicist, J. Willard Gibbs, in some papers on thermodynamics published from 1873 to 1878, and represents an important milestone in the history of science. Its usefulness for chemists in the systematization of heterogeneous equilibria was brought to light two or three decades later. Its validity is restricted to systems in real equilibrium and assumes that the intensive properties of every phase of a system are determined only by its temperature, pressure, and composition. The influence of such factors as surface exposure, electric, magnetic, and gravitational fields is assumed to be negligible.

PHASE DIAGRAMS

Derivation of phase diagrams

The subject of phase equilibria depends on graphical representation. With any system, the first step of experimental study is to establish what phases result under a variety of specific conditions by bringing together various proportions of the given substances. It is not yet possible to predict such information, at least in a quantitative sense. The results of the experiments are then plotted and embodied in phase diagrams that are graphical representations in two or more dimensions of the relationships among the variable factors.

Because phase changes are so much a part of the physical world, phase diagrams are pertinent to everyday existence: the melting of ice, the boiling of water, the forma-

tion of fog, the setting of cement, for example, are well known phase changes, the details of which can be predicted from phase diagrams. In the laboratory, processes such as extraction, crystallization, distillation, precipitation, the use of freezing mixtures, and the identification of substances all involve phase changes describable by phase diagrams. Many industrial operations—such as the manufacture of ceramics, alloys, glass, and salts—depend on knowledge of phase diagrams. Finally, geological studies of the history of minerals in igneous, sedimentary, and metamorphic rocks in Earth and moon surfaces are based on previously established phase equilibria.

While phase diagrams ideally describe only systems at equilibrium, the attainment of equilibrium is often a very slow process. In the interpretation of phase behaviour, therefore, the application of phase diagrams must be made with caution and an awareness that time may be an additional important factor.

Unary (one-component) systems. When only one component is present, there are considered to be no concentration variables, every possible phase being 100 percent of that component. The two variables of pressure and temperature suffice to determine the state of the system. Thus all possible phase relations can be shown by a graph in which pressure is plotted against temperature (see Figure 1). Since the number of components alpha

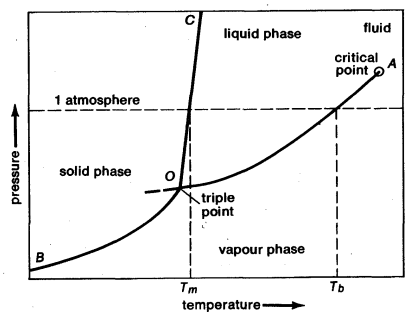

Figure 1: Phase equilibria for the solid, liquid, and vapour states of a substance (see text).

(α) equals one, and the number of degrees of freedom (F) equals two, one, and zero, by the phase rule, when the number of phases, beta (β) equals one, two, and three, respectively, systems with only one phase are bivariant (have two independent variables) and are represented by areas and defined by the two variables; two-phase systems are univariant (have one independent variable) and are represented by lines; three-phase systems are invariant (have no variables) and are represented by points. The lines represent the limits of the condition of bivariance. Three such lines (OA, OB, OC) meet at an invariant point, such as point O, known as a triple point. The substance thus will consist of a single liquid phase if pressure and temperature are such that the plotted point lies in the area partly enclosed by COA, designated liquid; the substance will consist of a single solid phase if the plotted point lies in the area partly enclosed by BOC; similarly, if the plotted point lies in the area AOB the substance will exist as a single vapour phase. Liquid and vapour phases can coexist only when pressure and temperature are such as to lie on OA, the vaporization curve. Solid and vapour phases can coexist only along OB, the sublimation curve (*i.e.*, the solid phase transforms reversibly into the gas without passing through a liquid phase), and solid and liquid can coexist only along OC, the fusion curve. Solid, liquid, and vapour can coexist only at the unique pressure and temperature of point O. AO can be extended for a short distance into the region for solid and, as such, represents a metastable (less stable) liquid–vapour equilibrium that, on being disturbed, yields the more stable solid-vapour equilibrium. The vaporization curve terminates at A, the critical point, beyond which liquid is no longer distinguishable from vapour, a condition called the supercritical fluid state. The sublimation and fusion lines, on the other hand, are often found to terminate in other triple points. OA gives the variation of the vapour pressure of the liquid with temperature, OB the variation of the sublimation pressure of the solid with temperature, and OC the variation of the melting point of the solid with pressure. The one-atmosphere dotted line intersects OC at temperature T_m, and OA at temperature T_b, T_m and T_b being, respectively, the normal melting and boiling points. (If, as with carbon dioxide, point O is above the one-atmosphere line, there are no such points—only a normal sublimation point.) OC is nearly vertical, because the melting point is only slightly sensitive to changes in pressure. The slopes of any of these univariant transition lines at any point thereon are governed by thermodynamic principles embodied in the Clausius–Clapeyron relation, which states that if ΔH is the heat absorbed when a given mass of one of the two phases is transformed to the other phase (under equilibrium conditions at that point), and ΔV is the corresponding increase in volume, then the ratio of a small change in pressure (dP), to a small change in temperature (dT) will equal the heat absorbed divided by the product of the temperature and the volume change, thus: $dP/dT = \Delta H/T\Delta V$. For transitions along OA and OB, ΔH and ΔV have the same sign, so the lines have a positive slope. This is also true usually along OC, but for exceptional cases, including water, ΔH and ΔV have opposite signs and, therefore, dP/dT is negative. Thus the melting point of ice is lowered by an increase in pressure. Point O for water is at 4.58 torr (one torr equals the pressure of $\frac{1}{760}$ of the atmosphere at standard conditions) and 0.0100° C (32.0180° F). (The melting point of ice, measured in the presence of air at ambient or normal atmospheric pressure, is 0.00° C [32.00° F], because the pressure is about 760 torr and because air is dissolved in the water.)

Thermodynamics of univariant transition lines

Polymorphic substances. Many substances are polymorphic—*i.e.*, they exist in more than one crystalline form—a property well illustrated by water. When such crystalline forms are stable under a given pressure and temperature, each will be represented by an area, as in Figure 2, that shows several polymorphic forms of ice (the

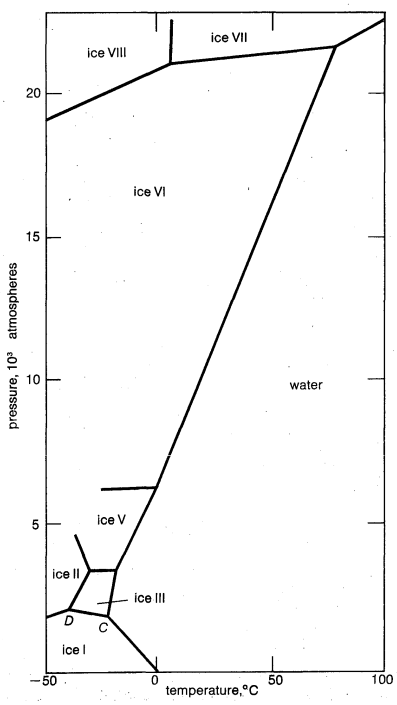

Figure 2: Equilibrium relations for high-pressure forms of ice.

various forms being identified by roman numerals) and is an extension to higher pressures of Figure 1 as applied to the substance water. Two such forms occupying adjacent areas may be said to be enantiotropic; *i.e.*, they are directly interconvertible and can coexist stably at pressures and temperatures anywhere on the line separating the two areas. In contrast, some substances, such as phosphorus,

exist in solid forms (*e.g.*, white phosphorus), that are not known to be stable under any conditions; on standing, they change spontaneously to a more stable form (*e.g.*, white phosphorus changes to red phosphorus). Such metastable forms are said to be monotropic, but the terms enantiotropic and monotropic are both chiefly of historic interest. Figure 2 shows the variety of ice forms existing under appropriate conditions of temperature and pressure. Ice IV, known only for heavy water, is metastable and is not shown. Ice VII has a density of nearly 1.7 grams per cubic centimetre and requires pressures of at least 21,700 atmospheres to be stable.

Other well-known substances exhibiting polymorphism are sulfur, carbon, iron, tin, silica, carbon tetrachloride, *p*-dichlorobenzene, ammonium chloride, and potassium nitrate. Rhombic and monoclinic sulfur are stable below and above 95.5° C (203.9° F), respectively, at one atmosphere pressure, but this temperature (at which they coexist) increases with pressure along a line similar to a fusion line and called a transition line. Crystalline carbon is known in both graphite and diamond forms, each having its own area of stability and bearing to each other a relation similar to that of ice I and ice III (Figure 2), in which ice I is replaced by graphite and ice III by diamond. With carbon, however, *DC* slopes upward (instead of down as with water) to the right, rising from approximately 22,000 atmospheres at room temperature to 200,000 atmospheres at 4,000° C (7,200° F). Thus diamonds can be formed from graphite only under immense pressures. (The temperature must also be high enough for an appreciable transition rate.) Diamonds remain unchanged at ambient pressure and temperature only because their conversion to graphite is extremely slow.

Liquid crystals. Finally, mention must be made of certain compounds, such as *p*-azoxyanisole, the solid form of which melts sharply at one temperature to give a milky, "liquid crystal" or mesomorphic phase that is fluid but anisotropic (with different properties in different directions) and, at a higher temperature, becomes clear and isotropic (uniform in all directions). Such substances, known since 1888, have only recently become of wide interest because of their unique properties.

Variables of binary system

Binary (two-component) systems. When two components are present there are, in addition to the pressure and temperature variables, two concentration variables, only one of which is independent because fixing the percent of one component in a phase fixes that of the other. Thus, the complete description of the phase behaviour requires a three-dimensional model, referred to three axes for ***P***, ***T***, and composition, respectively. A typical portion of such a model for a system of two volatile liquid components, *A* and *B*, that are mutually soluble (miscible) in all proportions, is shown in Figure 3. Along *AB* is plotted the concentration or composition in weight or mole percent (points *A* and *B* representing pure *A* and *B*, respectively). Because alpha equals two, then *F* equals three, two, one, or zero according as beta equals one, two, three, or four. Systems consisting of a single phase are thus represented in the model by volumes. If one regards Figure 3 as depicting a system that, within a limited range of pressure and temperature, shows a liquid phase and vapour phase or both, then *ab* on the *A* face of the model is part of the line *OA* of Figure 1 for component *A*, and *cd* is part of the line *OA* of Figure 1 for component *B*. Within the model lie two curved surfaces that meet along *ab* and *cd* and that, between *ab* and *cd*, envelop a region of space such that a section (slice) through the model at any temperature *T'*, called an isothermal (uniform temperature) section, gives a lenticular area (P_A to P_B). The space (volume) below the lower surface represents systems consisting entirely of vapour and containing both *A* and *B*, and the volume above the upper surface systems consisting entirely of liquid containing both *A* and *B*. The space between the surfaces represents systems consisting of both liquid and vapour phases. Every point on the upper surface is joined by an imaginary line to a corresponding point on the lower surface, these lines—called tie lines—being parallel to the *AB* axis. The two points that terminate each tie line give the values of pressure, temperature, and composition of the two coexisting phases. Because beta equals two in this region, *F* equals two. Regions of space crossed by such tie lines may be called ruled volumes. If Figure 3 covered a wider range of temperature and pressure, then other such pairs of curved surfaces could appear. Intersection of such pairs give ruled surfaces, which, in turn, intersect along lines parallel to *AB*, the details of which are available in extended works on the subject.

It is usually more convenient to consider sections of the solid model rather than the model itself. Figure 4, left,

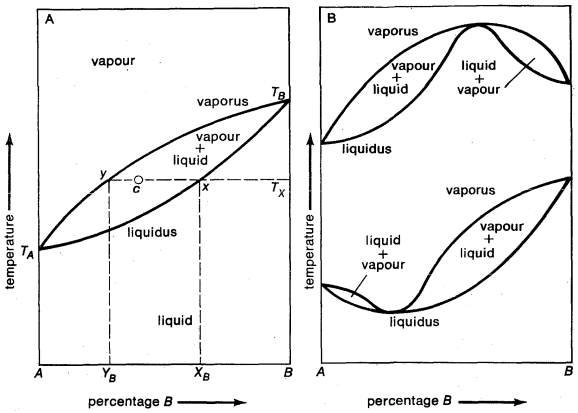

Figure 4: Three types of binary liquid–vapour relations at constant pressure (boiling-point diagrams) the curves in B have maxima and minima, respectively (see text).

is an isobaric section of Figure 3 taken at pressure *P'*, implying that the experimenter has fixed the pressure (throughout the system) at the value *P'*, conveniently one atmosphere. What was a volume in Figure 3 becomes an area in Figure 4, left, and what was a surface becomes a line. Thus, what were trivariant volumes are now areas, labelled "vapour" and "liquid"; what was a ruled volume is now a ruled area, marked "vapour + liquid," crossed by tie lines such as *yx* joining every point on the upper line (vaporus) to a corresponding point on the lower line (liquidus). With pressure fixed arbitrarily (isobaric) in this way, and composition and temperature variable, one-phase systems are said to be isobarically bivariant, two-phase systems isobarically univariant, etc. An isobarically invariant system, obtained by taking an isobaric section of the appropriate solid model (not shown) is represented by a (three-phase) tie line to be illustrated later (Figure 6 [left]). In like manner, one may draw isothermal sections of Figure 3, such as Figure 5 taken at temperature *T'*. P_A and P_B are the vapour pressures of *A* and *B*, respectively, at *T'*. The similarity of Figures 4, left, and 5 is evident. Such qualitative mirror-image relationships between isotherms and isobars are common.

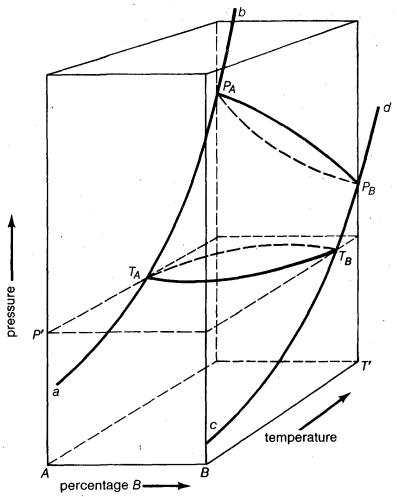

Figure 3: Portion of a typical solid model for a binary system.

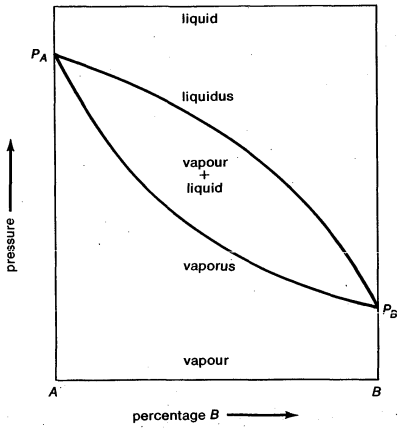

Figure 5: Binary liquid–vapour relations at constant temperature.

Simplest binary system. Figure 3 represents the simplest possible type of binary system and gives only the liquid–vapour relations. The labelling of the areas of the typical isobaric section, Figure 4, is self-explanatory. (T_A and T_B are boiling points of A and B.) In a closed system, an overall composition such as that of c, held at temperature T_X and pressure P', will yield a liquid of composition X_B and a vapour of composition Y_B. The ratio of the intercepts yc/cx on the tie line yx, gives the ratio of the quantity of liquid to the quantity of vapour phase. This principle is valid for all two-phase tie lines. If P' is the barometric pressure, the lower curve gives the boiling points of all solutions at that pressure. A solution of composition X_B boils at temperature T_X, and the vapour it gives has composition Y_B. Thus, the vapour is richer in A than the liquid. Continued removal of vapour from the boiling liquid causes the temperature and liquid and vapour compositions to change following the liquidus and vaporus lines, respectively, to the right. Such boiling-point diagrams are pertinent to fractional distillation of liquids. In general terms, most liquid solutions do not continue to boil at a fixed temperature but, because the vapour is richer in the more volatile components than the liquid, the temperature rises toward the boiling point of the least volatile component. Simultaneously both the remaining liquid and the vapour being formed become richer in the less volatile component. By proper arrangement of cooling apparatus, the vapours can be separated into samples or fractions such that each fraction has a different ratio of components. Usually the aim is to isolate one of the components, and, therefore, a specific fraction richest in that component will be distilled again, further reducing the unwanted components. This process of separating liquids by distilling them and trapping fractions for further distillation is fractional distillation.

Separation of liquids

Frequently, the solid model is such that its isobaric sections have the appearance of Figure 4, right (top and bottom), which show maxima or minima in the curves. At such unique points the two curves touch tangentially, and the liquid solutions distill unchanged in composition. This phenomenon is called azeotropy. Examples of liquid pairs belonging to this type, shown in Figure 4, left and right (top and bottom), are, respectively, methyl alcohol–water, acetone–chloroform, ethyl alcohol–water. Azeotropy prevents complete separation of a solution into its pure components by simple fractional distillation.

The comparative simplicity of Figures 3, 4, and 5 results from the assumed miscibility of liquids A and B and of their vapours. Similar diagrams result in considering equilibria between solid and liquid phases if solid A and solid B are miscible (continuous series of solid solutions) and if liquid A and liquid B are miscible. The previous discussion can be made pertinent by replacing the words liquid by solid, vapour by liquid, boiling by melting, and distillation by crystallization wherever they occur. Figure 4 then shows possible melting-point diagrams at constant pressure. The constant-pressure requirement is usually unimportant in melting-point diagrams.

More complex systems. A common solid–liquid relationship is one in which two components, A and B, have no miscibility as solids but are completely miscible as liquids. If the solids are not very volatile, an isobaric section at ambient pressure often has the appearance of Figure 6 (left), in which T_A and T_B are the respective melting points of A and B. The labelling of the various areas indicates, as before, what phases result when known mixtures are brought to equilibrium at a given temperature. For example, a mixture of composition X_B at temperature T_X will yield a liquid of composition l and solid B, lT_X being a tie line. The line T_BE is thus the solubility curve of solid B. A solution of composition l begins to freeze at temperature T_X. With further cooling, solid B continues to separate, and the liquid composition follows the line lE to E, whereupon the liquid solidifies without change in temperature to give an intimate mixture of solids A and B. Thus the line T_BE also shows the lowering of the freezing point of B by A. T_AE has an analogous meaning. The line cEd is a (three-phase) tie line where three two-phase areas come together and represents the coexistence of the three phases solid A, solid B, and liquid E. Because alpha equals two and beta equals three, and because pressure is constant, the system is isobarically invariant and therefore defines itself as long as all three phases are present. Hence the temperature is fixed at T_E and the liquid composition at E. Any attempt to dislodge the system from this state will be resisted if equilibrium is maintained. For example, if heat is added in an attempt to raise the temperature, solid A and solid B will melt and dissolve in each other to give more liquid of composition E, and this process, which is accompanied by the absorption of heat, will nullify the external heat input. Such a reversible phase reaction (which can be represented by the equation solid A + solid $B \rightleftharpoons$ liquid E) at an invariant point in a binary system, characterizes a system said to be at a (binary) eutectic point. (This statement applies even when solids A and B are solid solutions instead of pure substances.) The mixture of solids A and B in the proportions required by this equation is called the eutectic mixture, and it melts as though it consisted of one substance. Temperature T_E is the lowest temperature at which a liquid phase can form. Liquid, and solids A and B, can coexist at, and only at, temperature T_E. With vapour present, the system is at a quadruple point. The creation of a constant low-temperature environment by mixing the solids ice and salt is based on this eutectic phenomenon, as is also the use of low-melting alloys. Thus, the temperature of a mixture of solid potassium iodide and ice cannot rise above −23° C (−9° F), which is the T_E for this system, as long as both solids are present. The use of salt to melt ice on the streets, the purification of water by partial freezing, the use of sharpness of melting as a partial criterion of purity of a substance, the process of zone refining, and the determination of mixed melting points are all related to diagrams of the type represented by Figure 6 (left).

Ice–salt mixture

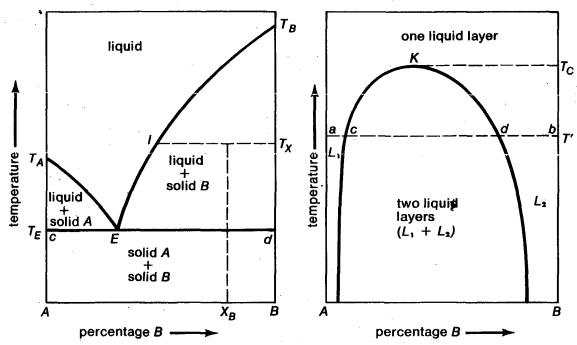

Figure 6: (Left) Binary system with eutectic and pure components as solid phases. (Right) System showing partial miscibility with upper critical solution point; L_1 = solution of B in A; L_2 = solution of A in B.

Between the extremes of complete miscibility and complete immiscibility lies partial miscibility, as exemplified

by the liquids ether and water mentioned earlier. Liquids *A* and *B* of Figure 6 (right) are in this category. Addition of *B* to *A* at temperature *T'* means following the line *acdb*. With small additions, only one layer is present (*a* to *c*); with larger additions, two layers (points *c* and *d*) result. Total compositions very rich in *B* again give only one layer (*d* to *b*). With rise in temperature, the miscibility gap (*cd*) often closes so that above T_C complete miscibility exists. Point *K* is an upper critical solution point. Less commonly, the gap closes with falling temperature, and in some examples it closes in both directions. Analogously, two solids may form solid solutions showing complete miscibility at one temperature and partial miscibility (discontinuous series of solid solutions) at another. The solids sodium chloride and potassium chloride, for example, are completely miscible above 500° C (900° F), yet only partially so below this temperature.

Complex variations. Many systems in their solid–liquid or liquid–vapour relations, combine the features just described. Thus a boiling-point diagram can involve partial miscibility of the liquid components with or without azeotropy. A melting-point diagram can combine partial miscibility of the liquids with immiscibility or with partial miscibility of the solids. Melting in systems with partial miscibility of the solid components may show eutectic behaviour, similar to that discussed above, or peritectic behaviour, outlined below. One or both of the components can be polymorphic. Solid, liquid, and vapour phases may appear in the same diagram. Supercritical phenomena may be encountered. Intercomponent compounds may form. Some of these are referred to below.

Components *A* and *B*, themselves frequently compounds, may form addition compounds (*C* in Figure 7).

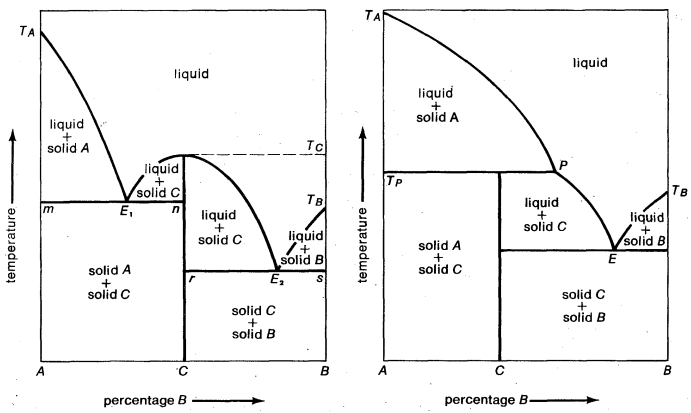

Figure 7: *Systems with intercomponent compounds* (*C*). (Left) Congruently melting compound. (Right) Incongruently melting compound.

In Figure 7 (left), which resembles two figures in juxtaposition—each similar to Figure 6 (left)—compound *C* melts congruently at T_C; *i.e.*, it melts to a liquid of the same composition. Lines mE_1n and rE_2s both represent eutectic points. In Figure 7 (right), *C* melts at T_P to a liquid, *P*, of a different composition and solid *A*; *i.e.*, *C* melts incongruently at T_P. The coexistence of solid *A*, solid *C*, and liquid *P* at temperature T_P, represented by the horizontal line at *P*, is an invariant system at constant pressure. Under these conditions, the system is said to be at a (binary) peritectic point (*cf.* eutectic point), characterized by the reversible phase reaction that can be written in equation form: solid $C \rightleftharpoons$ solid A + liquid *P*, which occurs on the addition or removal of heat and maintains the temperature at a constant value. The system consisting of copper and zinc, which includes ordinary brass, shows a series of intermetallic compounds and solid solutions; the system iron–carbon, which includes steel, shows the polymorphism of iron, compound formation, and solid solution.

Variables in ternary systems

Ternary and higher order systems. With a third component present, there are a maximum of four independent variables. It is thus necessary, for graphical representation, either to keep one variable constant or to ignore the effect of one of the variables (the one to which the system is least sensitive, commonly the pressure). This leaves the temperature and two independent concentration variables to be plotted as a solid model. In the absence of displacement reactions (in which parts of two components change places with each other in chemical reaction), the latter usually consists of a triangular prism as in Figure 8 (left),

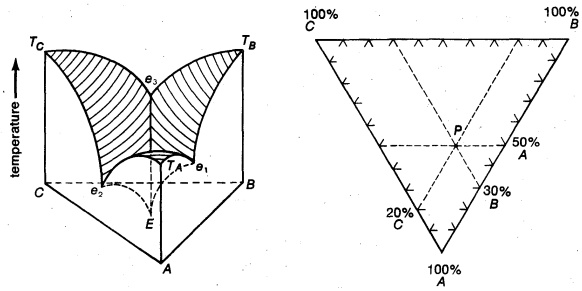

Figure 8: (Left) Freezing-point relations for a ternary system with pure components as solid phases. (Right) Method of plotting ternary composition with triangular coordinates.

the base of which is equilateral. Composition is plotted on triangular coordinates as illustrated in Figure 8 (right), in which point *P* represents the composition 50 percent *A*, 30 percent *B*, 20 percent *C* (either in weight or in mole percent). Temperature is measured vertically upward. Figure 8 (left) shows a typical solid–liquid relationship—that of three immiscible solids that form no compounds and that melt at T_A, T_B, T_C to give liquids that are completely miscible. Each of the three binary systems (*A–B*, *A–C*, *B–C*), which comprise the ternary, then shows the phase behaviour of Figure 6 (left) as seen on the vertical faces of Figure 8 (left). There are three curved surfaces sloping downward and inward, which intersect along the lines e_1E, e_2E, and e_3E, where e_1, e_2, and e_3 are the eutectic liquids of the respective binary systems. These surfaces give the (initial) freezing points of all solutions, the order in which the solids separate on cooling, and other details. Point *E*, a ternary eutectic liquid, gives the composition and temperature of the first liquid to form on heating, or last to remain on cooling. The cumulative effect on the lowering of the minimum temperature of melting through the addition of more components is evident. The curved surfaces may also be regarded as solubility surfaces. Figure 8 (left) is purposely simple, but other systems can be complicated by the presence of phenomena such as formation of compounds, partial or complete miscibility in the solid state, partial miscibility in the liquid state, ternary peritectic behaviour, presence of a vapour phase, etc. An extensively studied example is the complex system calcium oxide–aluminum oxide–silicon dioxide, $CaO–Al_2O_3–SiO_2$, because of its relation to the setting of portland cement.

When both pressure and temperature are held constant —*e.g.*, conveniently at one atmosphere and 25° C (77° F)—the phase relationships can be portrayed by a horizontal (isothermal) section of the triangular prism. The resulting plane triangular diagrams are widely used and illustrated in Figure 9. In this figure, for the system copper(II) chloride–potassium chloride–water; *i.e.*, $CuCl_2–KCl–H_2O$, at 75° C (167° F), the lines *ab*, *bc*, *cd*, and *de* are sections of curved surfaces of the prism (not

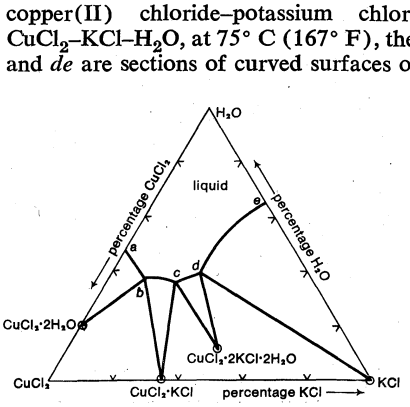

Figure 9: Phase diagram of $CuCl_2 \cdot KCl \cdot H_2O$ at 75° C.

shown) and give the compositions of liquids saturated with solid $CuCl_2 \cdot 2H_2O$, $CuCl_2 \cdot KCl$, $CuCl_2, \cdot 2KCl \cdot 2H_2O$ and KCl, respectively. Because tie lines join points representing coexisting phases, every point on the curved edge of each wedge-shaped region is joined by an imaginary tie line to the corresponding opposite corner of the wedge. Such diagrams are useful in determining, for example, the conditions under which these solids can be prepared at 75° C. Diagrams similar to Figure 8 (left) form the basis for purification by recrystallization where, for example, *C* is the substance to be purified, *B* is the impurity to be removed, and *A* is the solvent.

Figure 10 is for three nonreacting liquids, *A*, *B*, and *C*,

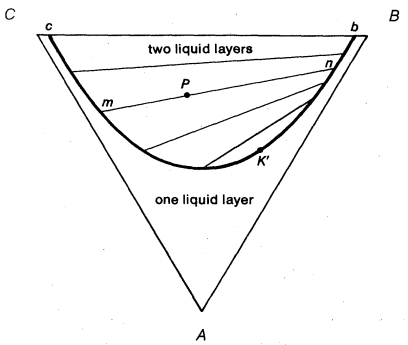

Figure 10: Typical ternary liquid system at constant temperature.

Three nonreacting liquids

in which the pairs *A–B* and *A–C* are miscible but the pair *B–C* is only partially so. Total compositions anywhere above the "binodal curve," *cK'b*, give two layers. For example, composition *P* gives layers of compositions *m* and *n*, respectively, *mn* being a tie line, several of which are shown. Below *cK'b*, only one phase is possible. As drawn, the slope of the tie lines indicates that there is more *A* in the *C*-rich layer than in the *B*-rich one. *K'*, where the tie lines have shrunk to a point, is called a plait point. Addition of sufficient *A* to the partially miscible *B–C* pair produces complete miscibility. Such systems are important in extraction processes.

Isothermal ternary diagrams often combine the phenomena typified by Figures 9 and 10. They may also involve the complications mentioned earlier. Systems with more than one binodal curve and systems with solid solutions have also been widely studied. When double-displacement reactions occur among the components a triangular diagram is not adequate.

Systems of four, five, and more components have been investigated but none completely. A historic study by a Dutch-born chemist, J.H. van't Hoff, of the solubility relations of the chlorides and sulfates of sodium, potassium, magnesium, and calcium in water was undertaken in connection with the utilization of the famous Stassfurt (now in East Germany) salt deposits and the determination of their geological history.

Phenomenology

In the 20th century, Phenomenology is mainly used as the name for a philosophical movement the primary objective of which is the direct investigation and description of phenomena as consciously experienced, without theories about their causal explanation and as free as possible from unexamined preconceptions and presuppositions. The word itself is much older, going back at least to the 18th century, when the Swiss-German mathematician and philosopher Johann Heinrich Lambert applied it to that part of his theory of knowledge that distinguishes truth from illusion and error. In the 19th century the word became associated chiefly with the *Phänomenologie des Geistes* (1807; Eng. trans., *Phenomenology of Mind*, 2nd ed., 1931), by G.W.F. Hegel, who traced the development of the human spirit from mere sense experience to "absolute knowledge." The so-called Phenomenological movement did not get under way, however, until early in the 20th century. But even his new Phenomenology includes so many varieties that a comprehensive characterization of the subject requires their consideration.

CHARACTERISTICS OF PHENOMENOLOGY

In view of the spectrum of Phenomenologies that have issued directly or indirectly from the original work of the Austrian-born German philosopher Edmund Husserl, it is not easy to find a common denominator for such a movement beyond its common source. But similar situations occur in other philosophical as well as non-philosophical movements.

Essential features and variations. Although, as seen from Husserl's last perspective, all departures from his own views could only appear as heresies, a more generous assessment will show that all those who consider themselves Phenomenologists subscribe, for instance, to his watchword, *Zu den Sachen selbst* ("To the things themselves"), by which they meant the taking of a fresh approach to concretely experienced phenomena, an approach, as free as possible from conceptual presuppositions, and the attempt to describe them as faithfully as possible. Moreover, most adherents to Phenomenology hold that it is possible to obtain insights into the essential structures and the essential relationships of these phenomena on the basis of a careful study of concrete examples supplied by experience or imagination and by a systematic variation of these examples in imagination. Some Phenomenologists also stress the need for studying the ways in which the phenomena appear in men's object-directed ("intentional") consciousness.

"To the things themselves"

Beyond this merely static aspect of appearance, some also want to investigate its genetic aspect, exploring, for instance, how the phenomenon intended—for example, a book—shapes ("constitutes") itself in the typical unfolding of experience. Husserl himself believed that such studies require a previous suspension of belief in the reality of these phenomena, whereas others consider it not indispensable but helpful. Finally, in existential Phenomenology, the meanings of certain phenomena (such as anxiety) are explored by a special interpretive ("hermeneutic") Phenomenology, the methodology of which needs further clarification.

Contrasts with related movements. It may also be helpful to bring out the distinctive essence of Phenomenology by confronting it with some of its philosophical neighbours. In contrast to Positivism and to traditional Empiricism, from which Husserl's teacher at Vienna, Franz Brentano, had started out and with which Phenomenology shares an unconditional respect for the positive data of experience ("We are the true positivists," Husserl claimed in his *Ideen zu einer reinen Phänomenologie und phänomenologischen Philosophie* [1913; "Ideas for a Pure Phenomenology and Phenomenological Philosophy"]), Phenomenology does not restrict these data to the range of sense experience but admits on equal

terms such non-sensory ("categorial") data as relations and values, as long as they present themselves intuitively. Consequently, Phenomenology does not reject universals; and, in addition to analytic a priori statements, whose predicates are logically contained in the subjects and the truth of which is independent of experience (*e.g.*, "All material bodies have extension"), and the synthetic a posteriori statements, whose subjects do not logically imply the predicate and the truth of which is dependent on experience (*e.g.*, "My shirt is red"), it recognizes knowledge of the synthetic a priori, a proposition whose subject does not logically imply the predicate but one in which the truth is independent of experience (*e.g.*, "Every colour is extended"), based on insight into essential relationships within the empirically given.

In contrast to phenomenalism, a position in the theory of knowledge (epistemology) with which it is often confused, Phenomenology—which is not primarily an epistemological theory—accepts neither the rigid division between appearance and reality nor the narrower view that phenomena are all that there is (sensations or permanent possibilities of sensations). These are questions on which Phenomenology as such keeps an open mind—pointing out, however, that phenomenalism overlooks the complexities of the intentional structure of men's consciousness of the phenomena.

In contrast to a Rationalism that stresses conceptual reasoning at the expense of experience, Phenomenology insists on the intuitive foundation and verification of concepts and especially of all a priori claims; in this sense it is a philosophy from "below," not from "above."

In contrast to an Analytic philosophy that substitutes simplified constructions for the immediately given in all of its complexity and applies "Ockham's razor," Phenomenology resists all transforming reinterpretations of the given, analyzing it for what it is in itself and on its own terms.

Phenomenology shares with Linguistic Analysis a respect for the distinctions between the phenomena reflected in the shades of meaning of ordinary language as a possible starting point for phenomenological analyses. Phenomenologists, however, do not think that the study of ordinary language is a sufficient basis for studying the phenomena, because ordinary language cannot and need not completely reveal the complexity of phenomena.

In contrast to an Existential philosophy that believes that human existence is unfit for phenomenological analysis and description, because it tries to objectify the unobjectifiable, Phenomenology holds that it can and must deal with these phenomena, however cautiously, as well as other intricate phenomena outside the human existence. (H.Sp.)

ORIGIN AND DEVELOPMENT OF HUSSERL'S PHENOMENOLOGY

Husserl's earlier development

Basic principles. Phenomenology was not founded; it grew. Its fountainhead was Edmund Husserl, who held professorships at Göttingen and Freiburg im Breisgau and who wrote *Die Idee der Phänomenologie* (Eng. trans., *The Idea of Phenomenology*, 1964) in 1906. Yet, even for Husserl, the conception of Phenomenology as a new method destined to supply a new foundation for both philosophy and science developed only gradually and kept changing to the very end of his career. Trained as a mathematician, Husserl was attracted to philosophy by Franz Brentano, whose descriptive psychology seemed to offer a solid basis for a scientific philosophy. The concept of intentionality, the directedness of the consciousness toward an object, which is a basic concept in Phenomenology, was already present in Brentano's *Psychologie vom empirischen Standpunkte* (1874): "And thus we can define psychic phenomena by saying that they are those phenomena which, precisely as intentional, contain an object in themselves." Brentano dissociated himself here from Sir William Hamilton, known for his philosophy of the "unconditioned," who had attributed the character of intentionality to the realms of thought and desire only, to the exclusion of that of feeling.

The point of departure of Husserl's investigation is to be found in the treatise *Der Begriff der Zahl* (1887; "The Concept of Number"), which was later expanded into *Philosophie der Arithmetik: Psychologische und logische Untersuchungen* (1891). Numbers are not found ready-made in nature but result from a mental achievement. Here Husserl was preoccupied with the question of how something like the constitution of numbers ever comes about. This treatise is important to Husserl's later development for two reasons: first, because it contains the first traces of the concepts "reflection," "constitution," "description," and the "founding constitution of meaning," concepts that later played a predominant role in Husserl's philosophy; and second, because it reflected two events—(1) a criticism of his book by Gottlob Frege, a seminal thinker in logic, who had charged him with confusing logical and psychological considerations, and (2) Husserl's discovery of the *Wissenschaftslehre* (1837; Eng. trans., *Logic and Scientific Methods*, 1971) by Bernard Bolzano, a Bohemian mathematician, theologian, and social moralist, and his view concerning "truths in themselves"—which led Husserl to an analysis and critical discussion of psychologism, the view that psychology could be used as a foundation for pure logic, which he clearly felt to be no longer possible.

In the first volume of *Logische Untersuchungen* (1900–01; Eng. trans., *Logical Investigations*, 1970), entitled *Prolegomena*, Husserl began with a criticism of psychologism. And yet he continued by conducting a careful investigation of the psychic acts in and through which logical structures are given; these investigations, too, could give the impression of being descriptive psychological investigations, though they were not conceived of in this way by the author. For the issue at stake was the discovery of the essential structure of these acts. Here Brentano's concept of intentionality received a richer and more refined signification. Husserl distinguished between perceptual and categorical intuition and stated that the latter's theme lies in logical relationships. The real concern of Phenomenology was clearly formulated for the first time in his *Logos* article, "Philosophie als strenge Wissenschaft" (1910–11; Eng. trans., *Philosophy as Rigorous Science*, 1965). In this work Husserl wrestled with two unacceptable views: naturalism and historicism.

Anti-naturalism

Naturalism attempts to apply the methods of the natural sciences to all other domains of knowledge, including the realm of consciousness. Reason becomes naturalized. Although an attempt is then made to find a foundation for the human sciences (*Geisteswissenschaften*) by means of experimental psychology, it proves to be impossible, because in so doing one is unable to grasp precisely what is at stake in knowledge as found in the natural sciences.

What a philosopher must examine is the relationship between consciousness and Being; and in doing so, he must realize that from the standpoint of epistemology, Being is accessible to him only as a correlate of conscious acts. He must thus pay careful attention to what occurs in these acts. This can be done only by a science that tries to understand the very essence of consciousness; and this is the task that Phenomenology has set for itself. Because clarification of the various types of objects must follow from the basic modes of consciousness, Husserl's thought remained close to psychology. In contradistinction to what is the case in psychology, however, in Phenomenology, consciousness is thematized in a very special and definite way, viz., just insofar as consciousness is the locus in which every manner of constituting and founding meaning must take place. In man's intuition, conscious occurrences must be given immediately in order to avoid introducing at the same time certain interpretations. The nature of such processes as perception, representation, imagination, judgment, and feeling must be grasped in immediate self-givenness. The call "To the things themselves" is not a demand for realism, because the things at stake are the acts of consciousness and the objective entities that get constituted in them: these things form the realm of what Husserl calls the phenomena.

Thus, the objects of Phenomenology are "absolute data grasped in pure, immanent intuition," and its goal is to discover the essential structures of the acts (*noesis*) and the objective entities that correspond to them (*noema*).

Anti-historicism

On the other hand, Phenomenology must also be distinguished from historicism, a philosophy that stresses the immersion of all thinkers within a particular historical setting. Husserl objected to historicism because it implies relativism. He gave credit to Wilhelm Dilthey, author of "Entwürfe zur Kritik der historischen Vernunft" ("Outlines for the Critique of Historical Reason," in *Gesammelte Schriften,* 12 vol. [1914–36], vol. 5, 6), for having developed a typification of world views, but he doubted and even rejected the skepticism that flows necessarily from the relativity of the various types. History is concerned with facts, whereas Phenomenology deals with the knowledge of essences. To Husserl, Dilthey's doctrine of world views was incapable of achieving the rigour required by genuine science. Contrary to all of the practical tendencies found in world views, Husserl demanded that philosophy be founded as a rigorous science. Its task implies that nothing be accepted as given beforehand but that the philosopher should try to find the way back to the real beginnings. This is tantamount to saying, however, that he must try to find the way to the foundations of meaning that are found in consciousness. Just as for Immanuel Kant the empirical has merely relative validity and never an absolute, or apodictic, validity, so for Husserl, too, what is to be searched for is a scientific knowledge of essences in contradistinction to a scientific knowledge of facts.

Basic method. The basic method of all Phenomenological investigation, as Husserl developed it himself—and on which he worked throughout his entire lifetime—is the "reduction": the existence of the world must be put between brackets, not because the philosopher should doubt it but merely because this existing world is not the very theme of Phenomenology; its theme is rather the manner in which knowledge of the world comes about. The first step of the reduction consists in the phenomenological reduction, through which all that is given is changed into a phenomenon in the sense of that which is known in and by consciousness; for this kind of knowing —which is to be taken in a very broad sense as including every mode of consciousness, such as intuition, recollection, imagination, and judgment—is here all-important. There are several reasons why Husserl gave a privileged position to intuition: among them is the fact that intuition is that act in which a person grasps something immediately in its bodily presence and also that it is a primordially given act upon which all of the rest is to be founded. Furthermore, Husserl's stress on intuition must be understood as a refutation of any merely speculative approach to philosophy.

This reduction reverses—"re-flects"—man's direction of sight from a straightforward orientation toward objects to an orientation toward consciousness.

Eidetic and transcendental reductions

The second step is to be found in the eidetic reduction. To get hold of consciousness is not sufficient; on the contrary, the various acts of consciousness must be made accessible in such a way that their essences—their universal and unchangeable structures—can be grasped. In the eidetic reduction one must forego everything that is factual and merely occurs in this way or that. A means of grasping the essence is the *Wesensschau,* the intuition of essences and essential structures. This is not a mysterious kind of intuition. Rather, one forms a multiplicity of variations of what is given, and while maintaining the multiplicity, one focusses attention on what remains unchanged in the multiplicity; *i.e.,* the essence is that identical something that continuously maintains itself during the process of variation. Husserl, therefore, called it the invariant.

To this point, the discussion of reduction has remained within the realm of psychology, albeit a new—namely, a phenomenological—psychology. The second step must now be completed by a third, the transcendental reduction. It consists in a reversion to the achievements of that consciousness that Husserl, following Kant, called transcendental consciousness, although he conceived of it in his own way. The most fundamental event occurring in this consciousness is the creation of time awareness through the acts of protention (future) and retention (past), which is something like a self-constitution. To do phenomenology was for Husserl tantamount to returning to the transcendental ego as the ground for the foundation and constitution (or making) of all meaning (German *Sinn*). Only when a person has reached this ground can he achieve the insight that makes his comportment transparent in its entirety and makes him understand how meaning comes about, how meaning is based upon meaning like strata in a process of sedimentation.

Husserl worked on the clarification of the transcendental reduction until the very end of his life. It was precisely the further development of the transcendental reduction that led to a division of the Phenomenological movement and to the formation of a school that refused to become involved in this kind of system of problems (see below *Phenomenology of essences*).

Basic concepts. In an effort to express what it is to which this method gives access, Husserl wrote:

Intentionality and constitution theory

> In all pure psychic experiences (in perceiving something, judging about something, willing something, enjoying something, hoping for something, etc.) there is found inherently a being-directed-toward. . . . Experiences are intentional. This being-directed-toward is not just joined to the experience by way of a mere addition, and occasionally as an accidental reaction, as if experiences could be what they are without the intentional relation. With the intentionality of the experiences there announces itself, rather, the essential structure of the purely psychical.

The phenomenological investigator must examine the different forms of intentionality in a reflective attitude because it is precisely in and through the corresponding intentionality that each domain of objects becomes accessible to him. Husserl took as his point of departure mathematical entities and later examined logical structures, in order finally to achieve the insight that each being must be grasped in its correlation to consciousness, because each datum becomes accessible to a person only insofar as it has meaning for him. From this position, regional ontologies, or realms of being, develop: for instance, those dealing with the region of "nature," the region of "the psychic," or the region of "the spirit." Moreover, Husserl distinguished formal ontologies—such as the region of the logical—from material ontologies.

In order to be able to investigate a regional ontology, it is first necessary to discover and examine the founding act by which realities in this realm are constituted. For Husserl, constitution does not mean the creation or fabrication of a thing or object by a subject; it means the founding constitution of its meaning. There is meaning only for consciousness. All founding constitution of meaning is made possible by transcendental consciousness. Speaking of this transcendental motif, Husserl wrote:

> It is the motif of questioning back to the last source of all achievements of knowledge, of reflection in which the knower reflects on himself and his knowing life, in which all the scientific constructs which have validity for him, occur teleologically, and as permanent acquisitions are kept and become freely available to him.

In the realm of such transcendental problems, it is necessary to examine how all of the categories in and through which one understands mundane beings or purely formal entities originate from specific modes of consciousness. In Husserl's view, the temporalization must be conceived as a kind of primordial constitution of transcendental consciousness itself.

Understood in this way, Phenomenology does not place itself outside the sciences but, rather, attempts to make understandable what takes place in the various sciences and, thus, to thematize the unquestioned presuppositions of the sciences.

Husserl's notion of the life-world

In his last publication, *Die Krisis der europäischen Wissenschaften und die transzendentale Phänomenologie: Einee Einleitung in die phänomenologische Philosophie* (1936; Eng. trans., *The Crisis of European Sciences and Transcendental Phenomenology,* 1970), Husserl arrived at the life-world—the world as shaped within the immediate experience of each man—by questioning back to the foundations that the sciences presuppose. In *Die Krisis* he analyzed the grounds that had led to the European crisis of culture and philosophy, which found its

immediate expression in the contrast between the great successes of the sciences of nature and the failure of the sciences of man. In the modern era, scientific knowledge had become fragmented into an objectivistic–physicalist and a transcendental knowledge. Until recently this split could not be overcome. It led, rather, to the attempt to develop the sciences of man in accordance with the procedures used in the exact sciences of nature (naturalism) —an attempt doomed to failure. In opposition to this attempt, Husserl wished to show that in the new approach one must reflect on the activities of the scientists.

> As the immediately given world, this merely subjective world, was forgotten in the scientific thematization, the accomplishing subject, too, was forgotten and the scientist himself was not thematized.

Husserl demonstrated this point by using the example of Galileo and his mathematization of our world. The truth characteristic of the life-world is by no means an inferior form of truth when compared to the exact, scientific truth but is, rather, always a truth already presupposed in all scientific research. That is why Husserl claimed that an ontology of the life-world must be developed—*i.e.*, a systematic analysis of the constitutive achievements the result of which is the life-world, a life-world that, in turn, is the foundation of all scientific constitutions of meaning. The stimulating change that occurred here consists in the fact that truth is no longer measured after the criterion of an exact determination. For what is decisive is not the exactness but, rather, the part played by the founding act.

It is in this connection that, rather abruptly, historicity, too, became relevant for Husserl. He began to reflect upon the emergence of philosophy among the Greeks and on its significance as a new mode of scientific knowledge oriented toward infinity; and he interpreted the philosophy of René Descartes, often called the father of modern philosophy, as the point at which the split into the two research directions—physicalist objectivism and transcendental subjectivism—came about. Phenomenology must overcome this split, he held, and thus help mankind to live according to the demands of reason. In view of the fact that reason is the typical characteristic of man, mankind must find itself again through Phenomenology.

LATER DEVELOPMENTS OF PHENOMENOLOGY

Phenomenology of essences. A different type of Phenomenology, the Phenomenology of essences, developed from a tangential continuation of that of the *Logische Untersuchungen*. Its supporters were Husserl's students in Göttingen and a group of young philosophers in Munich, originally students of Theodor Lipps, a Munich psychologist and philosopher—students who had turned away from Lipp's psychologism and discovered powerful support in Husserl. The Phenomenological movement, which then began to take shape, found its most tangible expression in the publication of the *Jahrbuch für Philosophie und phänomenologische Forschung* (1913–30), a Phenomenological yearbook with Husserl as its main editor, the preface of which defined Phenomenology in terms of a return to intuition (*Anschauung*) and to the essential insights (*Wesenseinsichten*) derived from it as the ultimate foundation of all philosophy.

Fruits of the movement in broader application

The 11 volumes of the *Jahrbuch* contained, in addition to Husserl's own works, the most important fruits of the movement in its broader application. Of the co-editors, Alexander Pfänder contributed chiefly to the development of phenomenological psychology and pure logic but developed also the outlines of a complete Phenomenological philosophy. Moritz Geiger applied the new approach particularly to aesthetics and Adolf Reinach to the philosophy of law. The most original and dynamic of Husserl's early associates, however, was Max Scheler, who had joined the Munich group and who did his major Phenomenological work on problems of value and obligation. A Polish philosopher, Roman Ingarden, did major work in structural ontology and analyzed the structures of various works of art in its light; Hedwig Conrad-Martius, a cosmic Realist at the University of Munich, worked intensively in the ontology of nature; and others made comparable contributions in other fields of philosophy. None of these early Phenomenologists, however, followed Husserl's road to transcendental Idealism; and some tried to develop a Phenomenology along the lines of Realism.

Heidegger's hermeneutic Phenomenology. Martin Heidegger, one of Germany's foremost philosophers at the middle of the 20th century, was inspired to philosophy through Brentano's work *Von der mannigfachen Bedeutung des Seienden nach Aristoteles* (1862; "On the Multifarious Meaning of Being According to Aristotle"). While he was still studying theology, from 1910 to 1911, Heidegger encountered Husserl's *Logische Untersuchungen*. From then on he pursued the course of Phenomenology with the greatest interest, and from 1916 he belonged to the narrow circle of students and followers of the movement. The typical character of the Phenomenological intuition was at that time the focus of Husserl's seminar exercises. To be sure, there appeared very early a difference between Husserl and Heidegger. Discussing and absorbing the works of the important philosophers in the history of metaphysics was, for Heidegger, an indispensable task, whereas Husserl repeatedly stressed the significance of a radically new beginning and—with few exceptions (among them Descartes, Locke, Hume, and Kant)—wished to bracket the history of philosophy.

Heidegger's basic work, *Sein und Zeit* (1927; Eng. trans., *Being and Time,* 1962), which was dedicated to Husserl, strongly acknowledged that its author was indebted to Phenomenology. In it, Phenomenology was understood as a methodological concept—a concept that was conceived by Heidegger in an original way and resulted from his questioning back to the meanings of the Greek concepts of *phainomenon* and *logos*. *Phainomenon* is "that which shows itself from itself," but together with the concept of *logos*, it means "to let that which shows itself be seen from itself in the very way in which it shows itself from itself." This conception of Phenomenology, which relied more on Aristotle than on Husserl, constituted a change that was later to lead to an estrangement between Husserl and Heidegger. For in *Sein und Zeit* there is no longer a phenomenological reduction, a transcendental ego, or an intuition of essences in Husserl's sense. Heidegger's new beginning was, at the same time, a resumption of the basic question of philosophy: that concerning the meaning (*Sinn*) of Being. His manner of questioning can be defined as hermeneutical in that it proceeds from the interpretation of man's situation. What he thematized is, thus, the explanation of what is already understood.

Heidegger's return to ontology

At the heart of *Sein und Zeit* lies Heidegger's analysis of the one (the man) who asks the question—who is capable of asking the question—concerning Being, who precisely through this capability occupies a privileged position in regard to all other beings, viz., that of *Dasein* (literally, "being there"). By conceiving of *Dasein* as being-in-the-world, Heidegger made the ancient problem concerning the relationship between subject and object superfluous. The basic structures of *Dasein* are primordial moodness (*Befindlichkeit*), understanding (*Verstehen*), and logos (*Rede*). These structures are, in turn, founded in the temporalization of *Dasein*, from which future, having-been (past), and present originate. The two basic possibilities of man's existing (from the Latin *ex* and *sistere*, "standing out from") are those in which *Dasein* either comes to its self (called authenticity) or loses itself (called inauthenticity); *Dasein* is inauthentic, for example, when it lets the possibilities of the choice for its own "ek-sisting" be given to it by others instead of deciding for itself. Heidegger's concept of care (*Sorge, cura*) has nothing to do with distress (*Bekümmernis*) but includes the unity of the articulated moments of man's being-in-the-world.

The hermeneutic character of Heidegger's thought manifested itself also in his interpretation of poetry, in which he discovered a congenial spirit in Friedrich Hölderlin, one of Germany's greater poets, of whose poetry he inaugurated a completely new interpretation; but it manifested itself equally well in his interpretation of metaphysics,

which Heidegger tried to envision as an occurrence determined by the forgottenness of Being, an occurrence in the centre of which man finds himself and of which the clearest manifestation is to be found in "technicity," the attempt of modern man to dominate the earth by controlling beings that are considered as objects.

The concept of transcendental consciousness, which was central for Husserl, is not found in Heidegger—which clearly shows how Heidegger, in *Sein und Zeit*, had already dissociated himself from Husserl's Phenomenology.

Other developments. Eugen Fink, for several years Husserl's collaborator, whose essay "Die phänomenologische Philosophie Edmund Husserls in der gegenwärtigen Kritik" (1933) led to a radicalization of Husserl's philosophical, transcendental Idealism, later turned in another direction, one that approached Heidegger's position and divorced itself at the same time from that of Husserl.

Ludwig Landgrebe, who was Husserl's personal assistant for many years, published in 1938 *Erfahrung und Urteil* ("Experience and Judgment"), the first of Husserl's posthumous works devoted to the genealogy of logic. Among German-language scholars, Landgrebe remained closest to Husserl's original views and has developed them consistently in several works.

DISSEMINATION OF PHENOMENOLOGY

Phenomenology in various countries. Following upon the work of Husserl, Phenomenology spread into a worldwide movement.

In France. One of the first French authors to become familiar with Husserl's philosophy was Emmanuel Lévinas, a pluralistic Personalist, who combined ideas from Husserl and Heidegger in a very personal way. Similarly, Jean-Paul Sartre, the leading Existentialist of France, took his point of departure from the philosophies of Husserl and Heidegger. His first works, *L'Imagination* (1936; Eng. trans., *Imagination: A Psychological Critique*, 1962) and *L'Imaginaire: Psychologie phénoménologique de l'imagination* (1940; Eng. trans., *The Psychology of Imagination*, 1950), remain completely within the context of Husserl's analyses of consciousness. Sartre explains the distinction between perceptual and imaginative consciousness with the help of Husserl's concept of intentionality, and he frequently employs the method of ideation (*Wesensschau*).

Jean-Paul Sartre's use of the method

In *L'Etre et le néant* (1943; Eng. trans., *Being and Nothingness*, 1956), an essay on Phenomenological ontology, it is obvious that Sartre borrowed from Heidegger. Some passages from Heidegger's *Was ist Metaphysik?* (1929; Eng. trans., *What is Metaphysics?*, 1949), in fact, are copied literally. The meaning of nothingness, which Heidegger in this lecture made the theme of his investigations, became for Sartre the guiding question. Sartre departs from Heidegger's analytic of *Dasein* and introduces the position of consciousness (which Heidegger had overcome).

The distinction between being-in-itself (*en-soi*) and being-for-itself (*pour-soi*) pervades the entire investigation. The in-itself is the opaque, matter-like substance that remains the same, whereas the for-itself is consciousness permeated by nothingness. The influence of the Idealist G.W.F. Hegel becomes apparent when the author tries to interpret everything in a dialectical way; *i.e.*, through a tension of opposites. The dialectic of men's being-with-one-another is central: thus, seeing and being-seen correspond to dominating and being-dominated. The basic characteristic of being-for-itself is bad faith (*mauvaise foi*), which cannot be overcome because facticity (being-already) and transcendence (being-able-to-be) cannot be combined.

The Phenomenological character of Sartre's analyses of consciousness consists in the way in which he elucidates certain modes of behaviour: love, hatred, sadism, masochism, and indifference. Although Sartre sees and describes these forms of behaviour strikingly and precisely, he limits himself to those modes that fit his philosophical interpretation. The significance of psychology, recognized by Husserl, emerges again in Sartre and leads to a demand for an Existential psychoanalysis.

Sartre's definition of man as a being of possibilities that finds or loses itself in the choice that it makes in regard to itself refers to Heidegger's definition of *Dasein* as a being that has to materialize itself. For Sartre, freedom is the basic characteristic of man; thus Sartre belongs to the tradition of the great French moralist philosophers.

In his later works, as in his *Critique de la raison dialectique* (1960; Eng. trans., *Search for a Method*, 1963), Sartre turned to Marxism, though he developed a method of understanding that was influenced by hermeneutics. Here the choice made by the individual is limited by social and psychological conditions. Sartre's outstanding two-volume interpretation of Flaubert, *L'Idiot de la famille; Gustave Flaubert de 1821–1857* (1971), is an example of this new method of understanding and interpretation, which combines Marxist elements with interpretations of a highly personal nature taken from depth psychology.

The Phenomenology of Maurice Merleau-Ponty

Maurice Merleau-Ponty (died 1961), who, together with Sartre and his associate Simone de Beauvoir, a writer and novelist, was an important representative of French Existentialism, was at the same time the most important French Phenomenologist. His works, *La Structure du comportement* (1942; Eng. trans., *Structure of Behaviour*, 1963) and *Phénoménologie de la perception* (1945; Eng. trans., *Phenomenology of Perception*, 1962), were the most original further developments and applications of Phenomenology to come from France. Merleau-Ponty gave a new interpretation of the meaning of the human body from the viewpoint of Phenomenology and, connected with this, of man's perception of space, the natural world, temporality, and freedom.

Starting from Husserl's later phenomenology of the life-world, Merleau-Ponty anchored the phenomena of perception in the phenomenology of the lived body (the body as it is experienced and experiences), in which the perceiving subject is incarnated as the mediating link to the phenomenal world. Such a phenomenology of human "presence" in the world was also to offer an alternative to the rigid dichotomy between Idealism and Realism, in which consciousness and world could be reciprocally related. Phenomenology thus became a way of showing the essential involvement of human existence in the world, starting with everyday perception.

Although it is true that Merleau-Ponty was originally close to Husserl in his thought, he later developed noticeably in the direction of Heidegger, a change that became particularly manifest in *L'Oeil et l'esprit* (1964; "The Eye and the Spirit").

Paul Ricoeur, a student of the volitional experience, whose translation of Husserl's *Ideen zu einer reinen Phänomenologie* brought Husserl closer to the younger French generation, writes in a Phenomenological vein but with the intention of further developing Husserl's conception of Phenomenology. Ricoeur's two-volume *Philosophie de la volonté* (1950–60; "Philosophy of the Will") also deals with the problems involved in the theological concept of guilt.

Suzanne Bachelard, who in 1957 translated Husserl's *Formale und transzendentale Logik: Versuch einer Kritik der logischen Vernunft*, has pointed to the significance of Husserl for modern logic; and Jacques Derrida, an original French thinker on the limits of thought and language, has combined Phenomenology and Structuralism in his interpretation of literature.

Husserl scholarship at Cologne and Louvain

In Germany. After World War II, interest in Phenomenology sprang up again in its own homeland. The influence of Ludwig Landgrebe in Cologne has been particularly felt, as have the activities of the Husserl Archives in Cologne, with editions by Walter Biemel, who also published *Philosophische Analysen zur Kunst der Gegenwart* (1968; "Philosophical Analyses of Contemporary Art") and essays on the relationships between Husserl and Heidegger. The circle around Gerhard Funke in Mainz, author of *Phänomenologie—Metaphysik oder Methode?* (1966), has also had a positive influence.

In other European countries. In Belgium, at the Cath-

olic University of Louvain, are located the entire posthumous works of Husserl, as well as his personal library. Thanks to the initiative of H.L. Van Breda, founder of the Husserl Archives, several scholars worked intensively on the manuscripts for several decades. By 1972, 12 volumes of collected works had been published. Van Breda was also the director of the *Phaenomenologica* series —totalling 42 volumes by 1972—in which the most important publications in the field of Phenomenology (taken in a very broad sense) have been published. Thus, mainly through Van Breda's efforts, Louvain has become the most important centre for Phenomenology. Van Breda also organized international colloquia on Phenomenology. The influence of Alphonse de Waelhens, a Belgian philosopher of fresh experience and author of *Phénoménologie et vérité* (1953) and *Existence et signification* (1958), also bears mentioning.

In The Netherlands, Stephan Strasser, who is oriented particularly toward phenomenological psychology, is especially influential. And in Italy, the Phenomenology circle centres around Enzo Paci. The Husserl scholar Jan Patocka, a prominent expert in Phenomenology as well as in the metaphysical tradition, is influential in Czechoslovakia; in Poland, Roman Ingarden has represented the cause of Phenomenology; and there are also important representatives in Yugoslavia, Portugal, England, South America, Japan, and India.

In the United States. In the United States, Phenomenology has lived a rather marginal existence for quite some time, notwithstanding the meritorious journal of *Philosophy and Phenomenological Research* founded by Husserl's student Marvin Farber, who is also the author of *The Foundation of Phenomenology* (1943). In recent years, however, a noticeable change has taken place, chiefly because of the work of two scholars at the New School for Social Research in New York, Alfred Schütz, an Austrian-born sociologist and student of human cognition (died 1959), and Aron Gurwitsch, a Lithuanian-born philosopher. Schütz came early to Phenomenology, developing a social science on phenomenological basis. Gurwitsch, author of *Théorie du champ de la conscience* (1957; Eng. trans., *The Field of Consciousness*, 1964), came to Phenomenology through his study of the Gestalt psychologists Adhemar Gelb and Kurt Goldstein. While in Paris, Gurwitsch influenced Merleau-Ponty. The essays on Phenomenology published by Gurwitsch in the United States are among the best. His comprehensive knowledge ranges from mathematics, via the natural sciences, to psychology and metaphysics. The work *The Phenomenological Movement* (2nd ed. 1965), by Herbert Spiegelberg, an Alsatian–American Phenomenologist, is the movement's first encompassing historical presentation.

The work of Farber, Schütz, and Gurwitsch

Phenomenology in other disciplines. Of greater significance is the role of Phenomenology outside of philosophy proper in stimulating or reinforcing phenomenological tendencies in such fields as mathematics and the biological sciences. Much stronger was its impact on psychology, in which Franz Brentano and the German Carl Stumpf had prepared the ground and in which the U.S. psychologist William James, the Würzburg school, and the Gestalt psychologists had worked along parallel lines. But Phenomenology has probably made its strongest contribution in the field of psychopathology, in which the German Karl Jaspers, a foremost contemporary Existentialist, stressed the importance of phenomenological exploration of a patient's subjective experience. Jaspers was followed by the Swiss Ludwig Binswanger and several others. The Phenomenological strand is also very pronounced in American Existential psychiatry, and has affected sociology, history, and the study of religion.

PROGNOSTICATION

At the turn of the fourth quarter of the 20th century, it remained to be seen whether Phenomenology could make solid contributions to philosophical knowledge. To this end, it needed to develop rigorous standards, which had not always been observed by some of its most brilliant practitioners, such as Max Scheler, and which were likely to be violated in a philosophy the ultimate appeal of which had to be made to intuitive verification. With this proviso, Phenomenology may well be qualified not only to become a bridge for better international communication in philosophy but also to shed new light on philosophical problems old and new, to reclaim for philosophy parts of man's everyday life-world that have been abandoned by science as too private and too subjective, and, finally, to give access to layers of man's experience unprobed in everyday living, thus providing deeper foundations for both science and life.

BIBLIOGRAPHY. Most of the classical works on Phenomenology were written by Husserl himself (see the bibliography of the HUSSERL article). In EDMUND HUSSERL, *Logische Untersuchungen*, 2nd ed., 2 vol. (1913–21; Eng. trans., *Logical Investigations*, 2 vol., 1970), one of the fundamental texts on Phenomenology, the phenomenological method is applied in the area of logic. The following works appeared in the journal *Jahrbuch für Philosophie und phänomenologische Forschung* (1913–30); Husserl's *Ideen zu einer reinen Phänomenologie und phänomenologischen Philosophie* (1913; Eng. trans., *Ideas: General Introduction to Pure Phenomenology*, 1931, reprinted 1969), through which Phenomenology established itself as transcendental philosophy and received worldwide reaction; *Vorlesungen zur Phänomenologie des inneren Zeitbewusstseins* (1928; Eng. trans., *The Phenomenology of Internal Time-Consciousness*, 1964); and *Formale und transzendentale Logik* (1929; Eng. trans., *Formal and Transcendental Logic*, 1969); MAX SCHELER, *Der Formalismus in der Ethik* (1916); and MARTIN HEIDEGGER, *Sein und Zeit* (1927; Eng. trans., *Being and Time*, 1962). The following works appeared in the series *Husserliana* (Husserl's collected works): *Cartesianische Meditationen und Pariser Vorträge* (1950; Eng. trans., *The Paris Lectures*, 1964), which contains the text of the Paris lectures of 1929 and the subsequent elaboration; *Die Idee der Phänomenologie* (1950; Eng. trans., *The Idea of Phenomenology*, 1964), an introduction to Phenomenology in five lectures from 1907; *Ideen*, 3 vol. (1950–52); *Die Krisis der europäischen Wissenschaften und die transzendentale Phänomenologie* (1954; Eng. trans., *The Crisis of European Sciences and Transcendental Phenomenology*, 1970), Husserl's later work (1934–37), significant for the problems regarding the life-world; *Erste Philosophie*, 2 vol. (1956–59), a critical history of ideas and a theory of reduction presented in a series of lectures, 1923–24; *Phänomenologische Psychologie* (1962), lectures from 1925, a different wording of the *Encyclopædia Britannica* article of 1927, with remarks by Heidegger and the Amsterdam addresses of 1925; *Zur Phänomenologie des inneren Zeitbewusstseins* (1966), text on the problem of time from 1893–1917 with lectures (in the middle) from 1905 on the inner time-consciousness (first edited by Heidegger); *Analysen zur passiven Synthesis* (1966), a phenomenological analysis having sensation as its subject matter; and *Philosophie der Arithmetik* (1970), early manuscripts from 1890 to 1901. See also JOSEPH J. KOCKELMANS, *Edmund Husserl's Phenomenological Psychology* (1967); and RUDOLF BOEHM, *Vom Gesichtspunkt der Phänomenologie* (1968).

In the series "Phaenomenologica" works are published that are written from a Phenomenological perspective. HERBERT SPIEGELBERG, *The Phenomenological Movement*, 2nd ed., 2 vol. (1965), worthy of particular mention, also appeared in this series. Since 1904 MARVIN FARBER has edited the journal *Philosophy and Phenomenological Research* (by no means, however, exclusively dedicated to Phenomenology). In England *The Journal of the British Society for Phenomenology* first appeared in 1970. In the United States the following journals have appeared: *Journal of Phenomenological Psychology* (semi-annual); *Research in Phenomenology* (1971); and *Analecta Husserliana: The Yearbook of Phenomenological Research.*

(W.Bi.)

Philadelphia

Philadelphia has been described either as the elegant but rather jaded great lady or as the overage and sickly spinster of American cities. A more realistic portrait of contemporary Philadelphia, however, must show it as a very new and vigorous city, arising in gracious counterpoint to the deep serenity of an older city that, for nearly three centuries, has provided gentle but firm intellectual, economic, and humanitarian direction to the nation at whose birth it played midwife.

An overview of the city

Philadelphia, the fourth-largest city in the United States and largest in Pennsylvania, displays many characteris-

tics of a small town. Its many trees, parks, and other open spaces and its quiet pace of life reflect in many ways the genteel Quaker heritage bestowed on the city by its founder, William Penn. Nearly everywhere are dignified reminders of the colonial and Revolutionary city and of Benjamin Franklin, a Philadelphian by adoption, who left his imprint on innumerable ongoing institutions, both cultural and commercial, in the city.

Beneath this facade, however, Philadelphia represents a physical presence of national and international stature. Though the population of the city proper slid to below 2,000,000 during the 1960s, it is the focus of more than 2,750,000 other persons in five counties in eastern Pennsylvania and three in neighbouring New Jersey. Its harbour, the largest freshwater port in the world, is the major element in the official agglomeration of Delaware River ports known as Ameriport, collectively the third-busiest shipping centre in the world. The enormous industrial production of the city and the surrounding metropolitan area, at least half of it representing products unknown as recently as 1945, represents a continuation of Philadelphia's early leadership in the Industrial Revolution and in American commerce and finance generally. Lying in the midst of the vast urban community stretching down the Atlantic Seaboard, the Philadelphia of the 1970s is an integral part of the turbulent fabric of contemporary social and economic life as well as a tranquil oasis joining together the spirit of America, past and present. (For information on related topics, see the articles PENNSYLVANIA; UNITED STATES, HISTORY OF THE.)

THE GROWTH OF THE METROPOLIS

Penn's plan

The founding ideals. William Penn acquired the province of Pennsylvania in 1681 from King Charles II of England as a place where his fellow Quakers could enjoy freedom of worship and a chance to govern themselves and develop their own way of life. The King made the grant, signing it on March 4, 1681, and proclaiming it the following April 2, partly to settle a debt owed to Penn's father, Admiral Sir William Penn, upon his death and also to complete the settlement of this Middle Atlantic region with Englishmen. Penn sent his cousin William Markham to take charge of affairs of government and also to lay out the city Penn named Philadelphia, city of "brotherly love," the name betokening his idealistic concepts. From England, Penn wrote in 1681 asking that "the Rivers and Creeks be sounded on my side of the Delaware River . . . in order to settle a great Towne, and be sure to make your choice where it is most navigable, high, dry, and healthy." He wanted every house to be placed in the middle of its own plot to provide ground about it "that it may be a greene Country Towne, which will never be burnt, and always be wholesome."

Penn had little chance to enjoy his city. He was forced to return to England in 1684 and was unable to return until 1699. By then, Philadelphia was a flourishing town with many shops and trading houses, as well as several hundred dwellings and some 10,000 people clustered close to the riverfront. Penn's governor declared the city already was the equal of New York "in trade and riches." Penn's policies throughout the colony of religious toleration and the right of the people to take part in the government, in addition to growing prosperity, soon began to attract thousands of English, Germans, and Scots-Irish settlers, and they all came by way of Philadelphia. Most of this immigration moved into the interior and, by 1770, even west of the Allegheny Mountains. This created new sources of farm, forest, and mineral wealth that Philadelphia could tap to add to its prosperity.

Economic growth. Philadelphia by the 1770s had grown to at least 30,000 persons in the central city, and it was the third most important business centre in the British Empire, overshadowed only by Liverpool and London. This position was due in large measure to the city's site at the confluence of the Delaware and Schuylkill rivers, which provided the city access to inland farm regions and to the coal and ore resources that supplied the early iron industry.

A visitor in 1756 wrote that "Everybody in Philadelphia deals more or less in trade," a tribute not merely to Philadelphia's location but also to the shrewd business talents of the Quaker merchants. A large and profitable system of triangular trade involved foodstuffs and wood products, such as lumber and barrel staves, that went from Philadelphia to the West Indies and there were exchanged for sugar, rum, and other West Indian products. These were carried to English ports, where they in turn were exchanged for English manufactures to be brought back to Philadelphia. The prosperous farm country of interior Pennsylvania supplied the Philadelphia merchant with his goods for the West Indies, and a profitable coastal trade existed with other colonies and directly with England. By the 1750s, Philadelphians had invested heavily in the flourishing charcoal–iron industry. Anthracite coal became a great new mineral resource of Pennsylvania 100 years later, and Philadelphia capital played a leading part in this industry as well as in the mining of bituminous coal farther to the west. Philadelphia continued its leadership in foreign commerce until about 1810, when New York, with an even more advantageous location, took over this position. It did not surrender its position as financial capital of the nation, however, until the 1880s.

Philadelphia's leadership in commerce and culture

Shipyards had flourished along the Delaware since colonial days. Most of what came to the city was raw material for manufacture, and Philadelphia became a major centre of the early Industrial Revolution in the United States. In 1785 Oliver Evans invented the first grist mill operated entirely by mechanical power. The city was a pioneer in textile manufacturing and took the raw iron from inland furnaces and made it into tools and implements, such as saws, huge iron castings for cotton-mill machinery, and the first American-built steam locomotives. By 1860 the value of Philadelphia's manufactures ran into several hundred million dollars, about 30 percent of the national total. Textiles, ships, iron products, leather, refined sugar, and boots and shoes were leaders, giving important aid to the Union in the Civil War.

Cultural dominion. Prosperity was translated into personal and community wealth, and it was natural that Philadelphia should assume early leadership in the arts, in science, and in culture. The young Benjamin Franklin came from Boston to become a great American leader in scientific and intellectual affairs. Philadelphia had the nation's first free library, its first hospital, and its first learned society, the American Philosophical Society—all founded by Franklin. Along with Franklin, there were men such as Benjamin Rush, the great physician, and David Rittenhouse, a paper manufacturer and early Philadelphia aristocrat, and many others. The city excelled in printing and publishing: by 1776 there were 23 printers and newspapers with circulations of from 500 to 3,000 copies. Fine private and public buildings were erected. One of them was Andrew Hamilton's Independence Hall, originally—and still—better known by Philadelphians as "the statehouse." Led by Benjamin West, Charles Willson Peale, and Gilbert Stuart, oil painting flourished in the colonial and Federal periods.

This leadership in commerce, thought, and culture, as well as its central location, brought to Philadelphia the delegates who formed the First Continental Congress in 1774 and a year later the Second Continental Congress, which proclaimed the Declaration of Independence and governed throughout the Revolution. The Constitutional Convention met in Philadelphia in 1787 and framed the federal Constitution, and the city served as the capital of the United States from 1790 to 1800. The nation celebrated its centennial in Philadelphia in 1876.

Political evolution. In the decades just before and following the Civil War, Pennsylvania fell into the hands of Philadelphia-based Republican political machines that, like their counterparts (usually Democratic) in other cities, were becoming increasingly sophisticated in methods of manipulating the political processes, especially through the newer immigrant groups, and profiting from the economic life of the state and city. They were instrumental in electing governors and U.S. senators, and, in the Depression years of the 1930s, the hard-hit city re-

Political machines and civic malaise

fused aid from the Democratic administration in Washington, D.C. Powerful bankers and industrial and business leaders, living for the most part outside the city, favoured this form of government because it kept taxes low, imposed little or no regulation on business, and maintained an aura of social calm through benign neglect or quiet but forceful repression.

About 1900 Philadelphia had been described as "corrupt but content," a status quo that Philadelphians were indeed content with until 1939, when a group known as the Young Turks and influenced by the nationwide New Deal of the Democratic Party began to agitate for charter reform and a city planning commission. Women and blacks were brought into the city's political life for the first time. In spite of continued machine domination of the city, the group began to realize its goals—with a "Better Philadelphia Exhibition" in 1947, a coalition of top business and financial leaders the following year, and a new charter in 1951. The election in 1952 of Joseph S. Clark as mayor signalled the moment for a new Philadelphia to leap off the drawing boards.

THE CONTEMPORARY CITY

Present-day Philadelphia spreads over about 128½ square miles (333 square kilometres) from the Delaware on the east across Schuylkill and beyond. The coterminous boundaries of Philadelphia city and county remain essentially as defined by the Consolidation Act of 1854.

The city and its people. *Physical layout.* The gridiron of streets in central Philadelphia, the first U.S. city to be so arranged, follows the original plans of William Penn. Midway between the two rivers, Penn Square, occupied by City Hall, is the centre of the plan. Four shady, fountained squares—Logan, Franklin, Washington, and Rittenhouse—are placed in each quadrant. Westward from Penn Square along John F. Kennedy Boulevard is the new Penn Center, a prime symbol of rejuvenated Philadelphia since the 1950s. The multilevel complex comprises high-rise offices and hotels, with interior courts and malls and underground walkways lined with shops and restaurants.

Benjamin Franklin Parkway provides a splendid vista as it cuts diagonally northwestward from Penn Square through the grid, encircling Logan Square and leading into Fairmount Park. The nation's largest landscaped park within city limits and the centre of the Centennial Exposition of 1876, Fairmount is one of the most frequent foregrounds for photographs of Philadelphia's skyline, adding to the city's reputation for shaded, sculpted elegance. Once a section of outlying estates of the wealthy, the park contains many fine old mansions maintained by the city as museums. Through it winds the narrow valley of Wissahickon Creek, whose rugged beauty has inspired generations of poets and painters.

Historic preservations and restorations

The oldest sections of Philadelphia—Southwark, Society Hill, and the Independence Hall area—lie to the east, along and inland from the Delaware. Southwark is the oldest, having been settled by Swedes in 1643. Those of its ancient and dilapidated houses that have escaped bulldozing for riverfront expressways resemble the edifices of Society Hill before its restoration in the 1950s. This latter area contains some of the city's finest old houses, taverns, and churches, though some high-rise apartment buildings, here as elsewhere, strike a dissonant note in the hearts of many Philadelphians.

Independence National Park, established in 1951, contains not only the hall itself with its famous Liberty Bell but also many other buildings used by the Revolutionary and early federal governments. Nearby, Elfreth's Alley, dating from 1690, contains 33 houses that make up the oldest continuously inhabited street in America. Included in the complex are Carpenters' Hall, site of the meeting of the First Continental Congress, and Philosophical Hall, home of the American Philosophical Society.

Throughout these areas and elsewhere, domestic architecture is characterized primarily by two- and three-story red-brick structures fronting directly on the sidewalks and containing impressive examples of colonial design both outside and inside. The Philadelphia Historical Commission has certified about 75 restored buildings predating 1800. Restoration of the old but habitable has been more characteristic than wholesale demolition and rebuilding throughout most of the city. Even in its downtown section, Philadelphia continues to be a city of shops rather than of huge merchandising outlets. It has nothing approaching New York's Fifth Avenue as a street of large stores. Chestnut Street is an attractive street of shops but has only two department stores. Pine and other streets are noted for such specialties as antique shops. Major features of the skyline are the massive contours of the city's many banking and financial institutions. Overall, downtown Philadelphia has about 350 office buildings.

The long stretches of Philadelphia north, south, and west of the intersection of Broad and Chestnut streets, a "city hub" of sorts just below Penn Square, contain numerous distinctive sections, often identified for generations with various ethnic groups that have filled the city during its long history. Among the more interesting is the Germantown section of North Philadelphia, settled in Penn's time by Germans and the home in the 18th century of wealthy Philadelphians fleeing the periodic yellow-fever epidemics of the riverside city. Much of North Philadelphia comprises a massive black and Puerto Rican ghetto. South Philadelphia contains notable Italian and other sections settled by European immigrants mainly in the 19th century.

The Philadelphians. Though Philadelphia has had most of the characteristics of an ethnic and racial pot nearly from its start, it lacks the steaming hurly-burly visible everywhere in its behemoth neighbour, New York, some 90 miles northeast. The Philadelphians by and large are not a street people, and their orientation has been so traditionally toward the home that the city became known as a "city of homes." Philadelphians are also great joiners, giving the city more social and other clubs than any other in America. Many of these are based in ethnic neighbourhoods, others are city wide, and still others serve the affluent "Main Liners" who reside in the plush suburbs that grew up in past centuries along the main line of the Pennsylvania (now Penn Central) Railroad.

Quaker tradition and ethnic mix

Much of this tradition dates from Philadelphia's early years, from the beliefs and attitudes not only of the Quakers but also of such German pietist sects as the Mennonites, who stressed personal religious experience rather than institutionalized formulations. A basic sobriety underlying these tenets led to many stringent laws that remain in both city and state. On the other hand, these groups strove for tolerance in all matters. Pennsylvania was among the few colonies admitting Catholics and Jews, and the Quakers long were leaders in seeking justice and the alleviation of inhumanity in racial and other human relations. Philadelphia still has innumerable small, endowed charities of Quaker origin to provide the poor with coal or food—as well as one of the oldest and strongest municipal commissions on human relations.

In ethnic mix, these early Protestant sects were challenged increasingly during the 1800s by Catholics of Irish, German, Polish, Slavic, and Italian origin. In 1840 the municipal tranquillity was jarred by anti-Catholic, nativist riots. By the early 1970s more than one-third of the Philadelphians and well over one-half the public-school population was black. The suburbs, by contrast, are almost 95 percent white. Problems of substandard and insufficient housing, delinquency, public health, crime, drug abuse, and other ills, by no means confined to the ghettoes, have somewhat dimmed the city's image. Efforts at public housing date back to 1937. Other municipal and federal bodies have continued efforts at urban renewal for both blacks and poor whites, usually following the pattern of rehabilitating neighbourhoods rather than razing them. Unusual is the fact that nearly 40 percent of the black families own their homes.

For many Philadelphians, a serious new problem was created during the late 1960s by the increasing militancy of many young blacks. This led in 1971 to signs of a backlash in the election as mayor of a tough law and order oriented former police commissioner; his support was surprisingly large, however, within the black community, in which there was fear of militant action.

Central Philadelphia and (inset) its metropolitan area.

An economic overview

The city's economy. More than 150 of Philadelphia's business enterprises were established in the 1700s, but the city's economy has changed greatly in recent decades. Such old and once-dominant industries as textile mills met stiff competition from the South. Industry was given a boost by World War II but began to decline later; thousands of jobs were lost in the 1960s. Nonmanufacturing and service industries, however, continued to increase employment into the 1970s. Although such old industries as textiles were declining, new industries, such as electrical products and appliances, grew. The area was a centre for phonograph and record making, along with radio and television set manufacturers. Apparel, food and food products, printing and publishing, and electrical machinery are leaders in manufacturing. A decline was evident also in the migrating of both people and business from the city to the suburbs. The Valley Forge area became a nest of business and industrial locations. Much of this planning and relocation is under the sponsorship of the public Philadelphia Industrial Development Corporation.

Research facilities. George Washington approved the first U.S. patent in 1790, to a Philadelphian named Samuel Hopkins for a better way of making potash. In today's economy, research and invention are keys to progress. In West Philadelphia is located the University City Science Center and Institute, a nonprofit project of over 20 universities and colleges with a multimillion-dollar commitment to research. General Electric, E.I. du Pont de Nemours & Company, Westinghouse, Monsanto Chemicals, Rohm and Haas, and the Philadelphia Electric Company are other large companies with extensive research programs within the metropolitan area. American Viscose, at Marcus Hook, is the world's largest producer of rayon. U.S. Steel's Fairless plant, on the Delaware at Morrisville, is the largest integrated steel plant built at one time. The area is a centre for research on and refining of petroleum. The computer age was born out of experiments at the University of Pennsylvania, where the first electronic computer was operated in 1945. More than 60 percent of the output of the Campbell Soup Company, at Camden, are foods newly developed in the last decade. A unit of Boeing Company, at Eddystone, is the most advanced helicopter research and design plant in the world.

Financial institutions. From its early days until about 1880, Philadelphia was the financial capital of the United States but lost this position to New York. It was the birthplace of American banking, and the first building and loan association was founded there. The city continues to be a major centre of banking, with its financial institutions remaining the oldest and among the most prosperous in the nation. Philadelphia also supplies the stock and exchange services demanded by modern business. The Philadelphia Commercial Exchange was set up in 1868 as an outgrowth of the older Corn Exchange Association of 1863 to regulate the then-flourishing grain and flour trade. The Philadelphia Bourse was organized in 1891, and the Maritime Exchange was founded in 1875. All three agencies are now housed in the Bourse Building. Philadelphia had the oldest stock exchange in the U.S., founded in 1790. The Philadelphia–Baltimore–Washington Stock Exchange was joined by Pittsburgh in 1969.

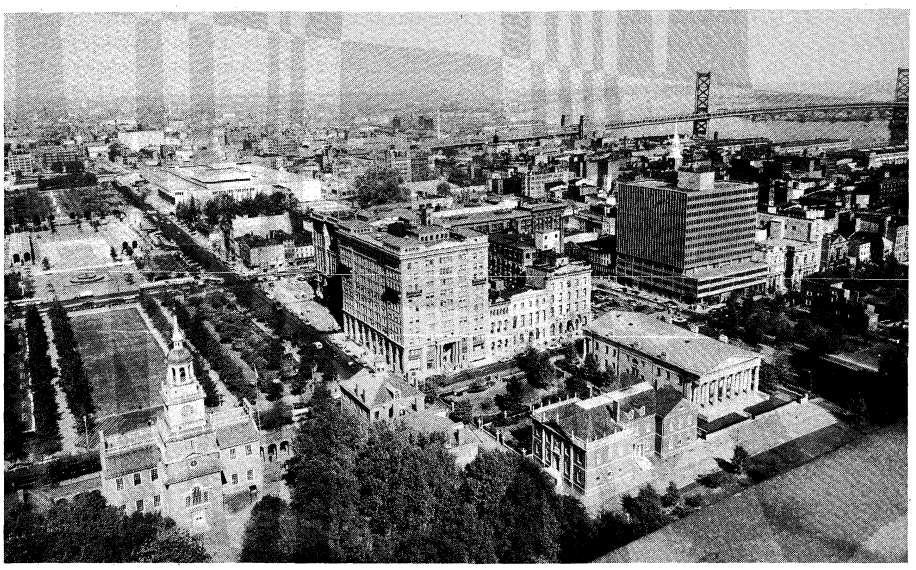
Government and municipal rejuvenation. The city–county consolidation in 1854 was a result of the inability of a colonial-type government by committees to adapt to the needs of a growing city for new public services; *e.g.*, better streets, police, transportation, sanitation, and schools. Ironically, Philadelphia had, in fact, led most cities in providing urban improvements, but they were too few and too slow, and the breakdown of law and order in the 1840s forced changes. Until the early 1950s the standard type of U.S. city government prevailed in Philadelphia, comprising an elected mayor and a city council elected from among candidates presented by the political parties in the political divisions, or wards. As in other large cities, this form was subject to pressures for special favours, such as street-railway franchises and public-works contracts; bribery and corruption were both inevitable and rampant.

The Greater Philadelphia Movement

The reform movement that began in 1939 was joined in 1948 by top business and financial leaders, who organized the Greater Philadelphia Movement, and together they took up the battle for an entirely new city charter. This document effectively removed the city council from its administrative role and increased the staff and powers of the mayor. A strong civil-service commission improved professional employment. The council, seven of whose members were elected by all the voters and ten by districts, was to review and approve taxes and budgets and enact ordinances. Philadelphia now had the first modern big-city charter in the United States; its approval by a 2 to 1 popular vote made it an expression of the desire of Philadelphians for better, more efficient, and honest city government.

The first mayors under the new charter were Joseph S. Clark and Richardson Dilworth, men devoted to making it work. From wealthy Republican families, both were lawyers who had revolted against the corruption and inefficiency of city government and had become Democrats. Men of the highest qualifications were selected for key positions, planning was made a virtue, and a $150,000,000 plan was launched at once for improvements in sewage and sanitation, playgrounds, lighting and streets, police and fire protection, and other basic services long neglected. The ambitious plan for a Penn Center involved removal of the old Pennsylvania Railroad "Chinese Wall" of overhead tracks that ran into the heart of the city at Broad Street and replacing it and Broad Street Station.

Renewal planning gave close attention to the need for better housing: the Philadelphia Housing Authority and the Philadelphia Redevelopment Authority, with federal and private aid, approached Philadelphia's housing in terms of improving neighbourhoods rather than total clearance followed by new high-rise apartments.



The preservation and restoration of the Independence Hall area was begun in cooperation with the National Park Service, and the restoration of neighbouring Society Hill was put in motion. This was not new housing for the poor but an effort that bore fruit to attract people in higher income brackets to restore or build houses in this historic inner-city district. Plans for improvement of the historic waterfront as a Penn's Landing area were launched.

Much of the work of the new city government is carried out through such housing redevelopment, parking, and other authorities. The Old Philadelphia Development Corporation was organized in 1956 as a quasi-public and private body to aid the new development plans. Proposals for Franklin Town, a development of housing and offices on a 50-acre tract north of the Benjamin Franklin Parkway, were launched in 1971. As in other similar undertakings, private enterprise was made an integral part of the project.

Public services. In 1970, more than 35,000 persons were on the municipal payroll, exclusive of the independent public-school unit. The largest single group was the police, who gave Philadelphia one of the best records of any American city in the reported crime rate. Street maintenance, fire protection, water supply, and recreation followed in number employed.

Though the Philadelphia metropolitan area has a per capita income that is the highest of any such area in the state, a large percentage of Philadelphians live below the poverty level. City, state, and federal agencies administer a full range of ameliorative social-service programs. The Philadelphia General Hospital cares for the indigent, and a department of public health operates a variety of services through ten health districts. With its Quaker tradition, Philadelphia is famous for its humanitarian concern and has a great variety of privately supported child-care, hospital, and other social services.

Transportation. A complex system of public and private trolley and bus lines was consolidated in 1963 by the state legislature's creation of the Southeastern Pennsylvania Transportation Authority (SEPTA) to plan, develop, and coordinate a regional transportation system in five southeastern counties and to fund projects by the sale

Philadelphia, with Independence Hall, Library Hall, and the Second Bank of the U.S. in the foreground. In the rear are the low-lying U.S. Mint on the left and the Benjamin Franklin Bridge.
H. Armstrong Roberts

of bonds. This system also contracts with the Reading and Penn Central railroads to service 12 radial commuter lines. Express buses provide rapid service between the inner and outer city.

A joint New Jersey–Pennsylvania commission operates five toll and 13 free bridges over the Delaware. The Schuylkill is bridged at a number of points and has a subway tunnel. The New Jersey–Pennsylvania–Delaware port authority administers Ameriport and the Benjamin Franklin and Walt Whitman bridges over the Delaware, the latter, with approaches, six miles in length. In the 1960s and early 1970s, it has carried out major improvement and expansion programs throughout the entire port area. Philadelphia International Airport, less than seven miles from the city centre, provides good nationwide and increasing numbers of international flights.

Food supply. The unique Food Distribution Center, a nonprofit corporation managed by a board of directors representing city government and private enterprise, is a prime example of how Philadelphia has joined the work of the private and public sectors to serve the best interests of both. Covering 388 acres, it is a food-industry park handling in a unified operation every food-marketing facility from ripening bananas to smoking fish; it comprises well over 100 stores plus warehousing and processing plants.

Cultural life and institutions. Every great city has a certain character not always easy to define. Much of the essence of Philadelphia lies in the features described previously—its small-town atmosphere, its parks and tree-shaded downtown square and streets, and its innumerable memorials to the American past, as well as its teeming riverside and factories and its diverse business institutions. There are other factors as well that contribute in their way to an understanding of Philadelphia's culture, considered in its broadest implications to comprise the life-styles of its people.

Parks and playgrounds. In addition to Fairmount Park, Philadelphia has Pennypack Park in the northeast, a semiwilderness setting with bridle paths, bird-watching trails, and an abundance of deer and other wildlife. More than 100 parks with playgrounds are located in all areas of the city, including the ghettoes.

Recreational facilities

Philadelphians have always been a sports-loving group, whether passive or participatory, though professional teams have always been the object, like the city itself, of a good-natured deprecation that is tolerated in natives but not in strangers. Fox hunting in the surrounding countryside is of old Quaker origins, while the Schuylkill is a major rowing site for collegiate and older individuals and crews, and Germantown harbours remnants of a once-lively city-wide enthusiasm for cricket.

The arts. In colonial days, Philadelphia was known as the "Athens of America," and it retains a high place in the artistic achievement of the nation. The Academy of Music, opened in 1857, is the home of the Philadelphia Orchestra, which is among the very finest orchestras of the world and was the first to broadcast and make records. The Robin Hood Dell Orchestra has presented outdoor concerts in Fairmount Park since 1930.

Philadelphia was the nation's theatrical centre until well after the Revolution, its stages having hosted the greatest players of Europe and America during three centuries. The Walnut Street Theatre, opened in 1809, is the oldest playhouse in active use in the English-speaking world. The Playhouse in the Park opened in 1952 as the first city-owned and -operated theatre of its kind. Professional theatre revolves generally around new plays trying out on their way into New York or road companies of proved Broadway hits.

Museums and galleries. Philadelphia was a pioneer in museums of all kinds. Charles Willson Peale's museum was housed in Independence Hall in the 1800s, but today the art museums are led by the Philadelphia Museum of Art. One of the world's great museums, it houses priceless collections of art from the Western Middle Ages onward and from the Orient. Others include the unique Rodin Museum, featuring the largest collection of sculptures by Auguste Rodin outside of Paris. The Historical Society of Pennsylvania has some 700 portraits by Benjamin West, James Copley, Gilbert Stuart, the four Peales, and other early American painters. The output of visual artists in Philadelphia and vicinity has been by and large conservative, though Thomas Eakins gained fame for work beyond his American contemporaries, and Mary Cassatt was among the few women in the Impressionist school of the late 19th century.

Other museums include the Civic Center Museum, originally organized in 1894 as the Commercial Museum to promote trade exhibitions. The Academy of Natural Sciences is the oldest of its kind in the U.S. The Franklin Institute Science Museum is full of marvellous things that move and can be moved, while the University Museum is a major feature of the University of Pennsylvania. There are, finally, many small museums housed in the restored buildings throughout the city.

Education. Philadelphia's public-school system is an independent governmental unit operating under a board of education appointed by the mayor on the recommendation of a citizens' nominating panel. The city's institutions of higher learning are headed by the privately endowed University of Pennsylvania, which was founded in 1740, opened the nation's first medical school (1765), and was the first designated "university" in the U.S.

Institutions of higher education

(1779). Temple University (1884) has acquired the reputation of "the people's college" and is known for work in the arts and social sciences. Catholic colleges include LaSalle and St. Joseph's. Philadelphia is also a centre for medical education, with several general schools and specialized schools in pharmacy, podiatry, optometry, and osteopathy. The Curtis Institute of Music (1924) is a leading music school, while the Pennsylvania Academy of Fine Arts (1805) is the oldest art school in the United States.

The media. *The Philadelphia Inquirer* and *The Philadelphia Evening Bulletin* are the city's major dailies, though *The Philadelphia Courier* has a long history of service to the black community. Several weeklies serve sections of the city or various linguistic and religious groups. The magazine *Philadelphia* appeared first in 1909; since the 1950s it has published lively and often controversial stories and commentary on the city's social and political life. The numerous television and radio channels include both commercial and "public" broadcasting.

Prospects. The Quakers represent only a very small percentage of Philadelphians in the 20th century, but they continue to exert, by both tradition and present-day activity, an influence far exceeding their numbers. It seems unlikely that Philadelphia will soon lose the pervading quiet and dignity that they more than any other force have implanted on the city. It is too early to estimate the impact of the militancy of the city's ghettoes or of the possibility of stern responses from the various power structures. In terms of ongoing civic renewal, successors of mayors Clark and Dilworth have been accused of a lessening appetite for the goals of the original reformers. Certainly the test of years under the charter of 1951 has shown the need for improvement and for change to most still newer circumstances; Philadelphia's renaissance, however—in its spiritual as well as its physical body—continues to command attention from American urban leaders.

Philip II Augustus, of France

Philip II Augustus, the first of the great Capetian kings of medieval France, destroyed the English-based Angevin Empire and greatly extended the influence of his dynasty. Born in Paris on August 21, 1165, the son of Louis VII of France and Adela of Champagne, Philip Augustus was crowned at Reims on November 1, 1179, so as to be associated as king with his father, who had fallen mortally ill. His uncles of the House of Champagne—Henry I, count of Champagne, Guillaume, archbishop of Reims, and Thibaut V, count of Blois and Chartres—hoped to use the youthful king to control France. To escape from their tutelage, Philip, on April 28, 1180, married Isabella, the daughter of Baldwin V of Hainaut and the niece (through her mother) of Philip of Alsace the count of Flanders, who promised to give the King the territory of Artois as her dowry. When Henry II of England arrived in Normandy, perhaps with the intention of responding to an appeal by the House of Champagne, Philip II entered into negotiations with him and, at Gisors on June 28, 1180, renewed an understanding that Louis VII had reached with him in 1177. As a result, the House of Champagne was politically isolated and Philip II was making all decisions for himself and acting as he saw fit when his father died, on September 18, 1180, leaving him sole king in name as well as in fact.

When the Count of Flanders allied himself with the Champagne faction, there followed a serious revolt against the King. In the Peace of Boves, in July 1185 (confirmed by the Treaty of Gisors in May 1186), the King and the Count of Flanders composed their differences (which had been chiefly over possession of Vermandois, in Picardy), so that the disputed territory was partitioned, Amiens and numerous other places passing to the King and the remainder, with the county of Vermandois proper, being left provisionally to Philip of Alsace. Thenceforward the king was free to run against Henry II of England.

Territorial expansion. *The struggle against the Plantagenets.* Henry's French possessions, the so-called Angevin Empire—consisting of Normandy, Maine, Anjou, and Touraine, with Aquitaine in the hands of his son, the future Richard I of England, and Brittany ruled by another son, Geoffrey (died 1186)—all were a constant menace to the French royal domain. Furthermore, there were long-standing disputes over the Vexin (between Normandy and the Île-de-France), Berry, and Auvergne.

Philip II launched an attack on Berry in summer 1187 but then in June made a truce with Henry, which left Issoudun in his hands and also granted him Fréteval, in Vendômois. Though the truce was for two years, Philip found grounds for resuming hostilities in the summer of 1188. He skillfully exploited the estrangement between Henry and Richard, and Richard did homage to him voluntarily at Bonmoulins in November 1188. Finally, by the Treaty of Azay-le-Rideau, or of Colombières (July 4, 1189), Henry was forced to renew his own homage, to confirm the cession of Issoudun, with Graçay also, to Philip, and to renounce his claim to suzerainty over Auvergne. Henry died two days later.

Philip Augustus and the Third Crusade

Richard, who succeeded Henry as king of England, had already undertaken to go on crusade (the Third Crusade) against Saladin in the Holy Land, and Philip now did likewise. Before his departure, he made the so-called Testament of 1190 to provide for the government of his kingdom in his absence. On his way to Palestine, he met Richard in Sicily, where they promptly found themselves at variance, though they made a treaty at Messina in March 1191. Arriving in Palestine, they cooperated against the Muslims at Acre, until Philip fell ill and made his illness a pretext for returning to France, quite determined to settle the succession to Flanders (Philip of Alsace had just died on the crusade) while Richard was still absent. Thus, by the end of 1191, Philip II was back in France.

In spite of promises he had made in the Holy Land, Philip at once prepared to attack the Plantagenet possessions in France. Informed of this, Richard also left the crusade but was taken prisoner while on his way back by the duke of Austria, Leopold V of Babenberg. Philip did everything he could to prolong his rival's captivity, but Richard was at last set free (1194) and went to war against Philip. The French king suffered a number of defeats (from that at Fréteval in July 1194 to that at Courcelles in September 1198) in a series of campaigns that were occasionally punctuated by negotiations. It was fortuitous for Philip, however, when Richard was killed in April 1199.

Richard's brother John was by no means as formidable a fighter. Moreover, his right to Richard's succession could be contested by Arthur of Brittany, whose father had been senior to John. To secure the succession, therefore, John came to terms with Philip: by the Treaty of Le Goulet (May 22, 1200), in return for Philip's recognition of him as Richard's heir, he ceded Évreux and the Norman Vexin to Philip; agreed that Isoudun and Graçay should be the dowry of his niece Blanche of Castile, who was to marry the future Louis VIII (Philip's son by Isabella of Hainaut); and renounced any claim to suzerainty over Berry and Auvergne. Shortly afterward, however, John entered into conflict with the Lusignan family of Poitou (in Aquitaine), who appealed to Philip as overlord. When he was summoned to appear before the royal court as a vassal of the French crown, John did not present himself, and Philip, in April 1202, pronounced John's French fiefs forfeit and undertook to carry out the sentence himself. He invaded Normandy, overran the northeast, and laid siege to Arques, while Arthur of Brittany, the son of Geoffrey, who died some years before, campaigned against John's supporters in Poitou; but John, marching south from Maine, captured Arthur at Mirebeau (August 1). In fury, Philip abandoned the siege of Arques and marched southwestward to Tours, ravaging John's territory on his way before returning to Paris. Guillaume des Roches, the powerful seneschal of Anjou, who had taken John's side, came to terms with Philip in March 1203.

Philip's conquest of Normandy

Resuming operations against Normandy, Philip occupied the towns around the great fortress of Château-Gaillard, to which he laid siege in September 1203, having overruled Pope Innocent III's attempts to mediate. John, who is reported to have murdered Arthur of Brittany in April, retired to England in December, and Château-Gaillard fell to Philip in March 1204. Rouen, the Norman capital, surrendered in June, after 40 days' resistance.

After his conquest of Normandy, Philip subdued Maine, Touraine, Anjou, and most of Poitou with less difficulty (1204–05), though the castles of Loches and Chinon held out for a year. He sought to secure his conquests by lavishing privileges on the towns and on the religious houses but otherwise left the local barons in power. Unrest, however, was endemic in Poitou, and in June 1206 John landed at La Rochelle. After a campaign in the south, he turned north toward the Loire. At Thouars in October 1206, he and Philip made a two-year truce, leaving John in possession of the reconquered Poitevin lands. In the following year, however, Philip invaded Poitou again; and, after a further campaign in 1208, only the south and part of the west of Poitou remained loyal to John (with Saintonge, Guyenne, and Gascony).

Philip next hoped to exploit the dispute between John and Pope Innocent III. While Innocent was threatening to declare John unfit to reign (1212), plans were being made for a French landing in England and for the accession of Philip's son Louis to the English throne. The plans had to be dropped when John made his submission to the Pope (1213). Throwing himself into schemes for revenge, John formed a coalition against France: the Holy Roman emperor Otto IV, the Count of Flanders (Ferrand, or Ferdinand, of Portugal), and the Count of Boulogne (Raynald, or Renaud, of Dammartin) were to invade the Capetian territory from the northeast while John attacked from the west, with the help of his Poitevin barons. John landed at La Rochelle in February 1214 and advanced into Anjou but was put to flight by Louis at La Roche-aux-Moines on July 2; his confederates were completely defeated by Philip in the decisive Battle of Bouvines on July 27. The Anglo-Angevin power in France and the coalition had both been broken in one month. Thus Philip, who, in 1213, had transferred Brittany to his cousin Peter of Dreux, was left without any significant opposition to his rule in France.

The Battle of Bouvines

The northeastern frontier and Languedoc. It was not only at the Plantagenets' expense that Philip enlarged the royal domain. His claim to Artois through his first marriage and his gains by the settlement of 1185–86 have been mentioned above, and he subsequently proceeded, step by step, to acquire the rest of Vermandois and Valois. His insistence on his suzerainty over vacant fiefs and on his tutelage over minors and heiresses was particularly effective with regard to Flanders, where two successive Flemish counts, Philip of Alsace (died 1191) and Baldwin IX (died *c.* 1205) had left no male issue.

Though he did not personally take part in the crusade proclaimed by Pope Innocent III against a Cathari religious sect in Languedoc, Philip Augustus allowed his vassals and knights to carry it out. Simon de Montfort's capture of Béziers and Carcassonne (1209) and his victory at Muret over Raymond VI of Toulouse and Peter II of Aragon (1213) prepared the way for the eventual annexation of eastern Languedoc to the royal domain six years after Philip's death and for the union of northern and southern France under Capetian rule.

Internal affairs. *The matrimonial conflict with the papacy.* Several years before he tried to take advantage of the papacy's quarrel with John of England, Philip Augustus had himself been in dispute with Rome. After the death (1190) of Isabella of Hainaut, he had married Ingeborg, sister of the Danish king Canute VI, on August 14, 1193, and on the next day, for a private reason, had resolved to separate from her. Having procured the annulment of his marriage by an assembly of bishops in November 1193, he took a Tirolese lady, Agnes, daughter of Bertold IV of Meran, as his wife in June 1196. Denmark, meanwhile, had complained to Rome about the repudiation of Ingeborg, and Pope Celestine III had countermanded it in 1195; but Celestine died (1198) before he could resort to coercion against Philip. The next pope, Innocent III, was sterner: in January 1200 he imposed an interdict on France. Philip, therefore, in September 1200, had to submit, pretending to be reconciled with Ingeborg. In fact, he refused to cohabit with her and kept her in semicaptivity till 1213, when he accepted her beside him—not as his wife but at least as his queen. Agnes had died in 1201, after bearing two children to Philip: Marie, countess of Namur (1211) and duchess of Brabant (1213), by successive marriages; and Philip, called Hurepel; count of Clermont.

Submission to Innocent III

Philip's relations with his subjects. Throughout his reign, Philip Augustus kept a close watch over the French nobility, which he brought effectively to heel. He maintained excellent relations with the French clergy, leaving the canons of the cathedral chapters free to elect their bishops and favouring the monastic orders. He knew, too, how to win the support of the towns, granting privileges and liberties to merchants and frequently aiding their struggles to free themselves from the seignorial au-

thority of the nobles. In return, the communes helped financially and militarily. Most of all, Philip gave his attention to Paris, not only fortifying it with a great rampart but also having its streets and thoroughfares put in order. For the countryside, he multiplied the number of *villes neuves* ("new towns"), or enfranchised communities.

The Capetian monarchy's hold on the huge royal domain as well as on the kingdom as a whole was considerably strengthened by Philip's institution of a new class of administrative officers, the royal *baillis* and the seneschals for the provinces, who were appointed by the king to supervise the conduct of the local *prévôts* ("provosts"), to give justice in his name, to collect the revenues of the domain for him, to call up the armed forces, and so forth.

Conclusion. Philip II Augustus died at Mantes on July 14, 1223. Knowing his own strength, he was the first of the Capetians not to have his eldest son crowned and associated with him during his lifetime; in fact, his conquests and strong government made him the richest and most powerful king in Europe, and prepared the way for France's greatness in the 13th century. (See also FRANCE, HISTORY OF.)

BIBLIOGRAPHY. For a concise outline of the reign of Philip Augustus, read the corresponding chapters of two famous publications: *The Cambridge Medieval History*, vol. 6; and BRIAN TIERNEY and SIDNEY PAINTER, *Western Europe in the Middle Ages, 300–1475* (1970). CARTELLIERI, *Philipp II August, König von Frankreich*, 4 vol. (1899–1922); C. PETIT-DUTAILLIS and P. GUINARD, *L'Essor des états d'occident* (1937); and A. LUCHAIRE, *Louis VII, Philippe-Auguste, Louis VIII* (1901).

(M.Pa.)

Philip IV the Fair, of France

An accomplished statesman, yet scrupulously attentive to his conscience, Philip IV the Fair, king of France from 1285 to 1314, established the French monarchy's prestige and authority over matters temporal and spiritual within Christian Europe and confirmed the supreme power of the king within the realm of France. He also instituted important reforms in the conduct of government. His determination to defeat any challenge to his authority within his kingdom was demonstrated in his lengthy duel with Pope Boniface VIII and in his relations with the Holy Roman Empire and other western European powers of the late 13th and early 14th centuries. The claim that the French monarch should by right serve as arbiter of Christian orthodoxy and morality was established not only by Philip's appeal to a general council of the church against Boniface and his campaign against the pope's reputation, but also by his assault on the crusading order of the Knights Templars. Within France Philip's reign saw the beginnings of large-scale consultation of royal subjects in assemblies, the issuance of important reform charters, and the development of policies permitting the marshalling of the realm's forces to meet attack.

Early years. Born at Fontainebleau in 1268 while his grandfather was still ruling, Philip, the second son of Philip III the Bold and grandson of St. Louis (Louis IX), was not yet three when his mother, Isabella of Aragon, died on her return from the crusade on which Louis IX had perished. The motherless Philip and his three brothers saw little of their father, who, stricken by Isabella's death, threw himself into campaigning and administrative affairs. His troubled childhood and the series of blows he suffered explain in some measure the conflicting elements in his adult personality. In 1274 his father married Marie de Brabant, a beautiful and cultivated woman, and with her arrival at court intrigue began to flourish. In the same year the two-year-old Jeanne, heiress of Champagne and Navarre, was welcomed as a refugee. Reared with the royal children, she would, when she was 12, become the bride of Philip the Fair.

Archives Photographiques, Paris

In 1276 Philip's older brother Louis died, and the shock of this event, which suddenly made Philip heir of the kingdom, was compounded by persistent rumours of poisoning and suspicions that Philip's stepmother intended to see Isabella's remaining sons destroyed. Vague allegations were circulated that Louis's death was linked with certain unspecified "unnatural acts" of his father. These rumours, never satisfactorily put to rest, together with the unexpected change in Philip's fortunes, apparently served to arouse in him feelings of insecurity and mistrust. Consequently, Philip turned elsewhere in search of a model for his own conduct. He found it in Louis IX, whose memory was increasingly venerated as the number of miracles attributed to him mounted. Reports of Louis's exacting standards of rulership and his saintly virtues were reinforced by the precepts of the religious advisers who surrounded the adolescent Philip. A more self-confident person might have been able to discriminate realistically among the sometimes artificially exaggerated stories and the utopian ideals. Philip, however, became convinced that it was his God-given duty to attain the lofty goals of his grandfather.

Influence of Louis IX

When Philip was 16, he was knighted and married to Jeanne of Navarre. In 1285 he accompanied his father to the south on a campaign to install Philip's brother Charles on the throne of Aragon. But he had no sympathy with the enterprise, which was backed by his stepmother and aimed against the King of Aragon, his late mother's brother. When his father died in October 1285, Philip immediately abandoned the venture.

Wars with England and Flanders. In the first years of Philip's reign the Aragonese affair was settled, and Philip intensified his predecessors' efforts to reform and rationalize the administration of the realm. He dispatched investigators to inquire into the conduct of royal officials and into infringements upon royal prerogatives. Philip persisted in seeking such reforms, which strengthened the monarchy's position but angered the nobles, townsmen, and ecclesiastics who had profitted from the laxer policies of earlier kings.

War with England began in 1294, initiating a ten-year period of conflict that severely strained Philip's resources. There had been some naval clashes, but full-scale war might well have been avoided had not Philip, perhaps in a fit of youthful bravado, decided to demonstrate his power over England's mighty Edward I, his vassal, for control of the duchy of Gascony. Philip's victories in 1297 may have satisfied his ambitions; but they brought no territori-

Repercussions of the war with England

al gain, for the many lands that Philip had seized were returned. Nevertheless the war was significant. First, the peace treaty of 1303 stipulated that Philip's daughter Isabella should marry the future Edward II of England—an alliance that led to years of peace between the two kingdoms. Second, during the war, Philip's vassal Guy of Dampierre, count of Flanders, had allied himself with Edward I, a move that Philip considered base treachery and that resulted in a breach between the two that persisted until long after Philip's death.

Before the peace, but after fighting with England had ceased, Philip moved to crush the Flemings, only to see a host of his nobles fall at Courtrai in 1302. This stunning defeat was redeemed two years later at Mons-en-Pévèle, where Philip showed great personal courage. Finally, in 1305, Philip forced Flanders to accept a harsh peace treaty that exacted heavy reparations and humiliating penalties. In financing the prolonged effort against Flanders, Philip had held assemblies and had bartered privileges and promises of reform for support in the war. Most important, in abandoning the property taxes that earlier had been levied for defense, he enforced the principle that all must fight to defend France but might purchase exemption if they wished. This successful policy was later employed as a regular wartime expedient by the French monarchy.

Conflict with the papacy. Philip's rupture with Boniface VIII can be considered a third consequence of the English war. Because the hostilities interfered with papal plans for a crusade, Boniface intervened aggressively and sometimes tactlessly to promote peace. In February 1296 he issued the bull *Clericis Laicos*, prohibiting lay taxation of clergy without papal approval. Both Edward I and Philip, affronted by this threat to their authority and their treasuries, responded with retaliatory measures, forcing Boniface to retreat and, in July 1297, to proclaim the legitimacy of clerical taxation without the pope's permission when the ruler attested its necessity. To mollify Philip, Boniface supported him against the Flemings and canonized Philip's grandfather Louis IX in 1297. The Pope's position in France was even weaker than he realized, for, at least as early as 1297, his enemies had spread charges against him, such as that he questioned the immortality of the soul or that he had plotted the death of his predecessor on the papal throne. Philip, for his part, had not rejected these stories out of hand.

New grounds for dispute developed in 1301, when Philip arrested Bernard Saisset, bishop of Pamiers, as a suspected traitor. Boniface, his confidence buoyed after the triumphant papal jubilee of 1300, determined not only to force Philip to send Saisset to Rome, but also to launch a frontal attack on the king's authority. In December 1301 Boniface suspended Philip's right to tax ecclesiastics and summoned the French clergy to Rome to discuss the King's governance and the state of the French Church. Saisset was permitted to go to Rome, but Boniface's other measures encountered immediate resistance. Philip had a papal bull burned and ceremoniously invoked curses on any of his sons who dared subordinate the kingdom to any power other than God's. In April 1302 he rallied public support in a large assembly. Undaunted by his humiliating defeat by the Flemings at Courtrai and by Boniface's declaration of the universal supremacy of the Roman pontiff in the bull *Unam Sanctam*, Philip held additional assemblies in the spring of 1303. He issued his own grand ordinance of reform that included remedies for administrative weaknesses enumerated by the Pope. Then, in response to appeals by his ministers Guillaume de Nogaret and Guillaume de Plaisians, Philip pledged to see Boniface judged for the heretical words and criminal and immoral deeds with which he had been charged.

Arrest of Boniface VIII

Boniface's plans to issue a personal sentence of excommunication against Philip were forestalled when Nogaret appeared in Anagni and seized Boniface on September 7, 1303. Nogaret probably intended to press Boniface to submit to conciliar judgment, but his plans were frustrated when troops, rallied by Boniface's Italian enemies, turned to violence and pillage. Two days later townsmen of Anagni freed the Pope, whose death the following month saved him from having to appear before a council to answer Philip's charges. Accusations against Boniface's memory, however, proved a useful negotiating device in dealing with his successor, Benedict XI, and even more so with Clement V, the Gascon-born pope who pleased Philip by transferring the papal curia from Rome to Avignon, a city near Philip's realm. Charges against Boniface were pressed until 1311, when Clement declared Philip's zeal praiseworthy and nullified all the offensive bulls that Boniface had issued after November 1301.

The years of peace between 1304 and 1313 allowed Philip not only to pursue his posthumous vendetta against Boniface but also to formulate plans to establish himself as the undisputed champion of orthodoxy. Before 1304 Philip had given thought to the moral implications of his deeds, taking steps to indemnify those harmed by coinage changes and advancing approved justifications of other wartime measures. After 1304 his scrupulousness became more apparent. He secured bulls from Pope Clement that absolved him from future crusading vows, annulled any obligation to return sums wrongfully taken from ecclesiastics for his wars, and—after lengthy negotiation—declared the Flemings subject to ecclesiastical sanctions if they failed to observe the peace treaty of 1305. In 1306 reformation of the coinage, long advocated by the church, was begun, and in later years Philip sought his subjects' advice concerning monetary policy. Philip's intensified preoccupation with questions of conscience and morals may have been prompted by the death in April 1305 of Queen Jeanne, a determined woman of scholarly inclinations and a devotee of Saint Louis. Philip never married again, and in the months after his wife's death he considered abdicating and assuming the kingship of the Holy Land as head of a consolidated crusading order.

Persecution of the Jews and Knights Templars. Philip soon found more practical ways of venting his grief and proving his dedication to God, while also advancing the material interests of a realm that was impoverished by long years of warfare. In 1306 he expelled all Jews from France, seizing their property and confiscating the monies owed to them. Philip's devotion to St. Louis was witnessed that same year by elaborate ceremonies in his honour, and Louis's anti-Semitic proclivities might have inspired Philip to act against the Jews, whose usefulness as a source of regular revenue had in any case been exhausted by his earlier repeated impositions.

Campaign to crush the Knights Templars

Similarly mixed motivations influenced Philip to attack the Knights Templars, the wealthy, powerful, independent crusading order that had long acted as the French monarchy's financial agent. Philip's newfound interest in uniting the crusading orders made him mistrustful of the Templars' opposition to such plans. Thus, he was receptive to charges of heresy and sodomy presented against them in 1305. His tentative overtures to Clement V were fruitless, but, with the support of Nogaret and his own Dominican confessor—who was also the papal inquisitor in France—Philip decided in September 1307 to seize all Knights Templars in France and to exhort his fellow rulers to follow his lead. At first dubious and reluctant, Clement V eventually supported Philip; he had been told of outraged anti-Templars appeals voiced in a large assembly of Philip's subjects, and he had heard damning confessions from the mouths of representatives of the order, many of whom had been tortured. Far-flung tribunals had gathered enough materials to cast doubts on the Templars' dedication, and, although not condemned as heretical, the order was quashed and its property assigned to the Knights Hospitallers. Whatever Philip's reasons for launching his attack against the order, his action brought him substantial financial gain despite Clement V's repeated attempts to protect the Templars' interests.

During the interwar years Philip asserted his independence of the Holy Roman Empire in diplomatic exchanges with imperial princes and the emperors themselves. He also fortified his eastern border by arranging marriages for his sons that extended French influence over the county of Burgundy and by exerting his authority over the city of Lyons. Less successful were his attempts to implement

his dream of gaining control of the empire. He failed to have his brother Charles elected emperor in 1308, nor did he succeed on behalf of his second son Philip in 1313.

Last years. This disappointment presaged the troubles of Philip's last year as king. In June 1313 his fortunes had reached a high point. Having knighted his sons, taken the crusader's cross, and issued coinage-reform ordinances, he witnessed the triumphal departure of his sons against the Flemings, who had been excommunicated for their failure to observe the treaty of 1305. When the Flemings capitulated and accepted a truce, Philip magnanimously ordered the return of money collected for the army. After these successes and demonstrations of royal grace, 1314 brought only troubles. Philip's stubborn resolve to defend morality and the faith was shown when, with royal acquiescence, the grand master of the Templars, Jacques de Molay, was burned at the stake after retracting his earlier confession. Far graver were the public trial and execution of two young squires convicted of adultery with Philip's daughters-in-law.

Scandal of the King's daughters-in-law

The death of Clement V was another blow, but an even greater one was the Flemings' fresh uprising. With his subjects' agreement, Philip mounted another campaign, but the negotiation of a truce caused difficulties. There were rumours of treason involving one of Philip's ministers and insistent demands for the restitution of all money collected for the war. Philip, who needed the funds, delayed, and a coordinated movement of opposition developed. Nobles in northern and eastern France presented their grievances to the King, who by early November was lying ill at Poissy, St. Louis's birthplace, recovering from a minor stroke. Having regained strength, he travelled to his own birthplace, Fontainebleau, and there, a day before his death on November 29, 1314, he halted collection of his last tax and provided for a crusading expedition to be conducted in his name.

Assessment. Philip was aloof, sternly reserved, and physically striking—tall, fine-featured, blond—hence his name, "the Fair." Frankly enjoying the trappings of monarchy, he built and maintained the palaces befitting his estate, but his chief concern was for the dignity of his office. He believed that he and his kingdom were guarded by God and chosen as special defenders of the Catholic faith. He valued the curative powers that he believed God's grace had given him. Proud of his orthodoxy and inspired by a priestly sense of mission, he was receptive to accusations of sin and heresy levelled against others, and he prosecuted ruthlessly those charged with such failings. A visionary idealist, he also possessed a fundamental sense of the possible and the necessary, and those of his grandiose schemes that exceeded the bounds of practicality were abandoned. As authoritarian and determined as he sometimes appeared, he lacked the firmness and independence of judgment that a surer sense of confidence in himself might have afforded him. He often turned for guidance to the intelligent and able ministers whom he promoted and protected, and he solicited the support of his subjects, who were called together with unprecedented frequence to endorse and sometimes to help construct royal policy. Such consultation may have been politically expedient, but, like the expressions of reassurance obtained from spiritual authorities, it also served to convince Philip of the legitimacy of his actions.

Philip was, by all accounts, an impressive ruler. Some Italian writers detested him and his line, but most contemporaries acknowledged his piety and good intentions, although many of them disapproved of his wars, his taxes, and his influential advisers. In the later years of the 14th century, when memory of these sources of complaint had faded, his reign was considered a golden age of freedom from burdensome and unjust taxation. Historians of recent times have differed in their judgments, and nationalistic and ecclesiastical biases have affected many assessments. It now seems possible to conclude, however, that the most striking accomplishments of his reign bear the ultimate impress of the complex personality of a scrupulous, suspicious, rigorous, visionary, determined man who fervently believed himself called by God to act as judge of the morals and welfare of his subjects.

Philip II of Macedonia

Philip II, king of Macedonia, made his country the ruling power in Greece and laid the foundations for Macedonia's expansion under his son Alexander the Great. Philip was born in 382 BC, a son of Amyntas III. In his boyhood he saw the Macedonian kingdom disintegrating while his elder brothers Alexander II and Perdiccas III, who each reigned for a few years, strove unsuccessfully against insubordination of their regional vassal princes, intervention of the strong Greek city Thebes, and invasion by the Illyrians of the northwest frontier. Philip himself spent some time as a hostage at Thebes, the leading city (with Athens) of this decade (370–360 BC), where the great Epaminondas, the most inventive tactician of all Greek generals until then, was in charge of the best army in Greece. These were probably the most formative years of Philip's education. When he returned to Macedonia his brother Perdiccas soon found him ready for a command.

Bust, tentatively identified as Philip II of Macedonia, middle of the 4th century BC. In the Ny Carlsberg Glyptotek, Copenhagen.

Macedonian recovery and expansion. Philip came to the throne suddenly and unexpectedly in 359, when Perdiccas was killed meeting an Illyrian invasion. The Illyrians prepared to close in; the Paeonians were raiding from the north, and two claimants to the throne were supported by foreign powers. In this crisis Philip showed a good sense of priorities by buying off his dangerous neighbours and, with a treaty, ceding Amphipolis to Athens. He used the time gained in military preparations. The army that later conquered Persia was developed all through his reign; but the decisive innovations in arms—the *sarissa*, a pike nearly half as long again as the spear of the Greeks—tactics, and training belong probably to this first year. In 358 he invaded Paeonia, and then he defeated the Illyrians decisively, in a battle that already suggests a master of war. The next year his marriage with Olympias, the Molossian princess of Epirus (the mother of Alexander the Great), helped to stabilize his western frontier. Now he ventured to antagonize Athens by recapturing Amphipolis, the strategic key securing

the eastern frontier and giving access into Thrace; and in 356 he took the west Thracian Crenides (renamed by him Philippi), a place newly founded to exploit new finds of silver and gold in Mount Pangaeum. These successes frightened his neighbours into forming a coalition against him, which was joined by Athens; but it achieved nothing.

The ten-year "war for Amphipolis" with Athens showed that the Athenians, with all their naval power, were quite unable to damage the continental and military power of Macedonia or even to save their own allies from Philip's attacks. Meanwhile he twice penetrated deeply into Thrace. And in the south a Thessaly divided against itself gave him an entry into Greece. These same ten years saw central Greece immersed in the Sacred War to liberate Delphi from its occupation by the Phocians, enabling Philip to intervene as the ally of Thebes and the Thessalian League of city states. His only great defeat in the field came in Thessaly in 353, owing (it seems) to overconfidence and failure of reconnaissance. The next year he retrieved it with a spectacular victory, which forced the Athenians to occupy Thermopylae and bar his path to the south. Characteristically Philip declined the trial of strength, prepared to wait for six years till he could gain Thermopylae by negotiation and without striking a blow. Meanwhile his Thessalian victory earned him election as president (*archōn*) of the Thessalian League (probably 352), a position unique for a foreigner in a Greek confederation and one that was to bind Thessaly to the kings of Macedonia for 150 years and more.

President of the Thessalian League

Philip's capture of Olynthus and annexation of Chalcidice in 348, enslaving the Olynthians and others of the Chalcidians, was disquieting to many. The Greeks themselves occasionally were brutal to small cities, but Olynthus was a large city. His enemies could affect a high moral tone and contempt for a barbarous Macedonian; but even his friends might have wondered whether he ought to be allowed into the heart of Greece with an army. Yet there were many ways in which he could serve them. Particularly, he could finish the Sacred War, which the Thessalians, Thebans, and others still could not finish for themselves. Athens could not prevent this now and had reason to fear that Philip's next campaign in Thrace (346) might challenge its own control of the sea route to southern Russia, its main source for imported corn. Significantly, however, it was Philip, and not Athens, who made the first overtures for peace, though all the military initiatives lay in his own hand. His plans for the future, in Greece and farther afield, included Athens as a willing ally not as a defeated enemy.

Even before the peace with Athens was ratified (346), the Athenian publicist Isocrates was inviting Philip to reconcile the four leading cities of Greece and to lead a united Greek alliance in a war of expansion against Persia. A step in this direction was Philip's intervention now to end the Sacred War, in recognition of which he was admitted to membership of the Delphic Amphictyony—an association of neighbouring states. The votes of the Thessalians and their clients gave him a control of its Council, which could be used on occasion for political and diplomatic ends. He lost no opportunity in the next years (346–343) of penetrating Greece without war, by winning and buying friends among the politicians of the smaller cities, intervening occasionally with subsidies or a force of mercenaries in their local disturbances. This policy made him some enemies, too, and it played into the hands of the great orator Demosthenes and others at Athens. Demosthenes saw Philip now as a bar to Athenian greatness and a threat to its freedom and existence; he talked tirelessly to warn the Athenians of the danger and to convince the Greeks in general that it was their danger too. Philip in these years conciliated Athens in small ways even under provocation, but he came to see that Demosthenes and the anti-Macedonians were beyond conciliation (343–342). Meanwhile, he reasserted his suzerainty over the neighbouring Illyrians, tightened his grip on Thessaly, and in 342 began the series of campaigns in Thrace that enabled him in two years to annex great parts of it as a province, and finally—to demonstrate his power against the Scythians settled on the southern banks of the Danube Delta. The events in Thrace caused two of his Greek allies, the cities of Perinthus and Byzantium, to review their position, and his coercion of them led to the two great sieges, which show the development of his artillery and allied arms, of which his son Alexander was to make greater use in Asia.

The declaration of war by Athens in 340 enabled him to raise the two sieges without undue loss of face, though he had failed to establish a threat to the Athenian corn route to southern Russia. Athens was to be intimidated now by invasion of its territory through central Greece, where the key position was held by Thebes, his ally hitherto, but of late a dissatisfied and recalcitrant one. His services to it in the Sacred War had been more than offset by his new position as its successful rival for leadership in and through the Amphictyony, and his moves toward hegemony in Greece could be seen in Thebes as encroachments. When Philip swept south with his army in November 339, he hoped to rush the Thebans into honouring their alliance and letting him through into Attica. But the Thebans listened to Demosthenes and to their own instinct of self-preservation. The Greek alliance became something formidable with the accession of Thebes, and Philip was forced, as a contemporary orator put it with only a mild exaggeration, "to stake his all on the issue of one short day." Chaeronea was a famous victory, gained by decisive blows of Philip's cavalry. But his real skill as a general can be seen, though dimly, in a manoeuvre of controlled retreat aimed at dislocating the advancing Greeks and creating gaps for the cavalry to strike. By winning this battle he had won the war.

Victory of Chaeronea

In the various peace treaties with the Greek states, Thebes had to admit a Macedonian garrison and its democratic constitution was replaced by a pro-Macedonian government; but Athens suffered neither invasion of its territory nor interference with its democracy and was not disarmed by dismantling of the walls or surrender of the navy. For Philip, Athens was the one Greek state from which he needed not neutrality or unwilling alliance but active cooperation. All past experience had shown that wars against Persia succeeded only when the Persians were denied the use of the Aegean, and for this the great Athenian navy was the first need. In Greece (outside Thessaly), Philip could have had no illusions about his own unpopularity, except among those of the well-to-do who were attracted by his court and his patronage; some cities also (especially the neighbours of Sparta) were glad to lean on Macedonia for support against an ancient enemy. Philip intended to involve all the Greeks with the Persian war. So Isocrates had advised him eight years before; but on the details of the ways and means he had no advice to offer. Philip himself organized the Greeks now to keep the peace with him and with each other and to support him in the Persian war overseas. In the constitutional details of his settlement of Greece he may well have had the help of Aristotle, free from his recent duties as tutor of the young Alexander.

Philip's so-called League of Corinth, established in 337, was an organization designed to preserve and perpetuate a general peace (*koinē eirēnē*), inaugurated when the delegates of all the states of Greece (except Sparta) and the islands swore to abide by it and to recognize Philip as president (*hēgemōn*) for this purpose. The general peace was a political innovation of the Greeks themselves, used several times in the past 50 years in attempts to stabilize affairs while promoting this or that hegemony. The peace had never lasted long because the leading Greek states had neither the power nor the mutual trust to create an effective organization for collective action against aggressors. Philip designed a council of representatives from all the states (*synedrion*), which was empowered to deliberate and decide on action to be taken in the event of the Peace being broken or threatened. After the decisions were made, their execution lay with Philip as *hēgemōn*. The states were under obligation to supply troops or ships to the *hēgemōn* on demand, by quotas corresponding to their voting power on the council. Though neither Philip

The League of Corinth

nor Macedonia had representatives on the council, it was the knowledge that the *hēgemōn* had the power of Macedonia in his hand that made this organization effective. As it happened, Corinth, where the inaugural meeting was held, was one of only three Greek cities with a Macedonian garrison, a fact the significance of which can have been lost on nobody.

Last years. Philip was wise, no doubt, to build on the foundation of the earlier practice of the Greeks themselves and also to refrain from organizing them in any permanent alliance that would have recalled too much the unpalatable experiences of the past. He was not, however, a Greek politician or even a Greek, but king of the Macedonians; and he cannot possibly have seen the settlement of Greece—as most modern historians have seen it—as the culmination of his life's work. For him it culminated nothing and was not even an end in itself but only a means. Chaeronea had brought the Greeks to order, and his plans required that they should stay in order now. The *synedrion* at Corinth heard his program for a Persian war and duly acclaimed it early in 337. Early next year an advance force of the Macedonian army crossed to Asia Minor. Philip would lead the grand army into Asia presently, and the Greeks would be with him.

This meteor fizzled out. The subtle, pliant, patient, calculating diplomatist, master of timing in politics and war, ended his life in a tale of irresponsible incompetence. The historian Theopompus, who saw Philip at close quarters, made much of his vices, his love of drink and debauchery, and his wild extravagance with money. Allowance made for this notably faultfinding and puritanical writer, Philip's character did contain some real ambiguities, extending into his domestic life. His "political marriages" were mostly opportune symbols of goodwill toward princes or groups worth conciliating, but his last marriage, in 338, to the Macedonian Cleopatra, led to a final break with Olympias, his queen, who left the country accompanied by the crown prince Alexander. Though Olympias was unpopular at court and though Cleopatra's connections were powerful and important, it was not "politic" to put the succession in jeopardy. Philip showed that he had never intended this result, by taking trouble to be reconciled with Alexander. The tradition that makes him infatuated with Cleopatra is probably right. If so, he misjudged fatally the amount of harm that could be done by marrying her.

Philip's assassination

With the preparations far advanced for the crossing into Asia, at the grand celebration of his daughter Cleopatra's marriage to Alexander of Epirus (brother of Olympias), Philip was assassinated by Pausanias, a young Macedonian noble with a bitter grievance against the young queen's uncle Attalus and against Philip for denying him justice. This was the official explanation, and Pausanias himself could add nothing to it; he was killed on the spot. Suspicion fell on Olympias and Alexander, those with most to gain from Philip's death, and many modern interpreters have followed it. Aristotle, however, clearly did not believe it. In his *Politics* a few years later he used this incident as an example of a monarch murdered for private and personal motives—which would have been a puerile indiscretion if either he or the world in general had ever taken the canard seriously.

Assessment. So ended, unworthily, the first of the great Macedonians. Everything known about him comes from Greek sources, which concentrate on his impact upon the Greeks and their history. Yet even more impressive, in view of Macedonia's troubled and undistinguished past, would be the full story of his unification and expansion of his own kingdom; his control of its regional princes, nobles, and gentry and their retainers, to form a great Macedonian people, symbolized by the finest army the world had seen; then, the continuing attrition by warfare and diplomacy, which in some 20 years reduced much of the Balkan peninsula to subservience. The apparently untidy record of his campaigns into Illyria or Thrace or of his interventions with diplomacy or arms (or both) in Thessaly, Euboea, the Peloponnese, which might suggest that repetition is a sign of incompetence, seem better interpreted as the work of a strategist operating always on several fronts, often preferring diplomacy to war, limited objectives to the grandiose, the smaller risks to the greatest; especially never forgetting that there is always another day. His decisive day at Chaeronea came, in a sense, because his true policy in Greece had failed, thanks partly to Demosthenes. But probably to take control of Greece without a Chaeronea was a real impossibility at this date (or indeed later).

Though Philip certainly wanted to be acceptable in Greece and did attract many important Greeks to his court, his philhellenism has been overrated: Olynthus and other Greek cities knew better. Though he cultivated the Athenians for reasons of high policy, there is no evidence that he ever in his life set foot in Athens, a remarkable piece of insouciance at every level. Pella, his capital, had long been a resort or refuge of great men of letters, and under Philip the connection with Plato's Academy was preserved, Theopompus was entertained, and Isocrates was invited; the leading actors of the Athenian stage appeared in Macedonia, too. Aristotle, whose father had been physician to Amyntas, Philip's father, spent three or four important years as Alexander's tutor. Philip presumably was at home with these people, but tradition says nothing of him as a man of letters himself or as an intellectual, though as an orator he could impress a party of Athenians which included Demosthenes and Aeschines and other professionals. His charm was great; he was by nature convivial, hospitable, and *bon viveur*. Undoubtedly he drank too much and too often, with the saving grace that he was known to listen to home truths even when drunk. As a commander in the field he was unwearying, and in action he fought like a lion; in the end he was really disfigured with old wounds. He was a general perhaps not of genius but of a very high order, with the tactical skill to coordinate the cavalry and infantry arms which were largely of his own creating. Making and training over the years a great army, he was paradoxically sparing and even cautious in using it.

Personal attributes

If he had survived to invade Asia, it would not have been to overthrow the Persian empire. He might have established a Macedonian empire in Asia, perhaps, but it would have been a Mediterranean empire in character. The Greeks would have benefitted by colonization, but the problem of Greek freedom would have remained, with the political domination of the higher culture by the lower. Philip was aware of the problem, and the League of Corinth, with its facade of freedom, was his answer. It did not deceive the Greeks or satisfy them; but no later Macedonian king could improve on it. Philip had made Macedonia, and now Macedonia and its kings made world history.

WUST, *Philipp II von Makedonien und Griechenland in den Jahren von 346 bis 338* (1938), an excellent analysis of Philip's later years.

(G.T.G.)

Philip II of Spain

Champion of the Roman Catholic Counter-Reformation, Philip II was king of Spain from 1556 to 1598. During his reign the Spanish Empire attained its greatest power and widest geographical extent but also suffered setbacks in its relations with the Protestant nations of northern Europe.

Philip was born at Valladolid on May 21, 1527, the son of the Holy Roman emperor Charles V and Isabella of Portugal. From time to time, the Emperor wrote Philip secret memoranda, impressing on him the high duties to which God had called him and warning him against trusting any of his advisers too much. Philip, a very dutiful son, took this advice to heart. From 1543 Charles con-

Philip II, oil painting by Titian (c. 1487/90–1576). In the Corsini Gallery, Rome.
Alinari

ferred on his son the regency of Spain whenever he himself was abroad. From 1548 until 1551, Philip travelled in Italy, Germany, and the Netherlands; but his great reserve and his inability to speak fluently any language except Castilian made him unpopular with the German and Flemish nobility.

Marriages

Philip contracted four marriages. The first was with his cousin Maria of Portugal in 1543. She died in 1545, giving birth to the ill-fated Don Carlos. In 1554, Philip married Mary I of England and became joint sovereign of England until Mary's death, without issue, in 1558. Philip's third marriage, with Elizabeth of Valois, daughter of Henry II of France, in 1559, was the result of the Peace of Cateau-Cambrésis (1559), which, for a generation, ended the open wars between Spain and France. Elizabeth bore Philip two daughters, Isabella Clara Eugenia (1566–1633) and Catherine Micaela (1567–97). Elizabeth died in 1568, and in 1570 Philip married another cousin, Anna of Austria, daughter of the emperor Maximilian II. She died in 1580, her only surviving son being the later Philip III.

King of Spain. Philip had received the duchy of Milan from Charles V in 1540 and the kingdoms of Naples and Sicily in 1554 on the occasion of his marriage to Mary of England. On October 25, 1555, Charles resigned the Netherlands in Philip's favour, and on January 16, 1556, the kingdoms of Spain and the Spanish overseas empire. Shortly afterward Philip also received the Franche-Comté. The Habsburg dominions in Germany and the imperial title went to his uncle Ferdinand I. At this time Philip was in the Netherlands. After the victory over the French at St. Quentin (1557), the sight of the battlefield gave him a permanent distaste for war, though he did not shrink from it when he judged it necessary.

His Castilian character

After his return to Spain from the Netherlands in 1559 Philip never again left the Iberian Peninsula. From Madrid he ruled his empire through his personal control of official appointments and all forms of patronage. Philip's subjects outside Castile, thus, never saw him, and they gradually turned not only against his ministers but against himself. This happened particularly in the Netherlands, in Granada, and in Aragon.

Method of government. By sheer hard work Philip tried to overcome the defects of this system. His methods have become famous. All work was done on paper, on the basis of *consultas* (that is, memoranda, reports, and advice presented him by his ministers). In Madrid, or in the gloomy magnificence of his monastic palace of El Escorial, which he built (1563–84) on the slopes of the Sierra de Guadarrama, the King worked alone in his small office, giving his decisions or, as often, deferring them. Nothing is known of his order of work, but all his contemporaries agreed that his methods dangerously, and sometimes fatally, slowed down a system of government already notorious for its dilatoriness. Painstaking and conscientious, Philip's craving for ever more information hid an inability to distinguish between the important and the trivial and a temperamental unwillingness to make decisions.

This was coupled with an almost pathological suspicion of even his most able and faithful servants. Margaret of Austria, duchess of Parma; the duke of Alba; Don John of Austria; Antonio Pérez; and finally, Alessandro Farnese—to name only the most distinguished—suffered disgrace. "His smile and his dagger were very close," wrote his official court historian, Cabrera de Córdoba. It was no exaggeration; for, in the case of Juan de Escobedo, the secretary of Don John of Austria, Philip even consented to murder. As a result, Philip's court became notorious for the bitterness of its faction fights. The atmosphere of the Spanish court did much to poison the whole Spanish system of government, and this played no small part in causing the rebellions of the Netherlanders (1568–1609), of the Moriscos of Granada (1568–70), and of the Aragonese (1591–92).

The black legend

Yet the "black legend" that, in Protestant countries, represented Philip II as a monster of bigotry, ambition, lust, and cruelty is certainly false. Philip's spare and elegant appearance is known from the famous portraits by Titian and by Anthonis Mor (Sir Anthony More). He was a lover of books and pictures, and Spain's literary Golden Age began in his reign. An affectionate father to his daughters, he lived an austere and dedicated life. "You may assure His Holiness," Philip wrote to his ambassador in Rome, in 1566, "that rather than suffer the least damage to religion and the service of God, I would lose all my states and an hundred lives, if I had them; for I do not propose nor desire to be the ruler of heretics." This remark may be regarded as the motto of his reign. To accomplish the task set him by God of preserving his subjects in the true Catholic religion, Philip felt in duty bound to use his royal powers, if need be, to the point of the most ruthless political tyranny, as he did in the Netherlands. Even the popes found it sometimes difficult to distinguish between Philip's views as to what was the service of God and what the service of the Spanish monarchy.

Foreign policy. For the first 20 years of his reign, Philip sought to preserve peace with his neighbours in western Europe. He was fighting a major naval war with the Ottoman Empire in the Mediterranean and, from 1568, he was faced with rebellion and war in the Netherlands. From the late 1570s, his policy gradually changed. The death (August 1578) without heirs of his nephew, King Sebastian of Portugal, opened up the prospect of Philip's succession to Portugal. He had to conquer (1580) by force what he regarded as his just, hereditary rights, but the rest of Europe was alarmed at this growth in Spanish power. Both England and France gave increasing support to the rebellious provinces of the Netherlands. Gradually, in the 1580s, Philip became convinced that the Catholic religion in western Europe, and his own authority in the Netherlands, could be saved only by open intervention against England and France. To this end he fitted out the Armada that, with the help of the Spanish Army in the Netherlands, was intended to conquer England (1588). He sent money and troops to support the League, the ultra-Catholic party in France, against Henry of Navarre and the Huguenots. He even claimed the throne of France for his daughter, Isabella Clara Eugenia, after the murder of Henry III in 1589. Again, even his Catholic allies found it difficult to distinguish between Philip's championship of the Catholic Church and the interests of Spain.

The Spanish Armada

All these plans failed. Henry of Navarre became a Catholic (1593) and Philip had to accept (Peace of Vervins, 1598) his succession as Henry IV of France. England and the northern Netherlands remained Protestant and unconquered. Yet Philip's reign as a whole was not a failure. He had defeated the great Ottoman offensive in the

Mediterranean at the Battle of Lepanto (1571). In the Iberian Peninsula he had completed the work of unification begun by the "Catholic Kings," Ferdinand and Isabella. Most important of all, in his own eyes, he had won great victories for the Catholic Church. If England, Scotland, and the northern Netherlands were lost, the southern Netherlands (the modern Belgium) had been preserved. In Spain and Italy he had prevented the spread of heresy, and his intervention in France was one of the factors that forced Henry IV to become a Catholic. When Philip II died of cancer at El Escorial on September 13, 1598, Spain was still at the height of its power; it took almost 50 years before it was clear that the Counter-Reformation would make no further major conquests.

BIBLIOGRAPHY. There are many biographies of Philip II but, as yet, no generally accepted or standard one. The fullest account of Philip II's life was written in the early 17th century by his official court historian, L. CABRERA DE CORDOBA, *Felipe Segundo, Rey de España*, 4 vol. (1876–77). Cabrera was very well informed, especially about life and personalities at Philip's court. His work has proved indispensable to all later biographers. The best full-scale modern political biography is R.B. MERRIMAN, *The Rise of the Spanish Empire in the Old World and the New*, vol. 4 (1934). The best example of the detailed work done in recent years on aspects of Philip's career is G. MATTINGLY, *The Defeat of the Spanish Armada* (1959), a book distinguished both by its impeccable scholarship and by the brilliance of its writing. An attempt to assess Philip II's aims and methods in the light of modern research is an article by H.G. KOENIGSBERGER, "The Statecraft of Philip II," in *European Studies Review*, 1:1–21 (1971).

(H.G.K.)

Philip the Good, Duke of Burgundy

The most important, most representative, and longest reigning of the four Valois dukes of Burgundy, who were among the leading European rulers between 1384 and 1477, Philip the Good has been acclaimed by historians both as the true founder of the Burgundian state in the Low Countries, from which modern Holland and Belgium draw their origins, and as the greatest patron of the arts north of the Alps. From 1419 until his death, in 1467, and especially in the years after 1435, the Duke of Burgundy was, with the possible exception of the king of France, the most powerful and successful ruler in the West.

Cliche des Musees Nationaux, Paris

Philip the Good, portrait attributed to Rogier van der Weyden (1399/1400–1464). In the Louvre, Paris.

Philip was born at Dijon, France, on July 31, 1396, the son of John the Fearless and Margaret of Bavaria. When he became duke of Burgundy at the age of 23, his first aim was to extricate himself as expeditiously as possible from the French affairs in which his father, Duke John, had been embroiled and that had led to his assassination in 1419. Holding the dauphin Charles (later Charles VII of France) answerable for his father's murder, Philip signed the Treaty of Troyes with King Henry V of England in 1420, a treaty in which the Queen of France, Isabella of Bavaria, conferred succession to the French crown on Henry and partitioned France among England, Burgundy, and her disinherited son, the dauphin Charles. Philip paid little attention to potential conquests in France and preferred to remain uncommitted there. He maintained his alliance with England, apart from a break in 1435–39 when he tried but failed to conquer Calais, but seldom gave England serious help against France. On the other hand, especially after 1435, when he acknowledged Charles as king of France and accepted his disavowal of the murder of John the Fearless, he did his best to be on reasonably good terms with the King of France. His real interests lay not in France but in the development of his own territories.

Conquests

Behind an impressive, if bizarre, facade of courtly splendour and chivalrous festivity, Duke Philip the Good was an aggressive opportunist who, especially in the first half of his ducal reign, concentrated on the task of attacking and swallowing up his smaller neighbours. Namur was purchased in 1420; Hainaut fell to Burgundian arms in 1427; the rich duchy of Brabant was taken over in 1430; and the combined counties of Holland and Zeeland were conquered in a long series of personally led and bitterly contested campaigns between 1424 and 1433. The crowning achievement of Philip's policy of territorial expansion was his conquest of the duchy of Luxembourg in 1443.

Patron of the arts

It was under Philip that the richness and extravagance of court life in the Middle Ages reached its apogee. Philip, whose personal tastes in clothes were relatively simple, loved to surround himself with all the pomp and pageantry that the age could command. In 1430 he founded a new order of chivalry, a Burgundian version of the British Order of the Garter, called the Toison d'Or, or Golden Fleece, membership of which was limited to 24 noblemen of proved valour and wide renown. Court was held at Brussels or Bruges, in Brabant and Flanders, respectively; or at Hesdin or Lille, in northeast France; or at some other centre. The best artists of the day were employed by Philip to paint his banners and pennons, to decorate his palaces and carriages, and to illuminate what was probably the finest collection of picture books ever put together. The artist Jan van Eyck accompanied a ducal embassy to Portugal to paint the King's daughter Isabella, so that Philip could see her likeness before committing himself to marrying her. Sculptors worked on tombs at Philip's command, exquisite tapestries were embroidered under his personal supervision, and a host of musicians, jewellers, goldsmiths, and other craftsmen and artists were employed at his court. The bawdy stories exchanged by Philip and his courtiers after dinner were collected into *Les Cent Nouvelles Nouvelles*, or "The Hundred New Short Stories." Some of the more elaborate banquets, notably the Feast of the Pheasant in 1454, at Lille, were open to the public, who could admire the endless array of model ships and towers, pies with people inside them, peacocks, swans, and eagles (mock or real), and other paraphernalia that accompanied the various dishes. Other entertainment was held from time to time in the form of tournaments or passages of arms, and Duke Philip's courtiers roamed about Europe issuing challenges and doing battle with their colleagues from other lands.

Duke Philip was tall, handsome, and bony in figure; his face was long and lean, with a high forehead, prominent nose, and bushy eyebrows. Excellent in health, he enjoyed hunting, tennis, archery, and jousting in his youth, but he turned in his later years to making clogs, repairing broken glasses, and soldering broken knives. His many bastard children caused the Bishop of Tournai (himself a bastard) to criticize him for what the ecclesiastic called "the weakness of the flesh." Some were brought up at court; others went into the church. His mistresses were kept out of affairs of state, and it was mere geographical convenience and economy that caused him to maintain several at once in the different towns where he held court. Self-assured and flamboyant almost to the end, he died, possibly of pneumonia, at Bruges on June 15, 1467.

(R.Va.)

Philip the Magnanimous, Landgrave of Hesse

Philip the Magnanimous was the father of political Protestantism and champion of the independence of the German princes against the Catholic emperor Charles V. He contributed decisively to the establishment of conditions under which German Protestants could freely develop their churches in each state and, through the religious Peace of Augsburg in 1555, to achieving for Lutherans equality with Catholics.

Philip the Magnanimous, as Landgrave of Hesse, portrait by Hans Krell, 1525. In the Wartburg Sammlungen, Eisenach, Germany.

Early years. Philip was born November 13, 1504, in Marburg. His father, Landgrave William II, was a cultivated, austere man and an experienced soldier. He died when Philip was barely five years old. Philip's mother, Duchess Anna of Mecklenburg, was a passionate, energetic, and ambitious woman; her relations with her son, however, were cool and were impaired by her second marriage in 1519 and by Philip's conversion to the doctrines of Martin Luther. As a victim of political forces he spent a gloomy youth, attaching himself increasingly to his older sister Elizabeth, later duchess of Saxony; throughout his life no one was closer to him than she.

In March 1518 the emperor Maximilian I declared Philip to be of age. While assuming the government in name, he retained his parents' capable counsellors, mostly lawyers by training, who imbued the young man with his parents' single-minded devotion to the welfare of the state. Philip eventually developed into a self-reliant politician. From his youth, he characteristically thought in terms of the territorial state, an attitude that was to determine his future relations with the Habsburg emperors. He ruled his territory in the spirit of an early enlightened despotism.

Formative influences

The landgraviate of Hesse had suffered greatly during his mother's regency, but Philip succeeded in bringing order to the confused administration of the state and, through skillful management of alliances, in freeing Hesse from its isolation in foreign affairs. In 1523 Philip, fighting alongside the powerful electors of the Palatinate and of Trier, defeated the rebellious imperial knight Franz von Sickingen. This victory also crushed the remaining opposition of the Hessian nobility and undoubtedly strengthened the young man's self-confidence. Two years later, in fact, he scored his first personal triumph when he suppressed the peasant revolt in the neighbouring imperial abbeys of Fulda and Hersfeld. He then advanced into Thuringia and, allied with the Elector of Saxony and the Dukes of Brunswick-Wolfenbüttel and Saxony, defeated Thomas Müntzer, a popular preacher from Mühlhausen/Thüringen, at a battle near Frankenhausen in May 1525. By this victory Philip saved the central German principalities from destruction.

Conversion to Protestantism. During these years, while the first storm of the Reformation was sweeping through Germany, Luther's teachings gained a firm hold in many Hessian localities and at the Landgrave's court. But it was not until the summer of 1524, after making a detailed study of the Bible, the writings of the Church Fathers, and the history of the church, that Philip himself joined Luther. At the same time, orthodox Catholic princes of south Germany were uniting to make common cause against the ecclesiastical innovations. After the defeat of the peasants this alliance was aimed to bring down the middle and north German princes as well, in order "to eradicate the damned Lutheran sect, the source of this revolt." Philip was deeply convinced that the religious question was at the same time a political one, and he was the first to recognize that freedom for the new faith would be secured only if Protestant sovereigns and towns united for defense. In May 1526 he won over the elector John of Saxony for a defensive alliance, which other north and east German princes then joined. Henceforward, he strove to unite the Protestant estates into a powerful alliance, which would render them unassailable and thus allow them to build their state churches.

Decree of the Diet of Speyer

Only when the decree of August 1526 of the imperial Diet of Speyer seemed to provide a legal basis for it and when a Hessian "synod" (partly church council and partly provincial diet) at Homberg had publicly discussed the religious question did Philip carry through the Reformation in his state. The outcome of the Homberg deliberations was the *Reformatio ecclesiarum Hassiae*, unique for its democratic–presbyterian church constitution and the ecclesiastical discipline of the congregations. On Luther's advice this reform, conceived by the former Franciscan Franz Lambert, was not carried out; instead Hesse became Protestant along the lines of the model provided by the Electorate of Saxony. Philip, however, continued to favour the teachings of the south German and Swiss reformers and consequently resolved to mediate between the Lutherans and the Zwinglians, adherents of the Swiss reformer Huldrych Zwingli. Within one year, 1527, Philip secularized all the monasteries. The new state church organization was now methodically built up. In order to ensure a new generation of clergy and officials, the Landgrave took the educational system in hand and founded the first Protestant university in 1527 at Marburg. On former monastic and church estates, he set up four hospitals for the insane, the first "psychiatric" hospitals known to medical history. Church and school were subordinated to the "common good." There arose the Protestant authoritarian state, which considered itself a taskmaster responsible for the religious and moral life of its subjects and dictated their beliefs. Like all his fellow princes, Philip was intolerant, but, in contrast to most, he respected the individual's freedom of conscience by permitting dissenters to emigrate. He soon showed this attitude in his dealings with the Anabaptists; his purpose was not to punish them as the imperial laws dictated but to convert them by clemency and instruction in doctrine; in this work Martin Bucer, the reformer from Strasbourg, was his helper. They introduced into Hesse in 1539 the rite of confirmation, which became a model for Protestant churches.

Leadership of the Protestant states. His agile and fertile mind, infectious energy, and fearlessness rapidly made Philip the leader of the Protestant estates. He continued to strive for a great Protestant alliance, for he clearly recognized that the situation of the Protestants would deteriorate if the Catholic emperor Charles V were to triumph in the struggle for European predominance. The way to change and reform began in 1529, when the second imperial Diet of Speyer repealed the first imperial Diet's decree of 1526. A group of princes and

towns led by Philip protested (hence Protestants) against the repeal on the epoch-making grounds that in questions of faith each imperial estate would have to justify itself before God alone.

Moreover, the Landgrave saw with growing apprehension that doctrinal differences between Protestants endangered the development of an all-embracing Protestant defensive alliance. His attempt at the Colloquy of Marburg, in October 1529, to bring about a theological settlement in personal discussion with the reformers, headed by Luther and Zwingli, essentially failed over the question of the communion. Thus, the ambitious plans he shared with Zwingli for a European alliance against the Catholic house of Habsburg remained only a dream.

Schmalkaldic League

Despite everything, Philip managed in 1531 to unite six princes and ten towns in the Schmalkaldic League, which was to serve as a defensive alliance. Although it had serious organizational shortcomings, the league gradually became the centre of Protestant politics. At the same time it became a rallying point for the enemies of the House of Habsburg, as well as for those Catholic princes who were fearful for their independence. The league, of which the Landgrave was the driving spirit, became, moreover, a factor in European politics. Philip reached the peak of his career in 1534, when he executed a campaign to restore Duke Ulrich of Württemberg, who had been driven from his state by the Habsburgs. As a result of his success, Württemberg was opened up to the Reformation, and Austria's power in south Germany was broken.

Decline. It was Philip's tragedy that he destroyed his own leading position a few years later by his extremely provocative marital transactions. In addition to his marriage to the duchess Christina of Saxony in 1523, he contracted a second marriage with Margarete von der Saale, a maid of honour of his sister Elizabeth. As a bigamist he fell under the judgment of the Emperor, with whom he now tried to come to terms; but while Philip and the Schmalkaldic League remained inactive and the other Protestant princes indulged in petty disputes, Charles V prepared to settle the religious problem once and for all by force of arms. In the summer of 1546 he attacked. The league's unwieldy organization, long deplored by Philip, now took its toll. Mistakes of leadership, lack of finance, and ultimately the attack by the Protestant duke Maurice of Saxony on the territory of his cousin the elector John Frederick of Saxony hastened the collapse. After the capture of the Elector,

Prisoner of the Emperor

Philip submitted himself to the mercy of the Emperor in June 1547. Deceived by the Emperor, he, too, was led away a prisoner. His long imprisonment in the Netherlands deeply affected his mental powers of resistance. In order to gain his freedom, he accepted the so-called Augsburg Interim, by which the Emperor attempted to restore the unity of the Catholic faith without interference from the princes. Philip, however, failed in his bid for freedom, for the Hessian population resisted conversion to Catholicism. Only after his son-in-law, the elector Maurice of Saxony, and Philip's eldest son, William, in alliance with other German princes and Henry II of France, unexpectedly rose against the Emperor in March 1552 were he and John Frederick released.

Aged and ailing, but also wiser, the Landgrave returned to his homeland. After the victory over the Emperor, the adherents of the Confession of Augsburg—the official Lutheran doctrine—succeeded in gaining a position of legal equality with the Catholics in the empire, in accordance with the Peace of Augsburg of 1555. In this respect Philip, who was far ahead of his time, expressed genuine tolerance for all Christian denominations. He continued to pursue his old plans for a Protestant union and strove on behalf of his embattled coreligionists in France and the Netherlands, but in his later years he cautiously remained in the background of the political stage. He devoted all his strength to the rebuilding of his state, which had been ravaged by war and by its occupation by foreign troops. By the time of his death in Cassel on March 31, 1567, his contemporaries were already referring to the warm-hearted and generous sovereign as the Magnanimous.

BIBLIOGRAPHY. There is as yet no modern biography of Philip. Valuable individual research is contained in the publications issued in 1904 to honour him: *Festschrift zum Gedächtnis Philipp des Grossmütigen*, published by the Verein für hessische Geschichte und Landeskunde (1904); *Philipp der Grossmütige*, published by the Historischen Verein für das Grossherzogtum Hessen (1904); and C.A. VON DRACH and G. KONNECKE, *Die Bildnisse Philipps des Grossmütigen* (1905). From the abundance of previously published works the following in particular should be mentioned: K. DULFER, *Die Packschen Händel: Darstellung und Quellen* (1958); W. HEINEMEYER, "Die Bildungspolitik des Landgrafen Philipp von Hessen," in *Hessisches Jahrbuch für Landesgeschichte 21* (1971); and "Landgraf Philipps des Grossmütigen Weg in die Politik," *ibid. 5* (1955); F.H. LITTELL, *Landgraf Philipp und die Toleranz* (1957); W.W. ROCKWELL, *Die Doppelehe des Landgrafen Philipp von Hessen* (1904); W. HANCOCK, "Philipp of Hesse's View of the Relationship of Prince and Church," *Church History*, 35:157–169 (1966). A bibliography of literature on Philip is given in K.E. DEMANDT, *Schrifttum zur Geschichte und geschichtlichen Landeskunde von Hessen*, vol. 1, pp. 203–212 (1965). General information is found in *The New Cambridge Modern History*, vol. 2, ch. 3 and 6 (1958). Philip's political correspondence is preserved in the Hessisches Staatsarchiv Marburg and has been calendared in F. KUCH and W. HEINEMEYER (eds.), *Politisches Archiv des Landgrafen Philipp*, 4 vol. (1904–59). All known sources for the history of the Reformation in Hesse are in W. SOHM and G. FRANZ (eds.), *Urkundliche Quellen zur hessischen Reformationsgeschichte*, 4 vol. (1915–55; 2nd ed. of vol. 1, 1957).

(W.He.)

Philippines

The Republic of the Philippines is an archipelago consisting of about 7,100 islands and islets, lying about 500 miles off the southeast coast of Asia. The total land area of the Philippines is 115,830 square miles (300,000 square kilometres); it had a population of about 38,000,000 in 1971. It is bounded on the east by the Philippine Sea (Pacific Ocean), on the south by the Celebes Sea, and on the west and north by the South China Sea. The Philippines takes its name from Philip II, king of Spain at the time of the Spanish colonization of the islands in the 16th century. Both the present capital, Quezon City, and the former one, Manila, still housing many governmental offices, are situated on Luzon, the largest island.

The archipelago spreads out in the form of a triangle, with the archipelago of Sulu and the island of Mindanao forming its southern base and the islands of Batanes, in the north, its apex. The islands stretch out for about 1,100 miles (1,800 km) from north to south and for about 650 miles from east to west at the archipelago's widest extent. Only 2,773 of the islands and islets have names, and only 462 have areas of one square mile or more; many are no more than reefs or small atolls. The large islands fall into three groups: (1) the Luzon group, consisting of Luzon (with a land area of 40,420 square miles) and Mindoro (3,759 square miles) in the north; (2) the Visayan group in the centre, consisting of Bohol (1,492 square miles), Cebu (1,703 square miles), Leyte (2,786 square miles), Masbate (1,262 square miles), Negros (4,906 square miles), Palawan (4,550 square miles), Panay (4,446 square miles), and Samar (5,050 square miles); and (3) Mindanao (36,537 square miles) in the south.

Because it was under Spanish rule for 333 years and under United States' tutelage for a further 50 years, the Philippines has many cultural affinities with the West. It is, for example, the only Roman Catholic country in Southeast Asia. Its peoples, however, most of whom were originally of Malay origin, are Asian both in consciousness and in aspiration. In many ways Filipino society is composed of paradoxes. While extremes of wealth and poverty exist, and while agricultural land is often owned by wealthy landowners, the Philippines is vigorously democratic. A country of rich resources, it is still far from developing its full potentialities. Economically it is primarily agricultural—its major exports being coconuts and coconut products, sugar, and abaca (Manila hemp). Educationally, however, it is among the most advanced

of Asian countries, maintaining more than 40 universities and 374 private colleges, and having a literacy rate of about 72 percent (for coverage of associated physical features, see CHINA SEA; PACIFIC OCEAN; for historical aspects, see PHILIPPINES, HISTORY OF THE).

THE NATURAL AND HUMAN LANDSCAPE

The physical environment. *Relief and drainage.* The irregular configuration of the archipelago, the coastline of more than 21,500 miles, the great extent of mountainous country with the mountains lying close to the sea in many places, the narrow and interrupted coastal plains, the generally northward trend of the river systems, and the lakes comprise the outstanding physical features of the Philippines. The islands have volcanic, coral, and all principal rock formations. The mountain ranges for the most part run in the same general direction as the islands themselves, approximately north to south. The Cordillera Central (central mountain chain) of Luzon, running north to the Pacific Ocean from the northern boundary of the central plain, is the most prominent chain. It consists of two, and in places three, parallel ranges, each of which averages 5,900 feet (1,800 metres) in height. The narrow Ilocos, or Malayan Range, lying close along the narrow west coast, rises in places to more than 5,000 feet and is seldom less than 3,500 feet in height; it is largely volcanic. This range and the Cordillera Central merge in Nueva Vizcaya Province to form the Caraballo Mountains. To the north of the latter, and between the two ranges, is the fertile Cagayan Valley, about 50 miles wide. In the southwestern part of northern Luzon are the rugged Zambales Mountains, consisting of more or less isolated old volcanic stocks (bodies of rock originally formed deep down under heat and pressure).

Mountain ranges

The central plain of Luzon, about 150 miles by 50 miles, is only about 100 feet above sea level except near its centre. The greater part of southern Luzon is occupied by isolated volcanoes and irregular masses of hills and mountains. The highest peak is Mayon (7,943 feet) near Legazpi in Albay Province.

Through the island of Palawan, about 25 miles wide, there extends a range with an average height of from 4,000 to 5,000 feet. Each of the Visayan Islands, except Samar and Bohol, is traversed longitudinally by a single range with occasional spurs. Several peaks in Panay reach an altitude of 6,000 feet or more. Mount Canlaon, on Negros is a volcano 8,087 feet high; other peaks reach an altitude of more than 6,000 feet.

There are several important ranges on Mindanao, the Diuata Range along the eastern coast being the most prominent. West of this lies the fertile Agusan Valley, 12 to 37 miles wide. Farther west and southwest is the valley of the Rio Grande de Mindanao, the largest river system on the island, and between its lower course and the southern coast lies a range trending northwest and southeast. On the southern border of the basin of Rio Grande de Mindanao River is Mount Apo, 9,691 feet high, the highest peak in the Philippines. Around Lake Lanao are a number of volcanic peaks. A low cordillera extends into Zamboanga Province.

The plains lying amid the mountains—for example the central plain of Luzon, the Cagayan plain of northern Luzon, the central plain of Panay, and the Agusan and Cotabato valleys on Mindanao—have the densest population of the islands, except in Cebu, where the people live mostly on the coastal plain because the interior is high and rugged. The most important rivers are the Cagayan, the Agno, the Pampanga, the Pasig, and the Bicol on Luzon and the Rio Grande de Mindanao and the Agusan-

on Mindanao. The Pasig, flowing through the city of Manila, is commercially important. The largest lake in the archipelago is Laguna de Bay, located south of Manila.

Volcanic areas

Volcanoes are the most conspicuous feature of the landscape, but there is relatively little volcanic activity. There are altogether about 50 volcanoes, of which 10 are known to be active. All gradations of volcanoes can be seen, from the almost perfect cone of Mayon, which has been compared to Fujiyama in Japan, to old, worn-down volcanic stocks, the present forms of which give little indication of their origin. The several distinct volcanic areas are in southwestern Luzon, southeastern Luzon, the mountain region in Camarines Norte, and in Negros, Mindanao, Jolo, and elsewhere. Seismic disturbances are common.

Climate. The climate is tropical and there are two marked seasons—the dry and the wet. The dry season generally begins in March and ends in June, and the wet season covers the rest of the year. During the wet season, rainfall is heavy in all parts of the archipelago except in Cebu and Zamboanga. Rain is heaviest along the eastern shores facing the Pacific Ocean. From June to December typhoons frequently strike the archipelago; in some years the number of typhoons reaches 200 or more. When accompanied by floods or high winds these typhoons, which are heaviest in Samar, Leyte, eastern Quezon Province, eastern Mindanao provinces, and the Batan Islands, cause great loss of life and property. Mindanao, except for the eastern and northeastern part, is generally free from typhoons.

November through February constitutes the most agreeable season; the air is cool and invigorating at night, and the days are pleasant and sunny. The cities of Baguio and Tagaytay on Luzon, the town of Malaybalay on Mindanao, and some other places, such as Lilio and Majayjay in Laguna, and Lucban in Quezon, experience a pleasant climate throughout the year; at times the temperature dips as low as 60° F (16° C). During the hot or dry season in most places, and especially in the cities of Cebu, Davao, and Manila, the temperature sometimes rises as high as 100° F (38° C).

Temperature ranges

Vegetation. Almost 40 percent of the land area of the islands is covered with forest. Many of the mountains are covered with dense forest. On northern Luzon the principal mountain tree is pine. In many places where the forests have been burned away their place has been taken by *cogon*, a tall coarse grass, or similar grasses. There are about 10,000 known species of flowering plants and ferns. Much of the vegetation resembles that found in Malaysia; and the vegetation of the coastal areas, including the mangrove swamps, is practically identical with that of similar areas throughout the Malay Archipelago. Himalayan elements occur in the mountains of northern Luzon, while a few Australian types are found at various altitudes. A majority of the plant species—about 60 percent—are indigenous; these include the dominant forest species. Members of the lauan (Philippine mahogany) family of trees often comprise a high percentage of the forest. There are many other valuable hardwoods as well as many softwoods. About 800 species of orchids occur, some of them very rare.

Animal life. There are about 220 species of mammals, among which are carabaos (water buffalo), goats, horses, hogs, cats, dogs, monkeys, squirrels, lemurs, mice, pangolin anteaters, chevrotains (mouse deer), mongooses, civet cats, and red and brown deer. The tamarau, a very small species of carabao, is found only on the island of Mindoro. There are at least 56 species of bats, many of which are peculiar to the Philippines; large fruit bats live in colonies. Early records show that there were once elephants on the islands.

There are about 1,000 species and subspecies of known birds, some of which are migrants. The bird life includes jungle fowl, pigeons, peacocks, pheasants, doves, parrots, hornbills, kingfishers, sunbirds, tailorbirds, weaverbirds, herons, and quails. Many species of birds are unique to the island of Palawan. The rare monkey-eating eagle is found only on Mindanao, Luzon, Mindoro, and Palawan.

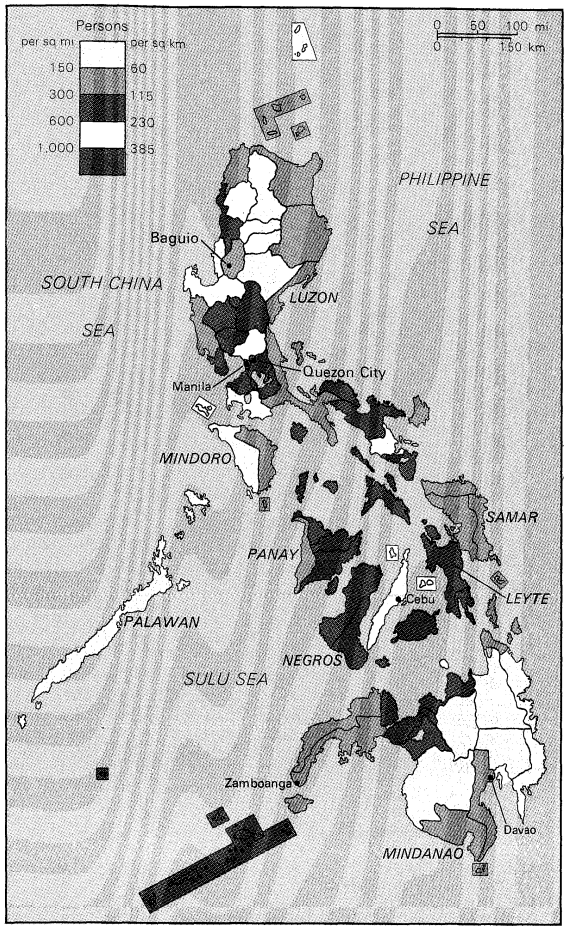
The landscape under human settlement. *Rural settlement.* Before the arrival of the Spanish in the 16th century, the people lived in small independent villages called *barangay*, each of which was ruled by a petty king called a *datu*. Settlement in rural areas today is focussed upon *poblaciones*, or small towns, originally founded by the Spanish that have agricultural populations numbering as many as 10,000 people. Roads or trails were built from the *población* in from four to six directions, like the spokes of a wheel. Along the roadsides, barrios or villages have grown up; these barrios are subdivided into smaller units called *sitios*. More people live in the barrios than in the *población*. A large barrio may be composed of as many as 1,000 households and have a population of 3,000 inhabitants or more. The cultivation of rice or corn, and fishing, provide the basic subsistence.

Towns and cities. While the Philippines has 1,369 municipalities, 30 municipal districts, and 58 chartered cities, almost all municipalities and all municipal districts are in fact rural communities.

Manila, Cebu, Jaro, Vigan, and Nueva Caceres (Naga) were granted city charters by the Spanish. More cities were founded under United States administration, and still more have been created since independence in 1946. Quezon City was built to be the capital of the Philippines.

Recently founded cities

In most of these cities, life has become increasingly complex as a result of the growth of population, business, and industry, and many of the problems of contemporary urban life have developed.



PEOPLE AND POPULATION

Groups historically associated with the contemporary country. *Ethnic groups.* The people of the Philippines are called Filipinos. Their ancestors, who were of the Malay or brown race, came to the Philippines from the southeastern Asia mainland as well as from what is now Indonesia. From the 10th century, contacts with China resulted in a group of mixed Filipino-Chinese descent who number about 10 percent of the entire population. An estimated 120,000 Chinese nationals also live in the country. Mixed Spanish-Filipino and Filipino-American types among the population may be distinguished by their fairer complexion, taller stature, and aquiline noses. While some emigrants have come from the Indian subcontinent, Indian-Filipino interracial mixture has been negligible, the Indian community numbering about 1,500. There are about 10,000 resident United States nationals (excluding military personnel). Spaniards number about 1,000. The aboriginal inhabitants of the islands were the Pygmies, or Negritos, also called Aetas or Balugas. From four foot five to four foot eight inches in height, and black-complexioned, they number about 30,000—one-twelfth of 1 percent of the total population.

Linguistic groups. Estimates of the total number of languages and dialects spoken in the Philippines differ; latest scholarly studies suggest that there are about 75 of them. Traditionally, seven major linguistic groups are identified. These are: (1) the Tagalog group, concentrated in Manila, the provinces of central and south central Luzon, and the island provinces of Mindoro, Marinduque, the most parts of Palawan; (2) Cebuano, in Cebu, Bohol, eastern Negros, western Leyte, and parts of Mindanao; (3) Ilongo, spoken in parts of Panay and western Negros; (4) Waray-Waray, spoken in Samar and Leyte; (5) Ilocano, dominant in many parts of northern Luzon; (6) Pampango, spoken in parts of central Luzon; and (7) Bikol, spoken in southern Luzon and on the islands of Catanduanes and Masbate. Other notable languages are Pangasinan and Ibanag, spoken in northern Luzon, and Aklan, spoken in Panay.

Pilipino

The national language of the Philippines, which is also the most widely spoken, is Pilipino, which is based on Tagalog; together with English, it is used as a medium of instruction in schools. Tagalog itself is the richest of all Philippine languages and has the most extensive written literature. Apart from Pilipino, there are two other official languages—English and Spanish. Only the United States and the United Kingdom have larger English-speaking populations than the Philippines.

Population density of the Philippines.

Religious groups. Out of an estimated population of almost 38,000,000, there are about 31,000,000 Roman Catholics; about 2,000,000 Aglipayans, adherents of a Filipinized form of Catholicism; almost 2,000,000 Muslims; about 1,500,000 followers of Iglesia ni Kristo, a form of Protestantism; and more than 500,000 Protestants. There are also some pagans and adherents of minor faiths.

Of late years Catholicism has been strengthened in the country by the increase in the number of Filipinos in the church hierarchy (cardinals, archbishops, and bishops), by the building of more seminaries, and by the increased involvement of the church in the social life of the country.

Demography. *Birth and mortality rates.* Because it is a Roman Catholic country and because most of its population is rural, the Philippines has a high birth rate. Birth control and family planning are rarely practiced.

Pestilence and epidemics may be said to be things of the past in the Philippines, but communicable diseases still constitute a problem. Thanks to education and good health conditions, life expectancy increased from 37.5 years in 1904, to about 52.5 in 1960, and to about 58 in 1968. The annual population increase of 3.3 percent is one of the highest in the world and represents a population increase of about 1,130,000 a year.

Immigration and emigration. There is a considerable amount of Filipino emigration, especially of manual workers and professional personnel. Many emigrants go to the United States, including Hawaii; to Okinawa in the Ryukyu Islands; to Guam in the Mariana Islands; to U.S. military bases in South Vietnam and Korea; and to Canada. There are more than 6,000 Filipino doctors and 8,000 Filipino nurses in the United States alone. Manual labourers usually go to Vietnam, Okinawa, Guam, and Hawaii, and to some parts of the U.S. mainland. Few Filipinos emigrate to other countries.

Distribution of population. In 1970 it was estimated that the population density numbered 327 people per square mile in the country as a whole. The population is unevenly distributed, with densities ranging between 41 and 3,962 per square mile. In Manila, there are about 89,000 persons per square mile. In Bukidnon Province on Mindanao the density is only 130, and in the Batanes Province on the Batan Islands it is only 136. About 3,295,000 people live in the northern Luzon region; about 5,099,000 in central Luzon; about 6,827,000 in southern Tagalog (excluding Manila); about 2,966,000 in the Bicol region of southeastern Luzon; about 5,413,000 in the east Visayan region; about 3,785,000 in the west Visayan region; and about 7,966,000 in Mindanao. The population of Quezon City is about 754,000.

Demographic trends. The population tends to move from rural areas to the towns and cities. Whereas at the beginning of the 20th century more than 80 percent of the population lived in rural areas, today only about 66 percent do so. Of those who have moved to the towns and cities, about 12 percent work in factories. The movement to the towns accelerated after World War II; Manila, for example, which today numbers 1,331,000, had a population of only 600,000 in 1931. Greater Manila today has a population of about 3,000,000. The farmlands, formerly to be found in its vicinity, have now been swallowed up by towns; two areas in particular—Pasay and Caloocan—have become cities in their own right, and Diliman now forms a part of Quezon City.

The movement to the towns

THE NATIONAL ECONOMY

Despite the government's optimistic view of progress made since independence, economic growth appears slow when compared to that of other Asian countries. The World Bank has estimated that between 1961 and 1968 the Philippines attained an average growth rate of less than 1 percent in its real per capita gross national product.

The extent and distribution of resources. *Mineral resources.* The Philippines is rich in mineral resources. There are deposits of gold in Mountain Province and Camarines on Luzon; iron ore in Surigao on Mindanao and Bulacan on Luzon; copper in Zambales on Luzon; lead and zinc in Marinduque; high-grade chromium in Zambales, Camarines Sur, and Pangasinan on Luzon, and Antique on Panay. Deposits of silver, nickel, mercury, molybdenum, (a silver-white element used as an alloy), cadmium (a white element resembling tin), and manganese are found in several other places. Nonmetallic minerals include cement, found in Cebu, Luzon, Romblon, Masbate, Panay, and Bohol; salt, found on Luzon; asbestos on Luzon; granite and marble on Romblon and Panay; asphalt in Leyte; mineral waters on Luzon and Mindanao; gypsum on Luzon; sulfur on Luzon; guano (sea bird manure used as fertilizer) and phosphate rock on Panay; and coal and silica in some other places.

Biological resources. About 40 percent of the Philippines' total land area is covered with rain forests. Of this, 12,000,000 hectares (46,000 square miles)—almost two-thirds of the forest area—abound with trees that have commercial value. Woods such as narra (a reddish wood used in cabinet-making), ipil (a very hard, durable wood), molave (a durable yellow hardwood), and kamagong (a dark wood with lighter grains running through it) are in particular demand. The lumbering industry, however, has tended to deplete the forest resources.

No fewer than 2,000 varieties of fish are in the seas surrounding the islands and in lakes, rivers, estuaries, and fish ponds. The most important commercial fishes are milkfish (a herringlike fish); *dilis* (anchovies); herring; sardines; mackerel; *alumahan* (mackerel); *tanginggi* (mackerel); lapu-lapu (grouper); snappers; *talakitok* (cavalla); *talilong* (mullet); barracuda; mudfish; and *dalagang bukid* (caesio). The people raise fish in ponds in some provinces of Luzon and Panay.

The Philippines' pearl fisheries constitute another biological resource. There are nine pearl beds in the Sulu Archipelago to the south. Pearl shells used for making buttons are exported to China, Hong Kong, and elsewhere. Tortoise shells and shells used for windows are exported to Singapore, Malaysia, and other countries.

*The area and population of Manila are excluded from the corresponding totals for Rizal Province. †Agusan Province was subdivided before the 1970 census into Agusan del Norte and Agusan del Sur. No breakdown of area or adjusted 1960 census figures is available. Figures given are for the entire Agusan Province. ‡Converted area figures do not add to total given because of rounding. §The total area was reported as land area, but appears to include some inland water. ‖Figures do not add to total given because of rounding.
Source: Official government figures.

Hydroelectric and other power resources. Hydroelectric power in the past has supplied only a small proportion of the country's electrical output, with thermal plants, most of which burn imported oil, supplying the major proportion. But with the completion of the Binga and Ambuklao dam projects on Luzon and the expansion of the Maria Cristina project on Mindanao, Philippine hydroelectric potential is being put to use. Irrigation and flood control are additional benefits of the Upper Pampanga River Project. The new Bataan thermal plant will serve as a supplement to the Luzon hydroelectric plants, especially during the dry season.

Sources of national income. *Agricultural resources.* The Philippines is chiefly an agricultural country. Its soil is rich and fertile, and its products grow abundantly throughout the year. The country's potential farmland amounts to more than 16,000,000 hectares, but only about half of this area is under cultivation.

The principal farm products are rice, coconut, sugar, abaca (Manila hemp), tobacco, corn, maguey (a fleshy fibrous plant used for making ropes, etc.), and pineapples. Many tropical fruit trees and plants are also raised, the most important being bananas, mangoes, lanzones (a grape-like fruit with a thick yellow skin), oranges, papaya, avocado, star apples (a bland-tasting purple fruit), atis (a white pulpy fruit), pomelos (a species of grapefruit), nangca (jackfruit), apples, strawberries, guavas, santol (a reddish fruit used for preserves), and durian (an edible fruit with a prickly rind and an offensive odour). Vegetables such as beans, tomatoes, pechay (Chinese cabbage), cabbages, mustard, lettuce, camotes (sweet potatoes), sugar beet, cassava, and squash are raised on farms and in gardens for domestic consumption.

Rice, the principal staple crop, is grown everywhere, but especially in the provinces of Batangas, Laguna, Nueva Ecija, Pampanga, Pangasinan, and Tarlac on Luzon; in Cotabato on Mindanao; in the western province of Negros and in the provinces of Capiz and Iloilo on Panay. More than 3,000,000 hectares, or almost one-half the total area under cultivation, is used for rice growing. In 1968 the Philippines became a rice exporting country for the first time for many decades. The increase in rice production was due primarily to the efforts of the government and Filipino farmers, assisted by the U.S. financed International Rice Research Institute.

The Philippines is the world's largest producer of coconuts and the principal exporter of coconut products. The area devoted to coconut production—about 2,000,000 hectares—is second only to that used for rice, and about

12,000,000 Filipinos are dependent upon this crop for their livelihood. The Philippines also produces about one-third of the world's copra (dried coconut meat used for oil extraction and as animal feed) output, which earns for the government about 40 percent of its total income from exports.

Sugar is the country's third largest export and earns a substantial amount of foreign exchange for the government. Sugarcane is grown extensively in the Batangas, Laguna, Pampanga, and Tarlac provinces of Luzon; in western Negros; and in Iloilo Province of Panay. About one-seventh of the Filipino population depends on this industry for a living. Current production amounts to about 2,000,000 tons, 60 percent of which is exported, mostly to the United States.

Manila hemp

Abaca, or Manila hemp, is the best hemp fibre available. It ranks high among the country's chief exports, although only about 200,000 hectares, or approximately 2 percent of the country's cultivated area, are used for its production, which employs about 3,000,000 people. It is grown extensively in the Davao provinces of Mindanao, in the Bicol region of Luzon, in Leyte, and in Samar.

Timber, lumber, and veneer products are the leading exports. Because of their high quality these products are in great demand. Other forest products include dyewoods, rattan, tanbarks, bamboo, gutta-percha (a gum), beeswax, rubber, and edible birds' nests.

Fishing also constitutes one of the most important of Filipino industries. Canned tuna is the principal fish exported. Commercial fishing is carried on primarily off Palawan, Negros, Mindanao, and Panay. Fish provides an important proportion of the protein in the Filipino diet.

Mining and manufacturing. Gold, silver, iron, copper, manganese, zinc, lead, coal, and chromite ore are mined. Manufactured products include cement, plywood, chemicals, electrical equipment, medical supplies, radios and musical instruments, plastics, and rubber and steel goods.

Financial services and foreign trade. In addition to the Central Bank of the Philippines, there are more than 40 commercial banks, some of which have more than 100 branches and agencies. Banking operations are also conducted by such other institutions as the Postal Savings Bank, the Agricultural Credit Administration, and the Development Bank of the Philippines. The principal exports, as mentioned, are timber, coconuts and coconut products, copra, sugar, and abaca, while the principal imports are machinery, fuel, textiles, electrical equipment, and transport equipment. The United States accounts for about 35 percent of the total trade of the Philippines; other trading partners are Japan, West Germany, The Netherlands, the United Kingdom, and Australia.

Management of the economy. *The private sector.* The economy of the Philippines is based on free enterprise; individuals and nongovernmental entities are free to participate in its development and management, sometimes with the aid, in whole or in part, of governmental credit. As a result of this encouragement, many manufacturing industries have been established since 1950; new businesses have, indeed, sprung up like mushrooms. Manufacturing firms have risen in number from fewer than 1,000 in 1949 to 29,000 in 1969, a rate of expansion that has been reflected in an increase in the variety of products available.

New manufacturing industries

The public sector. The government has assisted the private sector of the economy by exempting certain new industries from taxation for a certain period. Only nominal taxes are imposed on selected industries, and as already mentioned, credit, or loans on favourable terms, are available to others. Government banks, such as the Central Bank of the Philippines, the Philippine National Bank, the Development Bank, the Agricultural Bank, and others were established to encourage business, agriculture, and industry. Half of the original capital investments of thousands of private rural banks was provided by the government. Private development banks have likewise received governmental assistance. The National Economic Council and the Board of Investments have been created to help both public and private sectors in undertaking studies and in planning further economic development.

The government has also to some extent been engaged in business in its own right. It either owns or operates the National Development Company, the National Shipyards and Steel Corporation, the Philippine National Railways Company, the National Rice and Corn Administration, and other companies. The Philippine government has, however, on the whole been a failure in business because of the interference of party politics in management.

Taxation. The government derives its revenue from three major sources—first, from taxation; second, from earnings and other credits; and third, from extraordinary income, including the transfer from special funds (funds derived mainly from unexpended balances in the budget which are deposited as savings accounts that draw interest). About 85 percent of revenue is collected through the Bureau of Internal Revenue and the Bureau of Customs. The remainder is collected through other offices and represents receipts from land surveying and similar sources.

Internal revenue taxes constitute the largest portion of government income; customs revenues come from imported goods and from taxes on shipping. Revenues from earnings and other credits include service income, prior year credits, income from rentals, interest on investments, and miscellaneous receipts. Local governments have only limited taxing powers.

The main items of national expenditure are, in order of importance, education, representing about 30 percent of the total; public works and communications; national defense; the executive department; agriculture and natural resources; health; repayment of national debts; the judiciary; revenue collection; the Congress; foreign affairs; aid to local governments; social welfare; gratuities; and pensions.

Trade unions and employer associations. The strength of the trade unions is greater today than at any time in the past. The trade union movement is well established in Manila and in most other towns and cities. Farmers' or tenants' groups are also organized, as are the teachers and government employees. In the 1960s student groups sympathetic to labour and to political and social reform became active. Management, for its part, has organized company unions. Relations between trade unions and the employers union have been generally untroubled. The Court of Industrial Relations and the Court of Agrarian Relations have been effective in settling disputes between labour and management.

Economic politics. The government, through the National Economic Commission, the National Planning Commission, and other agencies, plans national economic development. In so doing, it has sought to increase economic independence, for while there have been advantages in the preferential trade relations between the U.S. and the Philippines, this trade resulted in the development of those industries that would primarily benefit the U.S. rather than the Filipino economy. While the trade preference agreements remained in force until 1974, new markets, including those in Communist countries, were explored. Trade with Japan is rapidly increasing as is that with The Netherlands, Indonesia, Canada, and Taiwan. Internally, there is to be an attempt to develop the Philippines as both an agricultural and an industrial country. A foreign investments incentive law was passed in 1969 by Congress to encourage joint investments by Filipino and foreign capital and to permit the use of foreign managerial skills. An attempt is also being made to encourage Filipino residents abroad to invest in the Philippines.

New markets

Problems and prospects. It has frequently been observed, first, that the Philippines is rich but that the people are poor, and, second, that the progress attained has been made by an insignificant number of individuals. Average per capita income still remains less than 1,000 pesos ($255) annually. About 55 percent of the people are still engaged in agricultural food production and only about 11 percent in manufacturing; about 2,000,000 people either have no work or are underemployed. About 10

percent of the people—those in the highest income group—receive 40 percent of national earnings, with the remaining 90 percent receiving the remaining 60 percent of this income. The government itself remains poor; despite its responsibility for a territory of 115,830 square miles and a population of about 38,000,000 people, its budgetary outlay for the financial year 1972–73 was still little more than U.S. $780,000,000. Historically, the traditional cacique (landowning) system, the personal ambitions of many government officials, and 400 years of colonial rule have brought about this condition. Full development of the economy and equitable distribution of the national wealth are the two main economic problems. By the mid-1970s various plans for bolder solutions, including several five-year plans, are expected to show results. Some observers have predicted revolution unless radical reforms are instituted to develop agriculture, commerce, and industry, to distribute more equitably wealth among the people, and to end the abuses of caciquism (the landownership system) and of the political machine.

Transportation. *Road networks.* Thousands of miles of roads—gravel, asphalt, and cement—link the towns on the archipelago's many islands. About 30 miles of modern expressways run north and south from Manila. Elsewhere on Luzon, most of the road to Laoag, 250 miles north of Manila, and the greater part of the road to Sorsogon in the south, are cemented, as are roads branching out to the city of Baguio and to the provinces of Batangas, Camarines Norte, Cavite, Pangasinan, and Zambales. Thousands of miles of roads (of various types) have also been constructed in Mindanao, Mindoro, Palawan, and the Visayas. About 750 miles of road were cemented and over 1,000 miles asphalted between 1966 and 1969 alone. A system of roads, bridges, and ferries to connect the islands of Luzon, Samar, Leyte, and Mindanao was under construction in the 1970s. At the end of 1970 about 450,000 motor vehicles were in use on the highways; the average of one motor vehicle for every 82 inhabitants is the highest of any Asian country except Japan. In Manila and in most other cities taxi services are usually available at low rates.

Railways. Two principal railroads operate in Luzon and Panay. The Luzon line, with about 730 miles of track, extends from San Fernando in La Union Province in the north to the city of Legazpi in Albay Province in the south. The railroad in Panay, about 90 miles in length, connects the city of Iloilo, in Iloilo Province, with Roxas City, in Capiz Province. Both railroads suffer from competitive air services and bus transport.

The port of Manila

Port facilities. The most important port is Manila, which handles from 70 percent to 80 percent of all shipping. Manila North Harbor accommodates domestic trade, while the Manila South Harbor, which can accommodate as many as 30 ships, handles shipping from abroad. Other ports used by international shipping are Cebu (next in importance to Manila), Iloilo, Davao, Zamboanga, Cagayan de Oro, Legazpi, and Bacolod. There are more than a hundred smaller ports.

Air transport. The international airport at Manila, like those at Hong Kong and Singapore, is a focal point for air routes and is used by about 25 air carriers. A separate terminal is used by domestic airlines. The Mactan airport, on Mactan Island near Cebu, is also international. There are also 77 other airports for domestic flights, all connected to Manila. The domestic airlines—apart from Philippine Air Lines, which is also international—are Air Manila, Filipinas Orient Airways, and Delta Air Lines.

ADMINISTRATION AND SOCIAL CONDITIONS

The constitutional framework. Work on a new constitution began in 1971. The Filipino constitution, which remains in force, adopted in 1935 and amended in 1940 and 1946, provides for a republican system of government in which sovereignty resides in the people and is exercised by them through universal suffrage. The national government provided for in the constitution has three independent, separate, but coordinate branches—the executive branch, the legislative branch, and the judiciary. At the head of the executive is the president, who is elected directly by a national election for a term of four years; he is forbidden by the constitution to hold office for more than eight consecutive years. A vice president, whose qualifications and tenure are similar to those of the president, is elected at the same time. Only natural-born Filipino citizens, 40 years of age or over, resident in the Philippines for at least two years before an election and qualified to vote, are eligible for the presidency. To assist him in his official functions, the president appoints department secretaries (or ministers), who are subject to confirmation by the Commission on Appointments—an independent body of 25 members, composed of 12 senators and 12 congressmen meeting under the chairmanship of the president of the Senate. Governmental departments include those for foreign affairs, finance, defense, education, social welfare, health, and agriculture and natural resources.

Laws are enacted by Congress composed of the Senate and the House of Representatives. The Senate is composed of 24 members who are elected by nationwide election for a term of six years. The qualifications for senator are the same as those for the presidency, except that the minimum age requirement is 35 years. One-third of the senators end their terms of office every two years; they may, however, be re-elected for an indefinite number of terms. The Senate, together with the president, enjoys treaty-making powers.

The House of Representatives is composed of not more than 120 members, who are elected for a term of four years and who may be re-elected an indefinite number of times. Members of the House of Representatives must be at least 25 years old.

The judiciary

The judiciary is composed of the Supreme Court, consisting of 11 justices, and of minor courts, including a court of appeals (composed of 15 justices), courts of first instance, and city and municipal courts. In addition, there are special courts concerned with industrial relations, agrarian relations, and family relations. Justices and judges of these courts are appointed by the president of the Philippines, subject to confirmation by the Commission on Appointments.

Other agencies created by the constitution are the Commission on Elections, the Presidential Electoral Tribunal, the Senate Electoral Tribunal, the House Electoral Tribunal, the General Auditing Office, and the Civil Service Commission.

Local government. The constitution empowers Congress to enact laws establishing local governments. The country is divided into 66 provinces, 4 subprovinces, 58 chartered cities, 1,369 municipalities, 30 municipal districts, and 29,948 barrios (villages). Each local unit has its defined territory. Cities, and even provinces, are, however, sometimes created primarily for political ends. Each province, city, municipality, municipal district, and barrio has its own local government, and its own elected and appointed officials. Each province is headed by a governor, each subprovince by a deputy governor, and each city or municipality by a mayor. The smallest political subdivision is the barrio, administered by a council, which is headed by a barrio captain.

The political process. *Elections.* Elections are held every four years. In electing the principal officials of both national and local governments, male and female voters must be citizens of the Philippines, must be 21 years of age or over, must know how to read and write, and must not have a mental disability or a criminal culpability.

Parties. Many political parties have existed since the early years of the 20th century, most of them having nationalistic leanings, but there is essentially a two-party system: the Nacionalista Party and the Liberal Party. Both parties are nationalistic with little ideological difference. Party strength is largely dependent upon the attractiveness of personal leadership.

The participation of the citizen. Most Filipinos take a keen interest in politics and the percentage of registered voters (almost 50 percent of the total population) who exercise the right to vote in elections (often 80 percent) is higher than in many other countries, including the United

States. Political meetings and rallies are well attended. Critics have claimed that vote-buying has become a common practice, that the strict laws governing limitation of election expenses are not enforced, and that only rich men, or candidates supported by them, win the elections.

Political developments. Filipinos adhere strongly to the democratic system. While they prefer free enterprise and reject Communism, Socialism has made some impression upon them and there is a growing movement to extend more government assistance to the less fortunate. Before World War II Socialism found adherents among the rural population of central Luzon and Manila. During the war they formed a guerrilla unit called Hukbalahap, meaning "Peoples' Army Against Japan." After the war they maintained their organization against what they termed a government of oligarchs. It appears that they maintain some sort of intelligence with the Communist government of China. Their activities are confined to central Luzon and are well under government control. Personal leadership remains, however, a key factor in political life—a circumstance which sometimes unfortunately encourages a degree of demagoguery.

Justice. Equal justice under the law for all is guaranteed by the constitution. The administration of justice is generally fair, especially at the higher level of the judiciary. Justices and judges enjoy fixed tenure and reasonably high compensation. The judiciary has consequently been less criticized than other branches of the government, and from 1900 to the present, the Supreme Court has retained the trust of the people.

The armed forces. The Department of National Defense is divided into four services: the army, the navy, the air force, and the constabulary (the national police force). Each branch has a commanding officer whose rank is at least that of brigadier general or, in the navy, commodore. Altogether about 58,500 men are in active service and many more in the reserves. Several army battalions have served in both the Korean and Vietnam wars. The armed forces are responsible for containing the dissident activities of the rebellious Hukbalahap movement in central Luzon, for controlling smuggling, and for maintaining order. Civilian authority prevails over military authority. Thus the president of the Philippines, who is commander in chief of the armed forces of the Philippines, is a civilian, as is the Secretary of National Defense.

Role of the U.S. in defense

Under a series of agreements reached in 1947, the United States maintains several military, naval, and air force bases in the Philippines. The agreements are in effect until the year 2046. The United States has also agreed to provide military assistance in the form of equipment and training, while the Philippines offers financial support to American advisers and trainees in the country.

Administration. *Educational services.* The largest governmental department is that of education, which administers the bureaus of public schools, private schools, and vocational education, as well as the Institute of National Language, the national library, the National Museum, and the National Historical Commission. The largest is the Bureau of Public Schools, which employs about 280,000 teachers and is responsible for the instruction of about 11,500,000 pupils. The Bureau of Private Schools supervises the private or nongovernmental schools, colleges, and universities, consisting in all of about 2,800 institutions, with a total enrollment of about 800,000 and a teaching staff or about 20,000. Five of the universities each have an enrollment of more than 30,000.

There are more than 40 universities, of which a third are located in greater Manila, the oldest being the University of Santo Tomás, founded in 1611.

Elementary education lasts for six years, secondary education for four years, and college courses last from four to nine years. Vocational schools offer specialized training. The government also administers a number of teacher training schools.

Health and welfare services. Health and welfare services are the responsibility of the Department of Health and the Department of Social Welfare. There are several national government hospitals, and each province and city also maintains its own hospitals. There are altogether more than 770 hospitals, both government and private. There are also almost 1,500 rural health units, each of them serving an average of about 25,000 people. In addition to the department of social welfare, there are a number of nongovernmental social welfare agencies, such as the Philippine National Red Cross, the Mental Health Association, the Community Chest, the Philippine Band of Mercy, the Social Welfare Council, and the Youth Coordinating Council.

Housing. The movement of population to the cities, especially to greater Manila, has resulted in a housing shortage. Many poorer people have consequently built makeshift huts—locally called *barung-barong*—on land belonging either to the government or to private individuals. The government has attempted to relocate the inhabitants of these shanties in multistoried apartments, but only a small proportion have so far been accommodated. Housing remains a major problem—a problem compounded by the associated problems of sanitation, public health, the maintenance of order, and the security of the individual's person and property.

Police services. The constabulary has divided the national territory into four regional zones—two on the island of Luzon, one in the Visayas, and one on Mindanao. Each province, including the cities within its territorial jurisdiction, is assigned a constabulary unit under a provincial command. Local police units are also maintained by the government in each city and municipality under the administrative and financial supervision of the local government.

Social conditions. *Wages and cost of living.* The daily minimum for most workers in greater Manila is ₱12 ($3.05); elsewhere it is ₱5.50 ($1.41). While governmental employees and most employees in the larger commercial concerns enjoy the benefits of this law, many others —including many municipal government employees and most labourers in rural areas—do not, primarily because of the inability of their employers to pay the amount. The ordinary wage earner consequently receives very little; the average annual wage barely exceeds ₱1,000 ($255). During the 1960s, moreover, the rising cost of living—especially after the devaluation of the Filipino peso in early 1970—sharply affected the small wage earner.

The minimum wage law

Health condition. Public health conditions have much improved since 1940. The last epidemic of smallpox, for example, occurred in 1930 and the last outbreak of cholera in 1934. There is, however, still an incidence of *el tor* (a type of cholera), tuberculosis, pneumonia, influenza, and diarrhea. Tuberculosis is the primary cause of death; pneumonia, bronchitis, and such viral diseases as influenza, measles, and poliomyelitis are still widespread. Malaria and leprosy have, however, been brought under control. Health education among the people has had much to do with improvement in health conditions.

Social and economic strata. The Philippines is a democratic country and has no caste system. Existing social and economic divisions are between the rich, the middle income group, and the poor. The divisions, however, are not immutable. The few haciendas (large landed estates), owned by the church or by Spanish families, that existed in the days of Spanish rule have partly disappeared. Some haciendas, however, still remain, but are now mostly owned by Filipino families. There are large plantations of sugar, rice, and other crops in Tarlac, Nueva Ecija, Pampanga, Bulacan, Laguna, Batangas, Negros, Iloilo and other provinces. As the value of businesses, industries, and real estate rose since independence some families acquired great wealth, constituting a group that has half-humorously been classified into three groups —the idle rich, the profligate rich, and the working rich. Billionaires and millionaires, although constituting only 2 percent of the population, own most of the wealth of the Philippines. But the majority of the population—more than 75 percent—still remain poor. A third group is constituted by the professionals, bankers, lawyers, physicians, teachers, office managers, and technologists—some of whom have acquired some wealth.

Thus today, at one extreme, the wealthiest individuals have an annual income of ₱100,000 ($25,650) or more each, whereas the per capita income of a labourer averages only ₱650 ($165) a year. This somewhat striking disparity of wealth is the origin of much of the current popular discontent. Although measures for land reform, social legislation, and a revision of the income tax laws have been introduced, the wealthy retain control of the economic and political life of the country.

CULTURAL LIFE AND INSTITUTIONS

While geographically the Philippines belongs to the East, culturally it is of the West. Its Oriental background still remains in the barrio with its bamboo and nipa (palm thatch) dwellings, its close-knit family system, and its folklore. In most large towns and cities, however, the Oriental culture has been replaced by Spanish and American culture. The presence of church, convent, and patio, certain folk dances, the *moro-moro* plays (*i.e.*, plays depicting the wars between "Moors" and Christians), the *Ati-atihan* (a passion play performed during Lent), and the Spanish language spoken still by the *ilustrados* (an élite claiming Spanish descent), testify to the vitality of Spanish culture. The English language, the public school system, and many of the appurtenances of modern living, demonstrate the degree of American influence. The Spanish and English languages in particular have contributed to an understanding and an appreciation of much in the West and have also to some degree inculcated Western standards. More, indeed, is often known of Western countries than of many Asian countries that, geographically, are closer neighbours.

The state of the arts. Early Spanish chroniclers testified that the early Filipinos carved the images of their *anitos* (gods and goddesses) and ancestors in wood. They also used various musical instruments such as gongs, drums, cymbals, stringed instruments, flutes (including nose flutes), and guitars. They performed appropriate songs and dances to celebrate courtship, marriage, the harvest, war, and other occasions. Many of these songs and dances, accompanied by the same musical instruments, have been preserved or reinterpreted today, and are presented by various dance and song groups. Some of these groups—such as the Bayanihan, the Filipinescas, the Baranggay, the Hariraya groups, as well as the Karilagan Ensemble, and the groups associated with the guilds of the Manila and Fort Santiago theatres—have performed not only in the Philippines but also in other countries. Many Filipino musicians and composers have risen to prominence, such as Antonio J. Molina, a composer and conductor, and Felipe P. de Leon, a composer known for his nationalistic themes.

Early Filipino art

Filipino painters have included Juan Luna (dean of Filipino painters), Fernando Amorsolo (known for his traditional rural scenes), Carlos V. Francisco (a muralist), Victorio Edades (a painter in the modern style), Vicente Manansala (a mural painter), and Arturo Rogerio Luz (an exponent of structural painting), while among sculptors Guillermo Tolentino and Napoleon Abueva are prominent. Tribesmen from mountainous northern Luzon and craftsmen at Paete, in Laguna Province, and Pampanga Province are famous for woodcarving, while Romblon Province is noted for its marble sculptures. Among Filipino architects, the most notable include Juan F. and Angel Nakpil, Fernando Ocampo, Leandro Locsin, Juan Arellano, Carlos Arguelles, and Tomas Mapua.

Folk traditions and popular culture. Filipinos have a rich folklore tradition. Myths and legends deal with such subjects as the origin of the world, the first man and woman on Earth, why the sky is high, why the ocean water is salty, and why there are different races. Other tales are associated with the Spanish conquest, while Muslim Filipinos have an epic called *Indarapatra and Sulayman*, and the Ilocanos of northern Luzon have another called the *Biag ni Lam-ang*. Most folktales and popular cultural traits are still to be found in remote barrios and *sitios*. Some authors, such as Dean S. Fansler, Maximo Ramos, and Armando and Carolina Malay, have compiled collections of these folktales.

Cultural institutions. The Bureau of Science and the National Museum, both in Manila, have gathered artifacts connected with many of the folk tales and popular beliefs. Nongovernmental organizations, such as the Conservation Society and some historical groups, have also sought to preserve the folklore heritage. A cultural centre in Manila was inaugurated in 1970 to encourage interest in the heritage of the Philippines, with emphasis on painting, sculpture, and the performing arts.

The mass media. The constitution guarantees freedom of press, speech, and assembly; and the mass media in the Philippines enjoys more freedom than in any other country in Asia and is among the most untrammeled in the world. Newspapers are published in English, Pilipino, Spanish, and many vernacular dialects in Manila, Cebu, Davao, and elsewhere. Radio and television broadcasting stations also provide news coverage, reaching a wider public. Transistor radio receivers diffuse news even in places where public electricity is not yet available. The most widely circulated daily newspapers are the *Manila Times*, the *Manila Chronicle*, the *Manila Daily Bulletin*, the *Philippines Herald*, and the *Daily Star*, all published in English. The *Taliba* and the *La Vanguardia* are published in Pilipino and Spanish, respectively.

Prospects for the future. The Republic of the Philippines has maintained a system of popular, representative government despite the wide gap between the small rich population and the poor majority. Minor political disturbances are viewed as natural to a developing nation; the desire for social welfare legislation is growing, and the increasingly politically active poor are becoming impatient. As the national economy expands, however, the government will acquire the means to improve the standard of living, and political stability within the country does not seem to be much threatened.

Philippines, History of the

In ancient times, the inhabitants of the Philippines were a diverse agglomeration of peoples who arrived in various waves of immigration from the Asian mainland and who maintained little contact with each other. The contemporary Filipino can boast of no great architectural reminders of vast kingdoms of the past, as in Java or Cambodia. The Philippines is the only nation in Southeast Asia that became subject to Western colonialism before it had developed either a centralized government ruling over a large territory or an advanced elite culture. Chinese traders had been resident since about AD 1000, and some cultural influences from South Asia, such as a Sanskrit-based writing system, were carried to the islands by the Indonesian empires of Śrivijaya and Majapahit; but in comparison with other parts of the region, the impact of both China and India on the Philippines was of little importance. The peoples of the Philippine archipelago, unlike most peoples of Southeast Asia, never adopted Hinduism or Buddhism.

Pre-Spanish history. According to what can be inferred from somewhat later accounts, the Filipinos of the 15th century must have been primarily shifting cultivators, hunters, and fishermen. Sedentary cultivation was the exception. Only in the mountains of northern Luzon, where elaborate rice terraces were built in the early centuries of the Christian era, were livelihood and social organization linked to a fixed territory. The lowland peoples lived in extended kinship groups known as *barangays* under the leadership of a *datu,* or chieftain. The *barangay,* usually numbering a few hundred persons, was usually the largest stable economic and political unit.

Barangay society

Within the *barangay,* the status system, though not rigid, appears to have consisted of five classes: the *datu* and his family; the nobility; the freeholder; the sharecropper; and, at the bottom, the debt peon or war captive, termed slaves by Spanish observers. The lowest status was inherited but, through manumission and interclass marriage, seldom extended over more than two generations. The fluidity of the social system was, in part, the consequence of a bilateral kinship system in which lineage was reckoned equally through the male and female line. Marriage was apparently stable, though divorce was socially acceptable under certain circumstances.

Animism was the religion of the early Filipino, a mixture of monotheism and polytheism in which the latter dominated. The propitiation of evil spirits required numerous rituals, but there was no religious hierarchy. In religion, as in social structure and economic activity, there was considerable variation between—and even within—islands.

This pattern, however, began to change in the 15th century, when Islām was introduced to Mindanao and the Sulu islands through Brunei. Along with changes in religious beliefs and practices came new political and social institutions. By the mid-16th century two sultanates had been established, bringing under their sway a number of *barangays.* A powerful *datu* as far north as Manila embraced Islām. It was in the midst of this wave of Islāmic proselytism that the Spaniards arrived. Had they come a century later or had their motives been strictly commercial, Filipinos today might be a predominantly Muslim people.

The Spanish period. Spanish colonialist motives were not, however, strictly commercial. The Spanish at first viewed the Philippines as a stepping stone to the riches of the Spice Islands, but, even after the Portuguese and Dutch had foreclosed that possibility, the Spaniards still maintained their presence in the archipelago.

Ferdinand Magellan headed the first Spanish foray to the Philippines in 1521, meeting an untimely death in Cebu. After three further expeditions had ended in disaster, Philip II, "the most Catholic of kings," after whom the islands are named, sent out Miguel López de Legazpi, who established the first permanent Spanish settlement, in Cebu, in 1565. The Spanish city of Manila was founded in 1571, and by the end of the 16th century most of the coastal and lowland areas from Luzon to northern Mindanao were under Spanish control. Friars marched with soldiers and soon accomplished the nominal conversion to Catholicism of all the natives under Spanish administration. But the Muslims of Mindanao and Sulu, whom the Spanish called Moros, were never completely subdued by Spain; a 20th-century U.S. army was to be required for that task.

Spanish rule for the first 100 years was exercised in most areas through a type of tax farming imported from the Americas known as the *encomienda.* But abusive treatment of the native tribute payers and neglect of religious instruction by *encomenderos,* as well as frequent withholding of revenues from the crown, led to the abandonment of the system by the end of the 17th century. The governor general, himself appointed by the king, began to appoint his own civil and military governors to rule directly.

The *encomienda*

Central government in Manila retained a medieval cast up to the 19th century, and the governor general was so powerful he was often likened to an independent monarch. He dominated the Audiencia, or high court, was captain general of the armed forces, and enjoyed the privilege of engaging in commerce for private profit.

Manila dominated the islands not only as the political capital. The galleon trade with Acapulco assured Manila's commercial primacy as well. This exchange of Chinese silks for Mexican silver kept in Manila those Spaniards seeking quick profit, as well as attracting a large Chinese community. The Chinese, despite several massacres at the hands of suspicious Spaniards, persisted and soon established a dominance of commerce that they have never relinquished.

Manila was also the ecclesiastical capital. The governor general was civil head of the church in the islands, but the archbishop vied with him for political supremacy. In the late 17th and 18th centuries, buttressed with the legal status of lieutenant governor, the archbishop frequently won. Augmenting their political power, religious orders, Catholic hospitals and schools, as well as bishops acquired great wealth, mostly in land. Royal grants and devises formed the core of their holdings, but many arbitrary extensions were made beyond the boundaries of the original grants.

Power of the church

The power of the church derived not simply from wealth and official status. The priests and friars had a command of native languages rare among lay Spaniards; and in the provinces they outnumbered civil officials. Thus, they were an invaluable source of information to the colonial government. The cultural goal of the Spanish clergy was nothing less than the full Christianization and Hispanization of the Filipino. In the first decades of missionary work, native animism was vigorously suppressed; old practices were not tolerated. But as the Christian laity grew in number and the zeal of the clergy waned, it became more and more difficult to prevent the preservation of ancient beliefs and customs under Catholic garb. Thus, even in the area of religion, pre-Spanish Filipino culture was not entirely destroyed.

Economic and political institutions were also altered under Spanish impact but perhaps less thoroughly than in the religious realm. The priests tried to move all the people into pueblos, or villages, surrounding the great stone churches. But the dispersed demographic patterns of the old *barangays* largely persisted. Nevertheless, the *datu*'s once hereditary position became subject to Spanish appointment.

Agricultural technology changed very slowly until the late 18th century, as shifting cultivation gradually gave way to more intensive sedentary farming, partly under the guidance of the friars. The socio-economic consequences of the Spanish policies that accompanied this shift reinforced class differences. The *datus* and other representatives of the old noble class took advantage of the introduction of the Western concept of absolute ownership of land to claim, as their own, fields cultivated by their various retainers, even though traditional land rights had been limited to usufruct. These heirs of pre-Spanish nobility were known as the *principalia* and played an important role in the friar-dominated local government.

The 19th century. By the late 18th century, political and economic changes in Europe were finally beginning to affect Spain and, thus, the Philippines. Important as a stimulus to trade was the gradual elimination of the monopoly enjoyed by the galleon to Acapulco. The last galleon sailed in 1811, and by the 1830s Manila was open to foreign merchants almost without restriction. The demand for Philippine sugar and abaca, or hemp, grew apace, and the volume of exports to Europe expanded even further after the completion of the Suez Canal in 1869.

The growth of commercial agriculture resulted in the appearance of a new class. Alongside the landholdings of the church and the rice estates of the pre-Spanish nobility there arose haciendas of coffee, hemp, and sugar, often the property of enterprising Chinese–Filipino mestizos. Some of the families that gained prominence in the 19th century still play an important part in Philippine economics and politics.

Not until 1863 was there public education in the Philip-

pines, and even then the church controlled the curriculum. Less than 20 percent of those who went to school could read and write Spanish, and far fewer could speak it properly. The limited higher education in the colony was entirely under clerical direction, but by the 1880s many sons of the wealthy were sent to Europe to study. There, nationalism and a passion for reform blossomed in the liberal atmosphere. Out of this talented group of overseas Filipino students arose the so-called Propaganda Movement. Magazines, poetry, and pamphleteering flourished. José Rizal, this movement's most brilliant figure, produced a political novel, *Noli me tangere* (Eng. trans., *The Social Cancer*), which had a wide impact in the Philippines. In 1892 Rizal returned home and formed the Liga Filipina, a modest reform-minded society, loyal to Spain, that breathed no word of independence. But Rizal was quickly arrested by the overly fearful Spaniards, exiled to a remote island in the south, and finally executed in 1896. Meanwhile, within the Philippines there had developed a firm commitment to independence among a somewhat less privileged class.

The Katipunan

Shocked by the arrest of Rizal, these activists quickly formed the Katipunan under the leadership of Andres Bonifacio, a self-educated warehouseman. The Katipunan was dedicated to the expulsion of the Spaniards from the islands, and preparations were made for armed revolt. Filipino rebels had been numerous in the history of Spanish rule, but now for the first time they were inspired by nationalist ambitions and possessed the education that made success a real possibility.

The Philippine Revolution. In late 1896, Spanish friars uncovered evidence of the Katipunan's plans, and its leaders were forced into premature action. Revolts broke out in several provinces around Manila. After months of fighting, severe Spanish retaliation forced the revolutionary armies to retreat to the hills. In December 1897 a truce was concluded with the Spaniards. Emilio Aguinaldo, son of a municipal mayor and commander of the rebel forces, was paid a large sum and was allowed to go to Hong Kong with other leaders; the Spaniards promised reforms as well. But reforms were very slow in coming, and small bands of rebels, distrustful of Spanish promises, kept their arms; clashes grew more frequent.

Meanwhile, war had broken out between Spain and the United States. After the U.S. naval victory at Manila Bay in May 1898, Aguinaldo and his entourage returned to the Philippines with the help of Admiral Dewey. Confident of U.S. support, he reorganized his forces and soon liberated several towns south of Manila. Independence was declared on June 12, which is now celebrated as Independence Day. In September a constitutional congress met in Malolos, Bulacan, drawing up a fundamental law derived from European and Latin American precedents. A government was formed on the basis of that constitution in January 1899, with Aguinaldo as president.

Meanwhile, U.S. troops had landed and, with important Filipino help, forced the capitulation in August 1898 of the Spanish commander in Manila. The Americans, however, would not let Filipino forces enter the city. It was soon apparent to Aguinaldo and his advisers that earlier expressions of sympathy for Filipino independence by Dewey and U.S. consular officials had little significance. They felt betrayed.

U.S. commissioners to the peace negotiations in Paris had been instructed to demand the cession of the Philippines to the U.S.; such cession was confirmed with the signing of the peace treaty on December 10, 1898. Ratification followed in the U.S. Senate in February 1899, but with only one vote more than the required two-thirds. Arguments of "manifest destiny" could not overwhelm a determined anti-imperialist minority.

War against the U.S.

By the time the treaty was ratified, hostilities had already broken out between U.S. and Filipino forces. Since Filipino leaders did not recognize U.S. sovereignty over the islands and U.S. commanders gave no weight to Filipino claims of independence, the conflict was inevitable. It took two years of counterinsurgency warfare—marked by several unfortunate similarities with the later U.S. military involvement in Vietnam—plus some wise conciliatory moves in the political arena to break the back of the nationalist resistance. Aguinaldo was captured in March 1901 and shortly thereafter appealed to his countrymen to accept U.S. rule.

The Filipino revolutionary movement had had two goals, national and social. The first goal, independence, though realized briefly, was frustrated by the U.S. decision to establish a new empire. The goal of fundamental social change, manifest in the nationalization of friar lands by the Malolos Republic, was ultimately frustrated by the power and resilience of entrenched institutions. Share tenants who had rallied to Aguinaldo's cause, partly for economic reasons, merely exchanged one landlord for another. In any case, the proclamation of a republic in 1898 had marked the Filipinos as the first Asian people to try to throw off European colonialism.

The period of U.S. influence. The juxtaposition of U.S. democracy and imperial rule over a subject people was sufficiently jarring to most Americans that, from the beginning, the training of Filipinos for self-government and ultimate independence—the Malolos Republic was conveniently ignored—was an essential rationalization for U.S. hegemony in the islands. Differences between Democratic and Republican policies focussed on the speed with which self-government should be extended and the date on which independence should be granted.

In 1899 President McKinley sent Cornell University president Jacob G. Schurman at the head of a five-man fact-finding commission to the Philippines. Schurman reported back that Filipinos wanted ultimate independence, but this had no immediate impact on policy. McKinley sent out the Second Philippine Commission in 1900, under William Howard Taft; by July 1901 it had established civil government.

In 1907 the Philippine Commission, which had been acting as both legislature and governor general's Cabinet, became the upper house of a bicameral body. The new 80-member Assembly was directly elected by a somewhat restricted electorate from single-member districts, making it the first elective legislative body in Southeast Asia. When Governor General Harrison appointed a Filipino majority to the Commission in 1913, the U.S. voice in the legislative process was further reduced.

Francis B. Harrison was the only governor general appointed by a Democratic president in the first 35 years of U.S. rule. He had been sent by Woodrow Wilson with specific instructions to prepare the Philippines for ultimate independence, a goal that he enthusiastically supported. During Harrison's term, a Democratic Congress in Washington hastened to fulfill long-standing campaign promises to the same end. The Jones Act, passed in 1916, would have fixed a definite date for the granting of independence if the Senate had had its way, but the House prevented such a move. In its final form the Act merely stated that it was the "purpose of the people of the U.S." to recognize Philippine independence "as soon as a stable government can be established therein." Its greater importance was as a milestone in the development of Philippine autonomy. Under Jones Act provisions, the Commission was abolished and was replaced by a 24-man Senate, almost wholly elected. The electorate was expanded to include all literate males.

Some substantial restrictions on Philippine autonomy remained, however. Defense and foreign affairs remained exclusive U.S. prerogatives. United States direction of Philippine domestic affairs was exercised primarily through the governor general and the executive branch of insular government. There was little more than one decade of thoroughly U.S. administration in the islands, however—too short a time in which to establish lasting patterns. Whereas Americans formed 51 percent of the civil service in 1903, they were only 29 percent in 1913 and 6 percent in 1923. By 1916 Filipino dominance in both the legislative and judicial branches of government also served to restrict the U.S. executive and administrative roles.

By 1925 the only American left in the governor general's Cabinet was the secretary of public instruction, who was also the lieutenant governor general. This is one

indication of the high priority given education in U.S. policy. In the first few years of U.S. rule, hundreds of schoolteachers came from the United States. But Filipino teachers were trained so rapidly that by 1927 they constituted nearly 99 percent of the 26,200 in public schools. The school population expanded 500 percent in a generation; education consumed one-half of governmental expenditures at all levels, and educational opportunity in the Philippines was greater than in any other colony in Asia.

U.S. educational policy

As a consequence of this pedagogical explosion, literacy doubled to nearly 50 percent in the 1930s, and educated Filipinos acquired a common language and a linguistic key to Western civilization. By 1939, 27 percent of the population could speak English, a larger percentage than for any of the native dialects. Perhaps more important was the new avenue of upward social mobility that education offered. In educational policy was found the only successful U.S. effort to establish a socio-cultural basis for political democracy.

United States attempts to create equality of economic opportunity were more modest and less successful. In a predominantly agricultural country the pattern of landownership is crucial. The trend toward greater concentration, which began in the 19th century, continued during the American period, despite some legal barriers. Vast U.S.-owned plantations were forestalled, but legal restrictions had little effect on those politically well-connected Filipinos who were intent on amassing fortunes. The percentage of farmers under share tenancy doubled between 1900 and 1935; and the frustration of the tenants erupted in three small rebellions in central Luzon during the 1920s and 1930s.

Nor was U.S. trade policy conducive to the diffusion of economic power. From 1909 the Payne-Aldrich Tariff Act allowed free entry of Philippine products into the U.S. market; at the same time U.S. products, mostly manufactured, were exempted from tariff in the Philippines. The free flow of U.S. imports was a powerful deterrent to industrial growth. Export agriculture, especially sugar, prospered in the protected U.S. market. Owners of mills and large plantations profited most, thus reinforcing the political dominance of the landed elite.

United States preparation of the Philippines for democratic self-government suffered from an inherent contradiction, perhaps not recognized at the time. Transferring governmental responsibility to those capable of undertaking it was not consistent with building a social and economic base for political democracy. Self-government meant, of necessity, assumption of power by those Filipinos who were already in positions of leadership in society. But these men came for the most part from the landed elite; preservation of their political and economic position was incompatible with equalization of opportunity. Even the expansion of an educated middle class did not necessarily result in a transformation of the pattern of power. Most middle class aspirants for political leadership adjusted to the values and the practices of the existing power elite.

Formation of political parties

Filipino leaders quickly and skillfully utilized the opportunities for self-government that the Americans opened to them. The Filipino political genius was best reflected in an extralegal institution—the political party. The first party, the Partido Federal, was U.S.-backed and stressed cooperation with the overlords, even to the point of statehood for the Philippines. But, when openly nationalist appeals were allowed in the 1907 election, the Partido Nacionalista, advocating independence, won overwhelmingly. The Federalists survived with a new name, Progressives, and a new platform, ultimate independence after social reform. But neither the Progressives nor their successors in the 1920s, the Democrats, ever gained more than one-third of the seats in the legislature. The Nacionalista Party under the leadership of Sergio Osmeña and Manuel Quezon dominated Philippine politics from 1907 until independence.

More significant than the competition between the Nacionalistas and their opposition was the continuing rivalry between Osmeña and Quezon. In fact, understanding this personality conflict provides more insight into the realities of prewar Philippine politics than any examination of policy or ideology.

In 1933 the U.S. Congress passed the Hare-Hawes-Cutting Act, which set a date for Philippine independence. The Act was a fulfillment of the vague pledge in the Jones Act; it was also responsive to the demands of a series of "independence missions" sent to Washington by the Philippine legislature. But this unprecedented transfer of sovereignty was decided upon in the dark days of the Great Depression—and with the help of some incongruous allies. The Depression had caused U.S. farm interests to look desperately for relief, and those who suffered real or imaginary hurt from the competition of Philippine products sought to exclude those products. They had already failed in a direct attempt to amend the tariff on Philippine imports but found that the respectable cloak of the advocacy of independence increased the effectiveness of their efforts. Tied to independence was the end of free entry into U.S. markets of Philippine sugar, coconut oil, rope, and other less important items. That these economic interests were able to accomplish what they did is partly explainable by the fact that their political clout was great compared to that of the small group of U.S. traders and investors in the Philippines.

The Philippine legislature rejected the Hare-Hawes-Cutting Act, apparently as a result of the Osmeña-Quezon feud, much to the displeasure of American officialdom. But, when Quezon came to Washington the following year to work for a new bill, the same alliance of forces in the U.S. Congress obliged by producing the almost identical Tydings-McDuffie Act. It was endorsed by Quezon and accepted with alacrity by the Manila legislature. It provided for a ten-year commonwealth during which the U.S. would retain jurisdiction over defense and foreign affairs. Filipinos were to draft their own constitution, subject to the approval of the president.

A constitutional convention was quickly elected, a constitution framed (which bears a strong resemblance to its U.S. model), and the document approved by plebiscite and by President Roosevelt. The last governor general, Frank Murphy, became the first high commissioner, with more of a diplomatic than a governing role. The commonwealth was inaugurated on November 15, 1935. The Nacionalista Party patched up its internal quarrels and nominated Quezon for president and Osmeña for vice president. They were elected overwhelmingly.

The Commonwealth

The commonwealth period was intended to be devoted to preparation for economic and political independence and perfection of democratic institutions. But even before the tragic events of 1941 the transition did not run smooth.

World War II. Japanese aggression in China prompted much attention to military preparedness. Nearly one-fourth of the national budget was devoted to defense. Gen. Douglas MacArthur, retiring as army chief of staff in Washington, was called by President Quezon to direct plans and preparations. Meanwhile, agrarian unrest festered, and leftist political activity grew. Quezon pushed significant reform legislation through the National Assembly, but implementation was feeble, despite the rapid accumulation of power in his hands.

The Japanese attack of December 8, 1941, came at a time when the U.S. military buildup had hardly begun. Before Christmas, Manila was declared an "open city," while Quezon and Osmeña were evacuated to MacArthur's headquarters on Corregidor. Despite a desire, at one point, to return to Manila in order to surrender, Quezon was persuaded to leave the Philippines in March on a U.S. submarine; he was never to return. Osmeña went too. Fil-American forces, under Gen. Jonathan M. Wainwright, surrendered in May. An Executive Commission, made up of more than 30 members of the old Filipino political elite, had been cooperating with Japanese military authorities in Manila since January.

The Executive Commission lasted until September 1943, when it was superseded by an "independent Philippine Republic." The president, chosen by the Japanese, was José Laurel, former associate justice of the Common-

The "independent Philippine Republic" under the Japanese

wealth Supreme Court and the only Filipino to hold an honorary degree from Tokyo Imperial University. Laurel was among a small group of Filipinos who had been longtime admirers of Japanese culture and were sympathetic to certain aspects of Japan's authoritarian politics. The scope of collaboration was much wider than this group, however. Over half of the Commonwealth Senate and more than one-third of the House served at one time in the Japanese-sponsored regime. Many Filipinos collaborated out of fear of retaliation, others in prospect of personal gain, and still others out of a patriotic desire to act as a buffer between the Japanese military and the Filipino people. Yet collaboration with Japan was neither as willing nor as widespread as elsewhere in Southeast Asia.

Nor should cooperation with the Japanese military by segments of the elite be equated with mass support for Japanese policies. Even before the fall of Bataan there were guerrilla units formed throughout the Philippines, some by U.S. officers but mostly by Filipinos. Most guerrilla units were middle class led and enthusiastically pro-U.S.; in central Luzon, however, a major force was the Hukbalahap, which, under Communist leadership, capitalized on earlier agrarian unrest. Though in a number of instances collaborators were secretly assisting guerrillas, many guerrillas in the hills were bitter against those who appeared to benefit from the Japanese occupation. The differences between the two groups became an important ingredient in early postwar politics. But the collaborators proved too influential to be punished, as some demanded.

The republic. Soon after the U.S. landings in Leyte in October 1944, civil government was returned to the Commonwealth, at least in name. Unlike the reactions elsewhere in Southeast Asia, Filipinos called the U.S. return liberation. Sergio Osmeña, who had become president on the death of Quezon in 1944, had few resources to deal with the problems at hand. Osmeña's role was complicated by the fact that he was not close to MacArthur; in fact, MacArthur chose to lionize a leading collaborator, who had also been in contact with U.S. military intelligence, Manuel Roxas. Other top figures in the Japanese puppet regime were jailed. By the time the Commonwealth Congress was reconvened, Senate president Roxas clearly had become MacArthur's candidate for president. He had the big money behind him, and his election was crucial for those collaborators who feared prosecution. Since Osmeña would not bow out, Roxas declared his candidacy in January 1946 and was nominated by the "liberal wing" of the Nacionalista Party. Thus was born the Philippines' second major political party, the Liberals. Osmeña, though he had the advantages of incumbency, was old and tired and did not fully use the political tools he possessed. In April, Roxas was elected by a narrow margin. The following month he was inaugurated as the last chief executive of the commonwealth and on July 4 became the first president of the Republic of the Philippines. In this first postwar election a defeated incumbent had quietly handed over the reins of power, thus strengthening constitutionalism in the Philippines.

Roxas, as expected, amnestied all Japanese collaborators except for those "small fry" who may also have committed felonies. In the 1949 election campaign there was an attempt to raise the collaboration issue against José Laurel, the Nacionalista presidential candidate, but it was not effective. In the fluidity of Philippine politics, "guerrillas" and "collaborators" were by that time to be found on both sides of all political fences.

The Philippines had gained independence in the "ashes of victory." Intense fighting, especially around Manila in the last days of the Japanese retreat, had nearly destroyed the capital. The economy generally was in shambles. Rehabilitation aid was obviously needed, and President Roxas was willing to accept some onerous conditions placed implicitly and explicitly by the U.S. Congress in order to get it. The conditions were such, in fact, that many Asians questioned Philippine "independence." The Bell Act in the U.S. extended free trade with the Philippines for eight years, to be followed by 20 years of gradually increasing tariffs. The U.S. demanded and received a 99-year lease on a number of Philippine military and naval bases in which U.S. authorities had virtually territorial rights. And finally, as a specific requirement for release of U.S. war-damage payments, the Philippines had to amend its constitution to give U.S. citizens equal rights with Filipinos in the exploitation of natural resources—the so-called Parity Amendment.

Philippine–U.S. relations. The changing character of Philippine–U.S. relations is a major theme in postwar Philippine history. The trend in recent years has been toward weakening of the link, achieved partly by a diversification of Philippine external ties and partly by more articulate anti-Americanism. Economic nationalism, though first directed against the local Chinese community's dominance of retail trade, by the 1950s was focussed on the special status of U.S. firms. Agitation against "parity" in the 1960s, however, has brought a commitment from both governments that it will not be continued beyond 1974, when the present agreement expires. Tariffs on U.S. goods—90 percent of the standard levy by 1968—and aggressive Japanese salesmanship allowed Japan to come abreast of the U.S., the Philippines' major trading partner, in 1970.

At independence the military ties with the United States were as strong as the economic. Manila was the site for the launching of the Southeast Asia Treaty Organization (SEATO) in 1954. The Philippines sent combat troops to Korea and engineers to South Vietnam. But the Military Bases Agreement of 1947 has been the greatest single cause of friction in U.S.–Philippine relations, triggering demonstrations in the front of the U.S. Embassy on several occasions. In the early 1970s, demands for the total withdrawal of the U.S. military by the 1980s had become increasingly vocal.

Reorientation of Philippine foreign relations in the 1960s took place in the midst of growing attention to the character of national identity. The easy acceptance of the idea of the Philippines as an Asian outpost of Christianity, characteristic of the early postwar period, has been increasingly rejected. Perhaps even more disturbing to Filipinos than questions raised by Asian neighbours about the nature of their sovereignty were doubts about their cultural identity. Asian ethnic origins were strong stimuli to the development of an Asian cultural identity. Artists, musicians, and writers have gone to pre-Spanish themes to find new inspiration. Historians, painfully aware that the nation's past has largely been chronicled by foreigners, have set about rewriting history. More important is the increasing trend toward seeking cultural identity through the national language. Along with nationalistic demands for the wider use of Pilipino (the national language, essentially Tagalog, the native tongue of Manila and its surrounding provinces) have come the deterioration of the quality of English teaching and the rapid expansion of Tagalog movies, magazines, and radio programs.

Given the size of the U.S. emotional and ideological investment in training for democratic self-government, the fate of the Philippines' democratic institutions is an important facet of Philippine–U.S. relations. For Filipinos themselves, who have adopted and adapted Western democracy with enthusiasm, it is a matter inextricably linked to the ability to maintain social order. Some observers have characterized the Philippines in the 1970s as "stable anarchy." Certainly, respect for law in the urban areas and among many rural officials is at a low ebb. Many laws are never enforced, and those that are enforced usually are implemented in a fashion reflecting day-to-day power relationships, not the intent of the legislation. In this context, it is not surprising that student violence—unknown in the Philippines before the late 1960s—and a now endemic agrarian violence have grown.

The "stable anarchy" of the 1970s

Social order did break down completely in many parts of the Philippines in late 1944 and early 1945, as two foreign armies fought their ways from island to island. In the aftermath of war, accumulated social injustice and diligent Communist organizing throughout central Luzon produced a rebellion that peaked in 1951; before the emer-

gence of new leadership in the military, under the then secretary of defense Ramon Magsaysay, and prior to certain steps toward social justice, the rebellion had been on the verge of catching fire around the Philippines. But for more than a decade thereafter, the noticeable trends were toward less violence and greater respect for democratic processes. Then, in the 1960s, deterioration set in.

Modernization proceeds: television networks, new factories, better roads, more automobiles and transistor radios, even more schoolhouses. But population growth is so great—at over 3 percent, one of the highest in the world—and the distribution of wealth so unequal that the average Filipino has seen no significant improvement in living standards in years. Meanwhile, foreign debts rise, and nationalism grows more strident. Christian–Muslim conflict, especially over land, has long simmered; in 1970 it escalated, and there was even talk of secession among Moro leaders. Communist-led insurgency in Luzon is expanding to new areas. Though the textbooks teach and the politicians espouse the right of the common man to choose his leaders and the leaders' duty to serve the nation, most observers claim that fraud, coercion, and lavish expenditure in the 1969 election were unprecedented. In September 1972 Pres. Ferdinand E. Marcos, charging a Communist plot to overthrow the government, placed the Philippines under martial law.

BIBLIOGRAPHY. The earliest centuries of recorded Philippine history are best analyzed in JOHN L. PHELAN, *The Hispanization of the Philippines* (1959), while massive documentation is provided in EMMA HELEN BLAIR and JAMES A. ROBERTSON, *The Philippine Islands, 1493–1898*, 55 vol. (1903–09). An important facet of 19th-century Philippines is described in EDGAR WICKBERG, *The Chinese in Philippine Life, 1850–1898* (1965). The noted Filipino historian, TEODORO A. AGONCILLO, covers the Philippine revolution in two volumes, *The Revolt of the Masses: The Story of Bonifacio and the Katipunan* (1956) and *Malolos: The Crisis of the Republic* (1960). Two major works on the American period are by a former governor general, W. CAMERON FORBES, *The Philippine Islands*, rev. ed. (1945), and a former vice governor general, J. RALSTON HAYDEN, *The Philippines: A Study in National Development* (1942), the more scholarly work. The Philippine independence movement and the Japanese threat to it is the focus of THEODORE FRIEND, *Between Two Empires: The Ordeal of the Philippines, 1929–1946* (1965). DAVID J. STEINBERG, *Philippine Collaboration in World War II* (1967), handles a sensitive subject with both frankness and tact. Post-World War II Philippine history has not yet been treated, however, in an authoritative scholarly volume.

(D.O.D.W.)

Philo of Alexandria

Philo of Alexandria, a Jewish contemporary of Jesus and the Apostle Paul and a key figure in understanding the spiritual crisis of the 1st century of the Christian Era, has a twofold importance for the history of thought. First, he occupies a unique position in the history of philosophy as the first to attempt, although unsystematically, to synthesize revealed faith and philosophic reason. And, second, he has an important place in the history of religion because he was regarded by Christians as a forerunner of Christian theology, especially in his view of the Logos as an intermediary between God and man. In a sense he may be regarded as the founder of medieval philosophy—Jewish, Arabic, and, above all, Christian.

Philo's family

Life. Little is known of the life of Philo. Josephus, the historian of the Jews who also lived in the 1st century, says that Philo's family surpassed all others in the nobility of its lineage. His father had apparently played a prominent role in Palestine before moving to Alexandria. Philo's brother Alexander Lysimachus, who was a general tax administrator in charge of customs in Alexandria, was the richest man in the city and indeed must have been one of the richest men in the Hellenistic world, because Josephus says that he gave a huge loan to the wife of the Jewish king Agrippa I and that he contributed the gold and silver with which nine huge gates of the Temple in Jerusalem were overlaid. Alexander was also extremely influential in Roman imperial circles, being an old friend of the emperor Claudius and having acted as guardian for the Emperor's mother.

Philo himself was born between 15 and 10 BCE ("Before the Common Era"). The community of Alexandria, to judge from the language of the Jewish papyri and inscriptions, had for nearly three centuries been almost exclusively Greek-speaking and indeed regarded the Septuagint (the 3rd-century-BCE translation of the Hebrew Bible into Greek) as divinely inspired. During the century and a half before Philo's birth, Alexandria had been the home of a number of Jewish writers whose works exist now only in fragments. These men were often influenced by the Greek culture in which they lived and wrote apologies for Judaism.

The Alexandrian Jews were eager to enroll their children of secondary school age in Greek gymnasiums, institutions with religious associations dedicated to the liberal arts and athletics; in them, Jews were certainly called upon to make compromises with their traditions. It may be assumed that Philo was a product of such an education: he mentions a wide range of Greek writers, especially the epic and dramatic poets; he was intimately acquainted with the techniques of the Greek rhetorical schools; and he praises the gymnasium. Philo's education, like that which he ascribes to Moses, most probably consisted of arithmetic, geometry, astronomy, harmonics, philosophy, grammar, rhetoric, and logic.

Like the cultured Greeks of his day, Philo often attended the theatre, though it had distinctly religious connotations, and he noted the different effects of the same music on various members of the audience and the enthusiasm of the audience for a tragedy of Euripides. He was a keen observer of boxing contests and attended chariot races as well. He also mentions the frequency with which he attended costly suppers with their lavish entertainment.

Jewish education

Philo says nothing of his own Jewish education. The only mention of Jewish education in his work indicates how relatively weak it must have been, because he speaks only of Jewish schools that met on the Sabbath for lectures on ethics. That he was far from the Palestinian Hellenizers and that he regarded himself as an observant Jew is clear, however, from his statement that one should not omit the observance of any of the Jewish customs that have been divinely ordained. Philo is critical both of those who took the Bible too literally and thus encountered theological difficulties, particularly anthropomorphisms (*i.e.*, describing God in terms of human characteristics), and those who went to excesses in their allegorical interpretation of the laws, with the resulting conclusion, anticipating Paul's antinomianism, that because the ceremonial laws were only a parable, they need no longer be obeyed. Philo says nothing of his own religious practices, except that he made a festival pilgrimage to Jerusalem, though he nowhere indicates whether he made more than one such visit.

In the eyes of the Palestinian rabbis the Alexandrian Jews were particularly known for their cleverness in posing puzzles and for their sharp replies. As the largest repository of Jewish law apart from the Talmud (compendium of Jewish law, lore, and legend) before the Middle Ages, Philo's work is of special importance to those who wish to discern the relationship of Palestine and the Diaspora (*i.e.*, Jewish communities living outside Palestine) in the realm of law *(halakah)* and ritual observance. Philo's exposition of the law may represent either an academic discussion giving an ideal description of Jewish law or the actual practice in the Jewish courts in Egypt. On the whole, Philo is in accord with the prevailing Palestinian point of view; nonetheless he differs from it in numerous details and is often dependent upon Greek and Roman law.

That Philo experienced some sort of identity crisis is indicated by a passage in his *On the Special Laws*. In this work, he describes his longing to escape from worldly cares to the contemplative life, his joy at having succeeded in doing so (perhaps with the Egyptian Jewish ascetic sect of the Therapeutae described in his treatise *On the Contemplative Life*), and his renewed pain at being forced once again to participate in civic turmoil. Philo appears to have been dissatisfied with his life in the bustling metropolis of Alexandria: He praises the Essenes—a Jewish sect

who lived in monastic communities in the Dead Sea area —for avoiding large cities because of the iniquities that had become inverterate among city dwellers, for living an agricultural life, and for disdaining wealth.

Embassy to Caligula

The one identifiable event in Philo's life occurred in the year 39 or 40, when, after a pogrom against the Jews in Alexandria, he headed an embassy to the emperor Caligula asking him to reassert Jewish rights granted by the Ptolemies (rulers of Egypt) and confirmed by the emperor Augustus. Philo was prepared to answer the charge of disloyalty levelled against the Jews by the notorious anti-Semite Apion, a Greek grammarian, when the Emperor cut him short. Thereupon Philo told his fellow delegates not to be discouraged because God would punish Caligula, who, shortly thereafter, was indeed assassinated.

Works. Philo's genuine works may be classified into three groups.

1. Scriptural essays and homilies based on specific verses or topics of the Pentateuch (the first five books of the Bible), especially Genesis. The most important of the 25 extant treatises in this group are *Allegories of the Laws*, a commentary on Genesis, and *On the Special Laws*, an exposition of the laws in the Pentateuch.

2. General philosophical and religious essays. These include *That Every Good Man Is Free*, proving the Stoic paradox that only the wise man is free; *On the Eternity of the World*, perhaps not genuine, proving, particularly in opposition to the Stoics, that the world is uncreated and indestructible; *On Providence*, extant in Armenian, a dialogue between Philo, who argues that God is providential in his concern for the world, and Alexander, presumably Philo's nephew Tiberius Julius Alexander, who raises doubts; and *On Alexander*, extant in Armenian, concerning the irrational souls of animals.

3. Essays on contemporary subjects. These include *On the Contemplative Life*, a eulogy of the Therapeutae sect; the fragmentary *Hypothetica* ("Suppositions"), actually a defense of the Jews against anti-Semitic charges to which Josephus' treatise *Against Apion* bears many similarities; *Against Flaccus*, on the crimes of Aulus Avillius Flaccus, the Roman governor of Egypt, against the Alexandrian Jews and on his punishment; and *On the Embassy to Gaius*, an attack on the Emperor Caligula (*i.e.*, Gaius) for his hostility toward the Alexandrian Jews and an account of the unsuccessful embassy to the Emperor headed by Philo.

A number of works ascribed to Philo are almost certainly spurious. Most important of these is *Biblical Antiquities*, an imaginative reconstruction of Jewish history from Adam to the death of Saul, the first king of Israel.

Philo's works are rambling, having little sense of form; repetitious; artificially rhetorical; and almost devoid of a sense of humour. His style is generally involved, allusive, strongly tinged with mysticism, and often obscure; this may be a result of a deliberate attempt on his part to discourage all but the initiated few.

Some of Philo's works are directed to Gentiles. Thus, the work *On the Life of Moses* contains much apologetic material. Such statements as that the philosophers Heracleitus and Zeno derived their theories from the Bible are obviously apologetic. Most of Philo's essays, however, are intended for sophisticated intellectual Jews who had found difficulties in accepting the biblical text literally. For them Philo developed the method of allegorical interpretation, used several centuries earlier by Greek scholars, especially the Stoics, in the interpretation of Homer, as well as by the Hellenistic Jewish philosopher Aristobulus a century before Philo. The fact that, according to Jewish tradition, the Bible need not be interpreted literally likewise facilitated Philo's choice of this method.

In his exposition of Scripture, Philo relied exclusively on the Septuagint translation, though his quotations do not always agree with the extant text of the Septuagint. The belief that the Septuagint was itself divinely inspired made it apparently unnecessary for him to refer to the original Hebrew. A debate has raged concerning whether or not Philo knew Hebrew; but his gross errors in etymologies of Hebrew names suggest that whatever slight knowledge of Hebrew he may have had was useless.

Thought. The key influences on Philo's philosophy were Plato, Aristotle, the Neo-Pythagoreans, the Cynics, and the Stoics. Philo's basic philosophic outlook is Platonic, so much so that Jerome and other Church Fathers quote the apparently widespread saying: "Either Plato philonizes or Philo platonizes." Philo's reverence for Plato, particularly for the *Symposium* and the *Timaeus*, is such that he never took open issue with him, as he did with the Stoics and other philosophers. But Philo is hardly a plagiarist; he made modifications in Plato's theories. To Aristotle he was indebted primarily in matters of cosmology and ethics. To the Neo-Pythagoreans, who had grown in importance during the century before Philo, he was particularly indebted for his views on the mystic significance of numbers, especially the number seven, and the scheme of a peculiar, self-disciplined way of life as a preparation for immortality. The Cynics, with their diatribes, influenced him in the form of his sermons. Though Philo more often employed the terminology of the Stoics than that of any other school, he was critical of their thoughts.

Influences on his thought

In the past, scholars attempted to diminish Philo's importance as a theological thinker and to present him merely as a preacher, but in the mid-20th century H.A. Wolfson, an American scholar, demonstrated Philo's originality as a thinker. In particular, Philo was the first to show the difference between the knowability of God's existence and the unknowability of his essence. Again, in his view of God, Philo was original in insisting on an individual Providence able to suspend the laws of nature in contrast to the prevailing Greek philosophical view of a universal Providence who is himself subject to the unchanging laws of nature. As a Creator, God made use of assistants: hence the plural "Let us make man" in Genesis, chapter 1. Philo did not reject the Platonic view of a preexistent matter but insisted that this matter too was created. Similarly, Philo reconciled his Jewish theology with Plato's theory of Ideas in an original way: he posited the Ideas as God's eternal thoughts, which God then created as real beings before he created the world.

Philo saw the cosmos as a great chain of being presided over by the Logos, a term going back to pre-Socratic philosophy, which is the mediator between God and the world, though at one point he identifies the Logos as a second God. Philo departed from Plato principally in using the term Logos for the Idea of Ideas and for the Ideas as a whole and in his statement that the Logos is the place of the intelligible world. In anticipation of Christian doctrine he called the Logos the first-begotten Son of God, the man of God, the image of God, and second to God.

His mysticism

Philo was also novel in his exposition of the mystic love of God that God has implanted in man and through which man becomes Godlike. According to some scholars, Philo used the terminology of the pagan religions and mystery cults, including the term *enthousiasmos* ("having God within one"), merely because it was part of the common speech of the day; but there is nothing inherently contradictory in Judaism in the combination of mysticism and legalism in the same thinker. The influence of the mystic notions of Platonism, especially of the *Symposium*, and of the popular mystery cults on Philo's attempt to present Judaism as the one true mystery is hardly superficial; indeed, Philo is a major source of knowledge of the doctrines of these mystery cults, notably that of rebirth. Perhaps, through his mystic presentation of Judaism, Philo hoped to enable Judaism in the Diaspora to compete with the mystery religions in its proselyting efforts, as well as in its attempts to hold on to its adherents. That he was essentially in the mainstream of Judaism, however, is indicated by his respect for the literal interpretation of the Bible, his denunciation of the extreme allegorists, and his failure to mention any specific rites of initiation for proselytes, as well as the lack of evidence that he was himself a devotee of a particular mystery cult.

The purpose of what Philo called mystic "sober intoxication" was to lead one out of the material into the eternal world. Like Plato, Philo regarded the body as the prison house of the soul, and in his dualism of body and

soul, as in his description of the flight from the self, the contrast between God and the world, and the yearning for a direct experience of God, he anticipated much of Gnosticism, a dualistic religion that became important in the 2nd century CE. But unlike all the Greek philosophers, with the exception of the Epicureans, who believed in limited freedom of will, Philo held that man is completely free to act against all the laws of his own nature.

Ethical and political theories

In his ethical theory Philo described two virtues, under the heading of justice, that are otherwise unknown in Greek philosophic literature—religious faith and humanity. Again, for him repentance was a virtue, whereas for other Greek philosophers it was a weakness. Perfect happiness comes, however, not through men's own efforts to achieve virtue but only through the grace of God.

In his political theory Philo often said that the best form of government is democracy; but for him democracy was far from mob rule, which he denounced as the worst of polities, perhaps because he saw the Alexandrian mob in action. For Philo democracy meant not a particular form of government but due order under any form of government in which all men are equal before the law. From this point of view, the Mosaic constitution, which embodies the best elements of all forms of government, is the ideal. Indeed, the ultimate goal of history is that the whole world be a single state under a democratic constitution.

Influence. Whether Philo was an original philosopher with a unified and consistent system or a mere preacher of sermons and whether his thought is a collateral branch of Pharisaic Judaism or a Hellenistic syncretism deeply influenced by the mystery cults, no one can dispute his influence. For the Jews his borrowings from the pagans and his philosophical and theological views apparently were considered too dangerous; and, except in the works of Josephus, his influence is not obvious until the Middle Ages, and then only indirectly. It is not until the 16th century that an explicit reference to Philo is found in Jewish literature, in the Hebrew work *Meor 'Enayim* of the Italian rabbi Azariah dei Rossi. The real importance of Philo lies in his influence on Neoplatonists, particularly his views on the mystic path to the knowledge of God, and, above all, on Christians. For the Christians his work provided a precedent for the synthesis of the Jewish and Greco-Roman traditions, and his view of the Logos provided a philosophical buttress for the doctrine of Jesus as mediator between God and man.

An indication of the high regard that the Christian tradition felt toward him is seen in legends that he met St. Peter and St. John. Although it is debatable whether Philo influenced the Gospel according to John, Paul's letters and, in particular, the Letter to the Hebrews show a strong similarity to Philo in both ideas and language. Philo was particularly influential on the Church Fathers Clement of Alexandria, Origen, and Ambrose. Further indications of Christian esteem for him are seen in the survival of the great majority of his works and the translation of some of his works into Latin and Armenian in the 4th and 5th centuries.

BIBLIOGRAPHY. H.L. GOODHART and E.R. GOODENOUGH, "A General Bibliography of Philo Judaeus," in Goodenough's *The Politics of Philo Judaeus, Practice and Theory*, pp. 125–348 (1938), an exhaustive classified listing of books and articles down to 1937; L.H. FELDMAN, *Scholarship on Philo and Josephus, 1937–1962* (1963), a classified critical bibliography; *Studia Philonica* (annual), a journal, exclusively devoted to Philo, published by the newly established (1971) Philo Institute at McCormick Theological Seminary, Chicago.

Greek text: LEOPOLD COHN and PAUL WENDLAND (eds.), *Philonis Alexandrini Opera quae supersunt*, 7 vol. (1896–1930), definitive, but lacks the fragments, the treatises extant only in Armenian, and Pseudo-Philo.

English translation: F.H. COLSON, G.H. WHITAKER, and R. MARCUS, *Philo* ("Loeb Classical Library," 10 vol. and 2 supplementary vol., 1929–62), an extremely careful translation, with brief notes and useful analytical introductions to each treatise.

Pseudo-Philo: M.R. JAMES, *The Biblical Antiquities of Philo*, prolegomenon by L.H. FELDMAN (1917, reprinted 1971), a clear, accurate translation. The prolegomenon is particularly concerned with the relationship to rabbinic and Hellenistic Jewish literature and with supplements to James's commentary.

Introductory works and surveys: E.R. GOODENOUGH, *An Introduction to Philo Judaeus*, 2nd ed. rev. (1963), a popular, lively, fair summary of Goodenough's previous work, with helpful suggestions on how to read Philo; H. CHADWICK, "Philo," in A.H. ARMSTRONG (ed.), *The Cambridge History of Later Greek and Early Medieval Philosophy*, pp. 137–157 (1967), the best-balanced, brief, comprehensive survey of Philo's thought.

Major works on Philo: E.R. GOODENOUGH, *By Light, Light: The Mystic Gospel of Hellenistic Judaism* (1935), a challenging, if one-sided, presentation of Philo as a mystic; SAMUEL BELKIN, *Philo and the Oral Law* (1940, reprinted 1968), a learned, occasionally forced, presentation of Philo as thoroughly acquainted with Palestinian Halakha; H.A. WOLFSON, *Philo*, 2 vol. (1947), a truly great, if controversial, work, stressing Philo's relationship to Palestinian Pharisaic Judaism and his importance for the history of philosophy; SAMUEL SANDMEL, *Philo's Place in Judaism* (1956), a well-balanced corrective to Wolfson, consisting of a case study of the account of Abraham in Philo as compared with rabbinic and other contemporary literature.

Philosophy, History of Western

This article pursues three basic purposes: (1) it attempts to provide a synoptic overview of the history of philosophy in the West; (2) it strives to relate philosophic ideas and movements to their historical background and to the cultural situation of their time; and (3) it is specially mindful of philosophy's changing conception of its own definition, its function, and its unique task.

The main divisions of this article are as follows:

I. Nature, involvements, and writing of the history of philosophy
  Philosophy in the Western tradition
  General consideration of the history of philosophy
    The writing of the history of philosophy
    Shifts in the focus and concern of philosophy through history
II. Ancient Greek and Roman philosophy
  The Pre-Socratic philosophers
    Cosmology and the metaphysic of matter
    Epistemology of appearance
    Metaphysic of number
    Anthropology and relativism
  The seminal thinkers of Greek philosophy
    Socrates
    Plato
    Aristotle
  Hellenistic and Roman philosophy
    Stoics
    Epicureans
    Skeptics
    Neo-Pythagoreans and Neoplatonists
III. Medieval philosophy
  Early medieval philosophy
  Transition to Scholasticism
  The age of the schoolmen
  Philosophy in the late Middle Ages
IV. Modern philosophy
  The Renaissance and early-modern period
    Dominant strands of Renaissance philosophy
    Rise of Empiricism and Rationalism
    Literary forms and sociological conditions
  The Enlightenment
    Classical British Empiricism and its basic tasks
    Nonepistemological movements in the Enlightenment
    Critical examination of reason in Kant
    Literary forms
  The 19th century
    German Idealism of Fichte, Schelling, and Hegel
    Positivism and social theory in Comte, Mill, and Marx
    Independent and irrationalist movements
  The 20th century
    Individual philosophies of Bergson, Dewey, and Whitehead
    Marxist thought
    Analytic philosophy
    Continental philosophy
    Concluding comments

I. Nature, involvements, and writing of the history of philosophy

PHILOSOPHY IN THE WESTERN TRADITION

Various conceptions of what philosophy is

It is a paradox faced by all of those who attempt to write the history of philosophy that the "philosophy" whose history they write probably would not have been defined exactly alike by any two of the major figures whom they judge it fitting to include in their account. For throughout its long and varied history in the West, "philosophy" has meant many different things. Some of these have been a search for the wisdom of life (the meaning closest to the Greek words from which the term is derived); an attempt to understand the universe as a whole; an examination of man's moral responsibilities and his social obligations; an effort to fathom the divine intentions and man's place with reference to them; an effort to ground the enterprise of natural science; a rigorous examination of the origin, extent, and validity of men's ideas; an exploration of the place of will or consciousness in the universe; an examination of the values of truth, goodness, and beauty; an effort to codify the rules of human thought in order to promote rationality and the extension of clear thinking. Even these do not exhaust the meanings that have been attached to the philosophic enterprise, but they give some idea of its extreme complexity and manysidedness.

It is difficult to determine whether any common element can be found within this diversity and whether any core meaning can be discovered for philosophy that could serve as a universal and all-inclusive definition. But a first attempt in this direction might be to define philosophy either as "a reflection upon the varieties of human experience" or as "the rational, methodical, and systematic consideration of those topics that are of greatest concern to man." Vague and indefinite as such definitions are, they do suggest two important facts about philosophizing: (1) that it is a reflective, or meditative, activity and (2) that it has no explicitly designated subject matter of its own but is a method or type of mental operation (like science or like history) that can take any area or subject matter or type of experience as its object. Thus, although there are a few single-term divisions of philosophy of long standing—such as logic, ethics, epistemology (the theory of knowledge), or metaphysics (theory of the nature of Being)—its divisions are probably best expressed by phrases that contain the preposition "of"—such as philosophy of nature or philosophy of mind or philosophy of law or philosophy of art.

Part of what makes it difficult to find a consensus among philosophers about the definition of their discipline is precisely that they have frequently come to it from different fields, with different interests and concerns, and that they therefore have different areas of experience upon which they find it especially necessary or meaningful to reflect. Thomas Aquinas (a Dominican friar of the 13th century), George Berkeley (a bishop of the Irish Church in the 18th century), and Søren Kierkegaard (a Danish divinity student in the 19th century) all saw philosophy as a means to assert the truths of religion and to dispel the Materialistic or Rationalistic errors that, in their opinion, had led to its decline. Pythagoras in ancient south Italy, René Descartes in the late Renaissance, and Bertrand Russell in the 20th century have been primarily mathematicians whose views of the universe and of human knowledge have been vastly influenced by the concept of number and by the method of deductive thinking. Some philosophers, such as Plato or the British philosophers Thomas Hobbes and John Stuart Mill, have been obsessed by problems of political arrangement and social living, so that whatever else they have done in philosophy has been stimulated by a desire to understand and, ultimately, to change the social and political behaviour of men. And still others—such as the Milesians (the first philosophers of Greece); Francis Bacon, an Elizabethan philosopher; and, in the 20th century, Alfred North Whitehead, a process metaphysician—have begun with an interest in the physical composition of the natural world, so that their philosophies resemble more closely the generalizations of physical science than those of religion or sociology.

Characteristic oppositions in philosophy

The history of Western philosophy reveals in detail the concentrated activity of a multitude of serious and able men reflecting upon, reasoning about, and considering deeply the nature of their experience. But throughout this manifold diversity certain characteristic oppositions habitually recur, such as the division between monists, dualists, and pluralists in metaphysics; between Materialists and Idealists in cosmological theory; between Nominalists and Realists in the theory of signification; between Rationalists and Empiricists in the theory of knowledge; between Utilitarians, self-realizationists, and proponents of duty in moral theory; and between partisans of logic and partisans of emotion in the search for a responsible guide to the wisdom of life.

Many of these fundamental oppositions among philosophers will be treated in the article that follows. But if any single opposition is taken as central throughout the history of Western philosophy at every level and in every field, it is probably that between the critical and the speculative impulses. These two divergent motivations tend to express themselves in two divergent methods: that of analysis and that of synthesis. Plato's *Republic* is an example of the second. The *Principia Ethica* (1903) of G.E. Moore, a founder of linguistic philosophy, is an example of the first. Beginning with a simple question about justice, *The Republic* in its discursiveness slowly but progressively brings more and more areas into the discussion: first ethics, then politics, then educational theory, then theory of knowledge, and finally metaphysics. Starting with one rather specific question, Plato finally managed to make his discussion as broad as the world. *Principia Ethica* does just the opposite. Beginning with a rather general question—What is good?—it progressively breaks up this question into a whole series of subordinate questions, analyzing meanings ever more minutely, growing narrower and narrower but always with the utmost modesty and sincerity, striving for increasing simplicity and exactitude.

The analytic, or critical, impulse treats any subject matter or topic by concentrating upon the part, by taking it apart in the service of clarity and precision. It was essentially the method of Aristotle and of Peter Abelard, a medieval Scholastic; of David Hume, a Scottish Skeptic, and Rudolf Carnap, a contemporary semantic Positivist; and of Russell and Moore. The synthetic or speculative impulse operates by seeking to comprehend the whole, by putting it all together in the service of unity and completeness. It is essentially the method of Parmenides, a Pre-Socratic monist, and of Plato; of St. Thomas and of Benedict de Spinoza, a modern Jewish Rationalist; of G.W.F. Hegel, a German Idealist, and of Whitehead. Throughout philosophy's history, each of the two traditions has made its insistent claim.

There is one philosophical tradition—that of Positivism—which sees philosophy as originating in the obscure mists of religion and coming finally to rest in the pure sunshine of scientific clarity. This represents a necessary progress, since Positivism considers it a scandal when philosophers speak a language that is not accessible to "verification"; it holds that bold and adventuresome philosophical speculation is at best mere self-indulgence, a passing state occurring when philosophic problems are raised prematurely—that is, at a time when philosophy does not possess the logical means to solve them.

Though Positivism represents a partisan view that it is not necessary to hold, it does express indirectly a basic truth—that the philosophic enterprise has always hovered uncertainly between the lure of religious seriousness and that of scientific exactitude. In the earliest philosophers of Greece, it is impossible to separate ideas of divinity and the human soul from ideas about the mystery of being and the genesis of material change, and in the Middle Ages philosophy was acknowledged to be "the handmaiden of theology." But the increased secularization of modern culture has largely reversed this trend, and the Enlightenment emphasis upon the separation of nature from its divine creator has increasingly placed philosophic resources at the disposal of those interested in creating a philosophy of science.

Yet philosophy's continuing search for philosophic truth leads it to hope, but at the same time to profoundly doubt, that its problems are objectively solvable. With respect to a total description of Being or a definitive account of the nature of values, only individual solutions now seem possible; and the optimistic hope for objective answers that secure universal agreement must be given up.

Comparison with art: living classics

In this respect, philosophy seems less like science than like art and the philosopher more like an artist than a scientist, for his philosophic solutions bear the stamp of his own personality, and his choice of arguments reveals as much about himself as his chosen problem. As a work of art is a portion of the world seen through a temperament, so a philosophical system is almost a vision of the world subjectively assembled. Plato and Descartes, Immanuel Kant, the pivotal figure of modern philosophy, and John Dewey, a U.S. Pragmatist, have given to their systems many of the quaint trappings of their own personalities.

But if philosophy is not true in the same sense as science, it is not false in the same sense either; and this gives to the history of philosophy a living significance, which the history of science does not enjoy. In science, the present confronts the past as truth confronts error; thus, for science, the past, even when important at all, is important only out of historical interest. In philosophy it is different. Philosophical systems are never definitively proved false; they are simply discarded or put aside for future use. And this means that the history of philosophy consists not simply of dead museum pieces but of ever-living classics—comprising a permanent repository of ideas, doctrines, and arguments and a continuing source of philosophical inspiration and suggestiveness to those who philosophize in any succeeding age. It is for this reason that any attempt to separate philosophizing from the history of philosophy is both a provincial act and an unnecessary impoverishment of its rich natural resources.

GENERAL CONSIDERATION OF THE HISTORY OF PHILOSOPHY

The writing of the history of philosophy. The writing of the history of philosophy is itself controlled by a series of cultural habits or conventions.

Ways of ordering the history. The ensuing article on the history of Western philosophy is divided into three sections—ancient, medieval, and modern—and this division is so pervasive today that it is difficult to remember that the threefold distinction is only as old as the end of the 17th century. This distinction—first employed in the writing of European history proper by Georg Horn of Leiden in his *Arca Noae: Sive Historia Imperiorum et Regnorum a Condito Orbe ad Nostra Tempora* (1666) and a generation later by Christophorus Cellarius, a German historian, in 1696—slowly spread to historical writing in all fields and was given definitive influence in philosophical writing through the series of lectures on *Philosophiegeschichte* ("History of Philosophy") that Hegel delivered first at Jena, then at Heidelberg, and finally at Berlin between 1805 and 1830. Since Hegel, it has been taken for granted as standard practice, although a host of cultural assumptions is implied by its use.

Stress on ideas versus stress on men

Treatment of the total field of the history of philosophy has been traditionally subject to two types of ordering, according to whether it was conceived (1) as primarily a history of ideas or (2) as a history of the intellectual products of men. In the first ordering, certain ideas, or concepts, are viewed as archetypal (such as matter or mind or doubt); and the condensations occurring within the flow of thought tend to consist of basic types or schools. Such ordering has characterized works such as Friedrich Lange's *Geschichte des Materialismus . . .* (1866; Eng. trans., *The History of Materialism*, 3rd ed., 1925), A.C. Ewing's compilation *The Idealist Tradition: From Berkeley to Blanshard* (1957), or Richard H. Popkin's *History of Scepticism from Erasmus to Descartes* (1960). In the second type of ordering, the historian, impressed by the producers of ideas as much as by the ideas themselves—that is, with philosophers as agents—reviews the succession of great philosophic personalities in their rational achievement. Such ordering has produced the more customary histories such as Émile Bréhier's *Histoire de la philosophie* (1926–32), Bertrand Russell's *History of Western Philosophy* (1945), and Karl Jaspers' *Die grossen Philosophen* (1957; Eng. trans., 1962–66).

These two different types of ordering depend for their validity upon an appeal to two different principles about the nature of ideas, but their incidental use may also be influenced by social or cultural factors. Thus, the biographers and compilers of late antiquity (among them, Plutarch, Sextus Empiricus, Philostratus, and Clement of Alexandria), impressed by the religious pluralism of the age in which they lived, thought of philosophers, too, as falling into different sects and wrote histories of the Sophists, the Skeptics, the Epicureans, and other such schools; whereas almost 2,000 years later, Hegel—living in a period of romantic historiography dominated by the concept of the great man in history—deliberately described the history of philosophy as "a succession of noble minds, a gallery of heroes of thought."

As between these two ordering principles, the article below will be eclectic (as has come to be the custom), devoting chief attention to outstanding major figures, while joining more minor figures, wherever possible, into the schools or tendencies that they exemplify.

Factors in writing history of philosophy. The type of ordering suggested above also has some relationship to the more general problems of method in the writing of the history of philosophy. Here there are at least three factors that must be taken into account: (1) the historian must understand how (at least in part) any philosopher's doctrines depend upon those of his predecessors; (2) he must understand that a man's philosophy occurs at a certain point of time in history and, thus, how it expresses the effects of certain social and cultural circumstances; and (3) he must understand how in part it stems from the philosopher's own personality and situation in life. This is only to say that the history of philosophy, to be at all comprehensive and adequate, must deal with the mutual interplay of ideas, of agents, and of cultural contexts.

Logical, sociological, and individual factors

The first factor may be called logical because it is the intellectual response that a given philosophy makes to the doctrines of its forerunners in which the very problems taken as central have often been given by the current climate of controversy. Thus, many of the details of Aristotle's ethical, political, and metaphysical systems arise in arguments directed against statements and principles of Plato; much of *An Essay Concerning Human Understanding* (1690) by John Locke, an initiator of the Enlightenment, is directed against current Cartesian presuppositions; and the *Nouveaux essais sur l'entendement humain* (written 1704; Eng. trans., *New Essays Concerning Human Understanding*, 1916) by Gottfried Wilhelm Leibniz, a broadly learned Rationalist, is, in turn, specifically directed against Locke.

The second factor may be called sociological because it considers philosophy, at least in part, as a direct form of social expression, arising at a certain moment in history, dated and marked by the peculiar problems and crises of the society in which it flourishes. From this perspective, the philosophy of Plato may be viewed as the response of an aristocratic elitism to the immediate threat of democracy and the levelling of values in 5th-century Athens—its social theory and even its metaphysics servicing the thrust toward an aristocratic restoration in the Greek world. Thus, the philosophy of St. Thomas Aquinas may be viewed as an effort toward doctrinal clarification in support of the institution of the medieval Roman Church, as the Saint spent his life obediently fulfilling the philosophic tasks set for him by his superiors in the church and the Dominican order. Thus, the philosophy of Kant, with all of its technical vocabulary and rigid systematization, may be viewed as an expression of the new professionalism in philosophy, a clear product of the rebirth of the German universities during the 18th-century Enlightenment.

The third factor may be called biographical or individual because, with Hegel, it recognizes that philosophies

are generally produced by men of unusual or independent personality whose systems usually bear the mark of their creators. And what is meant here by the individuality of the philosopher lies less in the facts of his biography (such as the wealth or poverty, the married state or bachelorhood that he shares with other men) than in the essential form and style of his philosophizing. The cool intensity of Spinoza's geometric search for wisdom, the unswerving (if opaque) discursiveness of Hegel's quest for completeness or totality, the relentless and minute analytic search for distinctions and shades of meaning that marks Moore's master passion ("to be accurate—to get everything exactly right"), these qualities mark the philosophical writings of Spinoza, Hegel, and Moore with an unmistakably individual and original character.

Shifts in the focus and concern of philosophy through history. Any adequate treatment of individual figures in the history of philosophy tries to utilize this threefold division of logical, sociological, and individual factors; but in a synoptic view of the history of philosphy in the West, one is particularly aware of the various shifts of focus and concern that philosophy has sustained and, indeed, of the often profound differences in the way that it defines itself or visualizes its task from age to age or from generation to generation.

Philosophy among the Greeks slowly emerged out of religious awe into wonder about the principles and elements of the natural world. But as the Greek populations more and more left the land to become concentrated in their cities, interest shifted from nature to social living; questions of law and convention and civic values became paramount. Cosmological speculation partly gave way to moral and political theorizing, and the preliminary and somewhat fragmentary questionings of Socrates and the Sophists turned into the great positive constructions of Plato and Aristotle. With the political and social fragmentation of the succeeding centuries, however, philosophizing once again shifted from the norm of civic involvement to problems of salvation and survival in a chaotic world.

Medieval and modern history

The dawn of Christianity brought to philosophy new tasks. Augustine, the philosophic bishop of Hippo, and the Church Fathers used such resources of the Greek tradition as remained (chiefly Platonism) to deal with problems of the creation, of faith and reason, and of truth. New translations in the 12th century made much of Aristotle available and prepared the way for the great theological constructions of the 13th century, chiefly those of the Scholastic philosophers Bonaventure, Albertus Magnus, Aquinas, Roger Bacon, and Duns Scotus. The end of the Middle Ages saw a new flowering of the opposite tendencies in the nominalist William of Ockham and the mystic Meister Eckehart.

The waning of the Middle Ages became the Renaissance. Universalism was replaced by nationalism. Philosophy became secularized. The great new fact was that of the mystery and immensity of the natural world. The best philosophic minds of the 17th century turned to the task of exploring the foundations of physical science, and the symbol of their success—the great system of Newton's physics—turned the philosophers of the Enlightenment to epistemology and to the examination of the human mind that had produced so brilliant a scientific creation. The 19th century, a time of great philosophical diversity, discovered the irrational and in so doing prepared the way for the oppositions between Analysis and Phenomenology and between Positivism and Existentialism that characterize the present situation in philosophy.

Although the foregoing capsule presentation of the history of philosophy in the West follows a strict chronology, it does not do justice to the constant occurrence and recurrence of dominant strands in the history of thought. It would also be possible to write the philosophic history of the Middle Ages simply by noting the complicated occurrence of Platonic and Aristotelian doctrines, of the Renaissance according to the reappearance of Greek Materialism, Stoicism, and Skepticism, and of the 18th century in terms of the competing claims of Rationalist and Empiricist principles. Thus, chronology and the interweaving of philosophic systems cooperate in a completed history of philosophy. (A.W.L.)

II. Ancient Greek and Roman philosophy

THE PRE-SOCRATIC PHILOSOPHERS

Cosmology and the metaphysic of matter. Because the earliest Greek philosophers focussed their attention upon the origin and nature of the physical world, they are often called cosmologists or naturalists. Though monistic views prevailed at first, they were soon followed by several pluralistic theories.

Monistic cosmologies. There is a consensus, dating back at least as far as the 4th century BC and continuing to the present, that the first Greek philosopher was Thales of Miletus, who flourished in the first half of the 6th century BC. At that time, the word philosopher (lover of wisdom) had not yet been coined. Thales was counted, however, among the Seven Wise Men (Sophoi), whose name derives from a term that then designated inventiveness and practical wisdom rather than speculative insight. Thales showed these qualities by trying to give the mathematical knowledge that he derived from the Babylonians a more exact foundation and by using it for the solution of practical problems—such as the determination of the distance of a ship as seen from the shore or of the height of the Pyramids. Though he was also credited with predicting an eclipse of the Sun, it is likely that he merely gave a natural explanation of one on the basis of Babylonian astronomical knowledge.

Thales of Miletus

The reason that Thales was considered to be the first Greek philosopher is that he was the first to give a purely natural explanation of the origin of the world, free from all mythological ingredients, declaring that everything had come out of water—an explanation based on the discovery of fossil sea animals far inland. His tendency (and that of his immediate successors) to give nonmythological explanations of the origin of the world was undoubtedly prompted by the fact that all of them lived on the coast of Asia Minor surrounded by a number of nations with civilizations much farther advanced than that of the Greeks, whose mythological explanations differed greatly both among themselves and from those of the Greeks. It appeared necessary, therefore, to make a fresh start on the basis of what a person could observe and figure out by looking at the world as it presented itself. This procedure naturally resulted in a tendency to make sweeping generalizations on the basis of rather restricted, but carefully checked, observations.

Thales' disciple and successor, Anaximander of Miletus (flourished mid-6th century), tried to give a more elaborate account of the origin and development of the ordered world (the cosmos). According to him, it developed out of the *apeiron*, something both infinite and indefinite (without distinguishable qualities). Within this *apeiron* something arose to produce the opposites of hot and cold. These at once began to struggle with each other and produced the cosmos. The cold (and wet) partly dried up (becoming solid earth), partly remained (as water), and—by means of the hot—partly evaporated (becoming air and mist), its evaporating part (by expansion) splitting up the hot into fiery rings, which surround the whole cosmos. Because these rings are enveloped by mist, however, there remain only certain breathing holes that are visible to men, appearing to them as Sun, Moon and stars. Anaximander was the first to realize that upward and downward are not absolute directions, but that downward means toward the middle of the Earth and upward away from it, so that the Earth had no need to be supported (as Thales had believed) by anything. Starting from Thales' observations, Anaximander tried to reconstruct the development of life in more detail. Life, being closely bound up with moisture, originated in the sea. All land animals, he held, are descendants of sea animals; man, specifically, is the descendant of an oviparous sea animal of the family of the cetaceans, the *Galeus levis*, that carries its young in a pouch after they have come out of the egg or later lets them return to it until they can fend for themselves. Gradually, however, the moisture will be partly dried up, partly evaporated, until in the end

Anaximander of Miletus

all things will have returned into the undifferentiated *apeiron*, "in order to pay the penalty for their injustice" —that of having struggled against one another.

Anaximenes of Miletus

Anaximander's successor, Anaximenes of Miletus (flourished second half of the 6th century), taught that air was the origin of all things. His position was for a long time thought to have been a step backward because, like Thales, he placed a special kind of matter at the beginning of the development of the world. But this criticism missed the point. Neither Thales nor Anaximander appear to have specified the way in which the other things arose out of the water or *apeiron*. Anaximenes, however, declared that the other types of matter arose out of air by condensation and rarefaction. In this way, what to Thales had been merely a beginning became a fundamental principle that remained essentially the same through all of its transmutations. Thus, the term *archē*, which originally simply meant "beginning," acquired the new meaning of "principle," a term that henceforth played an enormous role in philosophy down to the present. This concept of a principle that remains the same through many transmutations is, furthermore, the presupposition of the idea that nothing can come out of nothing and that all of the comings to be and passings away that men observe are nothing but transmutations of something that essentially remains the same eternally. In this way it also lies at the bottom of all of the conservation laws—those of the conservation of matter, of force, and of energy—that have been basic in the development of physics. Though Anaximenes of course did not realize all of the implications of his idea, its importance can hardly be exaggerated.

The first three Greek philosophers have often been called hylozoists because they seemed to believe in a kind of living matter. But this is hardly an adequate characterization. It is, rather, characteristic of them that they did not clearly distinguish between kinds of matter, forces, and qualities nor between physical and emotional qualities. The same entity is sometimes called fire and sometimes the hot. Heat appears sometimes as a force and sometimes as a quality, and again there is no clear distinction between warm and cold as physical qualities and the warmth of love and the cold of hate. To realize these ambiguities is important to an understanding of certain later developments in Greek philosophy.

Xenophanes and Parmenides

Xenophanes of Colophon (b. *c.* 560 BC), rhapsode and philosophic thinker, who emigrated from Asia Minor to Elea in southern Italy, was the first to bring out more clearly what was implied in Anaximenes' philosophy. He criticized the popular notions of the gods, saying that men made their gods in their own image. But, more importantly, he argued that there could be only one God, the ruler of the universe, who must be eternal.

For, being the strongest of all beings, he could not have come out of something less strong, nor could he be overcome or superseded by something else, because nothing could arise that is stronger than the strongest. The argument clearly rested on the axiom that nothing can come out of nothing and that nothing that is can really vanish. The axiom was made more explicit and carried to its extreme consequences by Parmenides of Elea (flourished first half of the 5th century BC), the founder of the so-called school of Eleaticism (*q.v.*), of whom Xenophanes has been regarded as the teacher and forerunner. In a philosophical poem Parmenides insisted that "what is" cannot have come into being and cannot pass away because it would have to have come out of nothing or to become nothing, whereas nothing by its very nature does not exist. There can be no motion either; for it would have to be a motion into something that is—which is not possible since it would be blocked—or a motion into something that is not—which is equally impossible since what is not does not exist. Hence everything is solid immobile being. The familiar world, in which things move around, come into being, and pass away, is a world of mere belief (*doxa*). In a second part of the poem, however, Parmenides tried to give an analytical account of this world of belief, showing that it rested on constant distinctions between what is believed to be positive—*i.e.*, to have real being, such as light and warmth—and what is negative—*i.e.*, the absence of positive being, such as darkness and cold.

It is significant that Heracleitus of Ephesus, a contemporary of Parmenides, whose philosophy was later considered to be the very opposite of Parmenides' philosophy of immobile being, came, in some fragments of his work, near to what Parmenides tried to show: the positive and the negative, he said, are merely different views of the same thing; death and life, day and night, or light and darkness are really one.

Pluralistic cosmologies. Parmenides had an enormous influence on the further development of philosophy. Most of the philosophers of the following two generations tried to find a way to reconcile his thesis that nothing comes into being nor passes away with the evidence presented to men by their senses. Empedocles of Acragas (flourished mid-5th century) declared that there are four material elements (he called them roots of everything) and two forces, love and hate, that did not come into being and would never pass away or increase or diminish. But the elements are constantly mixed with one another by love and again separated by hate. Thus, through mixture and decomposition composite things come into being and pass away. Because he conceived of love and hate as blind forces, Empedocles had to explain how living beings could arise. This he achieved by means of a somewhat crude anticipation of the theory of the survival of the fittest. In the process of mixture and decomposition the limbs and parts of various animals would be formed by chance. But they could not survive. Only when by chance they had come together in such a way that they were able to support and reproduce themselves would they survive. It was in this way that the various species were produced and continued to exist.

Empedocles and Anaxagoras

Anaxagoras of Clazomenae, a 5th-century pluralist, believed that because nothing can really come into being, everything must be contained in everything but in the form of infinitely small parts. In the beginning all of these particles had been mixed in an even mixture, in which nothing could be distinguished, much like the indefinite *apeiron* of Anaximander. But then *nous*, or intelligence, began at one point to set these particles into a whirling motion foreseeing that in this way they would become separated from one another and then recombine in the most various ways so as to produce gradually the world in which men live. In contrast to the forces assumed by Empedocles, the *nous* of Anaxagoras is not blind but foresees and intends the production of the cosmos including living and intelligent beings; but it does not interfere with the process after having started the whirling motion —a strange combination of a mechanical and a nonmechanical explanation of the world.

Leucippus and Democritus

By far of greatest importance for the later development of philosophy and physical science was an attempt by the Atomists Leucippus (flourished mid-5th century) and (in the following generation) Democritus to solve the Parmenidean problem. Leucippus found the solution in the assumption that, contrary to Parmenides' argument, the nothing *does* in a way exist, viz., as empty space. There are then, however, only two fundamental principles of the physical world, empty space and filled space—the latter consisting of the atoms, which, in contrast to those of modern physics, are real atoms; *i.e.*, they are absolutely indivisible because nothing can penetrate to split them. On these foundations, laid by Leucippus, Democritus appears to have built a whole system, aiming at a complete explanation of the varied phenomena of the visible world by means of an analysis of its atomic structure. This system begins with elementary physical problems such as that of why a hard body can be lighter than a softer one. The explanation is: that although the heavier body contains more atoms, they are equally distributed and of round shape; the lighter body, however, has fewer atoms, most of which have hooks by which they form rigid gratings. The system ends with educational and ethical questions. A sound and cheerful man, useful to his fellowmen, is literally well composed. Although destructive passions involve violent long-distance atomic motions, education

can help to contain them, creating a better composure. Civilization is produced by the necessities and needs of life, which compel man to work and to make inventions. When life becomes too easy because all needs are met, there is a danger that civilization will decay as men become unruly and negligent.

Epistemology of appearance. All of the post-Parmenidean philosophers, like Parmenides himself, presupposed that the real world is different from the one that men perceive. Thus, the problems of epistemology, or theory of knowledge, arose. According to Anaxagoras, everything is contained in everything. But this is not what people perceive. He solved this problem, however, by assuming that, if there is a much greater amount of one kind of particle in a thing than of all other kinds the latter are not perceived at all. The observation was then made that sometimes different persons or kinds of animals have different perceptions of the same things. He explained this phenomenon by assuming that like is perceived by like. If, therefore, in the sense organ of someone, there is less of one kind of stuff than of another, he will perceive it less keenly than the latter. This reasoning was also used to explain why some animals see better by night and others by daylight. According to Democritus, the atoms have no sensual qualities such as tastes, smells, or colours at all. Thus, he tried to reduce all of them to tactile qualities (explaining a bright white colour, for instance, as sharp atoms hitting the eye like needles), and he made a most elaborate attempt to reconstruct the atomic structure of things on the basis of their apparent sensual qualities.

Zeno of Elea

Also of very great importance in the history of epistemology was Zeno of Elea (flourished mid-5th century), a younger friend of Parmenides. Parmenides had, of course, been severely criticized because of the strange consequences of his doctrine that in reality there is no motion and no plurality either because there is just one solid being. To support him, however, Zeno tried to show that the assumption that there is motion and plurality leads to consequences that are no less strange. This he did by means of his famous paradoxes, saying that the flying arrow rests since it can neither move in the place in which it is nor in a place in which it is not and that Achilles cannot outrun a turtle because when he has reached its starting point, the turtle will have moved to a further point, and so on ad infinitum—that, in fact, he cannot even start running, for, before traversing the stretch to the starting point of the turtle, he will have to traverse half of it and again half of that and so on ad infinitum. All of these paradoxes are derived from the problem of the continuum. Although they have often been dismissed as logical nonsense, many attempts have also been made to dispose of them by means of mathematical theorems, such as the theory of convergent series or the theory of sets. In the end, however, the difficulties inherent in his arguments have always come back with a vengeance, for the human mind is so constructed that it has two ways of looking at a continuum that are not quite reconcilable.

Metaphysic of number. All of the philosophies mentioned so far are in various ways historically akin to one another. Toward the end of the 6th century, however, there arose quite independently another kind of philosophy, which only later entered into interrelation with the developments just mentioned: the philosophy of Pythagoras of Samos.

Pythagoras of Samos

Pythagoras travelled extensively in the East and in Egypt and, after his return to Samos, emigrated to southern Italy because of his dislike of the tyranny of Polycrates. At Croton and Metapontum he founded a philosophical society with strict rules and soon gained considerable political influence. He appears to have brought his doctrine of the transmigration of souls from the East. Much more important for the history of philosophy and science, however, was his doctrine that "all things are numbers," which means that the essences and structures of all things can be determined by finding the numerical relations contained in them. Originally, this, too, was a very broad generalization made on the basis of comparatively few observations: for instance, that the same harmonies can be produced with different instruments—strings, pipes, disks, etc.—by means of the same numerical ratios—1:2, 2:3, 3:4—in one-dimensional extensions; the observation that certain regularities exist in the movements of the celestial bodies; and the discovery that the form of a triangle is determined by the ratio of the lengths of its sides. But, because the followers of Pythagoras tried to apply their principle everywhere with the greatest of accuracy, one of them—Hippasus of Metapontum—around 450 BC made one of the most fundamental discoveries of the entire history of science, that of incommensurability, viz., that the quantitative relation between the side and diagonal of such simple figures as the square and the regular pentagon cannot be expressed as a ratio of integers, however great. At first sight this discovery seemed to destroy the very basis of the Pythagorean philosophy, and the school thus split into two sections, one of which engaged in rather abstruse numerical speculations while the other succeeded in overcoming the difficulty by ingenious mathematical inventions and laid the foundations of all quantitative science. Pythagorean philosophy also exerted a great influence on the development of Plato's thought in his later years.

The speculations described so far comprise in many ways the most important part of the history of Greek philosophy because all of the most fundamental problems of Western philosophy turned up here for the first time and one finds here the formation of a great many concepts that have continued to dominate Western philosophy and science down to the present day.

Anthropology and relativism. In the middle of the 5th century BC, Greek thinking took a somewhat different turn through the advent of the Sophists, a designation derived from the verb *sophizesthai*, "making a profession of being inventive and clever," for the Sophists—in contrast to the philosophers mentioned so far—asked money for their instruction. Philosophically, they were, in a way, the leaders of a rebellion against the preceding development, which more and more had resulted in the belief that the real world is quite different from the phenomenal world. "What is the sense of such speculations?" they said, since men do not live in these so-called real worlds. This is the meaning of a pronouncement of Protagoras of Abdera (flourished around the mid-5th century): "Man is the measure of all things, of those which are that they are and of those which are not that they are not." For man, the world is what it appears to him to be, not something else; and, though he meant man in general, he illustrated it by pointing out that even in regard to an individual man it makes no sense to tell him that it is really warm when he is shivering with cold, because for him it is cold—for him, the cold exists, is there.

The Sophists

His younger contemporary Gorgias of Leontini, famous for his treatise on the art of oratory, made fun of the philosophers in a book *Peri tou mē ontos ē peri physeōs* ("On that which is not, or on Nature"), in which—referring to the "truly existing world," also called "the nature of things"—he tried to prove (1) that nothing exists, (2) that if something existed, man could have no knowledge of it, and (3) that if nevertheless somebody knew it, he could not communicate his knowledge to others.

The Sophists were not only skeptical of what had by then become a philosophical tradition but also of other traditions. On the basis of the observation that different nations have different rules of conduct even in regard to things considered most sacred—such as the relations between the sexes, marriage, and burial—they concluded that most rules of conduct are rather conventional. What is really important is to be successful in life and to gain influence on others. This they promised to teach. Gorgias was proud of the fact that, having no knowledge of medicine, he was more successful in persuading a patient to undergo a necessary operation than his brother, a physician, who knew when an operation was necessary. The older Sophists, however, were far from openly preaching immoralism. They nevertheless gradually came under suspicion because of their sly ways of arguing. One of the later Sophists, however, Thrasymachus of Chalcedon (late 5th century), was bold enough to declare openly

that "right is what is beneficial for the stronger or better one"; *i.e.*, for the one able to win the power to bend others to his will.

THE SEMINAL THINKERS OF GREEK PHILOSOPHY

Socrates. By many of his contemporaries, Socrates (flourished 5th century BC) was also considered to be a Sophist because of his tricky arguments, though he did not teach for money and his aims were entirely different from theirs. Although there is a late tradition according to which Pythagoras invented the word philosopher, it was certainly through Socrates—who insisted that he possessed no wisdom but was striving for it—that the term came into general use and was later applied to all earlier serious thinkers. In fact, all of the records of his life and activity left by his numerous adherents and disciples indicate that he never tried to teach anything directly. But he constantly engaged in conversations with everybody—old and young, high and low—trying to bring into the open by his questions the inconsistencies in their opinions and actions. But though he never taught directly, his whole activity rested on two unshakable assumptions: (1) the principle never to do wrong nor to participate, even indirectly, in any wrongdoing and (2) the conviction that nobody who really knows what is good and right could act against it. He demonstrated his unshakable adherence to the first principle on various occasions and under different regimes. When, after the Battle of Arginusae, the majority of the Athenian popular assembly demanded death without trial for the admirals, Socrates, who on that day happened to be president of the assembly (an office changing daily), refused to put the proposal to the vote because it was wrong to condemn anyone without a fair trial, though the people threatened him shouting that it would be terrible if the sovereign people could not do as they pleased. When, after the overthrow of democracy, the so-called Thirty Tyrants, who tried to involve everybody in their wrongdoings, ordered him to arrest an innocent citizen whose money they coveted, he simply disobeyed. This he did although at that time such disobedience was still more dangerous than disobeying the sovereign people had been at the time of unrestricted democracy. Likewise, in the time of the democracy he pointed out by his questions the inconsistency of allowing oneself to be swayed by the oratory of a good speaker instead of first inquiring into his capability as a statesman, whereas in private life a sensible citizen would not listen to the oratory of a quack but would try to find the best doctor. When, after the overthrow of democracy, the Thirty Tyrants had many people arbitrarily executed, he asked everybody whether a man was a good shepherd who diminished the number of the sheep instead of increasing it and did not cease doing so when Critias, the leader of the Thirty, warned him to take heed not to diminish the number of the sheep by his own, Socrates', person. But the most fundamental inconsistency that he tried to show up everywhere was that most people by their actions showed that they considered what they found to be good, wonderful, and beautiful in others—such as, for instance, doing right at great danger to oneself—not to be good for themselves, and considered to be good for themselves what they despised and condemned in others. Though all of these stands won him the most fervent admiration of many, especially among the young of all classes, it caused also great resentment among leading politicians, whose inconsistencies were shown up publicly by him and his adherents. Though Socrates had survived unharmed through the regime of the Thirty—partly because it did not last long, partly because he was supported by some close relatives of their leader Critias—it was under the restored democracy that he was accused of impiety and of corrupting the youth and finally condemned to death, largely also in consequence of his intransigent attitude during the trial.

After Socrates' death his influence became a dominating one through the greater part of Greek and Roman philosophy down to the end of antiquity and was more or less noticeable even in all of the rest. Many of his adherents —among them Xenophon, a military man and a historian, and Aeschines of Sphettus, one of those present at his death—tried to preserve his philosophical method by writing Socratic dialogues. Some founded schools or sects that perpetuated themselves over long periods of time, Eucleides of Megara emphasizing the theoretical aspects of Socrates' thought, and Antisthenes stressing the independence of the true philosopher from material wants. The latter, through his disciple Diogenes of Sinope, who carried voluntary poverty to the extreme and emphasized freedom from all conventions, became the founder of the sect of the Cynics. Aristippus of Cyrene, traditional founder of the Cyrenaic school, stressed man's independence from material needs in a somewhat different way, declaring that there is no reason why a philosopher should not enjoy material goods as long as he is completely indifferent to their loss. Though Aristippus renounced his son because he led a dissolute life, the school that he founded (through his daughter and his grandson) was hedonistic, holding pleasure to be the good.

Founding of schools and sects

Plato. By far the most important disciple of Socrates, however, was Plato, a scion of one of the most noble Athenian families, who could trace his ancestry back to the last king of Athens and to Solon, the great social and political reformer.

Life. As a very young man Plato became a fervent admirer of Socrates in spite of the latter's plebeian origin. Contrary to his master, however, who always concerned himself with the attitudes of individuals, he believed in the importance of political institutions. In his early youth he had observed that the Athenian masses, listening to the glorious projects of ambitious politicians, had engaged in foolhardy adventures of conquest, which led in the end to total defeat in the Peloponnesian War. When, in consequence of the disaster, democracy was abolished, Plato at first set great hopes in the new oligarchy—especially since its leader, Critias, was a close relative. But he soon discovered, that—to use his own words—the despised democracy had been gold in comparison with the new terror. When the oligarchy was overthrown and the restored democracy, in 399, adopted a new law code—in fact, a kind of written constitution containing safeguards against rash political decisions—Plato again had considerable hope and was even inclined to view the execution of Socrates as an unfortunate incident rather than a logical consequence of the new regime. It was only some years later, when demagogy appeared to raise its head again, that he "despaired and was forced to say that things would not become better in politics unless the philosophers would become rulers or the rulers philosophers." He wrote a dialogue, the *Gorgias*, violently denouncing political oratory and propaganda and then travelled to southern Italy in order to study political conditions there. Again, however, he found the much vaunted *dolce vita* of the Greeks there, in which the rich lived in luxury exploiting the poor, much worse than the democracy at Athens. But at Syracuse he met a young man, Dion, brother-in-law of the ruling tyrant, Dionysius I, who listened eagerly to his political ideas and promised to work for their realization if any occasion should arise. On his return to Athens, Plato founded the so-called Academy, an institution for the education of philosophers, and in the following years elaborated, besides other dialogues, his great work, *The Republic*, in which he drew the outlines of an ideal state. Because it is the passions and desires of men that cause all disturbances in society, the state must be ruled by an elite who are governed exclusively by reason and supported by a class of warriors entirely obedient to them. Both ruling classes must have no individual possessions and no families and lead an extremely austere life, receiving the necessities of life from the working population, who alone are permitted to own private property. The elite receive a rigid education to fit them for their task. At the death of Dionysius I, Dion induced Plato to come to Syracuse again to try to persuade Dionysius' successor to renounce his power in favour of a realization of Plato's ideals. But the attempt failed, and in his later political works, the *Statesman* and the *Laws*, Plato tried to show that only a god could be entrusted with the absolute powers of the philos-

Visit to Syracuse

opher-rulers of his *Republic*. Human rulers must be controlled by rigid laws, he held—though all laws are inevitably imperfect because life is too varied to be governed adequately by general rules. But the *Laws* still placed strict restrictions on the ownership of property.

Philosophy. In the field of theoretical philosophy, Plato's most influential contribution was undoubtedly his theory of Ideas, which he derived from Socrates' method in the following way: Socrates, in trying to bring out the inconsistencies in his interlocutors' opinions and actions, had often asked what it is that makes men say that a certain thing or action is good or beautiful or pious or brave; and he had asked what people are looking at when they make such statements. Plato sometimes made Socrates ask what is the Eidos or the Idea—*i.e.*, the image —that a person has before him when he calls something "good." A definite answer was never given, however, because no abstract definition would be adequate, the purpose being rather to make the interlocutor aware of the fact that he somehow does look at something undefinable when making such statements.

Theory of Ideas

What was at first simply a way of somehow expressing something that is difficult to express developed into a definite theory of Ideas when Plato made the discovery that something similar could be observed in the field of mathematics. No two things in the visible world are perfectly equal, just as there is nothing that is perfectly good or perfectly beautiful. Yet equality is one of the most fundamental concepts not only in mathematics but also in everyday life—the foundation of all measurement. Hence, like the notion of the good and the beautiful, it appears to come from a different world, a world beyond that of the senses, a world that Plato then called the world of Ideas. All of the things, then, that men perceive with their senses appear to be but very imperfect copies of the eternal Ideas. The most important and fundamental of all, however, is the Idea of the Good. It is "beyond being and knowledge," being the foundation of both. Though this doctrine may seem fantastic to some moderns, it contains an important element of truth. "Being" in this connection does not mean existence, but being something—a man, a lion, or a house—being recognizable by its quality or shape. Without such shapes, which are copies of Ideas, there would be complete chaos, in which nothing would be recognizable. Furthermore, it is impossible to build up any system of knowledge without constantly preferring what is formed and, thus, recognizable to what is not, what is true to what is false, a sound logical conclusion to a logical fallacy, even an elegant scientific demonstration to a clumsy one; *i.e.*, without considering the former as good and the latter as bad. In this sense at least, there is no such thing as value-free science.

Myth of the cave

In the famous myth of the cave in the seventh book of *The Republic*, Plato likened the ordinary person to a man sitting in a cave looking at a wall on which he sees nothing but the shadows of the real things that are behind his back, and he likened the philosopher to a man who has got out in the open and seen the real world of the Ideas. Coming back, he may be less able to distinguish the shades because he has been blinded by the light outside; but he is the only one who knows real reality, and he conducts his life accordingly. In his *Theaetetus* Plato later criticized a sensualist theory of knowledge, anticipating the explanations of the 17th-century English sensualists. In the *Timaeus*, he tried to build up a complete system of physics, partly employing Pythagorean ideas. Most modern Positivists do not take Plato seriously any longer. But one of the greatest physicists of the 20th century, Werner Heisenberg, has insisted that the modern physicist still has to learn a good deal from Plato concerning the foundation of his science.

Aristotle. After Plato's death the Academy continued to exist for many centuries under various heads.

When Plato's nephew, Speusippus, was elected as his successor, his greatest disciple, Aristotle, left to go first to Assus and then to the island of Lesbos, where he met Theophrastus, who became his most gifted disciple. But soon thereafter he was called to the Macedonian court at Pella to become the educator of the crown prince, who was later to become Alexander the Great. After the latter had become the king, Aristotle returned to Athens and opened there a school of his own, whose members became known as the Peripatetics.

Philosophy. Aristotle had become a member of the Academy at the age of 17, in the year 367 (during Plato's absence in Sicily) under the acting chairmanship of Eudoxus of Cnidus, a great mathematician and geographer. It is a very controversial question as to how far Aristotle, during the 20 years of his membership in the Academy, developed a philosophy of his own differing from that of his master. But two things can be considered as certain: (1) that he soon raised certain objections to Plato's theory of the Ideas, for one of the arguments against it attributed to him is discussed in Plato's dialogue *Parmenides*, which Plato must have written soon after his return from Sicily, and (2) that it was during his membership in the Academy that Aristotle began and (to a considerable extent) elaborated his theoretical and formal analysis of the arguments used in various Socratic discussions—an enterprise that (when completed) resulted in the corpus of his works on logic, a new science, which Aristotle himself claimed to have originated and about which (until rather recent times) it used to be said that he completed it in such a way that hardly anything could be added.

Certainly, quite some time before his return to Athens to open a school of his own, Aristotle declared that it is not necessary to assume the existence of a separate realm of transcendent Ideas of which the individual things that men perceive with their senses are but imperfect copies; that the world of perceived things is the real world; and that it is necessary merely to be able to say that something is generally true of certain types or groups of things in order to build up a system of knowledge about them. Thus, it would be wrong to say that, having abandoned the theory of Ideas, Aristotle was left with a completely contingent world. The last chapters of his *Posterior Analytica* show, on the contrary, that he merely replaced Plato's transcendent Ideas with something (*katholou*) corresponding to them that the human mind can grasp in the individual things.

Teleology and perfection

Aristotle retained another very important element of the theory of Ideas in his teleology, or doctrine of purposiveness. According to Plato, individual things are imperfect copies of the perfect Ideas. Aristotle pointed out, however, that all living beings develop from an imperfect state (from the seed, the semen, through the germinating plant, or embryo, to the child and adolescent), to the more perfect state of the fully developed plant or the full grown mature animal or man—after which they again decay and finally die, having reproduced themselves. But not all individuals reach the same degree of relative perfection. Many of them die before reaching it; others are retarded or crippled or maimed in various ways in the process. It is, therefore, of the utmost importance for man to find out what the best conditions are for reaching the most perfect state possible. This is what the gardener tries to do for the plants; but it is even more important for man to do it in regard to himself. The first question, then, is that in which one asks what kind of perfection a human being as human can reach. In answering this question, Aristotle observed that man, being the social animal par excellence, can reach as an individual only some of the perfections possible for man as such. Cats are more or less all alike in their functions; they can fend for themselves. With bees and termites, however, it is different. They are by nature divided into worker bees, drones, and queen bees or worker termites, soldier termites, and queens. With human beings the differentiation of functions is much more subtle and varied. Men can lead satisfactory lives only on the basis of a division of labour and distribution of functions. Some human individuals are born with very great talents and inclinations for special kinds of activity. They will be happy and will make their best possible contribution to the life of the community only if they are permitted to follow this inclination. Others are less one-sidedly gifted and more easily adaptable to different functions. These people can also be

happy in shifting from one activity to another. That this is so is an enormous advantage that the human species has over all other animals because it enables it to adapt to all sorts of circumstances. But the advantage is paid for by the fact that no human individual is able to develop all of the perfections that are possible for the race as a whole.
