Sociologists who rely on the statistical method alone have denied the importance of mental disorder in the causation of suicide. This is not surprising, because mental illness in the population cannot be quantified. It is nevertheless an established fact that the incidence of suicidal acts among the psychiatrist's clientele is excessive. This does not mean that every person who commits such an act is psychiatrically ill in the clinical sense, although even in the absence of mental illness a suicidal act is an abnormal reaction to stress, abnormal being defined statistically—that is, not in keeping with the reactions of the large majority of persons to comparable situations.

The recognition of the importance of psychopathology in the causation of suicide does not invalidate sociological theories. The motivations underlying suicidal acts carried out by the mentally ill are fundamentally the same as in the general population, although they are derived from disorders of mood or from such abnormal contents of thought as delusions.

Theories of suicide. *Sociological theories.* The best known theory is Durkheim's, according to which the suicidal tendency is the result of collective forces acting upon the individual. Its strength varies inversely with the degree of cohesion that exists in society. Durkheim's classification of suicides into three types, mentioned above, was derived from the basic theory. Although he rejected psychology and psychopathology, his classification was essentially an excursion into social psychology. His basic theory has been criticized as being untestable, but in modified form it has been advocated by some more recent scholars. These scholars believe that disruptions of social relations are the causative factor in suicide and that the greater the incidence of such disruptions in a population the higher the suicide rate. Most suicide victims have experienced a set of disrupted social relations that is not found in the history of nonvictims with equal frequency.

Suicide and social disruption and isolation

Other scholars have attempted to combine the sociological with the psychodynamic approach. They have made four basic assumptions: aggression is due to frustration; business cycles change the hierarchical social status of persons and groups; loss of status causes frustration; suicide is an aggressive response to frustration generated by the flow of economic forces.

These and allied sociological theories depend largely on the reliability and validity of statistical data.

Psychological and social–psychological theories. The Freudian and Adlerian propositions, based on study of individuals, belong here. It can be seen that Adler's ideas about the causation of suicide tally with the sociological theories about the role of social isolation.

The concept of hope has been made the basis of a theory of suicide. According to this theory, suicide occurs when the life outlook is one of despairing hopelessness. Whether or not a person will commit a suicidal act in such a situation depends on a personality factor called the sense of competence, which is inversely related to the likelihood of suicide.

Other theories. The familial occurrence of suicides has given rise to the hypothesis that suicidal behaviour may be an innate inherited behaviour pattern. Studies in identical twins one of whom had committed suicide failed to confirm this hypothesis. The tendency of suicides to occur in families must therefore be explained by the mental mechanism of "identification" with a suicidal person. Seasonal fluctuations of the suicide rates, with a peak in spring, have remained unexplained. They may be related to depressive illness, which also shows the highest incidence in spring.

Existential views

Despair and the idea of death hold a central position in Existential philosophy, which has exerted a considerable influence on many European and some American psychiatrists and anthropologists. A Swiss psychiatrist described in great detail the experiences of a patient whose suicide appeared to follow inevitably from her way of "being in the world." Another author, a lay psychotherapist strongly influenced by Existentialism, rejects the principle of suicide prevention as a medical prejudice against death and advocates suicide if death is needed by the soul. There is nothing new in these ideas.

Treatment and prevention. Suicide presents social and medical problems, and no single approach can be expected to succeed in substantially reducing its incidence. Early recognition and treatment of mental disorders are important. There has been much progress in the treatment of depressive illness. But even if the latter could be eliminated, a sizable suicide problem would remain.

Preventive measures are called for on several levels, as stated in *Prevention of Suicide* (WHO Public Health Papers No. 35, 1968): (1) Medical emergency services are required to prevent the fatal outcome of suicidal acts, especially self-poisoning. (2) Persons who have made a previous attempt are more likely to die through suicide than those who have not. This high-risk group needs special medical and social attention over long periods. (3) Recognition of suicidal intent and provision of support and treatment, if necessary, can prevent suicide. The majority of people who commit suicidal acts have given a previous warning that was ignored. (4) Measures against social isolation and the furtherance of satisfying social relations within and outside the family appear to provide the most effective prophylaxis against suicidal tendencies.

In the last two decades special centres and organizations for the prevention of suicide have been created in many countries. Most of them are not under medical direction, though all of them have medical consultants. The telephone is used as a means of communication between lonely and desperate persons in need of support and helpers available day and night. There is evidence that this kind of service may help to avert suicidal acts. The best known of these telephone services is that of the "Samaritans," founded by Chad Varah, an Anglican minister, in London in 1953. They aim at giving psychological first aid as well as support by befriending the lonely and desperate. In 1971 this organization had 118 branches in the United Kingdom and nine in Commonwealth countries. Similar organizations have sprung up in other countries.

SUICIDE IN THE FUTURE

Suicide is a peculiarly human problem. There is no evidence that what seems to be self-destructive behaviour in animals is associated with the wish to die. At some stage of evolution, man must have discovered that he can kill not only animals and fellowmen but also himself. It is difficult to imagine man in the future without this potential, which has sometimes been proclaimed as one of the basic human freedoms. Suicidal acts will continue to be committed. There are no prospects that an antisuicidal substance will be discovered in the foreseeable future.

There are certain aspects of present-day society that make a substantial decline in the incidence of suicidal acts unlikely. The steady increase in the number of the aged, who contribute the majority of suicides, will make it difficult to prevent a rise in the suicide rates, especially if the incidence of suicide among the young should continue to go up. The young are both more openly aggressive against society and more demonstrative today than they

were in the first half of the 20th century. Both of these behaviour features contribute to suicidal acts. Prosperity has not proved an antidote against them. It has in fact made possible the emergence of subcultures of alienation with a tendency to withdrawal from reality with the aid of drugs. These movements, though allegedly dedicated to the enjoyment of life, have a strong self-destructive component. The continued increase in population will make it more difficult for the underendowed to hold their own. Economic crises are likely to multiply and to take their toll of suicide victims.

The outlook regarding suicide would be very black indeed if it were not for the strong urge to self-preservation inherent in the individual and in society. The emergence of nonprofessional movements toward self-help in the struggle against suicide can be seen as a manifestation of this tendency.

BIBLIOGRAPHY. There has been a veritable explosion of suicide research and of planned efforts at suicide prevention involving the community as a whole since the end of World War II. The classic sociological approach as presented in EMILE DURKHEIM, *Le Suicide* (1897; Eng. trans., 1951), and brought up to date in JACK P. GIBBS and WALTER T. MARTIN, *Status Integration and Suicide* (1964), was supplemented by ecological studies, such as PETER SAINSBURY, *Suicide in London* (1955); and an early study in Chicago, RUTH S. CAVAN, *Suicide* (1928). KARL A. MENNINGER, *Man Against Himself* (1938), had prepared the ground for the introduction of psychodynamics into this area. LOUIS T. DUBLIN, *Suicide* (1963), is the best link between the classical statistical and the various modern approaches. ANDREW F. HENRY and JAMES F. SHORT, JR., *Suicide and Homicide* (1954), combines sociology and psychodynamics.

Research on attempted suicide has been in the forefront of interest since the publication of KARL G. DAHLGREN, *On Suicide and Attempted Suicide* (1945); ERWIN STENGEL and NANCY G. COOK, *Attempted Suicide* (1958); and NORMAN L. FARBEROW and EDWIN S. SHNEIDMAN (eds.), *The Cry for Help* (1961). The most recent survey of the multifarious research and preventive activities in this area is *Suicidal Behaviors*, ed. by H.L.P. RESNIK (1968). Stengel has specialized in the follow-up and the study of the social effects of suicidal attempts, a line of research presented by him in *Suicide and Attempted Suicide*, rev. ed. (1969); and by NILS RETTERSTOL in *Long-term Prognosis After Attempted Suicide* (1970). These workers owe a great deal to epidemiology, which has introduced systematic follow-up (cohort) methods into the study of abnormal behaviour. Modern suicide research has also questioned the basic premises of sociological pioneers. The inviolable status of the suicide rate has been challenged by J.D. DOUGLAS in *The Social Meanings of Suicide* (1967).

There has been progress in the anthropological approach also. PAUL BOHANNAN (ed.), *African Homicide and Suicide* (1960); RAYMOND W. FIRTH, *Suicide and Risk-Taking in Tikopia Society* (1961); and MAMORU IGA, "Japanese Adolescent Suicides and Social Structure," in *Essays in Self-destruction*, ed. by EDWIN S. SHNEIDMAN (1967), dispel old myths and break new ground. Suicide prevention is no longer the preserve of sociologists and psychiatrists. It has become a matter of public concern spearheaded by lay organizations, described in EDWARD CHAD VARAH (ed.), *The Samaritans: To Help Those Tempted to Suicide or Despair* (1965). Meanwhile, those who want to preserve and promote suicide as one of the fundamental human freedoms have not remained idle either. In *Euthanasia and the Right to Death*, ed. by A.B. DOWNING (1969), the case for a gentle death when desired is made by distinguished advocates of voluntary euthanasia.

(E.St.)

Sui Wen Ti

As emperor of China, Sui Wen Ti (in Pin-yin romanization Sui Wen Di; personal name Yang Chien), with his ministers, reunified that country after it had experienced 300 years of instability, reorganized the institutions of state and society, and established China's second great Imperial order—that of the Sui (581–618) and T'ang (618–907) dynasties.

Wen Ti was born in 541 into a powerful family that had held high office under the non-Chinese dynasties that controlled North and Central China in the period of fragmentation. His ancestors had married into prestigious non-Chinese clans, and the culture of such families was as mixed as their descent. Until he reached the age of 13, Wen Ti was brought up by a Buddhist nun. He then briefly attended the school maintained by the state for the education of sons of nobles and officials; it is doubtful that he acquired more than the mere rudiments of composition, a bit of history, and some maxims of Confucian morality, for young men of his class devoted themselves chiefly to horsemanship, the hunt, falconry, archery, and military exercises.

He received his first military appointment at 14 and rose rapidly in the service of the Yü-wen, the non-Chinese ruling house of the Northern Chou dynasty (557–581), who, with their military prowess, would soon control all of North China. Wen Ti held a command in the campaign against the dynasty which controlled the northern plain and a post in the administration of the conquered territory. He had done well for the Chou, and, as part of his reward, he was permitted to marry one of his daughters to the Chou crown prince. When the Emperor unexpectedly became ill and died at 36 and the Crown Prince's sanity became doubtful, Wen Ti, his wife, and their confidants decided to seize the throne. The summer of 580 was crucial, for rival contenders and Chou loyalists rose in many places. But, with luck, ruthlessness, superior military force, and discord among his rivals, Wen Ti prevailed. He assumed the Imperial title, held an audience on March 4, 581, and Sui dynasty was founded.

Seizure of the throne

Wen Ti surrounded himself with able men, mostly of mixed descent and mostly from backgrounds similar to his own. An early move was the building of a new capital on a new site southeast of the Han capital of Ch'ang-an; it was built on a scale unprecedented in Chinese history. The Sui evidently meant to replace the weak regimes of the age of disunion with strong centralized government, to unify China by eliminating the feeble "legitimate" Chinese regime at Nanking, and to reassert Chinese power throughout east Asia. Wen Ti moved into his half-built capital in 583, and he immediately set his grand design in motion. Centralization required drastic reforms on many levels—for example, the entrenched families that held local office by hereditary right had to be replaced by a bureaucracy answerable to the throne. The hereditary rights and the institutions that supported them were quickly abolished; a method of selecting new men by examination and recommendation was devised; appointment powers were vested in the Board of Civil Office (Chinese Li Pu); and the "rule of avoidance" was instituted, forbidding officials to serve in their native places. Wen Ti planned the conquest of the south with his usual care and attention to detail. The eight-pronged assault by land and water overwhelmed the southerners; the integration of this culturally different area into the Sui empire began and was greatly facilitated by the canal system that Wen Ti had begun. Beyond China proper Sui power was less easily asserted against the formidable empires of the western and the eastern Turks, but fortune and Sui intrigues brought success; the Turkish empires were weakened by internal rivalries, and by 603 the Sui had broken Turkish power in the areas most vital to them: Turkistan and Mongolia. A Sui attempt to administer Vietnam was a failure, but, toward the close of Wen Ti's reign, Korea and Japan were beginning to notice the new paramount power in east Asia.

Foreign affairs

In the year 601, when Wen Ti was 60, he had solid grounds for satisfaction: the empire was reunified and at peace; the people were productive, and the officials—carefully selected, frequently rotated, and under constant checks—collected taxes, saw that the granaries were filled, and carried out imperial orders at the local level. Looking about him in his spacious capital city, Wen Ti could see a large and increasing population, the opulent mansions of his nobles and ministers, temples, and thriving marketplaces. Moreover, the arrival of tribute missions reminded him that Sui power was being felt by neighbouring peoples. Yet, for all his accomplishments, Wen Ti was deeply unhappy. Henpecked by his aging wife, on bad terms with his sons, deprived of many of his life-long confidants by death or by his wife's jealousy of them, haunted by feelings of guilt and nameless fear, he turned against state Confucianism and ever more ardently to Buddhism. On his birthday in 601, he began an

eaborate empire-wide series of observances. Shrines were built in key cities and towns; then the Emperor himself sealed holy relics in jars, which delegations of eminent monks carried into the provinces. At a set time throughout the empire, the relics were simultaneously enshrined with appropriate ceremony. By this act of grandiose public piety, Wen Ti followed in the footsteps of the great 3rd-century-BC Indian emperor Aśoka, who was, like himself, a unifying emperor. At the time he assuaged his feelings of fear and guilt and laid in a great store of spiritual merit (*karman*) to see him through the lives to come.

Three years later—at the end of one of the great reigns in Chinese history—he fell ill and died, his end possibly hastened by the son who succeeded him.

BIBLIOGRAPHY. ARTHUR F. WRIGHT, "The Formation of Sui Ideology, 581–604," in JOHN K. FAIRBANK (ed.), *Chinese Thought and Institutions*, pp. 77–84 (1957), deals with Wen Ti's life and with his principal advisors.

(A.F.W.)

Sukarno

Sukarno, known by no other name but by a score of titles, including engineer, doctor, proclaimer of independence, and great leader of the revolution, dominated Indonesian national life and politics for 40 years. He did so with unfailing panache—from the time he emerged to sudden prominence in Dutch colonial Bandung (1927) as a dazzling young rake, firebrand orator, and freedom fighter until he was displaced by General Suharto after being implicated directly in a conspiracy to convert the Republic of Indonesia into a people's republic linked to Communist China.

Magnum

Sukarno, 1965.

Early life. Sukarno was born on June 6, 1901, in Surabaja, East Java, in the then Dutch East Indies, the only son of a poor Javanese schoolteacher, Raden Sukemi Sosrodihardjo, and his Balinese wife, Ida Njoman Rai. Originally named Kusnasosro, he was renamed Sukarno for better omen after a series of illnesses. Known to his childhood playmates as Djago (Cock, Champion) for his looks, spirits, and prowess, he was as an adult best known as Bung Karno (*bung*, "brother" or "comrade"), the revolutionary hero and architect of *merdeka* ("independence").

Sukarno spent long periods of his childhood with his grandparents in the village of Tulungagung, where he was exposed to the animism and mysticism of serene rural Java. There he became a lifelong devotee of *wajang*, the puppet shadow plays based on the Hindu epics, as animated and narrated by a master puppeteer, who could hold an audience spellbound through an entire night. As a youth of 15, Sukarno was sent to secondary school in Surabaja and to lodgings in the home of Omar Said Tjokroaminoto, a prominent civic and religious figure. Tjokroaminoto treated him as a cherished foster son and protégé, financed his further education, and eventually married him off at age 20 to his own 16-year-old daughter, Siti Utari.

Sukarno's education

As a student, Sukarno chose to excel mainly in languages. He mastered Javanese, Sundanese, Balinese, and modern Indonesian, which, in fact, he did much to create. He also acquired Arabic, which, as a Muslim, he learned by study of the Qur'ān; Dutch, the language of his education; German; French; English; and, later, Japanese. In Tjokroaminoto's home he came to meet, admire, and sometimes to understudy emerging leaders who spanned the rapidly widening national political spectrum, from feudal princelings to fugitive Communist conspirators. The eclectic syncretism of the Tjokroaminoto ménage, like the romance and mysticism of *wajang*, imprinted itself indelibly upon Sukarno's mind and personality. He was later to treat nation making as a heroic theatrical, in which the clash of irreconcilable men and ideas could be harmonized through sheer poetic magic—his own.

Endowed with commanding presence, radiant personality, mellifluous voice, vivid style, a photographic memory, and supreme self-confidence, Sukarno was obviously destined for greatness. In Bandung in 1927, where he had just acquired a degree in civil engineering, he found his true calling in oratory and politics. He soon revealed himself as a man of charisma and destiny.

In both early and later life, Sukarno's amours were almost as politically significant as his oratory. He divorced Siti in 1923 and married his well-to-do and newly divorced landlady, Inggit Garnisih, a woman of 34. He divorced the childless and aging Inggit in 1943 and married the beautiful young Fatmawati, by whom he had five children, including his eldest son, Guntur Sukarnaputra (born 1944). In 1954 he surreptitiously took a second wife, Hartini (as a Muslim, he was entitled to four wives), a dubious divorcée who bore him two children. In the early 1960s he also married Ratna Sari Dewi, a Japanese who bore him a daughter in 1967. Next was the comely young Harjati, then the yet younger and comelier Yurike Sanger. Sukarno also engaged in a lifelong series of liaisons featuring Dutch, Russian, American, Chinese, Japanese, Filipino, and Mexican beauties, among many others.

Imprisonment by the Dutch

Indonesian independence. For his challenge to colonialism Sukarno spent two years in a Dutch jail (1929–31) in Bandung and over eight years in exile (1933–42) on Flores and Sumatra. When the Japanese invaded the Indies in March 1942, he welcomed them as personal and national liberators. During World War II the Japanese made Sukarno their chief advisor and propagandist, their recruiter for labourers, soldiers, and prostitutes. Sukarno pressured the Japanese to grant Indonesia its independence and, on June 1, 1945, made the most famous of many celebrated speeches. In it he defined the Pantjasila, or Five Principles (nationalism, internationalism, democracy, social prosperity, and belief in God), still the sacrosanct state doctrine. When the collapse of Japan became imminent, Sukarno at first wavered. Then, after being kidnapped, intimidated, and persuaded by activist youths, he declared Indonesia's independence (August 17, 1945). As president of the shaky new republic, he fuelled a successful defiance of the Dutch, who, after two abortive "police actions" to regain control of their former colony, formally transferred sovereignty on December 27, 1949.

Life at the Sukarno court

From his revolutionary capital in Jogjakarta Sukarno returned in triumph to Djakarta on December 28, 1949. There he established himself, his collection of paintings, and his numerous retinue in the splendid palace of the Dutch governors general. He proceeded to preside urbanely over a spectacle that was at once diverting and disturbing. His increasingly numerous and outspoken critics maintained that Sukarno inspired no coherent programs of national organization and administration, rehabilitation, and development, such as were quite clearly necessary. He seemed instead to conduct a continuous series of formal and informal audiences and a nightly

soiree of receptions, banquets, music, dancing, movies, and *wajang*. Indonesian politics became increasingly frenzied, with Sukarno himself engaged in devious manoeuvres that made stabilization impossible. The Indonesian economy foundered while Sukarno encouraged the wildest of extravagances. To be sure, the nation scored impressive gains in health, education, and cultural self-awareness and self-expression. It achieved, in fact, what Sukarno himself most joyously sought and acclaimed as "national identity," an exhilarating sense of pride in being Indonesian. But it did so at a ruinous cost.

After "dreaming" in late 1956 of "burying" the feuding political parties in Indonesia and thus achieving national consensus and prosperity, Sukarno dismantled parliamentary democracy and destroyed free enterprise. He ordained "Guided Democracy" and "Guided Economy" for the achievement of MANIPOL-USDEK and RESOPIM-NASAKOM—arcane acronyms symbolizing policies but signifying dictatorship.

Sukarno's personal and political excesses, as epitomized eventually by his neo-Marxist, crypto-Communist ideology and his infamous cabinet of 100 corrupt and cynical ministers, induced a continuous state of national crisis. Sukarno narrowly escaped recurrent attempts at assassination, the first in 1957. Regional insurrections broke out in Sumatra and Sulawesi in 1958. Inflation escalated the cost-of-living index from 100 in 1958 to 18,000 in 1965 and on up wildly to 600,000 in 1967. In 1963, after shouting repeatedly "To hell with your aid" (1950–65 total: $1,000,000,000 U.S.) Sukarno all but broke with the United States. After having exacted $1,000,000,000 U.S. in Soviet armaments and other items, he next affronted Moscow. On January 20, 1965, Indonesia formally withdrew from the United Nations because the latter supported Malaysia, which Sukarno had vowed to "crush" as "an imperialist plot of encirclement." Yet, until 1965, Sukarno was still able to stir the Indonesian masses to near-hysterical belligerency. Millions of Indonesians sang and shouted his slogans, "volunteered" for his causes, and acclaimed Sukarno as "Great Leader of the Revolution," "Lifetime President" (his official title), oracle and warrior of the NEFOS—his acronym for the "New Emerging Forces"—in violent conflict with NEKOLIM—the neocolonialism, capitalism, and imperialism of the "doomed" Western powers.

The coup of 1965. The nation was shocked and shaken out if its trance by a coup of September 30, 1965, in which Sukarno himself was clearly implicated. A clique of Communist and military conspirators caused six top army generals to be kidnapped, tortured, mutilated, and murdered. They seized a few key urban points and proclaimed a new revolutionary regime. General Suharto, the commander of the Djakarta garrison, swiftly reversed the coup. There ensued an oblique contest for power between Suharto and Sukarno while some 300,000 or more Communists and alleged Communists were being slaughtered. As the nation recoiled in horror, activist youths demanded the political demise of Sukarno, the Sukarnoists, and Sukarnoism and the total reform and reorganization of the state. On March 11, 1966, Sukarno was obliged to delegate wide powers to Suharto, who subsequently became acting president (March 1967) and then president (March 1968), as Sukarno sank into disgrace and dotage.

At 7:00 AM on June 21, 1970, aged 69, Sukarno died in the Central Military Hospital of his old kidney complaint and many complications. Suharto decreed a quick and quiet funeral. Nevertheless, at least 500,000 persons, including Inggit (aged 83), Fatmawati, Hartini, Dewi, their children, and virtually all of Djakarta's important personages, turned out to pay their last ambivalent respects. Next day another 200,000 assembled in Blitar, near Surabaja, for the official service followed by burial in a simple grave alongside that of his mother. The cult and ideology of Sukarnoism are now proscribed. The late Sukarno record is now deeply deplored. But the luminous Bung Karno of 1927 and 1949, the Bapak Republick Indonesia, survives the great leader of the 1960s, by then so sadly tarnished and diminished.

Süleyman I the Magnificent

Süleyman I, known to the Turks as Kanuni, the Lawgiver, and to the Christian world as the Magnificent, sultan of the Ottoman Empire from 1520 to 1566, extended Turkish influence in both Europe and Asia; his reign witnessed the unfolding of all that was most characteristic and brilliant in Ottoman civilization. The only son of Sultan Selim I, Süleyman was born in November 1494 or April 1495. He became *sancak beyi* (governor) of Kaffa in the Crimea during the reign of his grandfather Bayezid II and of Manisa in western Asia Minor in the reign of Selim I.

Süleyman succeeded his father as sultan in September 1520 and began his reign with campaigns against the Christian powers in central Europe and the Mediterranean. Belgrade fell to him in 1521, and Rhodes, long under the rule of the Knights of St. John, in 1522. At Mohács, in August 1526, Süleyman broke the military strength of Hungary, the Hungarian king, Louis II, losing his life in the battle. The vacant throne of Hungary was now claimed by Ferdinand I, the Habsburg archduke of Austria, and by John (János Zápolya), who was *voivode* (lord) of Transylvania and the candidates of the "native" party opposed to the prospect of Habsburg rule. Süleyman agreed to recognize John as a vassal king of Hungary, and in 1529, hoping to remove at one blow all further intervention by the Habsburgs, he laid siege to Vienna. Difficulties of time and distance and of bad weather and lack of supplies, no less than the resistance of the Christians, forced the Sultan to raise the siege. The campaign was successful, however, in a more immediate sense, for John was to rule thereafter over most of Hungary until his death, in 1540. A second great campaign in 1532, notable for the brilliant Christian defense of Güns, ended as a mere foray into Austrian border territories. The Sultan, preoccupied with affairs in the East and convinced that Austria was not to be overcome at one stroke, granted a truce to the archduke Ferdinand in 1533.

By courtesy of the trustees of the British Museum

Süleyman I (centre), detail of an engraving of a panel by Pieter Coecke van Aelst showing a procession through Istanbul, 1533.

The death of John in 1540 and the prompt advance of Austrian forces once more into central Hungary drove Süleyman to modify profoundly the solution that he had imposed in the time of John. His campaigns of 1541 and 1543 led to the emergence of three distinct Hungarys—Habsburg Hungary in the extreme north and west; Ottoman Hungary along the middle Danube, a region under direct and permanent military occupation by the Ottomans and with its main centre at Buda; and Transylvania, a vassal state dependent on the Porte and in the hands of John Sigismund, the son of John Zápolya. Between 1543 and 1562 the war in Hungary continued, broken by truces and with few notable changes on either side; the most important was the Ottoman capture of the Banat of Temesvár (Timişoara) in 1532. After long negotiations a peace recognizing the status quo in Hungary was signed in 1562.

The campaigns against Persia

Süleyman waged three major campaigns against Persia. The first (1534–35) gave the Ottomans control over the region of Erzurum in eastern Asia Minor and also witnessed the Ottoman conquest of Iraq, a success that rounded off the achievements of Selim I. The second campaign (1548–49) brought much of the area around Lake Van under Ottoman rule, but the third (1554–55) served rather as a warning to the Ottomans of the difficulty of subduing the Şafavid state in Persia. The first formal peace between the Ottomans and the Şafavids was signed in 1555, but it offered no clear solution to the problems confronting the Ottoman sultan on his eastern frontier.

The naval strength of the Ottomans became formidable in the reign of Sultan Süleyman. Khayr ad-Dīn, known in the West as Barbarossa, became *kapudan* (admiral) of the Ottoman fleet and won a sea fight off Preveza, Greece (1538), against the combined fleets of Venice and Spain, which gave to the Ottomans the naval initiative in the Mediterranean until the Battle of Lepanto in 1571. Tripoli in North Africa fell to the Ottomans in 1551. A strong Spanish expedition against Tripoli was crushed at Jarbah (Djerba) in 1560, but the Ottomans failed to capture Malta from the Knights of St. John in 1565. Ottoman naval power was felt at this time even as far afield as India, where a fleet sent out from Egypt made an unsuccessful attempt in 1538 to take the town of Diu from the Portuguese.

The later years of Süleyman were troubled by conflict between his sons. Mustafa had become by 1553 a focus of disaffection in Asia Minor and was executed in that year on the order of the Sultan. There followed during 1559–61 a conflict between the princes Selim and Bayezid over the succession to the throne, which ended with the defeat and execution of Bayezid. Süleyman himself died during the night of September 5/6, 1566, while he was besieging the fortress of Szigetvár in Hungary.

Domestic achievements

Süleyman's reign was notable for more than military and naval exploits. He surrounded himself with administrators and statesmen of unusual ability, men such as his grand viziers (chief ministers) İbrahim, Rüstem, and Mehmed Sokollu. *'Ulama'* (specialists in Islāmic law), notably Abū al-Su'ūd (Hoca Çelebi) and Kemalpaşâ-zade, made the period memorable, as did the great Turkish poet Bâkî and the architect Sinan. Süleyman built strong fortresses to defend the places he took from the Christians and adorned the cities of the Islāmic world (*e.g.*, Mecca, Damascus, and Baghdad) with mosques, bridges, aqueducts, and other public works. In Istanbul, Süleyman's capital, the architect Sinan built several famous mosques for him, including the one bearing his name (Süleymaniye Cami), and others for his viziers Rüstem and Mehmed Sokollu. In general, Süleyman completed the task of transforming the previously Byzantine city of Constantinople into Istanbul, a worthy centre for a great Turkish and Islāmic empire.

Süleyman was, to his subjects, the "Lawgiver." The edicts bearing his name, though for the most part interpretative rather than original, nevertheless represent a sustained effort to adjust the complex structure of the Ottoman state to the circumstances of a new age. To his contemporaries in Europe Süleyman was "il magnifico," "the magnificent sultan." It was the Venetian Andre Navagero who paid him the rarest of compliments when he wrote that Süleyman, provided he were well informed, did injustice to no one.

(V.J.P.)

Sulfide Minerals

Sulfide minerals are a large and important group of compounds of great value to man. Although many sulfide minerals are known, their abundance is considerably less than that of some other mineral types, such as the silicate minerals and phosphate minerals (*qq.v.*). Included within the sulfide mineral group, although not sulfides in the chemical sense, are metallic arsenides, tellurides, antimonides, and selenides.

Sulfide minerals are the source of many common base and precious metals and, with the exception of a few metals such as iron, titanium, tin, and gold, are the ore minerals of most metals used in technology. They are the ore minerals of lead, zinc, copper, nickel, silver, antimony, bismuth, and others and also are the source of many less common metals such as cadmium, indium, rhenium, and selenium. These rarer metals occur in trace amounts in many common sulfides and are recovered in smelting and refining processes.

Most of the sulfide minerals are simple structurally and show high symmetry in their crystal forms. They have many of the properties of metals, such as metallic luster and electrical conductivity, characteristics that are attributed to metal–metal bonding in their structures.

The elements that occur as sulfide minerals have been termed chalcophile ("copper-loving") by Victor Goldschmidt. Naturally occurring sulfides are known for the elements: Silver, Ag; iron, Fe; lead, Pb; arsenic, As; rubidium, Ru; copper, Cu; cobalt, Co; mercury, Hg; antimony, Sb; tin, Sn; thallium, Tl; nickel, Ni; manganese, Mn; bismuth, Bi; molybdenum, Mo; gold, Au; zinc, Zn; calcium, Ca; platinum, Pt; tungsten, W; and cadmium, Cd. Elements that substitute for sulfur in the sulfide minerals are selenium, Se; tellurium, Te; As; Sb; and Bi. There are, in addition, other elements that, although not occurring as sulfide minerals, show a strong affinity for sulfide minerals and occur as important trace elements. Among these, gallium, Ga; indium, In; germanium, Ge; rhenium, Re; chromium, Cr; niobium, Nb; and tantalum, Ta, are important.

The geochemical environment in which sulfide minerals form is a broad one and ranges from high temperatures and pressures that exist at great depth in the earth's crust to the reducing environment at the surface in restricted basins or swamps. In addition, several sulfide minerals are known from meteorites (*q.v.*). Because of the chemically reduced state of sulfur in these minerals, they tend to be unstable in the oxidizing conditions present at the earth's surface. Air and water, probably aided by organic compounds and bacteria, act to decompose most sulfides within relatively short periods of geological time.

Except for dissemination in some sedimentary rocks, these minerals tend to occur in isolated concentrations. These concentrations make up mineral bodies such as veins or fracture fillings, pipelike bodies, replacements of pre-existing rocks in the shape of blankets and, where man has found it economical to extract the minerals, they are known as ore bodies. Compositionally, most mineral bodies tend to represent concentrations of a discrete metal sulfide or combinations of certain metals. Thus, one refers to the major copper sulfide concentrations of the southwestern U.S., of South Africa, and of the Kazakh S.S.R.; the lead-zinc sulfide concentrations of the Mississippi Valley, U.S., and of Morocco; and the deposits of silver-bearing minerals of western Mexico, to mention only a few.

This article treats the physical properties and chemical composition of the sulfide minerals, and their classification, genesis, and occurrence in nature. For further information on the economic importance and occurrence of sulfide minerals see ORE DEPOSITS; see also MINERALS

for the relation of sulfide minerals to other minerals, and GEOCHEMICAL EQUILIBRIA AT HIGH TEMPERATURES AND PRESSURES for a general discussion of phase equilibria of relevance.

CLASSIFICATION OF SULFIDE MINERALS

Unlike silicate minerals, for which a general classification based on crystal structure exists, sulfide minerals are classified basically according to their chemical compositions or formula type, and are subdivided within the type on the basis of their structures. Nearly all of the sulfide minerals have structural arrangements that belong to six basic types, four of which are important. These arrangements are close-packing combinations of metal and sulfur, governed by ionic size and charge.

Structural types

The simplest and most symmetrical of the four important structural types is the sodium chloride structure, in which each ion occupies a position within an octahedron composed of six oppositely charged neighbours. The most common sulfide mineral crystallizing in this manner is the ore mineral of lead, galena (PbS).

A type of packing that involves two sulfide ions in each of the octahedral positions in the sodium chloride structure is the pyrite structure. This is a high symmetry structure and is that of the common iron sulfide, pyrite (FeS_2). A group of more complex sulfide minerals also exhibit this structure. Ullmannite, (Ni, Co, Fe) (Sb,As,Bi)S, in which sulfide pairs in the pyrite structure are replaced by the B subgroup metal Sb, As, or Bi in combination with a single sulfide ion, is an example.

The second discrete structural type is that of sphalerite, ZnS in which each metal ion is surrounded by six oppositely charged ions arranged tetrahedrally. In addition to sphalerite, greenockite, CdS, the sulfide ore mineral of cadmium, alabandite, the sulfide of manganese, and the selenide and telluride of mercury all crystallize with this structure.

A third structural type is that of the mineral fluorite. In this structure, the metal cation is surrounded by eight anions, and each anion in turn is surrounded by four metal cations. The reverse of this structure, that is the metal cation surrounded by four anions and each anion surrounded by eight metal cations, is known as the antifluorite structure and is the arrangement of several of the more valuable precious metal tellurides and selenides, among which is hessite, Ag_2Te, silver telluride, the important ore mineral of silver.

Two structural arrangements that give rise to hexagonal symmetry are the wurtzite, ZnS, and molybdenite, MoS_2, structures. In the wurtzite structure, both metal and sulfide ions are surrounded by four of their opposite charge. The tetrahedral arrangement of ions gives rise to hexagonal symmetry and the second crystalline form of zinc sulfide. The other hexagonal structure is the molybdenite structure and consists of the metal ion coordinated with six sulfur ions and each sulfur ion coordinated with three metal ions. This particular structure is markedly layered and gives rise to the characteristic platelike cleavage in molybdenite.

One series of five closely related sulfide minerals crystallize in the spinel structure, common as an arrangement for oxide minerals, in which the oxygen or sulfur ions are close packed and the metal ions are in tetrahedral and octahedral coordination. In the series of cobalt and nickel sulfides (linnaeite series), nickel and cobalt occur in nearly continuously varying amounts in three named minerals between the two end members. The vacant sites and latitude for variation of composition in the spinel structure make this possible.

One mineral group—the argentite group—exists in the cesium chloride or body-centred cubic structure at elevated temperatures.

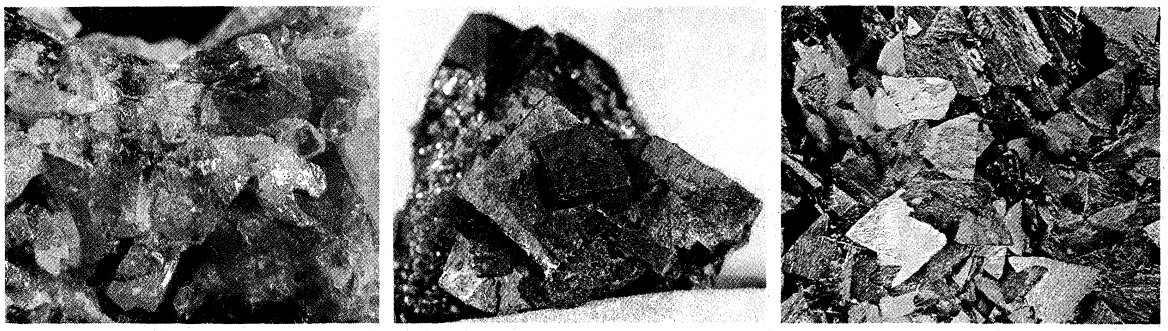
The structures described above are ideal ones; and when ionic charge and size are ideal, minerals that form in them give rise to crystal forms of high, usually isometric, symmetry. Certain combinations of metals and sulfur, however, can take the positions in many of the structures and by distorting or extending the ionic distances create typical crystal forms of lower symmetry. Examples of this are chalcopyrite, which through distortion of the sphalerite structure becomes tetragonal rather than isometric; and cinnabar, which through modifying the sodium chloride structure becomes hexagonal rather than isometric.

Chemical classification

The common means of classification of the sulfide minerals is that utilized in *Dana's System of Mineralogy*, 7th edition. The classification is based on chemical composition, denoted by the symbols A_mX_n; minerals are then further grouped within a given type on the basis of similar structural-crystallographic characteristics.

The notation A_mX_n refers to the chemical composition in a general way; A_m refers to the stoichiometric quantity of the metal or metals, and, X_n refers to the corresponding quantity of the cation, usually sulfur. Thus, pyrite, FeS_2, belongs to that group of minerals of the general composition AX_2, and argentite, Ag_2S, belongs to that group of general composition A_2X. This chemical classification usually indicates little of the structural or crystallographic nature of the minerals. Pyrite, FeS_2, for example, has completely different properties from molybdenite, MoS_2, with which it is classified on chemical grounds. Nonetheless, the chemical classification allows a generalized typing of minerals and within the types of the A_mX_n classification, sulfide minerals with similar structural properties can be classified according to groups.

AX sulfide mineral type. Within this formula type, which is further separated into six groups, are included



(Left) Realgar from Getchell, Nevada. (Centre) Galena crystals from Galena, Illinois. (Right) Chalcopyrite crystals from Oklahoma.

many of the most common and widely sought ore minerals of the base metals. The groups of the AX type include the galena group, the sphalerite group, the chalcopyrite group, the wurtzite group, the niccolite group, and the covellite group. Minerals within each of the groups have nearly identical crystal class and the AX minerals have high symmetry.

Galena group. Minerals related to galena, PbS, to the selenides and tellurides of lead (clausthalite and altaite), and the rarer minerals alabandite, MnS, and oldhamite, CaS, make up the group. These minerals have the sodium chloride structure and similar crystal morphologies but otherwise exhibit many different properties. Their lustres range from the bright metallic lustre of galena to the dull and vitreous lustre of alabandite. All except oldhamite occur in crystals of high quality and cleavage is good to perfect. Except for oldhamite, which is known chiefly from meteorites, all occur as ore minerals formed at depth in the earth's crust.

Sphalerite group. Four minerals: sphalerite, ZnS; metacinnabar, HgS; tiemannite, HgSe; and coloradoite, HgTe, belong to this group. All crystallize with the sphalerite structure and belong to the isometric system. Except for sphalerite, all have metallic lustres. Metacinnabar and cinnabar constitute a major source of the metal mercury. Metacinnabar is a black metallic mineral, unlike cinnabar, which is red and tends to be earthy.

Sphalerite, the ore mineral of zinc, is one of the most unusual of all of the sulfide minerals because of its wide variety of colours and lustre. Known commonly by the term zinc blende, it is a common mineral that is commonly misidentified or not identified. Its colour ranges from nearly white, through the hues of yellow, red, green, blue, and brown, to black. The black variety is common and is known to the miner as blackjack, to the mineralogist by the varietal name marmatite. Sphalerite can include within its structure a variety of other metals as trace elements; indium, selenium, and germanium, and significant amounts of cadmium, iron, and manganese are typical. The recovery of wastes in the smelting of zinc ores is a process that yields considerable quantities of these rare elements for use by man. Much of the cadmium, indium, and selenium used in technology has been so derived.

Chalcopyrite group. Chalcopyrite, $CuFeS_2$, and stannite, Cu_2FeSnS_4, are the two principal members of this group of minerals. Both crystallize in structures that represent slight modifications of the sphalerite structure. Stannite is the rarer of the two and is known from tin veins. Chalcopyrite is one of the major ore minerals of copper. Both are metallic and where stannite occurs it is invariably associated with chalcopyrite.

Wurtzite group. Wurtzite, ZnS, is an unstable and thus rare form of sphalerite. It has many of the physical properties of sphalerite, such as resinous lustre and dark colour, and is known from many localities in the world. The second mineral assigned to this group is the rare mineral greenockite, CdS. Rarely crystalline, the mineral commonly occurs as coatings on sphalerite and in the oxidation products that remain after destruction of sphalerite by atmospheric processes. Its most diagnostic characteristic to the naked eye is a bright yellow-orange colour.

Niccolite group. Five minerals are typical of this group; four belong to the hexagonal system and one to the isometric. The most widespread and common of the five minerals is pyrrhotite, $Fe_{1-x}S$, a sulfur-deficient iron sulfide that occurs in geologic environments believed to represent very high temperatures of formation. Niccolite, NiAs, and breithauptite, NiSb, are compounds of nickel; niccolite is the most common.

Pentlandite, $(Fe,Ni)_9S_8$, is a common ore mineral of nickel and is found very closely associated, and finely intergrown with, pyrrhotite. The simple sulfide of nickel, millerite, NiS, is anomalous in its occurrence if it is contrasted with the other nickel minerals of this group. Most frequently it is found as a low-temperature mineral that has filled openings and has replaced calcite. It sometimes occurs as an alteration of other nickel sulfide minerals.

All minerals of this group are of metallic lustre, tend to be somewhat brittle, and have moderate hardness.

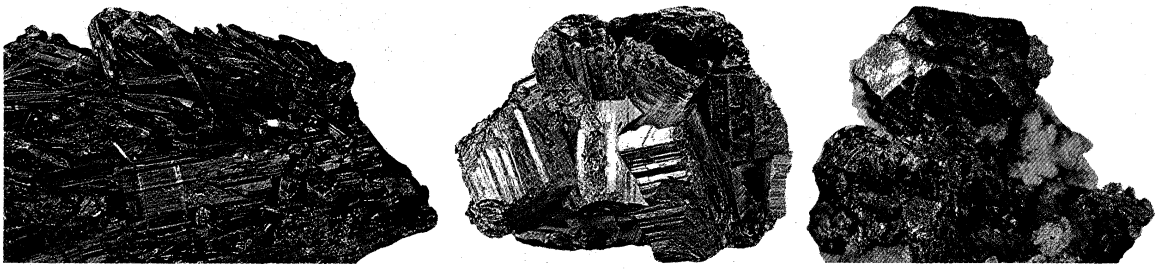
Covellite group. Covellite, CuS, and klockmannite, CuSe, are the two type minerals of this group. Both are hexagonal and possess good cleavage. Klockmannite is the rarer of the two. Covellite occurs as an oxidation product of other copper sulfides and is the bright, almost iridescent, blue mineral that usually forms much of the oxidized coating on chalcopyrite, chalcocite, bornite, and enargite.

A number of other minerals belong to this group, among them cinnabar, HgS, the principal ore mineral of mercury and realgar, AsS. Both of these minerals are formed in low-temperature, low-pressure environments such as those near hot springs. Because cinnabar decomposes readily at temperatures in excess of 580° C (1,080° F), and probably at temperatures of 150° C (300° F) in some solutions, it is believed to be closely related to the periphery of the volcanic-hotspring environment. Cinnabar is a red mineral of high specific gravity that most commonly occurs as very small crystals in earthy coatings or vein fillings. Realgar is unstable in the atmosphere and degenerates from a brilliant orange-red, translucent, crystalline aggregate to powdery material.

Other AX minerals of importance are two platinum minerals, cooperite and braggite, PtS, which are known from the high-temperature platinum deposits of Africa. Herzenbergite, SnS, is rare but known from the tin deposits of Bolivia, and empressite and muthmannite, both tellurides of silver, are rare minerals of this group.

A_2X sulfide mineral type. Minerals with this general formula include silver, copper, and gold tellurides, selenides, and sulfides. They have been separated into two crystallographic groups, namely those characterized by argentite, Ag_2S, that are isometric, and those typified by chalcocite, Cu_2S, that are orthorhombic. Most of the minerals of this type assume an isometric symmetry at elevated temperatures (chalcocite is hexagonal) and revert to a lower-symmetry form, usually orthorhombic, when cool. Structurally, most are body-centred cubic or antifluorite in their arrangement. All minerals of this type are metallic in lustre and soft.

Argentite group. Common and important minerals of this group are argentite; digenite, a sulfur-deficient copper sulfide, $Cu_{2-x}S$; hessite, Ag_2Te; and petzite, Ag_3AuTe_2.



(Left) Stibnite from Arnsberg, Westphalia, Germany. (Centre) Pyrite from Butte, Montana. (Right) Argentite from Freiberg, Saxony, Germany.

All are isometric and body-centred cubic. Argentite is one of the most important ore minerals of silver and occurs in low-temperature ore depositional environments. Digenite is a mineral associated with other copper minerals, particularly chalcocite. Difficult to identify, it probably has been overlooked in many early studies of copper minerals and erroneously identified as chalcocite. Hessite and petzite are commonly extracted with other sulfide minerals in many of the old gold and silver mining districts of North America, and are known from many telluride-bearing veins of Europe, Asia, and South America.

Chalcocite group. The minerals chalcocite, Cu_2S; stromeyerite, CuAgS; and acanthite, Ag_2S are all orthorhombic, and acanthite represents the low-temperature phase of argentite. Chalcocite is the copper mineral mined historically from the large copper deposits of western North America. In these deposits it occurred as a secondary mineral, derived from the destruction, by surface processes, of pyrite, chalcopyrite, and bornite. Chalcocite also is believed to have formed by primary processes acting within the earth's crust, but the occurrence of the mineral in its primary form is believed to be much rarer than its occurrence as a secondary mineral. Chalcocite occurs with copper sulfide deposits around the world and, although largely mined out from the "enriched blankets" that it formed, is still common and a mineral of major economic importance. Stromeyerite in small amounts occurs with other minerals of silver and copper in deposits of those metals.

A_3X sulfide mineral type. Two minerals typify this composition. They are dyscrasite, Ag_3Sb, and stibiopalladinite, Pd_3Sb. These are minerals of high specific gravity, of metallic lustre, and white to gray colour. Dyscrasite is an uncommon associate of some silver minerals and base-metal sulfide minerals in veins. Stibiopalladinite is an associate of the platinum deposits of South Africa. The contrast in conditions of formation of the deposits that contain these minerals is significant. The silver veins that contain dyscrasite are presumed to have formed under lower confining pressures and temperatures than the rocks that contain stibiopalladinite. In spite of their close chemical and structural characteristics, they represent somewhat extreme conditions with regard to their environment of formation.

AX_2 sulfide mineral type. A greater number of sulfide minerals belongs to this type than to any other. Groups consist of the structural types pyrite, FeS_2; cobaltite, CoAsS; loellingite, $FeAs_2$; arsenopyrite, FeAsS; molybdenite, MoS_2; and krennerite, $AuTe_2$. Virtually all of the minerals of this type are metallic to submetallic in lustre, and many are hard, although those of the krennerite group are soft. The structures of minerals of this type include the pyrite structure and its modifications and the layered structure of molybdenite and tungstenite.

Pyrite group. Approximately half a dozen minerals are known that belong to the pyrite group; among these, pyrite is the most widespread and significant. These minerals crystallize with the pyrite structure and all are isometric. Other minerals include the sulfides of ruthenium and platinum and the arsenides of iron and platinum.

Pyrite is the most abundant of all sulfide minerals and is the so-called fool's gold. It is present in amounts ranging from slight to overwhelming in virtually every deposit of sulfide minerals. Its bright, brassy lustre, and distinctive habits of crystal form and hardness allow its easy recognition under most circumstances. Its environment of formation ranges from the stagnant and reducing environment of modern and ancient swamps to the very high temperature and pressure environment of deeply derived sulfide ore deposits. Pyrite plays a major part in the processes that weather sulfide mineral deposits because of the ease with which it is decomposed into sulfuric acid and ferric sulfate by atmospheric processes.

Economically, pyrite is used in many parts of the world where the oxide minerals of iron are not abundant and as an ore of iron and in reduction of the mineral; sulfur is recovered and used to produce acid.

Another important mineral in this group is the compound sperrylite, $PtAs_2$. This mineral, originally found near Sudbury, Ontario, is known also from the platinum deposits of South Africa. Its chemical inertness and hardness contribute to its stability in the surface environment, where the mineral is sometimes found in placer deposits with gold and precious stones.

Cobaltite group. Three minerals, cobaltite, CoAsS; gersdorffite, NiAsS; and ullmannite, NiSbS, make up this group; all crystallize with the pyrite structure. In place of the paired sulfur ions in the structure, they contain the nickel or cobalt ion combined with paired As-S or Sb-S occupying the S-S position. All are isometric, all exhibit a metallic lustre, and all are of about equal hardness. Cobaltite is found in association with nickel minerals in primary veins or replacements. Gersdorffite and ullmannite are associates of other nickel minerals in primary deposits of minerals of that metal. Considerable latitude in the structure of these minerals allows for substitution of iron for cobalt and of cobalt and iron for nickel. In addition, bismuth and arsenic substitute for antimony in pairing with sulfur in ullmannite.

Löllingite group. Löllingite, $FeAs_2$; safflorite, (Co,Fe)As_2; and rammelsbergite and pararammelsbergite, $NiAs_2$, are characteristic minerals of this group. All crystallize in the orthorhombic system. Except for rammelsbergite, they occur as well-formed crystals. All have bright metallic lustres and tend to be white rather than gray in colour.

All occur in moderate-temperature, deep-seated, geological environments and all are associates of arsenic minerals. Safflorite is associated with other cobalt minerals, and rammelsbergite with other nickel minerals. Comparatively rare, they nonetheless make up minor amounts in the total mineral assemblage of ores of nickel and cobalt.

Arsenopyrite group. These are minerals of lower symmetry than the types discussed above, occurring as monoclinic or triclinic crystals. Except for arsenopyrite, FeAsS, and possibly glaucodot, (Co,Fe)AsS, they are comparatively rare minerals. Arsenopyrite is the most common arsenic mineral. As with the cobaltite group, there is considerable substitution for sulfur by arsenic and antimony, and rarely by bismuth. A considerable range of compositions exists between glaucodot and arsenopyrite, and cobalt and iron substitute readily within certain limits in the structure.

Arsenopyrite forms in a broad range of geological environments in which the sulfide minerals are formed. The antimonian iron arsenide, gudmuntite, and other members of the group are formed, however, under lower pressures and temperatures than those with which arsenopyrite is ordinarily associated.

Molybdenite group. Two minerals, molybdenite, MoS_2, and tungstenite, WS_2, make up a separate structural assemblage within this compositional type. These two minerals crystallize in the hexagonal system and assume the molybdenite structure. Both minerals are soft and sectile (capable of being cut by a knife with a smooth cut) and occur in scaly aggregates. Because of their structure, they tend to cleave perfectly into platy laminae. For this reason, they feel oily and as a result of this structure, molybdenite is commonly used as a lubricant; it exhibits much the same properties as graphite.

Molybdenite is the chief ore mineral of molybdenum and occurs as a late-stage mineral in processes giving rise to granites and associated end-member rocks. It occurs with quartz, gold, tungsten, and tin in molybdenum deposits and is an important ore mineral in many large low-grade copper deposits. Molybdenite is also a source of rhenium and germanium, both elements that occur as trace metals in the sulfide.

Tungstenite is extremely rare, known from only one locality in the U.S., Salt Lake County, Utah, where it occurs with other base- and precious-metal sulfides.

Krennerite group. Three comparatively rare but important minerals occur in this group, all tellurides of gold and silver: krennerite, $AuTe_2$; calaverite, $AuTe_2$; and sylvanite $(Ag,Au)Te_2$. These minerals exhibit low symmetry, crystallize in the orthorhombic and monoclinic systems, have high specific gravity, and are soft. They are of metallic lustre, white in colour, and are brittle rather than sectile or ductile.

The three minerals have been important historically in making up parts of the precious-metal-ore mineral suite mined extensively from veins in Europe and North America. They also occur in Australia and are found in low-temperature veins with other base-metal sulfides and precious-metal tellurides and sulfosalts.

AX_3 sulfide mineral type. One group of minerals is defined for this compositional type. A series of cobalt and nickel arsenides makes up the group, consisting of the mineral skutterudite, $(Co,Ni)As_3$, at one extreme and nickel-skutterudite, $(Ni,Co)As_3$, at the other. All of isometric crystalline form, they are difficult to distinguish from one another without benefit of chemical analysis. They are found in association with other cobalt and nickel minerals in primary deposits of those metals and are known from a number of localities in Europe and North America.

A_2X_3 sulfide mineral type. Minerals belonging to this type are sulfides of the B subgroup metals, As,Sb, and Bi, and one mineral is a selenide. They are separated into one group, the stibnite group, and two other unclassified minerals of dissimilar crystallographic characteristics. All tend to be quite soft. Although uncommon, most of them are important ore minerals of the metals they contain. They are formed in veins and replacements of low temperature of formation, and appear to be related to the volcanic environment.

Stibnite group. Stibnite, Sb_2S_3, the ore mineral of antimony, bismuthinite, Bi_2S_3, an ore mineral of bismuth, and guanajuatite, Bi_2Se_3 are the members of this group. All are metallic, are some shade of gray in colour, and tend to be sectile. Their crystal habit is prismatic although the habit of guanajuatite is fibrous. Stibnite is found with other low-temperature minerals such as cinnabar and marcasite. Bismuthinite, in contrast, is a product of high-temperature environments and is an associate of arsenopyrite; it is locally found associated with pegmatites.

Orpiment (As_2S_3) does not belong to the group, but, except for crystal character (monoclinic), it has most of the other properties of the stibnite group. Its lustre tends to be resinous and its colour is yellow. It occurs with realgar, from which it alters, and is derived from low-temperature and hot-spring environments.

A_3X_2 sulfide mineral type. Three minerals, including bornite, Cu_5FeS_4, an important ore mineral of copper, are representative of this type. The other two, maucherite, $Ni_{11}As_8$, and umangite, Cu_3Se_2, are rare. Bornite is the bluish, metallic, iridescent mineral of copper deposits known as "Peacock-copper" and can be recognized by the pinkish colour on a freshly broken surface that tarnishes rapidly to the bluish iridescence. Its environment of formation is broad from the standpoint of physical conditions, and it is known from low-temperature deposits as well as those formed at very high temperature and pressure. Almost as abundant as chalcopyrite, it occurs in copper and other base-metal deposits the world over.

AX_4 sulfide mineral type. This type, as with the AX_3 type, is composed of a series of cobalt-nickel sulfides in which there is more or less continuous composition between the end members, linnaeite, Co_3S_4, and polydymite, Ni_3S_4. Five minerals make up the end and intermediate members of the series. All have brilliant metallic lustres on fresh surface and all tarnish to some shade of red or violet. They crystallize in the isometric system in the spinel structure and are octahedral in form. The minerals occur with other sulfide minerals and with minerals of cobalt, nickel, and copper. They are rare.

A_4X_3 sulfide mineral type. Three uncommon minerals are assigned to this type. They are dimorphite, As_4S_3; rickardite, Cu_4Te_3; and weissite, Cu_5Te_3. Dimorphite is known only from fumaroles. The other two minerals are rare associates of other telluride minerals in such deposits.

A_mX_n m:n > 3:1 sulfide mineral type. Two groups of minerals make up this type. One, the tetradymite group, is a series of bismuthian telluro-sulfides, tellurides, and sulfides. The other is a group of copper arsenides.

Tetradymite group. Five minerals, all with similar properties, make up this group. They are tellurobismuthite, Bi_2Te_3; tetradymite, Bi_2Te_2S; grünlingite, Bi_4TeS_3; joseite, Bi_3TeS(?); and wehrlite, Bi_3Te_2(?). All are soft, laminar, metallic minerals with white or bright colour. Of the five, tetradymite is the most common, occurring worldwide with other tellurides, base-metal sulfides, and with gold in gold-quartz veins.

Copper arsenide group. Two distinct minerals and a third of doubtful validity belong to this group. Algodonite, Cu_6As, and domeykite, Cu_3As, are defined species, with algodonite crystallizing in the hexagonal system and domeykite forming in the isometric system. The doubtful species is whitneyite, an ill-defined copper arsenide that may belong to the series. Both algodonite and domeykite are gray in colour, bright on fresh surface, and dull when tarnished. Both minerals are known from copper deposits in North and South America and they are associates of the copper minerals in the deposits of the Upper Peninsula of Michigan, in the United States.

OCCURRENCE OF SULFIDE MINERALS IN NATURE

Sulfide minerals occur in all rock types. They may be syngenetic, that is formed at the same time and under the same conditions as those that formed the rock that encloses them. In other occurrences, they may be epigenetic, formed later than the rock that encloses them. Examples of syngenetic sulfides include pyrite in sedimentary rocks, such as shales or sandstones (*qq.v.*), chalcopyrite disseminated in felsic igneous rocks, and certain of the magmatic segregation deposits in which sulfide segregations occur conformably with rock structures.

Examples of epigenetic deposits of sulfide minerals are the common replacements of wallrock of veins by base- and precious-metal sulfides, the replacement of selected sedimentary beds by thick blankets of massive base-metal sulfides, and the deposition in open spaces of rocks of many sulfide mineral types.

Characteristic rock associations

On a worldwide basis, there is a rather consistent, although inadequately explained, association of certain metals and their primary minerals with certain rock types. Vein deposits of gold are commonly associated with diorites of igneous origin; nickel is commonly associated with norite, an ultramafic rock; lead and zinc extensively occur with sedimentary rocks, usually carbonates, and are related to igneous activity; silver commonly is associated as vein and replacement deposits with andesites of volcanic origin; and copper occurs with igneous rocks of diorite to quartz monzonite composition. No consistent rule, however, can be established to predict sulfide mineral type on the basis of associated rock type. Although a mineral deposit may be valuable because of one suite of sulfide

minerals, it also may contain an abundance of other minerals, many of them sulfide minerals, not valuable in the particular setting.

Sulfide minerals in ore deposits. Ore deposits (*q.v.*) range from simple mineralogy and principal value in one or two minerals of the same metal sought to large, district-wide distribution of numerous minerals that may be selectively extracted and processed for different elements. In many mining districts, sulfide and sulfosalt minerals are distinctly zoned. A classic example of such zoning is at Butte, Montana. An inner core of quartz-molybdenite is surrounded by a zone of copper sulfides. A zone of mixed copper and zinc ores surrounds the copper zone, and this mixed zone gives way at its outer edge to a peripheral zone in which are found ore minerals of zinc, manganese, and silver.

The common ore-minerals of most elements are sufficiently consistent worldwide that it is possible to list the significant minerals of most deposits of certain elements. See also NATIVE ELEMENTS.

Copper deposits. Principal sulfide minerals of copper deposits are chalcopyrite, bornite, and chalcocite. Lesser amounts of covellite and cuprian sulfosalt minerals occur, as do stromeyerite and some tellurides and selenides. Pyrite is a common associate and minor amounts of galena and sphalerite occur. Present in small amounts but nonetheless economically significant in many deposits of the Western Hemisphere is molybdenite.

Lead deposits. The chief ore mineral of lead is galena. Its common associates are sphalerite and pyrite. In addition to these minerals, lead deposits commonly are sources of silver, which may occur as a trace element in galena or in very fine-grained phases of silver tellurides, arsenides, or sulfides.

Zinc deposits. Sphalerite is the major ore mineral of zinc, and its common associates are galena and pyrite. Also extracted from these deposits is cadmium from the mineral greenockite.

Nickel-iron deposits. Pentlandite is the major ore mineral of nickel deposits. Pyrite is sometimes present, as are other nickel arsenides such as niccolite and maucherite.

Silver and gold deposits. Although native gold is the major mineral of gold deposits, and sulfosalts minerals are a major source of silver, there are some sulfide minerals important as ores. These are tellurides and selenides, together with the sulfide argentite. Among the ore minerals are hessite, petzite, empressite and muthmannite.

ORIGIN OF SULFIDE MINERALS

The formation of sulfide minerals, like all minerals, is a function of their environment. Because sulfides are deposited both in the subcrustal environment by processes acting within the earth and at the surface of the earth, it is necessary to consider the characteristics of both environments. In the earth's crust, temperatures are high and approach the melting point of silicate minerals. Pressures are likewise high, as a result of the confining pressure of overlying rocks. In contrast to the surface of the earth, water and oxygen concentrations in the crust are low. At the earth's surface, in contrast, temperatures and pressures are low, and oxygen, water, and organic material are plentiful. In each of these environments, sulfur and the metals with which it combines behave in manners that are predictable in a broad way, and it is clear that the environment exerts a profound influence upon the nature of the minerals deposited and their associations.

Subcrustal formation

Most sulfide minerals found at depth within the earth are the result of processes that give rise to modification of pre-existing rocks (metamorphism) or melting and recrystallization or rock formation by crystallization of a silicate melt. Sulfide minerals occur with the metamorphic and igneous rocks and result from the processes that form the rocks. Sulfur and metals can occur in the rocks that are modified; or, it is believed, they occur in a highly dispersed state as primordial material in rocks that lie beneath the crustal layer.

Material that gives rise to the igneous rocks in which sulfide minerals are found or with which they are closely associated is considered by many to have been molten at one time and to have been a silicate melt. During the cooling of this melt, sulfur and metals are progressively enriched in the uncrystallized portion because they cannot be incorporated in the rock-forming silicate minerals (*q.v.*) being formed. Along with water and gases such as carbon dioxide, sulfur and metals form a separate system that is immiscible with the silicate melt.

This system may be concentrated or dispersed within a cooling silicate mass. If highly dispersed, then sulfides eventually form as dispersed grains in the igneous rock. If concentrated at one or several locations above the silicate melt, the gas-sulfur-metal system may escape as the result of a geological accident such as faulting or fracturing or by encountering different rocks with increased permeability. The fluid moves down the pressure gradient, usually upward, where it loses heat to the surrounding rocks, changes composition by reaction with them, and deposits the sulfide minerals as vein deposits or replacements in the system.

Metals, derived in the destruction of other rocks, and sulfur, the product of the biogenic cycle, are incorporated in sedimentary rocks (*q.v.*). As these rocks become buried and are subjected to higher and higher temperatures, recrystallization of the sedimentary minerals takes place, and these minerals become the rock-forming silicate minerals of metamorphic rocks (*q.v.*). Similarly, metal and sulfur are excluded from these minerals and are subject to movement as an immiscible system down existing pressure gradients. Thus, metamorphism or diagenesis may act in the same way that melting does to produce a sulfide-water system.

A limiting condition upon the temperature of formation of any mineral is that of its melting temperature under the conditions in which it forms. Another limiting condition is the solubility of the sulfide in the gas or transporting phase that deposits it. Even if it is below its melting temperature, a sulfide mineral will not form if it is soluble in the system from which it would crystallize. A broad range of melting temperatures exists for the sulfide minerals, and in a general way this range is consistent with the inferred environment of their formation. Those minerals of high melting temperature are usually from high-temperature environments, although they also may be found in lower-temperature ones. An example is pyrite, which, with a melting temperature of 743° C (1,370° F), is believed to have formed at room temperatures in some environments. On the other hand, cinnabar, which has a melting temperature of 580° C (1,080° F) (approximate sublimation point of metacinnabar), is soluble in some

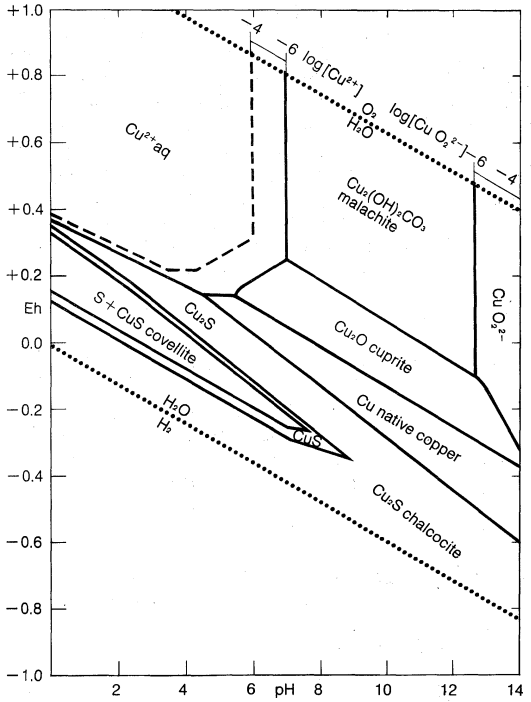
Cobalt (Co), nickel (Ni), and iron (Fe) substitution in sulfide minerals at 800° C and 25 atmospheres water vapour pressure. Tie lines connect pairs of coexisting mineral phases under these conditions in the stability fields of skutterudite plus loellingite (KIFJ), skutterudite (KIGA), and skutterudite plus rammelsbergite (ABCG). Compositions are in mole-percent Co–Ni–Fe, and squares indicate the total composition of samples (see text).

fluids at temperatures of 150° C (300° F); it is for this reason that it is believed to represent low temperatures of formation.

Mineral stability fields. Experimental work after 1920 resulted in a considerable body of information related to high-temperature equilibria in sulfide systems. The data are numerous and the system Co-Ni-Fe-As is representative. The diagram illustrates the variation in composition allowable within defined species of some systems and the corresponding variation in physical properties as substitution of other elements progresses. The diagram shows sulfide relationships at 800° C (1,500° F).

The behaviour of sulfides at low temperatures and pressures is defined by a different set of parameters, because the temperatures and pressures may be held fairly constant. Instead of temperature and pressure, the stability fields of minerals can be shown in terms of their relationship to concentration, oxidation potential (Eh), or oxidizing-reducing conditions, and to pH, or acidity-alkalinity. The diagram of the sulfur species shows the relationships of various copper minerals to their oxides, which form at higher conditions of Eh. The upper boundary of the native copper field, for example, shows the conditions under which cuprite will form in nature.

From R. Garrels and C. Christ, *Solutions, Minerals, and Equilibria* (1965); Harper & Row



Stability relations among some copper compounds in the system Cu-H_2O-O_2-S-CO_2 at 25° C and one atmosphere total pressure.

Paragenesis of sulfide minerals. The microscope allows close examination of sulfide mineral suites, and from this examination a sequence of formation may be determined. This sequence, termed paragenesis, allows further determination of the trends or directions that an ore-forming process takes. The consistency of these relationships of mineral formation and time is noteworthy.

SOME TYPE LOCALITIES OF SULFIDE MINERALS

Chalcopyrite. Kitzbühel, Tyrol, Austria; Freiberg, in Saxony; Rammelsberg, in the Harz Mountains; Río Tinto, in Spain; Braden, in Chile; in Cornwall, at Camborne and Carn Brea; at Ducktown, Tennessee; at Jerome, Arizona; and at the Noranda Mine, Quebec.

Sphalerite. Příbram, Czechoslovakia; Kapnik, Romania; in the Binnatal, Switzerland; Cumberland, at Alston Moor; at Ämmeberg, Sweden; Cananea, Mexico; Mississippi Valley, U.S.; and Joplin, Missouri.

Galena. At Tarnowitz, in Upper Silesia; Chemnitz (now Karl Marx Stadt) in East Germany; at Andreasberg in the Harz Mountains; in Cumberland at Weardale; in the Tri-State District, U.S.; from the Alta Mine, Wicks, Utah; and Inyo County, California, U.S.

Chalcocite. St. Just, St. Ives, and Camborne, in Cornwall; in Joachimsthal in East Germany; Bristol, Connecticut, U.S.; Butte, Montana, U.S.; and at the Kennecott Mine, Alaska.

Pyrrhotite. Sudbury, Ontario; in Transylvania, at Kisbanya; at Bottina, in Tuscany; at Falun, in Kopparberg, in Sweden; at Andreasberg, in the Harz Mountains; in Brazil at Minas Gerais; and from Ducktown, Tennessee.

Stibnite. in the Harz Mountains; in England, at Calston; Sarawak, Borneo; Puno, Peru; in the Coeur d'Alene district, Idaho, and Kern County, California.

Bismuthinite. Bolivia in the tin veins; Cumberland, England; Guanajuato, Mexico; at Schneeberg in Saxony; and at various localities in Colorado.

Pyrite. In the Tri-State District of U.S.; Bingham Canyon, U.S.; at Cornwall; in many locations in Colorado; at New Almaden, California; Elizabethtown, Ontario; and numerous localities throughout the world.

Sulfur Products and Production

Sulfur, a yellow, nonmetallic element, occurs in sedimentary and volcanic deposits and exists in several different forms, the most stable being orthorhombic sulfur, a crystalline form that melts at about 116° C (about 241° F). (The properties of sulfur are described in the article NATIVE ELEMENTS.) Liquid sulfur can be ignited and burns with a characteristic deep blue flame. Sulfur was discovered in prehistoric times and has been used ever since for making sulfur dioxide, sulfuric acid, carbon disulfide, and other compounds. *Sulfur* is Latin for "burning stone," which explains the archaic English term brimstone.

Sulfur has been widely used for religious ceremonies, to purify containers, and for bleaching cloth. The Romans also used it in warfare and medicine. In the Middle Ages, alchemists gave sulfur an important place. Many chemists long doubted the elemental nature of sulfur, but in 1777 Antoine Lavoisier classified it definitively as an element, and experimental confirmation was developed in 1809.

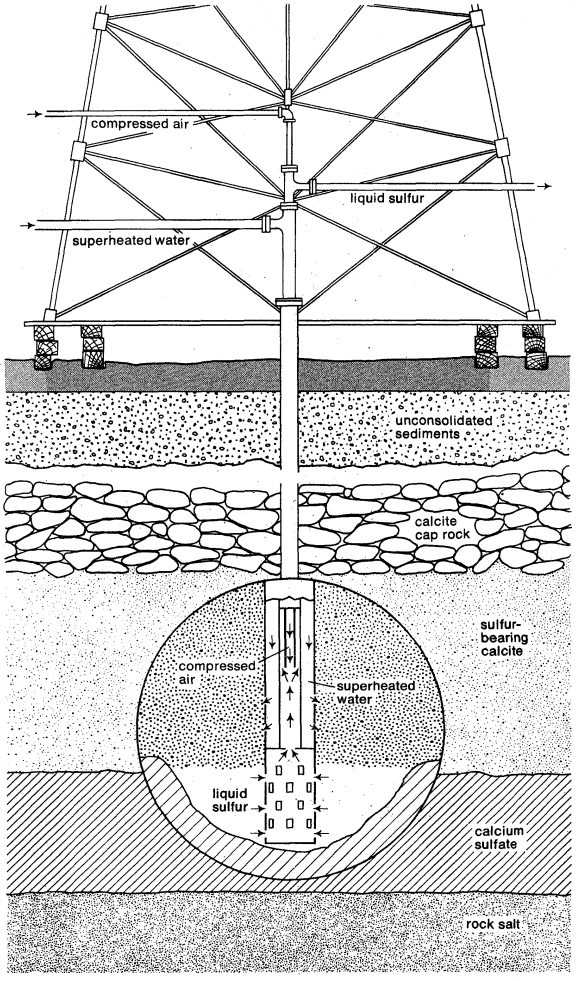
Occurrence. Sulfur, sulfides, and sulfates constitute about 0.06 percent of the Earth's crust. Most of the world's sulfur production is from elemental sulfur that forms the calcareous horizon of the cap rock of salt domes (*q.v.*) around the Gulf of Mexico and Tehuantepec, Mexico. In Sicily sulfur is produced from sedimentary deposits. Volcanic deposits are exploited in Japan, Indonesia, and South America, especially Chile. An increasingly important source of sulfur is natural gas, which in the western Canadian prairies, southwestern United States, and southern France contains up to 40 percent hydrogen sulfide. Vast amounts of sulfur compounds are contained in the Athabasca tar sands of Canada. In Scandinavia and some other countries, sulfur is produced from naturally occurring compounds of sulfur and iron such as pyrite, pyrrhotite, and chalcopyrite. Other important sulfur-containing minerals are galena (lead sulfide) and sphalerite (zinc sulfide). Gypsum, its anhydrite (calcium sulfate), and barite (barium sulfate) are the best known sulfates. Sulfur occurs also in organic substances.

Mining and recovery. In Sicily, where until the beginning of the 20th century most sulfur was produced, the element is refined by methods developed in antiquity. Native ore is piled in cylindrical kilns (calcaroni) and ignited. About one-third of the material burns, and the heat from the combustion melts the remainder, which is

cast in blocks. In a somewhat improved smelter, called a Gill furnace, hot gases are recirculated to preheat the ore. In Japan the prevailing recovery method is distillation from retorts.

The Frasch process

Since 1900, as the result of the so-called Frasch mining method developed by Herman Frasch, the United States has become the largest sulfur producer. This process, applied to salt domes, has made sulfur of a high purity available in large quantity and has helped establish sulfur as one of the four most important basic chemical commodities. Wells are drilled from 200 to 2,000 feet (60 to 600 metres) into the sulfur formation (see illustration).



Sulfur well.
Superheated water causes the sulfur to melt from the deposit and flow to the bottom. From there it is forced to the surface by air pressure.

The well is lined with a six-inch pipe in which a one-inch air pipe and a three-inch water pipe are concentrically placed. Superheated water, injected into the circular space between three- and six-inch pipes, penetrates the cap rock through holes on the bottom of the pipe. As the sulfur melts, it settles to the bottom of the deposit. From there it is pumped to the surface by applying air pressure through the central well pipe. Several wells operate under the ocean floor in the Gulf of Mexico. From these offshore platforms sulfur is pumped several miles through insulated pipes in liquid form along the ocean floor. Once on the surface, the sulfur is collected in reservoirs, or sumps, and from there transferred to vats or bins to solidify for storage and stockpiling. Vats may contain as much as 300,000 tons of sulfur.

In addition to sulfur obtained in elemental form, about 4,000,000 tons are recovered in the United States each year from natural gas, petroleum refinery gases, pyrites, and from smelter gases from the processing of copper, zinc, and lead ores. In most cases, sulfur is separated from other gases as hydrogen sulfide and then converted to elemental sulfur by the so-called Claus process, which involves partial burning of hydrogen sulfide to sulfur dioxide, with subsequent reaction between the two to yield sulfur.

Another important source of sulfur may lie in the large volume of sulfur dioxide emitted into the atmosphere by coal-fired steam power plants and other large coal-consuming facilities. In the early 1970s, techniques to collect this sulfur dioxide and convert it into usable sulfur were developed. If economically or politically feasible, such techniques could double sulfur production in the United States and provide numerous small sulfur sources throughout the world.

World production

World production and consumption of sulfur have increased steadily, except during periods of long recessions, since the inception of the Frasch process. In the early 1970s, about 12,300,000 tons of elemental sulfur were being produced annually in the United States and Mexico alone; France was producing about 1,900,000 tons and Canada about 4,900,000 tons as a by-product of natural gas production. Canadian production is rising rapidly; in most countries production is relatively steady. Poland, Scandinavia, the Soviet Union, Spain, Japan, Chile, and China produced smaller but significant quantities.

Refining and purification. Sulfur quality and chemical purity are reflected by its colour. Bright sulfur is brilliant yellow and 99.9 percent pure, or better. Dark sulfur contains 0.5 to 5 percent organic matter. The oldest production method, melting by heating ores, produces dull yellow or even dark sulfur that contains organic impurities. These are difficult to remove because they react slowly with sulfur. The Frasch process yields up to 99.9 percent sulfur. Clean Frasch sulfur is bright sulfur, as is by-product sulfur recovered through the Claus process.

Bulk quantities of the element are now shipped almost entirely as liquid. Japanese and Sicilian sulfur is sold in ingots, and some broken-rock brimstone is shipped in lumps.

Special forms of sulfur used in the rubber industry

For the rubber industry and other special uses, sulfur is transformed into the following special forms:

Flowers of sulfur is sulfur refined by sublimation—that is, condensation from the vapour phase without passage through the liquid phase. It contains 25 to 30 percent amorphous sulfur, which is insoluble in carbon disulfide. Its main uses are in rubber vulcanizing, the preparation of insecticides, fungicides, and pharmaceuticals.

Precipitated sulfur is precipitated from a sulfur compound such as thiosulfate or polysulfide solution and used primarily for pharmaceutical purposes.

Roll sulfur, refined sulfur cast into convenient shapes and sizes, is used for fumigation, burning, and bleaching. It is sometimes referred to as stick, or cannon, sulfur.

Commercial flour sulfur is prepared by milling (grinding) refined sulfur to a very fine particle size. It is used for vulcanizing rubber and in the manufacture of gunpowder and dyes.

Colloidal sulfur has such a small particle size that it remains suspended in water. It is prepared from thiosulfate and used in the manufacture of insecticides and pharmaceuticals.

Uses. Sulfur is one of the four basic raw materials of the chemical industry (the other three being coal, limestone, and salt). Eighty-five percent of all sulfur used is first converted into sulfuric acid, and nearly 80 percent of this is used in fertilizer production. Sulfur dioxide is used in leaching ores and in bleaching cloth and food products, and it is an important intermediate chemical in the chemical industry. Other important uses include inorganic pigments, cellulosic fibres, nonferrous metallurgy, pulp and paper, and petroleum refining. Many other products, such as cements, dyes, food preservatives, photographic materials, sugar, and textiles, depend on sulfur in various stages of manufacture.

Hydrogen sulfide can be formed by the reaction of hydrogen with liquid sulfur. It is a colourless gas, poisonous when inhaled, and has the odour of rotten eggs. Often used as a reducing agent, it is oxidized by chlorine, bromine, and iodine to sulfur—the excess halogen oxidizing

the sulfur to sulfuric acid—and by concentrated sulfuric acid to sulfur and sulfur dioxide. It can be converted to elemental sulfur with a good yield by combining with oxygen, a process increasingly used to produce sulfur from natural gas and oil. Some metallic sulfides, containing small amounts of heavy metal salts, are phosphorescent. Zinc sulfide is used in luminous paints and, combined with traces of a radium salt, has been used for hands and figures on luminous watch dials.

Carbon disulfide, formed by direct union of carbon and sulfur at high temperatures, is important commercially, primarily in the preparation of viscose rayon. Nitrogen tetrasulfide, formed by passing ammonia through carbon disulfide dissolved in benzene, is used as an insecticide and fungicide and may have future value as an ignition promoter in diesel fuels. Other sulfides have also been prepared, but their uses are minor.

The sodium salt of hyposulfite is used commercially and serves as a reducing agent in the dye industry. Sulfurous acid and its salts are excellent and cheap reducing agents and are also used as disinfectants and food preservatives. Calcium bisulfite and magnesium bisulfite are used to extract lignin from wood in preparing wood pulp. Thiosulfates are used extensively in photography.

Sulfur monochloride and sulfur dichloride are used to vulcanize rubber. The oxychlorides are useful reagents for the introduction of sulfoxides, sulfone, or chlorine groups into organic molecules. Chlorosulfonic acid, prepared by reacting hydrochloric acid directly with sulfur trioxide, reacts readily with water to form sulfuric and hydrochloric acids. It fumes in air and has found application as a smoke producer in military operations. Its most useful application is as a sulfonating agent in organic chemistry.

The aromatic sulfur compounds, usually nitrogen derivatives, find extensive use as accelerators in the vulcanization of rubber. The second type of reaction, oxidation of organic sulfur compounds, yields materials that, with the exception of the disulfides and the peroxides, are not analogous to oxygen compounds in structure. The most important of these compounds are the sulfuric acids, alkyl sulfates, and their derivatives, which are used extensively as medicinals (sulfa drugs), detergents, lubricants, and dyestuff intermediates.

Sulfur is also used for a variety of other purposes. Combined with sand or gravel, it yields acid-resistant, quick-setting cements that can be used for house construction, sewage pipes, and road surface repairs. Large-scale tests with sulfur foam indicate that it might become commercially important as an insulating material in the construction of houses and road beds. It is used as an insecticide and fungicide for plants and animals. Sulfur ointments are used in treating skin rashes and acne, and sulfur pills are still widely used medicinally as a tonic. A major use is as plant food, especially in alkaline soil.

Organic sulfur compounds are important plasticizers and are incorporated into polymers.

The FREEPORT SULPHUR COMPANY, *Freeport Sulphur Handbook* (1959); and TEXAS GULF SULPHUR COMPANY, *Properties of Sulphur* (1961), contain much useful information that is nowhere else available. B. MEYER (ed.), *Elemental Sulfur: Chemistry and Physics* (1965), contains a review of sulfur qualities produced and a chapter on products. A more recent account of this subject may be found in the *Kirk-Othmer Encyclopedia of Chemical Technology*, 2nd ed., vol. 19, pp. 337–364 (1969).

(C.B.M.)

Sulla, Lucius Cornelius

Lucius Cornelius Sulla, Roman general and dictator, carried out great constitutional reforms aimed at reinforcing the republican character of the Roman government. His reforms did not, however, prevent the extinction of the republic only a few decades after Sulla's death. He was born in 138 BC, the son of a politically unimportant patrician family. He early showed a taste for luxury and aspired to a political career, which he began in 107 BC, under the command of Gaius Marius, as a quaestor (financial magistrate) in Africa in the war against King Jugurtha of the Numidians. His spectacular capture of Jugurtha by trickery marked the start of his feud with Marius. Although Marius continued to use Sulla in the war against the invading Cimbri, in 103 BC his jealousy became obvious, and Sulla transferred to the service of Marius' co-commander.

Early career

Sulla, marble bust. In the Vatican Museum.
Alinari

After service as a Roman praetor (one of the chief magistrates) in 94 BC, Sulla fought in the Social War (90–89 BC), the struggle of Rome's Italian allies to obtain Roman citizenship. He became one of the two consuls—the highest office in the republic—in 88 and was placed in command of the war against King Mithradates VI of Pontus in Asia Minor. By his marriage—his fourth—to Caecilia Metella, in 88 BC, he formed important alliances. But Marius, through his alliance with the tribune Publius Sulpicius Rufus of the popular party, succeeded in being appointed commander instead. Sulla marched on Rome, Sulpicius was killed, and Marius escaped.

In 88 Sulla set off for Greece in charge of the war against Mithradates. By the spring of 87 most of Greece was in his power, and after a long siege he captured Athens in 86. Mithradates' general was pursued into Boeotia and finally defeated in two battles in 86.

At a meeting in 85 between Sulla and Mithradates at Dardanus on the Hellespont, the latter accepted a punitive treaty. Order was restored in Asia and Greece, and Mithradates became a vassal of the Romans again. In the summer of 83, Sulla, after a lengthy stay in Athens, returned to Brundisium in southern Italy with 40,000 men and enormous plunder.

During his absence, Sulla had been declared a public enemy by the ruling popular party. His laws were repealed, his house was destroyed, and his family and friends fled to join him in Greece. In 86 the former consul Lucius Valerius Flaccus was sent to replace Sulla in the Asian command. But Sulla's luck did not desert him; Flaccus was murdered by his lieutenant.

From Brundisium, Sulla began his march on Rome, joined by opponents of the popular regime. Through most of the ensuing civil war Sulla was opposed by the consuls Gnaeus Papirius Carbo and the younger Marius (whose father had died in 86). Sulla's victory of Colline Gate in the northern environs of Rome and the fall of Praeneste at the end of 82 ended the war, which was followed by massacres and proscriptions.

Sulla was appointed dictator under the Lex Valeria (Valerian law), which vested constituent, legislative, military, and judicial power in him, without, however, for the first time in Rome's history, limiting the duration of his dictatorship.

The state was reorganized and the new legislation enacted in 81, at the start of which year (January 27–28) Sulla celebrated his victory over Mithradates. In the speech delivered at the close of the ceremony, he chose for himself the name of Felix (Epaphroditos in Greek documents).

By his extensive program of constitutional reform he intended mainly to re-establish the supremacy of the Senate in the Roman state, and many of his reforms did indeed survive to the end of the republic. Of value were the increase of the number of courts for criminal trials; a new treason law, Lex Cornelia de Majestates, designed to prevent insurrection by provincial governors and army commanders; the requirement that the tribunes had to submit their legislative proposals to the Senate for approval; and various laws protecting citizens against excesses of judicial and executive organs. At the beginning of 79, Sulla resigned and withdrew to the neighbourhood of Puteoli (modern Pozzuoli) in Campania. This action caused a sensation in Rome; many different explanations have been given, starting with the classical writers. Most commonly accepted is the view that Sulla's resignation was an act of honesty by a man who had pledged to step down as soon as his reforms had been carried out. Henceforth a private citizen, he continued to write his memoirs. Active to his very last days, Sulla was struck down by a fever in the spring of 78. He left behind two children by Metella and a posthumous daughter by his fifth wife, Valeria.

Assessment

Sulla, a soldier and a politician, a dictator and a reformer, a man of contradictions in an age of contradictions, is the subject of contradictory opinions expressed by both classical and modern writers. The classical writers of Sulla's time or shortly thereafter found it difficult to form an opinion of him; they noted the discrepancy of the Sulla "who follows up good beginnings with evil deeds." Generally, their attitude was a negative one, with references to despotism, slavery, cruelty, and inhumanity, and the absence of any principle of good government. The opinions held by modern writers cover a spectrum ranging from Sulla the enigma (because of his resignation), to Sulla the monarch, to Sulla the honest reformer.

Sulla was the exponent of a decadent patriciate that tried everything in its power to save itself by instituting reforms that, while not without democratic aspects, lacked inner vitality. From the long-term perspective, Sulla's actions seem meaningless; but viewed in their historical context they are justified by the transitional character—both in its military and political aspect—of his age. Inspired by a glorious past, interpreting an extremely volatile present, and heralding a future faithful to tradition, Sulla played a historical role, conclusively shaping and epitomizing the republican ideal shortly before it became submerged. But he was mistaken about the significance of his reforms: he was a temporary dictator because he wanted no one else who might follow him to become a dictator for life; yet by his example he unwittingly paved the way for Julius Caesar.

LAFFI, "Il mito di Silla," *Athenaeum*, 45:177–213, 255–277 (1967), a study of the fortune of the Sullan regulation of the state, including evaluations of his work with respect to history and historiography.

(E.Va.)

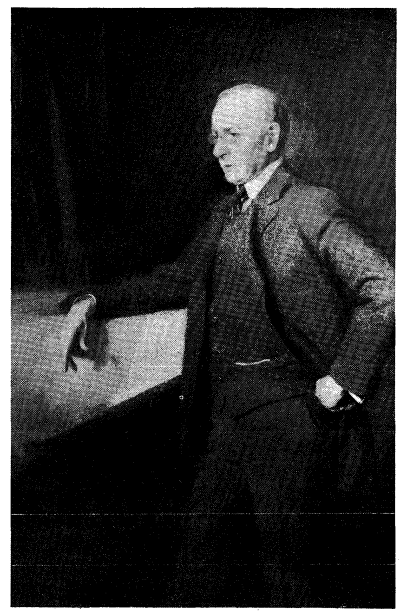
Sullivan, Louis

Louis Sullivan is regarded as the spiritual father of modern U.S. architecture and is particularly identified with the aesthetics of skyscraper design. He was a spokesman for the reform of architecture, an opponent of historical eclecticism, and did much to remake the image of the architect as a creative personality. His own designs are characterized by richness of ornament.

Early years in Boston

Louis Henry Sullivan was born in Boston, Massachusetts, on September 3, 1856, of Patrick, a dancing master, and Adrienne Françoise (List) Sullivan. His Irish-born father and Swiss-born mother had emigrated to the United States in 1847 and 1850, respectively, and were married in 1852. Their older son, Albert Walter, was born in 1854.

By courtesy of the Chicago Historical Society



Louis Sullivan, oil painting by Frank A. Werner, 1919. In the collection of the Chicago Historical Society.

Sullivan attended public schools in the Boston area and spent summers on his grandparents' farm in nearby South Reading. When his parents moved to Chicago in 1869, Sullivan stayed behind with his grandparents and later with neighbours, commuting to school in Boston.

In September 1872 he entered Massachusetts Institute of Technology, which had the first architectural school in the United States (founded 1865). Sullivan was an impatient architectural student and left at the end of the year with thoughts of studying at the École des Beaux-Arts in Paris or of being an apprentice to an architect. He discussed his ideas in New York with Richard Morris Hunt, one of the fashionable architects of the day and the first American to study architecture at the Beaux-Arts. Hunt suggested he work with the Philadelphia firm of Furness and Hewitt. Sullivan was hired, staying for several months until work dwindled in the economic panic of 1873. In November he left for Chicago and was soon employed in the architectural office of a prominent figure in the development of the style of the Chicago school, William Le Baron Jenney. The office foreman, John Edelmann, became his future friend.

The idea of studying in Paris persisted, however, and in July 1874 he sailed for Europe. Sullivan worked hard to pass the difficult entrance examinations for the Beaux-Arts, although after he was accepted he proved to be a restless and erratic student. He made a brief excursion to Florence and Rome. A romantic young man with sideburns, he affected a certain swagger in dress. During the single year he remained in Paris, he was attached to the atelier of the architect Émile Vaudremer.

Work in association with Adler. Back in Chicago in June 1875, Sullivan worked briefly as a draftsman for a

number of firms. One such job was for the recently formed firm of Johnston and Edelmann. It was John Edelmann who made the momentous introduction of Sullivan to his future partner Dankmar Adler. In 1879 Sullivan joined Adler's office and in May 1881, at the age of 24, became a partner in the firm of Adler and Sullivan, Architects. Their 14-year association produced more than 100 buildings, many of them landmarks in the history of U.S. architecture.

Collaboration with Adler

Sullivan's brilliance as a designer was complemented by Adler's business ability, his tact with clients, and his knowledge of technical matters, especially acoustics. After coming to Chicago in 1861, Adler had worked as a draftsman, and he returned to the city after serving in the Civil War. In 1871 he formed a successful partnership with Edward Burling that lasted until 1879. As an independent architect Adler designed Central Music Hall in Chicago (1879), which was the prototype of theatres later designed by the firm of Adler and Sullivan. Adler was a consultant on acoustics and in his later years was a writer on the technical and legal aspects of architecture.

Although Adler and Sullivan did substantial residential work, it was in their commercial work that they made their art-historic contribution. Most of their buildings were in Chicago, where the commercial expansion of the 1880s resulted in many important commissions.

The early years of the Adler and Sullivan practice did not result in buildings of lasting interest, however. It was the commission in 1886 to design the Auditorium Building in Chicago that marked the first period of Sullivan's design maturity. This project was a curious combination of a hotel and office block wrapped in a U-shape around an 3,982-seat auditorium for opera. Completed in December 1889, it is a ten-story-high building of granite and limestone with a 17-story tower. The noble arcaded exterior is very simple in profile, has little ornament, and owes much to the architect H.H. Richardson's design for the Marshall Field Wholesale Store, then recently completed in Chicago. The interior, however, is lavishly decorated with relief ornament and coloured stencilled patterns, all of which brought forth Sullivan's great talent for designing ornamentation. The interior of the auditorium (restored 1967) is particularly opulent and features gilded plasterwork and countless electric light bulbs. The decoration, which is dazzling and properly theatrical, owes nothing to historical eclecticism. The astonishingly effective acoustical design of the auditorium was the work of Adler, who was also responsible for all structural and mechanical aspects of the building.

Even before the auditorium proper was complete, the Adler and Sullivan firm moved to offices on the 16th floor of the tower, then the highest office suite in Chicago. It was there that the young Frank Lloyd Wright spent six years as apprentice to Sullivan. Wright left in 1893 after a quarrel with Sullivan, and it was not until 1914 that the friendship was renewed. He always acknowledged, however, the influence of Sullivan in shaping his work and ideas.

Influence of Sullivan on Wright

The ten-story Wainwright Building in St. Louis is the most important skyscraper designed by Sullivan. Unlike the Auditorium Building, the exterior walls of which are solid masonry and load bearing, it is of steel frame throughout, an idea advanced by William Le Baron Jenney in 1883–85 in Chicago. Jenney and others were unable to give visual expression to the height of a tall building and often resorted to unsuitable historical styles. Sullivan, however, took the problem in hand and made his design a "proud and soaring" unity. He gave his building a two-story base, above which the vertical elements are stressed and the horizontals, being recessed, are minimized. These vertical rhythms are capped by a deep decorative frieze (corresponding to the 10th floor) and a simple projecting cornice. The Guaranty (now Prudential) Building in Buffalo, New York, by Adler and Sullivan is similar to the Wainwright Building except that it has 16 stories and its surface is sheathed in decorative terra-cotta instead of red brick. Both buildings are among the best of Adler and Sullivan's work, the latter being the last work of their partnership.

The 1893 Columbian Exposition held in Chicago was a great disappointment to Louis Sullivan. The opportunity to design an international fair with imagination was passed over in favour of a loose adaptation of Classical architecture. The spectacle of an ensemble of these all-white buildings was an enormous success with the public. The Adler and Sullivan contribution was the Transportation Building, which stood apart and was painted in various strong colours as if in protest. It was a long, low arcaded building with a large polychromed archway entrance (the so-called "Golden Door"). Not all visitors were impressed by the neo-Roman grandeur of the fair. André Bouilhet, a delegate representing a Parisian decorative-arts union, praised the originality of the Transportation Building. Furthermore, he arranged for a small exhibit in Paris of Sullivan's work, including a plaster cast of the "Golden Door" and some photographs of his taller buildings. The exhibit later went to Russia and Finland. This European recognition, however, did not allay Sullivan's bitterness. He considered the Exposition a rejection of the progressive architecture that he saw developing in the Midwest. "The damage wrought by the World's Fair," he wrote, "will last for half a century from its date, if not longer. It has penetrated deep into the constitution of the American mind." It is with this event that Sullivan ended the *Autobiography of an Idea* (1924), his account of his career and his architectural theories.

Later work. The economic depression that began in 1893 severely curtailed commissions. With a lucrative offer as designer and agent for the Crane Elevator Company, Adler reluctantly decided in 1895 to withdraw from architecture. Sullivan reacted badly, accusing Adler of disloyalty. Adler's new job proved unsatisfactory, and he decided to return to architecture six months later. His offer to re-establish the firm was unwisely refused by Sullivan, and Adler opened his own office in another part of the Auditorium Building, where he practiced until his death in 1900.

In 1895, proud and optimistic, Sullivan began to practice by himself. His temperament was unsuited, however, to the handling of all of the phases of architectural practice. New work was very slow in coming. George Grant Elmslie, whom he had hired in 1889 at the age of 18, remained a loyal employee. Nevertheless, he was aware of Sullivan's shortcomings:

> He could be arrogant and unnecessarily decisive . . . prone to give advice where not needed, to good clients . . . he lost many jobs because he would not compromise his ideals, nor play fast and loose with vital conceptions of what was fitting for the purpose intended.

A simple tabulation of Sullivan's 20 commissions (many of them small) during the last 30 years of his life indicates the near collapse of his practice.

Among the few major commissions Sullivan received was the one for the Schlesinger & Mayer department store in Chicago, occupied by Carson Pirie Scott & Co. since 1904. Two connecting units were built between 1899 and 1904, and a third unit was added in 1906 by Daniel H. Burnham and Co., largely following Sullivan's original design. In contrast to the vertical emphasis of the Wainwright and Guaranty buildings, which are offices, the design for this department store stresses the horizontal. Particularly notable are the rectangular "Chicago windows"—each a large fixed pane flanked by moveable sash windows. The elegant simplicity of the upper floors is in contrast to the lavish decoration of the first two, which have windows that were treated as display windows, with the architectural decoration forming rich picture frames. This cast-iron ornament is based on a combination of geometric and stylized floral forms. Much of it is thought to have been designed by Elmslie, in emulation of Sullivan's style. In any case, the decoration of the Carson Pirie Scott Store, particularly the ornament over the main entrance, represents the height of Sullivan's achievement as a designer of architectural ornamentation. Only the decorative panels that once surrounded Sullivan's Gage Building in Chicago were a match for its decorative exuberance.

Commission for the Carson Pirie Scott Store

Greater plastic richness and a heightened subjectivity are clearly apparent in Sullivan's work after 1895. His 12-story Bayard (now Condict) Building in New York was richly embellished with molded terra-cotta and cast-iron ornament.

As his flourishing years with Adler became a provoking memory, Sullivan grew lonely and difficult. He became estranged from his brother Albert, who was a successful official of the Illinois Central railroad and who also lived in Chicago. The middle-aged Sullivan became something of a recluse, seeking solace in writing and in visits to his winter cottage in Ocean Springs, Mississippi. His marriage in 1899 to Margaret Davies Hattabough did little to bring lasting happiness; they were separated in 1906 and divorced in 1917 without having had children. With declining income, Sullivan moved to progressively cheaper hotels in an effort to economize. By 1909 a lack of commissions reduced him to desperate straits; he was forced to sell his library and household effects. Perhaps an equal loss was the departure that year of Elmslie, his assistant for 20 years, who went to join forces in Minneapolis with William Gray Purcell, an architect who had worked briefly for Sullivan in 1903.

Designs of banks in small towns

Particularly noteworthy projects undertaken in his last years were seven banks in a number of small Midwestern towns, beginning with the National Farmers' (now Security) Bank in Owatonna, Minnesota. Sullivan's work habits had become erratic, and it is known that this particular design is primarily the work of Elmslie, his last effort before leaving Sullivan's employ. The Owatonna bank has a simple cube form pierced on two sides by large arched windows. Its walls of red sandstone and brick, which convey a sense of security, are ornamented by bands of coloured mosaic and blue-green glazed terra-cotta. The balance between simple form and decoration in this structure has been much admired. The square interior was designed in harmony with the exterior: semicircular murals appear opposite the two arched windows.

Another attractive bank design is that of the Merchants' National Bank in Grinnell, Iowa (1914). Like the Owatonna bank, it has a relatively austere form, relieved by imaginative, intricate ornament. The facade is embellished with a spectacular decorative frame for the circular window above the entrance. Sullivan's last commission was the facade for the Krause Music Store in Chicago (1922).

Sullivan had to abandon his Auditorium tower suite in 1918 for a small second-floor office. In 1920 he had no office at all and was reduced to living in one bedroom, being supported by donations from friends. His workplace came to be a desk in the office of a Chicago terra-cotta company, where he was able to complete two significant projects: the writing of his *Autobiography* and the completion of 19 plates for *A System of Architectural Ornament According with a Philosophy of Man's Powers* (1924). He died on April 14, 1924, a week after he had received published copies of these two works. Sullivan was buried in Graceland Cemetery in Chicago, next to the graves of his parents and within sight of the Getty and Ryerson Tombs, which he had designed. Later, a modest stone was erected by friends. Much later, in 1946, the American Institute of Architects awarded him its Gold Medal.

Sullivan's writings

Assessment. Sullivan's importance lies in his writings as well as in his architectural achievements. Unfortunately, his prose style was sometimes obscure and verbose. He thought of himself as a philosopher-architect and assumed the role of teacher in *Kindergarten Chats*, which first appeared in 1901 as a series of articles in *Interstate Architect and Builder*. In 1905 he sought, unsuccessfully, a professorship in architecture at the University of Michigan. Sullivan's writings transcended the daily concerns of architectural practice and entered the realm of poetry. These writings, which are subjective and metaphorical, suggest directions for architecture, rather than explicit doctrines or programs. Sullivan himself warned of the danger of mechanical theories of art.

Sources of Sullivan's ideas have been traced to the mid-19th-century writings of two Americans, the sculptor Horatio Greenough and the essayist Ralph Waldo Emerson, as well as to the English naturalist Charles Darwin. Darwin's writings on evolution, particularly on organic growth, left their mark on European writers on architecture and, in turn, on Sullivan's own thinking. The French architect César-Denis Daly, for example, in an essay reprinted in a Chicago architectural journal, stated that

> each style of architecture . . . being born of the intellectual and moral forces of a human society . . . , has become naturally the expression of a certain civilization . . . The adoption by one age of a style . . . other than that which it has itself created, is hence in itself a false principle.

In a similar vein, the contemporary German architect Gottfried Semper wrote, "Style is the conformity of an art object with the circumstances of its origin and . . . its development." Out of such inquiries into the nature of style came Sullivan's own dictum "form follows function," a phrase that should not lead one to conclude that Sullivan believed that a design should be a mechanistic visual statement of utility. Rather, he believed that architecture must evolve from and express the environment in addition to expressing its particular function and its structural basis. It has been said that Sullivan was the first U.S. architect to think consciously of the relationship between architecture and civilization.

Importance of the skyscraper in his work

The skyscraper was central to both Sullivan's writing and practice, and it is on this subject that his thought is most concise. His pre-skyscraper commercial buildings in Chicago, such as the Rothschild Store and Troescher Building, show a conscious clarification and opening up of the facade. This simplification is carried into his "skyscrapers," the Wainwright and the Guaranty, which are conceived as "a single, germinal impulse or idea" that permeates "the mass and its every detail with the same spirit." The exceptional clarity of Sullivan's designs has lost some of its impact because contemporary architecture has in part absorbed his ideas. Sullivan considered it obvious that the design of a tall office building should follow the functions of the building and that, where the function does not change, the form should not change. Unfortunately, Sullivan's most dramatic skyscraper design, the Fraternity Temple (1891), intended for Chicago, was never built. This was to be a symmetrical structure with bold step-back forms and a soaring 35-story central tower.

In his designs Sullivan combined emphatically simple forms with rich decoration. For him ornament was integral and necessary to architecture. He believed

> that a decorated structure, harmoniously conceived, well considered, cannot be stripped of its system of ornament without destroying its individuality. It has been hitherto somewhat the fashion to speak of ornament . . . as a thing to be put on or omitted, as the case might be. I hold to the contrary—that the presence or absence of ornament should, certainly in serious work, be determined at the very beginnings of the design.

Sullivan's position on ornament has largely fallen out of favour because of the emphasis in postwar architecture on the almost total elimination of architectural ornament.

Sullivan was just as much a revolutionary in his ornament as he was in his use of plain surfaces and cubic forms. His ornament was not based on historical precedent but rather upon geometry and the stylized forms of nature. Although his early ornament has some links to that of the Gothic Revival style and to the Queen Anne style, his mature ornament, seen best in his works at the turn of the century, is indisputably his own. It stands as a curious yet unrelated parallel to Art Nouveau ornamentation in Europe. Crisp yet fluid, tightly constructed yet exuberant, these designs remind one of Sullivan's feeling that architecture should not only serve and express society but also illuminate the heart.

MAJOR WORKS

Rothschild Store, Chicago, Illinois (1880–81); Troescher Building, Chicago (1884); Auditorium Building, Chicago (1886–89); Wainwright Building, St. Louis (1890–91); Schiller Building, Chicago (1891–92); Transportation Build-

ing, Columbian Exposition, Chicago (1893; demolished); Guaranty (now Prudential) Building, Buffalo, New York (1894–95); Condict (formerly Bayard) Building, New York (1897–99); Gage Building, Chicago (1898–99); Carson Pirie Scott Store, Chicago (1899–1904); National Farmers' Bank (now Security Bank and Trust Company), Owatonna, Minnesota (1907–08).

BIBLIOGRAPHY. HUGH MORRISON, *Louis Sullivan: Prophet of Modern Architecture* (1935), is the standard biography, which also includes an evaluation of Sullivan's work. WILLARD CONNELY, *Louis Sullivan As He Lived: The Shaping of American Architecture* (1960), is a more personal account, although the full story of his later years will probably never be known. Sullivan's own *Autobiography of an Idea* (1924) and *Kindergarten Chats* (published serially in 1901–02), are indispensable for a grasp of Sullivan's architectural theory. The 1947 Wittenborn edition of the latter, *Kindergarten Chats and Other Writings* (rev. 1918), includes eight additional essays by Sullivan and a bibliography of writings by and about him. JOHN SZARKOWSKI, *The Idea of Louis Sullivan* (1956), contains dramatic photographs. ALBERT BUSH-BROWN, *Louis Sullivan* (1960), is a brief, interpretative account of Sullivan's contributions and is well illustrated.

Sumerian Language

Sumerian is the oldest written language in existence. First attested about 3100 BC in southern Mesopotamia, it flourished during the 3rd millennium BC. About 2000 BC, Sumerian was replaced as a spoken language by Semitic Akkadian (Assyro-Babylonian) but continued in written usage almost to the end of the life of the Akkadian language, around the beginning of the Christian era. Sumerian never extended much beyond its original boundaries in southern Mesopotamia; the small number of its native speakers was entirely out of proportion to the tremendous importance and influence Sumerian exercised on the development of the Mesopotamian and other ancient civilizations in all their stages.

History. Four periods of Sumerian can be distinguished: Archaic Sumerian, Old or Classical Sumerian, New Sumerian, and Post-Sumerian.

Archaic Sumerian covered a period from about 3100 BC, when the first Sumerian records make their appearance, down to about 2500 BC. The earliest Sumerian writing is almost exclusively represented by texts of business and administrative character. There are also school texts in the form of simple exercises in writing signs and words. The Archaic Sumerian language is still very poorly understood, partly because of the difficulties surrounding the reading and interpretation of early Sumerian writing and partly because of the meagreness of sources.

Old, or Classical, Sumerian

The Old, or Classical, period of Sumerian lasted from about 2500 to 2300 BC and is represented mainly by records of the early rulers of Lagash. The records are business, legal, and administrative texts, as well as royal and private inscriptions, mostly of votive character, in letters, both private and official, and in incantations. These sources are much more numerous than those of the preceding period, and the writing is explicit enough to make possible an adequate reconstruction of Sumerian grammar and vocabulary.

During the period of the Sargonic dynasty, the Semitic Akkadians took over the political hegemony of Babylonia, marking a definite setback in the progress of the Sumerian language. At this time the Akkadian language was used extensively throughout the entire area of the Akkadian empire, while the use of Sumerian gradually was limited to a small area in Sumer proper. After a brief revival during the 3rd dynasty of Ur, the New Sumerian period came to an end about 2000 BC, when new inroads of the Semitic peoples from the desert succeeded in destroying the 3rd dynasty of Ur and in establishing the Semitic dynasties of Isin, Larsa, and Babylon.

The period of the dynasties of Isin, Larsa, and Babylon is called the Old Babylonian period, after Babylon, which became the capital and the most important city in the country. During this time the Sumerians lost their political identity, and Sumerian gradually disappeared as a spoken language. It did, however, continue to be written to the very end of the use of cuneiform writing. This is the last stage of the Sumerian language, called Post-Sumerian.

In the early stages of the Post-Sumerian period the use of written Sumerian is extensively attested in legal and administrative texts, as well as in royal inscriptions, which are often bilingual, in Sumerian and Babylonian. Many Sumerian literary compositions, which came down from the older Sumerian periods by way of oral tradition, were recorded in writing for the first time in the Old Babylonian period. Many more were copied by industrious scribes from originals now lost. The rich Sumerian literature is represented by texts of varied nature, such as myths and epics, hymns and lamentations, rituals and incantations, and proverbs and the so-called wisdom compositions. For many centuries after the Old Babylonian period, the study of Sumerian continued in the

Babylonian schools. As late as the 7th century BC, Ashurbanipal, one of the last rulers of Assyria, boasted of being able to read the difficult Sumerian language, and from an even later period, in Hellenistic times, there are some cuneiform tablets that show Sumerian words transcribed in Greek letters.

Rediscovery. Around the time of Christ, all knowledge of the Sumerian language disappeared along with that of cuneiform writing, and in the succeeding centuries even the name Sumer vanished from memory.

Unlike Assyria, Babylonia, and Egypt, whose histories and traditions are amply documented in biblical and classical sources, there was nothing to be found in non-Mesopotamian sources to make one even suspect the existence of the Sumerians in antiquity, let alone fully appreciate their important role in the history of early civilizations.

Decipherment of Sumerian cuneiform

When the decipherment of cuneiform writing was achieved in the early decades of the 19th century, three languages written in cuneiform were discovered: Semitic Babylonian, Indo-European Persian, and Elamite, of unknown linguistic affiliation. Only after the texts written in Babylonian had become better understood did scholars become aware of the existence of texts written in a language different from Babylonian. When the new language was discovered it was variously designated as Scythian, or even Akkadian (that is, by the very name now given to the Semitic language spoken in Babylonia and Assyria). It was only after knowledge of the new language had grown that it was given the correct name of Sumerian.

Characteristics. The linguistic affinity of Sumerian has not yet been successfully established. Ural-Altaic (which includes Turkish), Dravidian, Brahui, Bantu, and many

other groups of languages have been compared with Sumerian, but no theory has gained common acceptance. Sumerian is clearly an agglutinative language in that it preserves the word root intact while expressing various grammatical changes by adding on prefixes, infixes, and suffixes. The difference between nouns and verbs, as it exists in the Indo-European or Semitic languages, is unknown to Sumerian. The word *dug* alone means both "speech" and "to speak" in Sumerian, the difference between the noun and the verb being indicated by the syntax and by different affixes.

The distinctive sounds (phonemes) of Sumerian consisted of four vowels, *a, i, e, u,* and 16 consonants, *b, d, g, ŋ, h, k, l, m, n, p, r, s, ś, š, t, z.* In Classical Sumerian, the contrast between the consonants *b, d, g, z* and *p, t, k, s* was not between voiced (with vibrating vocal cords) and voiceless consonants (without vibrating vocal cords) but between consonants that were indifferent as to voice and those that were aspirated (pronounced with an accompanying audible puff of breath). The semivowels *y* and *w* functioned as vocalic glides.

In the noun, gender was not expressed. Plural number was indicated either by the suffixes *-me* (or *-me* + *esh*), *-hia,* and *-ene,* or by reduplication, as in *kur* + *kur* "mountains." The relational forms of the noun, corresponding approximately to the cases of the Latin declension, include: *-e* for the subject (nominative), *-a(k)* "of" (genitive), *-ra* and *-sh(e)* "to," "for" (dative), *-a* "in" (locative), *-ta* "from" (ablative), *-da* "with" (commitative).

The Sumerian verb

The Sumerian verb, with its concatenation of various prefixes, infixes, and suffixes, presents a very complicated picture. The elements connected with the verb follow a rigid order: modal elements, tempo elements, relational elements, causative elements, object elements, verbal root, subject elements, and intransitive present–future elements. In the preterite transitive active form, the order of object and subject elements is reversed. The verb can distinguish, in addition to person and number, transitivity and intransitivity, active and passive voice, and two tenses, present–future and preterite.

Several Sumerian dialects are known. Of these the most important are *eme-gir,* the official dialect of Sumerian, and *eme-SAL,* the dialect used often in the composition of hymns and incantations (see also WRITING, FORMS OF).

BIBLIOGRAPHY. ARNO POEBEL, *Grundzüge der sumerischen Grammatik* (1923), partly out of date, but still the only full grammar of Sumerian in all its stages; ADAM FALKENSTEIN, *Grammatik der Sprache Gudeas von Lagaš,* 2 vol. (1949–50), a very thorough grammar of the New Sumerian dialect, and *Das Sumerische* (1959), a very brief, but comprehensive survey of the Sumerian language; CYRIL J. GADD, *Sumerian Reading Book* (1924), outdated, but the only grammatical tool in English; SAMUEL N. KRAMER, *The Sumerians* (1963), provides a general introduction to Sumerian civilization. There is no vocabulary, not even a glossary, of Sumerian; only sign lists exist, such as ANTON DEIMEL, *Šumerisches Lexikon,* vol. 1, 3rd ed. (1947) and vol. 2–4 (1928–50).

(I.J.G.)

Sun

The dominant body of the solar system, the Sun is Earth's nearest star, eight light-minutes (93,000,000 miles) away from it. It is a typical star, approximately midway between the largest and the smallest, the brightest and the faintest stars known. On the basis of its temperature and radius (see below) it is called a G1 type dwarf star.

The Sun's energy comes from the conversion of hydrogen to helium at a temperature of about 15,000,000 degrees Kelvin (27,000,000° F), deep in its core where pressures are many thousand million (10^9) times that of the Earth's atmosphere at sea level and the density is 150 times that of water. The energy released in the core by nuclear processes slowly works its way to the surface, where it is radiated into space. The enormous energy output, of which the Earth intercepts only one part in 2,200,000,000, has been sufficiently constant over geologic time scales of hundreds of millions of years for complex life-forms, governed by cycles of day and night, by seasons, or by tides, to develop.

The visible surface of the Sun is the photosphere (Figure 1, top). Above it a layer 5,000 kilometres (3,100

miles) thick constitutes the inner atmosphere, or chromosphere, while above this lies the exceedingly tenuous high-temperature corona, which extends to the Earth and beyond. The Sun has a magnetic field; it rotates; it generates energy in its core. The outflow of energy from the deep interior through the surface, and the surface manifestations of the magnetic field and solar rotation combine to make a complex and fascinating picture of solar phenomena that can be observed in great detail. Their study constitutes modern solar astronomy.

The Sun's distance, defined as the semi-major axis of the Earth's orbit, the average of its greatest and least distances from Earth, is the astronomical unit, adopted by the International Astronomical Union as 149,600,000 kilometres, or 92,957,000 miles. Because the Earth's orbit is elliptical, its distance from the Sun varies during the year. It is closest to the Earth on January 3 when it is 147,103,000 kilometres (91,410,000 miles) and farthest from the Earth on July 4 when it is 152,106,000 kilometres (94,519,000 miles).

History of solar observations

For centuries the Sun was worshipped as a deity and was, therefore, not often the subject of physical study. Anaxagoras, the 5th-century-BC philosopher of Athens, supposed a great meteorite, which fell at Aegospotami in the daytime about 467 BC, to have come from the Sun, and he concluded that the Sun was a mass of red-hot iron larger than the Peloponnesus. With the invention of the telescope, Galileo Galilei, Johannes Fabricius, Christoph Scheiner, and Thomas Harriot almost simultaneously (1610–11) discovered sunspots (Figure 1), but it was the genius of Galileo that recognized their true nature as solar phenomena. Two centuries later, a German amateur astronomer, Samuel Heinrich Schwabe (1843), having diligently observed the Sun for 33 years, announced that the average number of spots varies cyclically with a period of about ten years. In 1852 the cyclic period was found to be 11.2 years and the possibility of there being still another period of 80 years was recognized. In 1858 it was noted that the sunspots of a new cycle appear at latitudes of ±30° and, as the cycle progresses, the spots break out closer to the Sun's equator so that the last spots of the cycle appear at about ±8°.

Table 1: Data for the Sun

Distance	149,600,000 km 92,957,000 mi
Mean angular diameter	31′59.3″
Diameter	1,392,000 km (864,950 mi) (109.3 times the Earth's diameter)
Surface area	6.087×10^{12} km² (2.35×10^{12} sq mi) (12,000 times the Earth's area)
Volume	1.412×10^{18} km³ (3.387×10^{17} cu mi) (1,306,000 times the Earth's volume)
Mass	1.99×10^{30} kilograms (2.19×10^{27} tons) (333,400 times the Earth's mass)
Mean density	1.41, *i.e.*, less than 1½ times that of water
Escape velocity to infinity from the Sun's surface	618 km per sec (384 mi per second)
Effective temperature	5,740° K
Total energy output	3.86×10^{33} ergs per second
Radiation from the Sun's surface	6.35×10^{10} ergs/cm²/sec
Brightness at the centre of the disk	8.23×10^{5} lamberts
Candlepower	3.17×10^{27} candles
Light flux	141,400 lux, at the Earth's mean distance, outside the atmosphere 103,000 lux, the average illumination from the Sun at the zenith
Period of rotation	
Equator	26.9 days (synodical)
Sunspot zone (16° N)	27.3 days (synodical)
Pole	31.1 days (synodical)
The Sun's interior	
Density	150 gm/cm³
Temperature	15,000,000° K*
Pressure	4×10^{17} dynes/cm² (4×10^{11} atmospheres)
The Sun as a star	
Spectral type	G1
Colour index	Mpg-Mpv = +0.45
Visual magnitude	Mpv = −26.86
Absolute visual magnitude	Mpv = +4.71
Velocity in space relative to nearby stars	19.4 km per sec in the direction of Lyra (Vega). The motion of the local stars of which the Sun is a member is about the galactic centre with a velocity of 220 km per sec

*Different calculations give results from 13,000,000°–25,000,000°.

A German mathematician and astronomer, Carl Friedrich Gauss, established the first magnetic observatory in 1834 at Göttingen. Others soon followed. Small daily magnetic changes were shown to be related to the sunspot cycle in 1857. In 1904 intense magnetic storms were found to be associated with the passage of large sunspot groups over the central meridian.

Establishment of the first magnetic observatory

Many important advances in solar astronomy have resulted from the construction of new telescopes and ancillary instrumentation of great sophistication. The physical and chemical nature of sunspots became known only after the development of the spectroscope. In 1870 dark bands were discovered in the spectrum of light radiated from sunspots, indicating the presence of molecular compounds; furthermore, it was postulated that the widening and splitting of some lines and the complete reversal of some dark lines to bright ones were caused by gaseous eruptions in the neighbourhood of sunspots—now called flares. The outflow of gases from the cooler dark centre of the spot (the umbra) to the edge of the penumbra, or outer part, at a speed of two kilometres per second (somewhat greater than one mile per second) was discovered spectroscopically in 1909. A reverse flow, inward, toward the centre of the spot, for the gases at the highest levels of the atmosphere above it, was found in 1913. The invention of the spectroheliograph by the U.S. astronomer George Ellery Hale in 1891 made possible the examination of the Sun in hydrogen light, calcium light, and the light radiated by ions or atoms of other elements, bringing out a wealth of detail in the chromosphere. In 1908 Hale looked for splitting and polarization of some atomic lines (the Zeeman effect) in spot spectra, but it required the large solar tower telescopes and pit spectrograph designed and constructed by Hale at Mount Wilson Observatory, California, now part of the Hale Observatories, to prove the magnetic character of sunspots. Between 1914 and 1924 Hale developed the laws of alternating sunspot polarity (see below). Although he also attempted to measure the Sun's general magnetic field, reliable measures were achieved only after the invention of the photoelectric magnetograph in 1948.

Joseph von Fraunhofer, a German physicist with greatly improved spectroscopes of his own construction, had visually found and mapped many (574) dark lines in the solar spectrum; to the strongest of these he assigned letters—*e.g.*, A, a, B, C, D—that are still used to identify the lines. The physical significance of the dark lines was explained by another German physicist, Gustav Robert Kirchhoff, in 1859. Kirchhoff conceived the idea of a hot Sun surrounded by cooler layers of vapour, which he called the reversing layers, in which the dark lines were supposed to have been formed. By comparison of laboratory spectra with the solar spectrum, the presence of eight elements in the Sun was later established. Henry Augustus Rowland, a U.S. physicist, published in 1897 a 40-foot photographic map of the solar spectrum that was of the highest quality and that allowed for the presence of 39 chemical elements in the Sun. Rowland's map extended to the ultraviolet limit caused by terrestrial ozone. This limit has only recently been surpassed by observations from space; now the spectrum has been mapped from the visible to less than one angstrom (10^{-10} metre). Toward red, the solar spectrum was recorded to 53,000 angstroms in 1888. Today, with new detectors, the limit is set only by terrestrial water vapour bands that obscure the infrared spectrum beyond 25 micrometres (25×10^{-6} metre). The complete spectrum can be observed only from very high altitudes, above the water-vapour absorption and the ozone absorption.

Attempts to measure the temperature of the Sun

The determination of the Sun's temperature has been one of the most difficult problems in solar astronomy. The English astronomer Sir John Herschel at the Cape of Good Hope and Claude-Servais-Mathias Pouillet in France (1837) observed that the vertical rays of the Sun, if totally absorbed, would raise the temperature of a layer of water 1.8 centimetres deep by 1° C per minute. The

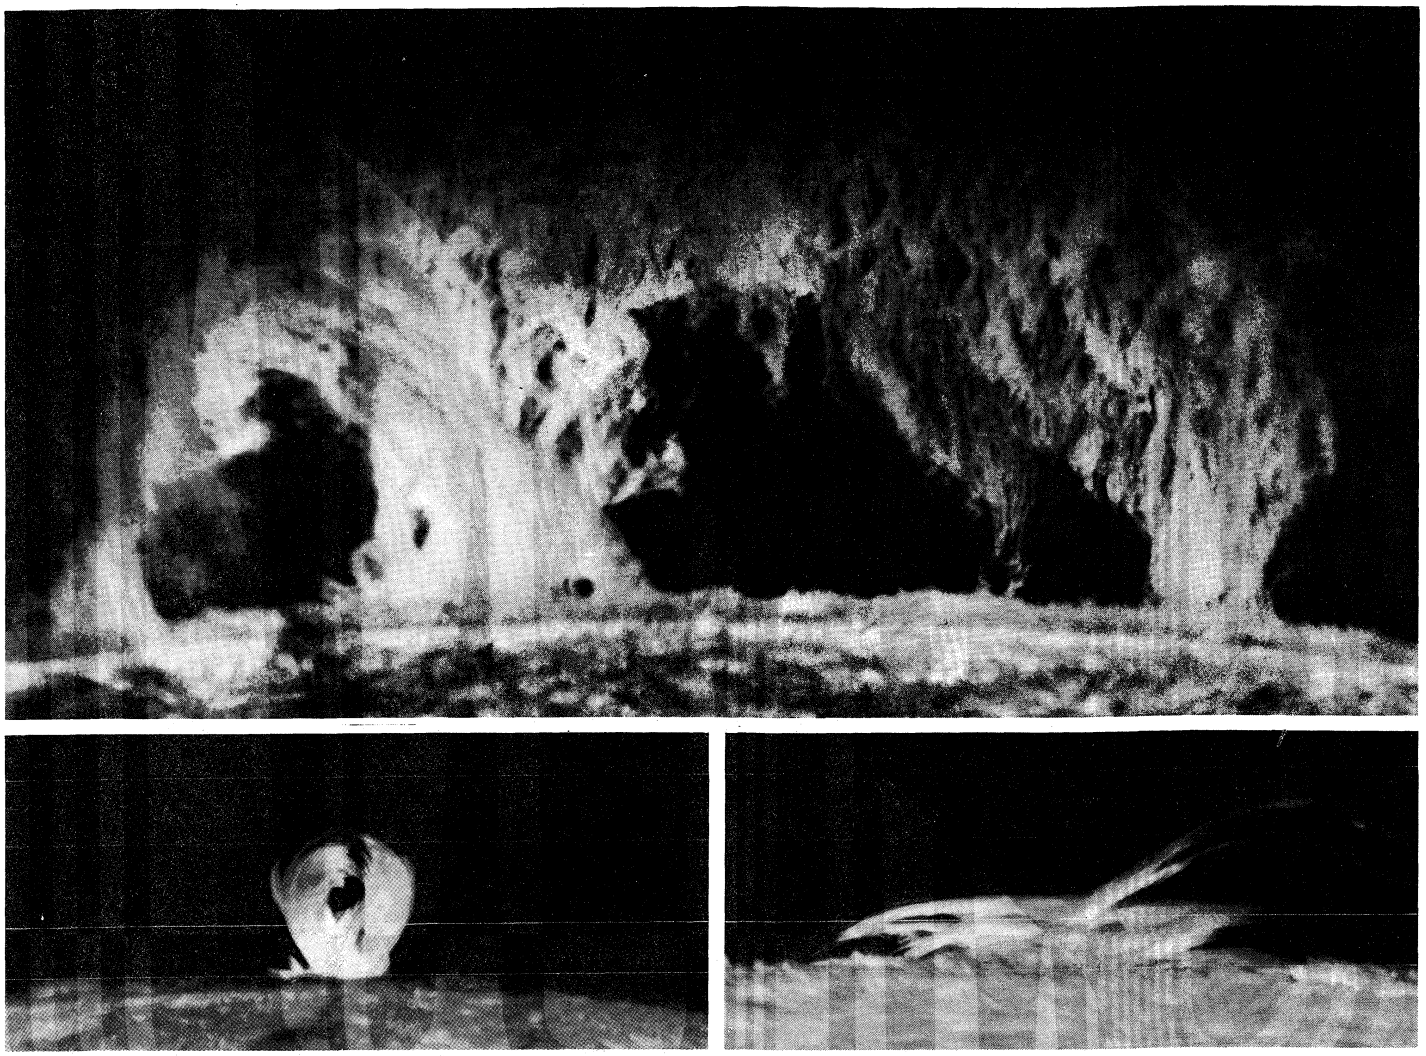

Figure 2: Solar prominences showing streamers, arches, loops, and other phenomena in the light of hydrogen (H-alpha). (Top) March 11, 1971. (Left) August 3, 1970. (Right) September 23, 1971.
By courtesy of Hale Observatories

measurement is in principle easy, but atmospheric absorption has been the uncertain factor. The problem was solved in 1881 and again in 1904, when it was shown that extrapolations must be made for solar radiation of different wavelengths, to determine what the intensity of each would be if there were no intervening air; and the values for all wavelengths must then be summed. A value of 1.96 calories per square centimetre per minute was obtained for the solar constant (the flux of total radiation received outside the Earth's atmosphere per unit area at mean Earth–Sun distance), that only recently has been improved by observations from balloons and high-flying aircraft. Early estimates of the Sun's temperature ranged from 1,461° C (2,660° F) to 10,000,000° C (18,000,000° F). Transforming the solar constant into the energy radiated by the Sun and thence into its effective temperature was impossible until the law that connects the temperature of a surface with the amount of heat radiated per second—the Stefan-Boltzmann law—was established about 1880.

The Moon, with its opaque disk of almost exactly the same apparent size as the Sun, and with a sharply defined edge, has been valuable to the solar astronomer at times of solar eclipse. In the Middle Ages, prominences on the Sun (see Figure 2) that became visible during eclipses were thought to be part of the Moon's atmosphere, mirages, clouds, or holes in the Moon. During an eclipse of July 1860, which crossed Spain, prominences were successfully photographed, and, by observing the motion of the Moon across them, it was demonstrated that these were solar. During an eclipse of August 1868, observers in India and in England, struck by the brilliance of the prominences, independently showed that they might be seen in broad daylight simply by opening the slit of a spectroscope and aiming it just outside the brilliant disk of the Sun's photosphere. The invention (1930) of the coronagraph made it possible for the first time to study the corona without an eclipse from high-altitude stations and on a nearly continuous basis. With a modified instrument, the K-coronameter (1950), which uses photoelectric detection, it became possible to view the corona through hazy skies at sea level, and measurements at very clear sites were greatly extended, to large distances from the limb of the Sun.

The mysterious coronal spectrum—at first attributed to the mythical element coronium—was discovered in 1941 to be made up of the so-called forbidden lines of highly ionized atoms of iron, nickel, and other elements. The lines are described as forbidden because they are almost impossible to produce in the laboratory.

Detection of radio waves

Radio waves from the Sun were first detected in 1942 on British radar sets. It was suggested that the bursts of radio energy were associated with an active sunspot visible on the surface of the Sun and, in particular, with the large solar flare of February 28. In the same year, a weak background radio emission, or noise, was detected from the "quiet" Sun; *i.e.*, the Sun observed when sunspots and related phenomena are at a minimum. The science of radio astronomy has since become a large and important field of solar research.

The modern concept of energy generation in the Sun's interior follows from Sir Arthur Stanley Eddington's suggestion that only through nuclear processes could sufficient energy be produced to have sustained the output of energy from the Sun throughout the known lifetime of the solar system. More details were provided in 1937 and 1938 when the energy production from nuclear reactions, capable of transforming hydrogen to helium, were calculated. Later experimental and theoretical work has given improved values for all the reactions considered possible for energy production.

The quiet Sun

PHOTOSPHERE

The visible luminous surface of the Sun is the photosphere or light sphere. When carefully examined through a telescope, it is seen to have a mottled appearance called granulation (Figure 3); the most conspicuous objects to be seen, however, are sunspots which form and dissipate and partake in the solar rotation. The photosphere radiates most of the Sun's energy; it comprises a thin but rather opaque layer approximately 400 kilometres (290 miles) thick, the temperature of which varies from 10,000° K (about 18,000° F) at the bottom to 4,200° K (about 7,560° F) at the top. A typical density in the photosphere is around 10^{-8} gram per cubic centimetre, about $\frac{1}{1,000}$ that of air at sea level.

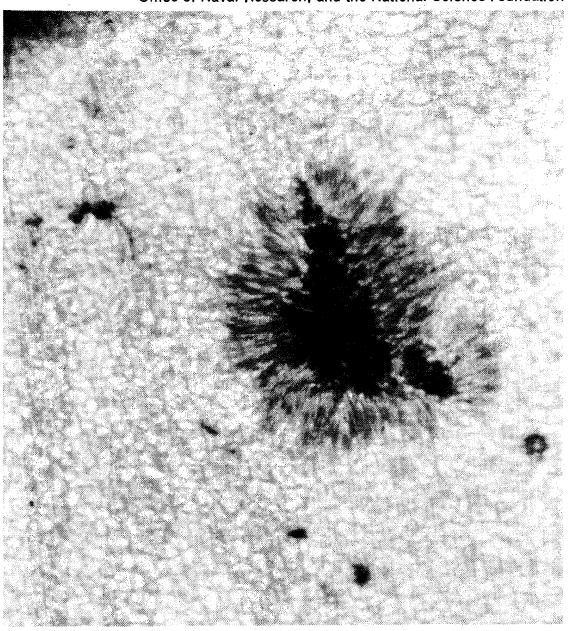

Figure 3: Granulation on the Sun showing a sunspot (centre right), which appears dark by contrast with the hotter regions surrounding it.

Granulation. About 4,000,000 granules, each one the top of a hot cloud of gas, cover the surface of the Sun. Because of their small size—300 to 1,450 kilometres, or 190–900 miles—they can be seen and photographed from the ground only when the Earth's atmosphere is steady and free of turbulence. Excellent photographs have been made with telescopes carried by balloons to heights of 20 kilometres—about 12 miles. The best of these show that granules are irregular, often polygonal, and that each is surrounded by a narrow, relatively dark, lane. They last about seven to ten minutes. A typical bright granule starts as a small grain the diameter of which grows to about 1,500 kilometres (930 miles) before it divides into several parts that spread and fade. Each granule rises with a speed of about 0.5 kilometre (about 0.3 mile) per second; as the energy radiates, the gas cools and descends rapidly in the dark intergranular lanes. A remarkable five-minute vertical oscillating motion of the granules was discovered in 1962. It has also been observed that after a bright granule forms, its upward movement sets the chromosphere into oscillation, which then continues for three to five periods after the disappearance of the exciting granule.

Limb darkening. The limb of the Sun (the visible edge) appears darker than the centre. The direct view downwards at the centre of the solar disk penetrates, on the average, into deeper, hotter layers of the photosphere; at the limb the higher, cooler layers are seen. Limb darkening (which exists for all stars) is due solely to a temperature gradient in the atmosphere, the deeper layers being hotter. Conversely, measures of the limb darkening lead to a determination of the temperature distribution with depth.

The Sun's temperature. The Sun emits energy over all wavelengths, from X-rays to radio waves. Approximately 40 percent of the emitted energy is in the visible portion of the spectrum, 50 percent is in the infrared, and the remainder is in the ultraviolet. Radiation escaping from the Sun's surface into space comes from different depths of the Sun's atmosphere, each with a different temperature. The boundary temperature is about 4,200° K (about 7,000° F), but the eye can see to depths where the temperature is 10,000° K; the Sun has, however, a well-defined effective temperature, namely, that of an equal sphere radiating a like amount of total energy in accordance with physical (blackbody) radiation laws. From the total energy radiated a temperature of about 5,700° K, roughly 10,000° F (see STAR) is found. Different (colour) temperatures are derived from different spectral regions. A colour temperature of 6,000° K (11,000° F) fits the whole visible spectrum reasonably well.

Solar energy

It is not easy to describe the enormous output of solar energy. If the Sun were enveloped in a shell of ice 40 feet thick, it would thaw its way out in one minute of time. If an ice bridge two miles in diameter could be built, spanning the immense distance of 93,000,000 miles from Sun to Earth, and, if by some means, the whole of the Sun's radiation could be concentrated upon this ice bridge, in one second it would be water and in seven seconds more it would be dissipated into vapour. Though the energy received at the Earth's surface amounts to over 4,000,000 horsepower per square mile, to harness it effectively is difficult. To achieve high temperatures requires concentrators or large parabolic collectors, such as those used in solar furnaces. Except for the very specialized experimental usage in heating homes, in cooking, in solar furnaces and solar-heat engines, which are subject to the variations of the weather and to day and night alternation of temperature, the present economic picture is not particularly favourable to the general utilization of solar energy.

The Sun's rotation and sphericity. Galileo gave the first proof of the Sun's rotation and shape. He noted the Sun's roundness and saw that the apparent motion of sunspots in parallel lines with diminished movement at the limbs could be explained if the spots were on the surface of a sphere rotating from east to west. Modern spectrographic observations of the Doppler shift (a change of wavelength with motion toward or away from the observer) of Fraunhofer lines show that the equator is rotating faster than the poles. Unlike some stars, which rotate rapidly and are strongly flattened oblate spheroids, the Sun is a slow rotator and is so nearly spherical that it is uncertain whether any flattening can be detected. A polar diameter 70 kilometres less than the equatorial diameter has been suggested by some observations. The ellipticity of the Sun has been of interest to scientists because the gravitational field of a nonspherical body affects planetary orbits in a way different from that of a sphere. It has been suggested that part of the perihelion advance (a gradual rotation of the point closest to the Sun, which is otherwise very satisfactorily explained by the theory of of relativity) of Mercury's orbit could be explained in this manner.

The Fraunhofer spectrum. The solar spectrum, within the wavelength interval 2950–10,000 angstroms, shows about 25,000 so-called Fraunhofer dark lines (see above *History of solar observations* and Figure 1, centre). The

identification of elements in the Sun is still carried out by the classical method comparing the solar lines with lines observed in the laboratory for both wavelength and intensity. Care must be taken to distinguish between solar lines and lines produced by water vapour, oxygen, and other constituents of the Earth's atmosphere.

Element identification

About 73 percent of the lines have been identified; 63 elements and 11 molecules are recorded. Iron contributes the greatest number (5,458) of identified lines. There are 1,453 lines from chromium, 1,344 from titanium, 856 from nickel, 388 from zirconium, 1,572 from solar cyanogen, and 1,477 from terrestrial water. For many elements, however, only a few lines are observed, for example: two from beryllium, two from silver, six from platinum, one from gold. The majority of the unidentified lines are faint and probably due to molecules and to the faint lines of the abundant elements in the Sun.

Modern techniques of spectrum analysis make use of the most powerful spectrographs that can be built. This makes it possible to study each spectrum line in detail for position, shape, depth and width.

A Fraunhofer line has considerable width because of the turbulent motions of the solar gases and collisions caused by neighbouring atoms. The resulting line profile, measuring the intensity against wavelength (or frequency), is that of an inverted bell-shaped curve near the line centre with broad, shallow wings, which, for strong lines, may extend many angstroms from the line centre.

The Fraunhofer spectrum has been extended to include lines in the far ultraviolet from rocket observations above the Earth's atmosphere. Within the far ultraviolet region, in the interval 3000–2097 angstroms, 7,146 lines are observed. Below 2100 angstroms, the intensity of the spectrum drops and by 1500 angstroms the radiation comes from the chromosphere and the absorption spectrum has turned into an emission spectrum. This emission spectrum contains the strong resonance lines of the elements first identified from weaker subordinate lines in the visible spectrum. Also, higher stages of ionization for a given element are observed in the far ultraviolet emission spectrum.

The Sun's infrared spectrum is dissected by numerous terrestrial water vapour absorption bands. Thus, at ground level the solar spectrum must be observed in the "windows" between the bands. To observe the entire infrared spectrum of the Sun, it is necessary to use a vehicle such as a high-flying aircraft, a stratospheric balloon, or a space vehicle that can carry the infrared spectrometer above all, or most of, the Earth's absorbing atmosphere. In the wavelength interval 11,984–25,578 angstroms, 1,786 solar lines and 6,911 telluric lines—*i.e.*, lines caused by substances in Earth's atmosphere—have been listed. Silicon, iron, carbon, carbon monoxide, and titanium contribute most of the solar lines, while water vapour, carbon dioxide, methane, and isotopic bands of these molecules make up most of the telluric lines.

The chemical composition of the Sun. The proportions (abundances) of the elements in the Sun can be determined directly only for the surface layers, the so-called solar atmosphere. In the interior, the abundances of the elements may be different because the elements are transformed there at different rates by nuclear reactions. The chemical composition of the solar atmosphere is thought to be representative of the composition of the Sun at the time of its formation, before such alterations occurred. This initial composition is relevant to the study of the evolution of the Sun and the stars. The chemical composition of the solar atmosphere can be determined in various ways, which depend on the types of observation available.

Solar cosmic rays are emitted from active regions of the Sun. Abundances of the following light elements have been derived from analysis of solar cosmic rays: helium, beryllium jointly with boron, carbon, nitrogen, oxygen, fluorine, and neon. Since the heavier elements are difficult to separate by nuclear counting methods, their abundances are generally given for groups, such as phosphorus to scandium and titanium to nickel.

Abundances derived from observations of the solar emission lines that originate in the higher chromosphere and the corona are called coronal abundances. The coronal-emission spectrum may be analyzed in two different ways, depending on whether the observations were secured on the disk or above the limb of the Sun. The far-ultraviolet-emission lines observed on the disk of the Sun are produced by atoms in many different stages of ionization. Analyses have been carried out for the more abundant atoms, such as helium, carbon, nitrogen, oxygen, neon, sodium, magnesium, aluminum, silicon, phosphorus, sulfur, calcium, and iron. The emission lines in the interval 3000–10,000 angstroms seen above the solar limb are a result of "forbidden" electron transitions within atoms; *i.e.*, transition almost impossible to obtain on Earth. Since the forbidden emission lines originate in the corona, and are thus extremely weak compared to the radiation from the body of the Sun, they can only be observed at the time of a total solar eclipse or by means of a coronagraph. The known forbidden emission lines are due to argon and calcium, and to atoms of the iron group, such as chromium, manganese, iron, cobalt, and nickel, all of them being highly ionized.

The most commonly used method of determining the abundance of elements in the solar atmosphere makes use of the solar absorption (Fraunhofer) spectrum, which extends from the near ultraviolet, through the visible, into the infrared wavelength regions. The majority of Fraunhofer lines are formed in the lowest layers of the solar atmosphere, that is, the photosphere and low chromosphere. The abundances derived from these lines are called photospheric abundances.

Photospheric abundances

The determination of photospheric abundances is based on a measurement of the intensity of the lines. With modern instruments a solar spectrum line can be recorded at very high resolution (Figure 4) and, consequently, the intensity distribution in the line (the line profile) can be obtained with very good precision. The line profile and the measurement of the total intensity absorbed by each line depend not only on the abundance and physical characteristics of the particular atom (or molecule) producing the line but also on the physical conditions (temperature, density) that prevail in the layers of line formation. Thus, in an analysis of the solar spectrum, both the physical state of the solar atmosphere and its chemical composition are determined at once.

In Table 2 the results of abundance determinations for the photospheric and the coronal abundances, both as determined in 1968, are shown. For the elements lithium,

beryllium, boron, iron, lead, bismuth, thorium and uranium, more recent and more accurate photospheric abundance results are given here. The differences between photospheric and coronal abundances of certain elements are essentially due to the uncertainties in the abundance determinations, both from the Fraunhofer spectrum and the emission spectrum.

From Table 2 it can be seen that only a minute portion of the solar gas is made up of elements heavier than helium, that about 15 percent is helium, and that the bulk of the solar gas is constituted of hydrogen.

CHROMOSPHERE

The relatively transparent chromospheric layers form a complex transition zone about 5,000 kilometres, or 3,000 miles, thick between the low-temperature photosphere and the high-temperature corona. The chromosphere temperature increases outward from about 4,500° K (about 8,000° F) to 1,000,000° K (1,800,000° F), whereas the density decreases rather rapidly from about 10^{12} particles per cubic centimetre at the base to about 10^{9} particles per cubic centimetre at the top. The chromosphere is a region of great activity, visible at the time of a solar eclipse as a bright-coloured arc from which the "flash spectrum" originates. The low chromosphere is a

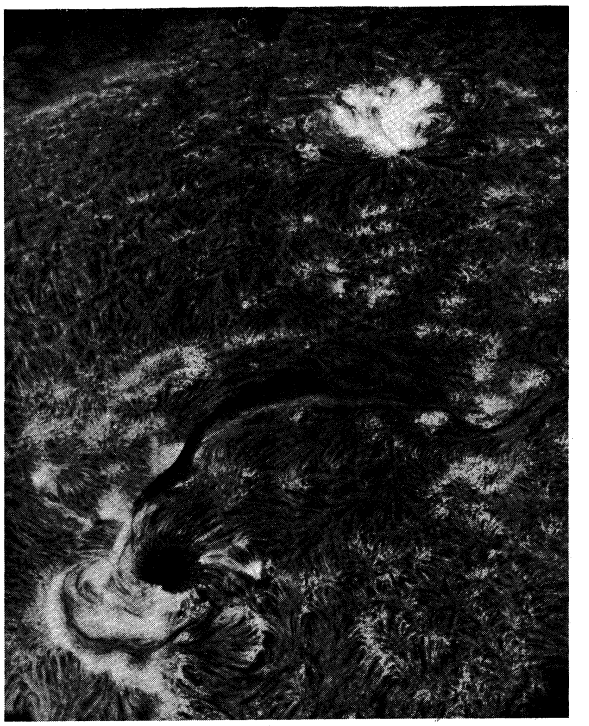

Figure 5: High-resolution photograph of sunspot in hydrogen (H-alpha) light shows bright plages and dark filamentary structures (prominences) on the Sun.

relatively homogeneous layer of gas, about 1,500 kilometres thick, from which emerges, geyser-like, a multitude of upward-moving jets called spicules. At about 8,000 kilometres the spicules stand apart as separate entities and it is thought that the hot coronal gas reaches down between them. The chromospheric gas is quite transparent to continuous radiation but opaque to light in the cores of strong Fraunhofer lines. As a result, if the Sun is viewed in the monochromatic light of a Fraunhofer line, its substance is visible. By selecting lines of different strengths the astronomer can choose the depth of observation; thus, the chromospheric layers can be figuratively peeled like an onion. Through equipment capable of isolating a spectrum line a fraction of an angstrom in width, the Sun presents a picture of fine and coarse structures (Figure 5). Much of the fine structure visible in the cores of metal lines is due to Doppler displacements from ascending and descending volumes of gas. The periodic character of this motion has been discussed in the section on granulation above. Photographs that are taken in the light of one particular wavelength, called the hydrogen-alpha line, show a very coarse mottling, which near the sunspots becomes more or less organized into filamentary whorls.

Flash spectrum. During a total solar eclipse there is a moment when the photosphere is just hidden by the

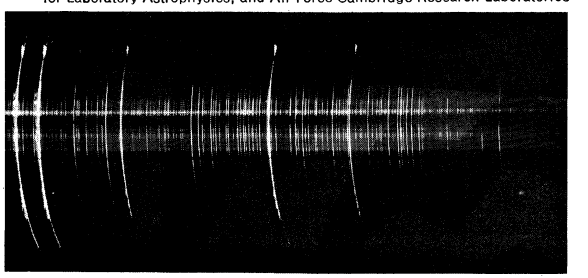

Figure 6: Flash spectrum of the Sun in ultraviolet light. The two bright spectral lines at left, showing prominence structure, are the H and K lines of ionized calcium. The bright line in the centre is a line of ionized titanium at 3685Å. Frequency increases from left to right, wavelength from right to left. Obtained at the solar eclipse of February 1962 in New Guinea.

Moon, leaving exposed the chromospheric layers, which appear as a thin, orange-red crescent along the edge of the Moon. The light from this crescent is found to have a bright-line spectrum, which, for a few seconds, "flashes" in and out of view as the Moon moves across the Sun's atmosphere, hence the name "flash spectrum" (Figure 6). The brightest lines and those which extend to the greatest heights are lines of hydrogen, helium, and calcium; when examined in detail the spectrum is nearly, but not quite, identical with the Fraunhofer spectrum, the differences reflecting the different physical state of the photospheric and chromospheric layers. Lower pressures and higher temperatures favour greater ionization and excitation. Characteristic flash spectra show an enhancement of high-excitation lines and the appearance of a great number of lines from singly ionized iron, titanium, nickel, chromium, and the rare earths.

Spicules. A 19th-century Italian astronomer, Angelo Secchi, described the chromospheric layers viewed at the limb as like a burning prairie. He had seen through his spectroscope a forest of superimposed jets, "the spicules," each lasting only a few minutes. Spicules appear as tiny, bright surges, less than 500 kilometres (300 miles) in diameter, moving upward with velocities of 20–30 kilometres per second to heights of 8,000 kilometres above the photospheric layers. They are often grouped in rosettes or brushlike shapes. They number about 100,000 and have an average lifetime of five to 15 minutes. On the basis of spectroscopic and radio studies, a spicule column is believed to have temperatures of 10,000° K (18,000° F) in the core and 50,000° K on the surface. The denser core material emits lines of calcium and hydrogen and radio waves of millimetre and centimetre wavelengths. The hot sheath is the source of the far-ultraviolet emission of highly ionized atoms and of the lines of neutral and singly ionized helium.

Supergranulation. Spectroheliograms made, for example, with calcium light show a coarse pattern in addition to smaller mottles, which are due to a network of cells about 30,000 kilometres in diameter called supergranules. In these cells an expansion of material takes place from centre to edge with a speed of about ½ kilometre per second. These supergranules, which number about 5,000 at any time, have been identified as deep convection cells with a lifetime comparable to a day. It is observed that the flow of material from centre to edge tends to collect the majority of spicules on the cell boundaries and to sweep up the magnetic field domains so that the cellular pattern is visible on magnetic maps as well as on spectroheliograms.

CORONA

The corona is a luminous, high-temperature, rarefied gas envelope of the Sun. Close to the Sun it is about $\frac{1}{1,000,000}$ as bright as the solar disk. Its brightness decreases rapidly with distance, so that at two solar radii the brightness is less than one percent of that of its innermost parts; hence, the feeble light is visible only at the time of a total eclipse or through a coronograph. The corona has a kinetic temperature of about 2,000,000° K (about 3,600,000° F) out to several solar radii. Because of its high temperature it evaporates continuously, producing an outward flow of electrically charged particles called the solar wind, which extends beyond the vicinity of the Earth. The highly ionized coronal gas has a density of the order of 5×10^8 atoms per cubic centimetre at its base; the density decreases with height, diminishing by a factor of 2.7 approximately every 50,000 kilometres (30,000 miles).

Form and structure. The corona owes its beauty to its form, which is made up of streamers, filaments and rays of pearly white light. Polar plumes, fanning out like iron filings about the poles of a magnet, suggest north and south magnetic poles for the Sun. At sunspot maximum the corona is globular in form with streamers in all directions, while the minimum phase is characterized by polar plumes and long equatorial streamers extending outward many solar radii.

Corona light has three components: the so-called *L*-, *K*-, and *F*-coronas. The *L*-corona, which contributes only about 1 percent of the coronal light, refers to the line spectrum emitted by the highly ionized atoms of the coronal gas, which in such a state is called a plasma. The light of the *K*-corona is caused by scattering of photospheric light by fast-moving free electrons near the Sun. The *K*-component is strongest in the inner corona where the electron density is highest. Since the electrons move at very great speeds (of the order of 6,000 kilometres per second), the photospheric Fraunhofer lines are here completely washed out by the scattering process and, consequently, the *K*-component reveals a continuous spectrum only. The *F*-component is caused by diffracted photospheric light from interplanetary dust particles. Its spectrum is that of the photosphere; *i.e.*, a continuous spectrum intersected by the Fraunhofer lines. The *F*-component is an extension of the zodiacal light into the region close to the Sun. The *L*-component and the *K*-component represent the true corona.

The *F*-, *K*-, and *L*-coronas

The corona may also be studied on radio heliograms, and on X-ray pictures made from above the Earth's atmosphere. The solar radio emission at wavelengths greater than one metre originates in the corona, and at the other end of the electromagnetic spectrum, any wavelength shorter than 200 angstroms can be emitted only by the corona. X-ray pictures show the regions of strongest coronal condensation. Comparison of observations over different parts of the electromagnetic spectrum show that the corona is very inhomogeneous and that its form, structure, and intensity change considerably with the level of activity on the surface of the Sun.

The quiet Sun emits radio waves. At metre wavelengths the emission comes from great heights where the electron density is less than 3×10^7 electrons per cubic centimetre—half a solar radius from the photosphere. At ten metres, the corresponding height is ten solar radii. Thus, the corona can be examined by the radio astronomer, layer by layer, in different radio wavelengths, just as the optical astronomer examines the chromosphere, layer by layer, with the spectroheliograph.

Physical properties. The most remarkable property of the corona is its high kinetic temperature, 1,500,000 to 2,500,000° K. This follows from many types of observation: (1) The coronal spectrum was shown in 1941 to be emitted by atoms of iron, nickel, calcium, and argon that had lost ten to 14 electrons. Such a degree of ionization can come about only by collisional ionization by energetic electrons driven by high temperatures in a low-density gas. (2) The coronal emission lines are much broader than the Fraunhofer lines and if this is interpreted as Doppler broadening by random motion of the emitting atoms, a temperature of about 2,000,000° K (3,600,000° F) is indicated. (3) The brightness of the Sun in radio wavelengths longer than 100 centimetres is about 1,000,000° K (1,800,000° F). (4) Finally, the density gradient of the electron gas has been shown to follow an exponential decrease with height and results in a temperature of 1,500,000° K.

It is generally believed that the energy source supplying the heating of the corona lies in the mass motions of granules and spicules in the photosphere and chromosphere. The interaction can take place by direct collision between the atoms of the spicule and those of the corona or by the transfer by shock waves (hydromagnetic, acoustic) of energy from below to the chromosphere and corona.

The solar wind. It was predicted in 1958 that the high temperature of the corona would cause some of it to boil off the Sun, and that the coronal particles would appear in the neighbourhood of the Earth as a solar wind moving with speeds of 300–1,000 kilometres (about 190–600 miles) per second. Though it had been suggested as early as 1951 that the behavior of certain comet tails could be explained by the interaction of a solar plasma from the Sun with the comet, not until satellites explored the space around the Earth was direct proof forthcoming. A space probe from the United States to Venus in 1962 established the wind's existence and showed that there is a steady stream of protons and electrons in the vicinity of

the Earth with a density of about one to ten particles per cubic centimetre and carrying with them an associated magnetic field ranging from two to 40 microgauss. Thus interplanetary space is filled with a fully ionized hot plasma of coronal origin. At solar minimum the average flow into space amounts to 10^{33} particles per second; this mass loss is thought to be supplied from below by the dissipation of spicules.

A changing pattern of active regions covers the surface of the Sun and proceeding from each is a positive or negative magnetic field, which is carried by the plasma. Because of the Sun's rotation and the steady outflow of material, the magnetic field lines trace curves in space—Archimedean spirals in the equatorial plane.

The active Sun

The active Sun is characterized by the growth and decay of magnetic fields together with all the associated phenomena observed at many different levels of the solar atmosphere: sunspots with associated very bright areas called faculae, plages (other bright areas not necessarily associated with sunspots), flares, surges, prominences, coronal condensations, and the emission of radio, X-ray, and cosmic-ray bursts (see Figure 1 and below).

CENTRES OF ACTIVITY

A centre of activity is an area formed by the arrival from below of a localized strong magnetic field at the Sun's surface. Its description includes all of the transient interrelated phenomena listed above. A few centres of activity may live 200 days or more (eight to ten solar rotations); most are short-lived lasting one to two weeks.

Life history of a typical centre of activity

The life history of a typical centre of activity is given below. In the first few days a bipolar magnetic region (one showing both north and south magnetic polarity) develops, without spots, followed later by bright areas known as faculae and coronal extensions projecting from them. The coronagraph shows stable ray and arch structures about 150,000 kilometres long above the region. After two to three days the most important (spot) phase starts with the formation of a small spot and a rapid extension of the fine lineal elements—small prominences—in the neighbourhood of the spot. A second spot forms shortly afterward, followed by the formation of numerous small spots between the larger bipolar pair. A few flares and flare surges take place. After about ten days the group of spots reaches its maximum size. Each spot appears to be embedded in a large, complex penumbral region of converging filaments. Flare activity reaches its maximum along with the associated phenomena of solar radio bursts, enhanced X-ray emission, and, rarely, cosmic rays from super flares. By 27 days—one solar rotation—the activity has decayed and all spots except the preceding spot have disappeared. Flare activity is greatly reduced, but the bright facular areas (extremely bright areas associated with sunspots) continue to increase in size. Next, a stable prominence filament forms on the poleward side of the region, which, after the lapse of 50 days, cuts the facular region in half, separating regions with opposite magnetic polarity. The prominence filament now extends for 100,000 kilometres (about 60,000 miles) and is oriented more or less east and west, drawn out by the Sun's differential rotation. At about the 80th day, the facular area breaks up, but the filament continues to lengthen. After 100 days the faculae have disappeared completely and the prominence filament reaches its maximum length. In the succeeding days it shortens and drifts poleward where it still may have an identity after 150–250 days.

SUNSPOTS

Physical nature. In appearance a sunspot consists of two parts: a dark core, the umbra, surrounded by a filamentary border called the penumbra. Single spots comprise about 40 percent of the total. Normally, they are in complex groups exhibiting great variety of form and shape, often covered with brilliant "bridges," giving the impression of great turmoil. The smallest spots of a group are mere pores without penumbra, a few hundreds of kilometres in diameter, whereas the largest spots exceed by several times the diameter of the Earth. Large spot groups may extend over one-sixth of the diameter of the Sun and are easily visible to the naked eye at sunset when the Sun's intensity is much reduced. At the Sun's limb (visible edge) a large spot may appear as a slight depression in the Sun's surface.

Sunspots are dark only in contrast to the surrounding photosphere, for, in fact, they are brighter and hotter than molten tungsten. From their observed brightness a spot temperature of 3,800° K (6,800° F) is obtained, as compared to 5,700° K for the photosphere. At spot temperatures, a number of chemical compounds are stable. The spectrum lines of many radicals and molecules, cyanogen, carbon monoxide and hydrides of nitrogen, carbon, oxygen, and magnesium, also known in the disk spectrum, strengthen greatly in the spot, indicating increased abundance; also lines of calcium, silicon and fluorine hydrides, and titanium and zirconium oxides show in the spectrum of a sunspot.

Magnetic property of sunspots

The predominant property of sunspots is their intense magnetic field. In general, the larger the spot, the stronger is the magnetic field. A small spot typically has a field of about 500 gauss (a gauss is a unit of magnetic field strength), a large spot, 4,000 gauss. By comparison, Earth's natural magnetic field at the surface is somewhat less than one gauss, and the overall solar magnetic field is now believed to be about the same. In a simple spot the field is nearly axisymmetric; it has its maximum value at the centre of the umbra and decreases to a very small value at the outer edge of the penumbra. On the average, the lines of magnetic force stand vertical to the Sun's surface at the centre of the umbra but diverge outward so that at the edge of the penumbra the direction of the field has an inclination of about 70° to the vertical. An explanation of the relative coolness of sunspots must involve their associated magnetic fields. After the magnetic field is formed the region cools, presumably because convection, bringing energy from below—as exhibited by the surrounding granulation—is stopped. A balance is achieved when the gas pressure, the magnetic pressure, and the mass flow of material in and out of the spot are in equilibrium.

The sunspot cycle. That spots are not always equally numerous on the surface of the Sun is apparent to anyone who examines the Sun telescopically on every clear day. But it was not until 1851 that astronomers were able to find a regular periodicity of about ten years. At sunspot minimum the Sun may remain spotless for weeks; at maximum several large groups containing dozens of spots are generally visible on its surface. Complete records of the Wolf sunspot numbers (named after the Swiss solar astronomer Rudolf Wolf, whose work on the behaviour of sunspots was fundamental) are known for the past 120 years. Monthly means have been established from 1749 and the epochs of maximum and minimum are known from the year 1610.

Sunspot numbers

Because of the wide fluctuations of the daily number of spots, the level of solar activity is generally expressed as a running mean of a month or a year. The average interval between maximum is 11.2 years but is quite variable, ranging from eight to 16 years. The ascent to maximum, which averages 5.2 years, is steeper than the decline. In addition to the 11-year cycle, a low-amplitude 80-year cycle is recognized, though observations have not yet extended over an interval long enough to define the long wave completely. Sunspot numbers show an 11-year period, but the true length of the cycle is 22 years, when account is taken of the alternation of the sign of spot magnetic fields. The leading spot of a bipolar group in the northern hemisphere has a magnetic polarity opposite that of the leader in the southern hemisphere; and the polarity of the leaders reverse at the beginning of each 11-year cycle. Thus, the magnetic period of the Sun is twice the 11-year cycle.

The number of spots in each cycle is quite variable. Attempts have been made to fit the observed numbers by superposition of cycles, but, in general, these have failed to predict succeeding cycles. Others have tried to relate

the sunspot cycle to planetary influence, particularly that of Jupiter, which revolves around the Sun in a period of 11.8 years. Apparently the true cause of sunspots is deeply seated in the Sun itself.

Each new cycle begins with the appearance of a few spots at about ±30° north and south latitude. Four years later in the cycle, at sunspot maximum, the zone of eruption is at ±15° latitude, while the last few spots of the cycle appear at ±8°. When the latitude of spots, without regard to size, is plotted as a function of time, a so-called butterfly diagram results. This shows that new spots of a new cycle can appear at high latitudes before the disappearance of low-latitude, old-cycle spots, and suggests each new cycle is in some ways independent of the old.

Magnetic field theories

Many of the known features of the sunspot cycle have been explained by a theory of magnetic-field amplification by solar differential rotation. Very much simplified, the theory postulates that the Sun's differential rotation slowly winds up the lines of magnetic force like string on a ball. These lines of force, called flux ropes, which are formed beneath the surface, become buoyant and tend to rise to the surface; thus, bipolar magnetic regions (sunspots) are formed where the flux rope loops through the surface. One worker has separated the field into three components and adopted an interior rotation faster than the exterior with a strong concentration of radial shear toward the equator. With suitable parameters, he was able to reproduce with remarkable exactitude all the phenomena connected with the solar cycle.

OTHER PHENOMENA

Faculae, plages. Bright granulated structures, visible in white light, toward the Sun's limb, are called faculae. That they appear only near the limb and not at the centre of the disk means that the higher facular parts emit more radiation than the surrounding high photospheric layer and the lower parts emit less than the local photosphere. The temperature excess amounts to 250° C (480° F) at the most.

Spectroheliograms of the active Sun reveal large, bright areas closely associated with the photospheric faculae. These chromospheric faculae, or plages, are the extension of the photospheric faculae into the chromosphere. Ultraviolet plages and X-ray plages are observed coming from the high chromosphere and corona. Radio plages are also observed in the centimetre and decimetre radio wavelengths.

Prominences, filaments. Prominences are among the most beautiful of solar phenomena (see Figure 2). A typical fully developed quiescent prominence is a thin fish-tailed, or ribbon-like, gaseous structure standing above the Sun's surface; it may attain a size of 200,000 kilometres (125,000 miles) long, 40,000 kilometres high, and 6,000 kilometres thick. As seen on the disk, in hydrogen-alpha spectroheliograms, prominences appear as long, dark structures called filaments. At the Sun's limb projected against the dark sky they are seen as bright clouds composed of a myriad of fine threads. Generally, prominences are connected by appendages to the Sun's surface or rest upon it, but a few stand free. Like clouds, prominences take many fanciful forms. From their appearance and mode of formation they have been classified into the following types: active prominences, eruptive, sunspot, tornado, quiescent, and coronal prominences.

Time-lapse motion pictures of solar prominences

Time-lapse motion pictures reveal the intricate motions of prominences. Thus viewed, they show at least two active groups of the first type: prominences that appear as great funnels with downward-curving streamers feeding knots of material from the prominence into a nearby active area; and the spectacular arched prominences in which material condenses from the corona and moves down along each arm, often for several days, into a spot region. Quiescent hedgerow-type prominences are carried in, and are supported against the pull of gravity by, a trough of magnetic field lines; they separate regions of opposite magnetic polarity on the Sun's surface and may last for months. The large-scale structure of such quiescent prominences is fairly constant, but the fine structure shows much motion, generally downward. On occasion, a nearby solar flare may trigger great activity in the prominence such that it either flows downward into an active region and disappears, or that a portion of it may erupt from the surface of the Sun with velocities of 200–500 kilometres, or about 125–310 miles, per second. Strangely, the activity appears not to destroy the magnetic-field configuration, for there is a tendency for the prominence to reappear a few days later, phoenix-like, in its former place and form.

Spectroscopy reveals the physical conditions in prominences. There are both hot and cold prominences. Cold prominences with kinetic temperatures of 8,000° to 10,000° K (14,000°–18,000° F) show sharp spectral lines: the Balmer lines of hydrogen, H and K of calcium, and a number of lines of ionized and neutral metals. Active prominences, loops and surges, with temperatures up to 100,000° K (180,000° F) show lines broadened by thermal motions of the atoms; the metal lines are weak and ionized helium lines appear.

Flares. In plage areas, sudden and distinct brightenings occur from time to time. These brightenings, called flares, last from a few minutes for small ones, up to several hours for very large ones. Solar flares are among the most violent and dramatic events that occur on the Sun, yet, with few exceptions, they cannot be seen in white light and may well go unnoticed. They are easily seen, however, in the red light of hydrogen and they produce a number of effects observable at the Earth that make them of considerable importance.

Flares are classified by area and brightness on a scale of increasing importance, from − 1 to + 3, the latter group comprising only 1 percent of the total. As seen in hydrogen light, a typical large flare starts as a brightening of a pre-existing filamentary structure in the neighbourhood of a sunspot. The rise to maximum brightness is sudden, taking place in two to five minutes, with a rapid spreading of the flare area, the brightest parts of which are often elongated. The flare lasts about one hour longer during which a bifurcation and separation of the luminous ribbon and subsequent fading of the flare take place. Frequently, after the onset of a flare, a surge of gas is ejected with a velocity of perhaps 100 kilometres (about 60 miles) per second. A great flare can create an expanding magnetohydrodynamic wave, a complex effect involving both magnetic and hydrodynamic forces, propagating through the corona. Its passage is seen by the successive activation of disk filaments as it spreads over the surface with velocities of 1,000 kilometres (600 miles) per second and for distances of over 500,000 kilometres.

Geophysical phenomena

Many geophysical phenomena are caused by radiation and particle emission from flares. For example, simultaneously with the observed flare there is often a fade-out of shortwave-radio communication caused by a flash X-ray penetrating to the ionosphere of the Earth and greatly increasing its ionization and absorption. Plasma clouds from the flare region moving out at 2,000 kilometres (1,250 miles) per second produce auroras and geomagnetic storms a day or so later. Cosmic-ray particles from very large flares have been observed to penetrate to ground level. In the polar regions, measurements of cosmic-radio noise show a marked decrease, caused by bombardment of the upper atmosphere by high-energy protons from the flare.

Observations of the X-ray spectrum during a flare detect a great increase in the emission at the shorter X-ray wavelengths down to below ten angstroms. This reveals the existence of localized regions with temperatures of the order of 25,000,000° K and more. The formation of such regions is explained as being due to thermal electrons heated by accelerated electrons, which, in turn, are responsible for the microwave emission connected with flares. Usually the enhanced X-ray emission caused by the flare phenomenon appears after the emission at radio frequencies, but the X-ray emission lasts much longer and decays more slowly than the microwave emissions.

In addition to the above-mentioned flare-associated X-ray emission (so-called quasi-thermal due to the heating of localized regions), bursts of very short wavelength

X-ray and radio phenomena

(hard) nonthermal X-rays may occur which are observed in the range between about one and ten angstroms. They may last from a couple of seconds up to two minutes. Since the energies of these bursts are of the order of 10^4–10^6 electron volts, some of their electrons must be moving with velocities of between 60,000 to about 300,000 kilometres or, about 37,000 to 186,000 miles, per second. Consequently, the bursts are felt to be due to bremsstrahlung radiation (that emitted by decelerating electrons) or to synchrotron radiation, produced by electrons accelerating in a curved path. The hard X-ray bursts are correlated with various types of radio bursts which also are produced by the acceleration of particles to high speeds. There is, however, not always a one-to-one correspondence between X-ray and radio emission in a flare or any other flare phenomenon.

The interaction of high-energy electrons, protons, and nuclei in the solar atmosphere may also produce gamma rays in a flare region. A few major flares have been observed to eject gamma-ray bursts with energies up to one million electron volts (*i.e.*, the energy that would be gained by an electron in moving through a potential energy difference of 1,000,000 volts). Like X-ray bursts, gamma-ray bursts are short-lived phenomena; their duration, being of the order of a few seconds to a minute, depends on the time the high-energy particles are trapped in the solar plasma.

The radio phenomena associated with a large flare are numerous and complex; different events appear at different frequencies and different times. During the flash phase of a large flare, a stream of high-energy electrons moving with one-third of the speed of light are ejected from the flare into the corona to generate waves moving at speeds faster than the speed of light in the plasma called Cherenkov plasma waves and fast-drift radio bursts, that is, bursts of radiation at rapidly changing radio wavelengths. These are observed in the frequency range 600 to 20 megacycles per second. In five to ten minutes other fast electrons are trapped in the magnetic field and their oscillation, possibly between magnetic-mirror points, produces a broadband burst over areas of about one-quarter of the Sun's disk. Electrons accelerated downward from the ejection area of the flare plunge into the chromosphere creating X-rays and microwave bursts. In addition to the high-speed electrons, the flare explosively ejects a dense plasma cloud at a velocity of 1,000 kilometres (600 miles) per second. This cloud may interact with the corona at supersonic velocities to form shock waves and radio bursts. The magnetic field embedded in this plasma moving out from the Sun holds electrons moving at a high fraction of the speed of light, which emit synchrotron radiation that can be followed with radio telescopes as a moving burst. From deep in the flare site microwave emissions continue, generated by synchrotron and bremsstrahlung processes (see above). Continuous radio emission continues for hours at metre wavelengths.

Energy release

The physical causes of flares are still unknown, though it is believed that the energy released by a flare (about 10^{32} ergs in a large flare) must come from the intense magnetic or electric fields associated with the solar active regions. It has been estimated that the energy released by a single flare would be enough to provide electric power for the whole world for 1,000,000 to 100,000,000 years at the current rate of use, depending upon the size of the flare.

Coronal condensations. The corona is far from uniform. Coronal condensations occur over centres of activity. They dominate the scene in X-ray photographs of the Sun and can be observed with radio telescopes. The condensations are shaped in the forms of rays, brushes, loops, or arches, and are often associated with hot prominences. They vary rapidly in brightness (a factor of 2 in two hours is not uncommon) but may remain stable in form for quite some time; in fact, over a large, highly developed spot group or centre of activity, a condensation may remain visible for several months. At the time of a flare the structure of a condensation may suddenly undergo change and show great activity; arch streamers, for example, may expand outward with velocities of 500 kilometres (about 310 miles) per second. In a coronal condensation, the electron temperature approaches 5,000,000° K and the particle density is five to ten times greater than that of the surrounding quiet corona. At radio frequencies coronal condensations manifest themselves by enhancement of the radio emission in centimetre and decimetre wavelengths. By far, the greatest enhancement, about 80 times greater than in the quiet corona, can be observed in the X-ray region, in which the emission is proportional to the square of the electron density.

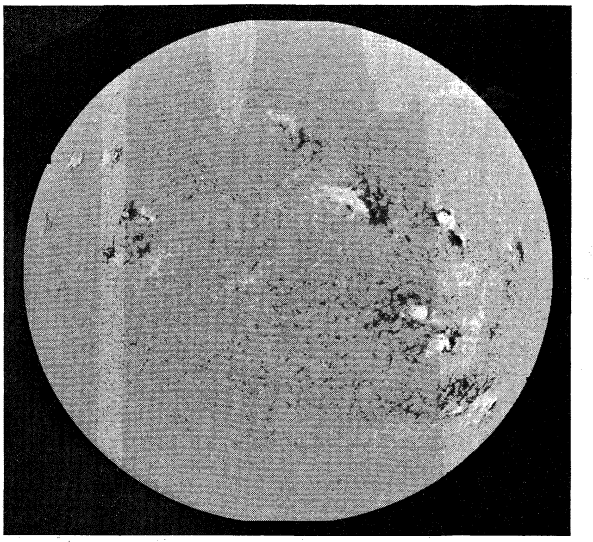

Figure 7: Photospheric magnetic fields on the Sun. The dark and light areas correspond to positive and negative (north and south) polarities. The bipolar nature of most regions is indicated. The figure shows a computer-generated photograph or map built up of direct photoelectric scans covering the entire visible surface.

The Sun's general magnetic field. The existence of a weak polar magnetic field for the Sun has long been assumed. The measurement of small magnetic fields by the Zeeman effect is exceedingly difficult; hence, it need not be surprising that, although early measurements of polar photospheric fields gave values of 20–50 gauss, modern measurements have indicated much smaller values, of the order of one gauss, roughly the same as the natural magnetic field at the surface of the Earth. How the observed photospheric field is related to the internal field is not known. The field observed in the photosphere in the polar regions is not the dipole field but results from the slow migration and expansion of magnetic remanents from centres of activity in the sunspot zones to the polar regions. Furthermore, the irregular or random eruption of magnetic flux in the spot zones is eventually reflected in the polar fields and explains why the Sun has, on occasion, had a magnetic south pole simultaneously at both north and south poles and why there is often a lack of perfect symmetry between the two hemispheres. Figure 7 shows a continuous plot of the photospheric magnetic field.

The solar interior: energy generation and evolution of the Sun

The internal structure of the Sun is determined by its chemical composition, by its mass, and by its previous history. Today, with the development of large, fast computers, theoretical solutions to equations governing the structure of the Sun can be found in a few minutes and the evolutionary track showing the changes in the structure and compositions followed for billions of years.

The development of a mathematical model of the Sun would require that the chemical composition be known throughout its mass, and this is not known. Hence, a sequence of models must be computed and compared to the true Sun. It has been suggested that the flux of neutrinos from the hydrogen-burning fusion reactions in the

Sun's interior (see below) may allow direct observations of conditions in the Sun's core, and investigators have set up detectors to capture the neutrinos. The results so far indicate that the central temperature of the Sun is less than 20,000,000° K, but results have not yet fixed the chemical composition.

The Sun radiates 3.86×10^{33} ergs of energy every second (from energy = mass times velocity of light squared, $e = mc^2$; this corresponds to a mass loss of 4,700,000 tons per second or 1×10^{-11} solar mass per year). Nuclear reactions are the only possible means that can produce such a great amount of energy. In the hot, dense core of the Sun, within about one-tenth of a solar radius of the centre, nuclear fusions liberate the energy that is emitted millions of years later at the surface of the Sun. The most important fusion process in the Sun is the so-called proton–proton reaction or hydrogen-burning. The fusion of two hydrogen atoms, the nuclei of which are called protons, produces a deuterium atom and releases a positron and a neutrino.

Nuclear reactions

The neutrino escapes with the velocity of light and the positron quickly collides with an electron, whereby they annihilate each other, producing a very high-energy photon of radiation, called a gamma ray. The collision of the deuterium atom with another proton produces an atom of the light helium isotope of atomic mass 3, called helium-3, and the emission of another gamma ray. Eventually, two helium-3 atoms collide and in doing so, produce an ordinary stable helium atom of atomic mass 4 and release two protons and a gamma ray. In total, two electrons and six protons are used up in the production of one stable helium atom; two new protons are rebuilt and two neutrinos and five gamma rays are released in the process, which provide the energy radiated away at the solar surface. About 5 percent of the energy is carried away by the neutrinos (see NUCLEAR FUSION).

The Sun is presently in a state of equilibrium with a balance between its total energy production and its luminosity. The evolution of the Sun has been considered by many theoreticians. The U.S. astrophysicist Icko Iben sees a million years as having been taken for the mass of gas that is now the Sun to evolve from a wholly convective state to a body with a radiative core. The radiative core then grows to encompass nearly all the Sun's mass. After 10^7 years the brightness reaches a minimum and then increases. At 2.3×10^7 years nuclear burning begins. At 2.6×10^7 years a convective core appears and the Sun begins to take on a form much like its present one at 3.7×10^7 years. As the conversion of carbon to nitrogen proceeds to burn carbon rapidly, the convective core is replaced by the condition of radiative equilibrium, in which the amount of energy received is everywhere exactly passed on throughout the mass. In 4.5×10^9 years the brightness increased to the present solar value. At its present stage the Sun consists of about 60 percent hydrogen by weight. After about 6×10^9 years a slight change in mass and luminosity may be recognizable. During the past 4.5×10^9 years, that is, since the formation of the Earth's crust, the Sun has virtually remained unchanged.

Future evolution

The future evolution of the Sun is expected to be similar to that of other normal stars. Eventually all hydrogen will be burned up and nuclear reactions involving helium and heavier atoms will take over. This will change the chemical composition of the Sun; as a result, the Sun will increase in size and luminosity and thus turn into a red giant star. Computations on evolutionary models predict that in a few times 10^9 years the Sun will reach the red giant stage. Finally, when all nuclear energy sources are used up, the Sun will reach its last evolutionary stage, that is, it will become a white dwarf, a star of small radius. Its radius will be about 100 times smaller than it is now. Its internal temperature and its luminosity will gradually decrease on a time scale of 10^9 years and, eventually, the Sun will become a black dwarf, a very dense, nonluminous object of degenerate matter. The total lifetime of the Sun is estimated to be some 10^{10} years.

BIBLIOGRAPHY. A large fraction of modern solar research is published in *Solar Physics* (1967–), a monthly journal for solar research and the study of solar–terrestrial relations.

(A.K.P./E.A.M.)

Sung T'ai Tsu

The Sung dynasty, which ruled China from 960 to 1279, was founded by Sung T'ai Tsu (in Pin-yin romanization, Song Tai Cu), an outstanding military leader, statesman, and emperor, who laid the foundations for the essential political institutions of a remarkable epoch. The political order of his dynasty combined to a surpassing degree freedom of discussion, innovation in bureaucratic methods, internal reform, peace, and stability. This atmosphere undoubtedly facilitated the pioneering in economic techniques, scientific advances, and achievements in philosophy, art, and literature that distinguished the Sung period.

Chao K'uang-yin (who posthumously received the dynastic temple name of T'ai Tsu, or Grand Ancestor) was born in 927 in a military base at the former capital, Lo-yang. He was the second son of a military officer, Chao Hung-yin. China was then in chaos. The once great T'ang dynasty, fragmented by rebellions, had been extinguished in 907. A succession of warlords—Chinese, part Chinese, or foreign—claimed the Imperial throne briefly in devastated North China, while the more prosperous south was divided among satraps who were independent in fact and sometimes in name. The boy's forbears had in three previous generations won a certain standing as military leaders under one or another Imperial claimant, and his father reached a post of high command before his death in 956. The wisdom and foresight of Chao K'uang-yin's remarkable mother influenced his decisions even after her death in 961.

Rise to power

At about age 20 Chao joined a leader whose adoptive father soon afterward established the Later Chou dynasty at K'ai-feng; Chao's patron succeeded to the throne in 954 and fought to extend his sway into South China and to eliminate a rival who, established to the north in Shansi and supported by the Khitan empire, laid claim to the rule of China. Through a series of daring and successful actions Chao quickly rose to the chief command of the Later Chou forces.

Early in 960 Chao's patron died and was followed on the throne by his son, a child. At this time the armies of the Khitan and their Chinese allies prepared a concerted invasion. Chao marched northward to meet them. Discontent arose among Chao's troops, who in the crisis did not wish a child as ruler. When the army was encamped for the night at a bridge outside the capital, the officers awakened Chao (who had drunk well before retiring), hailed him as emperor, robed him in Imperial yellow, mounted him on horseback, and urged him to return and take over the government; the records, which are unverifiable on this point, imply that Chao lacked forewarning of the coup. On the officers' pledge of obedience and promise not to molest the existing Imperial family and its councillors, the public buildings, and the homes of the people, Chao complied. He named his dynasty the Sung.

Sung T'ai Tsu, portrait by an unknown artist. In the National Palace Museum, Taipei.

In rapid succession the dissident Chinese states now came under the new emperor's control. In 963 two submitted voluntarily and two more were conquered. By 976 all but the northern rival house were mastered, and its Khitan backers had seen more than one defeat. In that year the Sung armies were mobilized against this last rival when the emperor T'ai Tsu died at the age of 49. Within three years his younger brother T'ai Tsung, who succeeded him, completed the unification of China (except for a small area near Peking that remained in Khitan hands).

The task of unification had not been easy, and in parts of China revolts of local autonomists further complicated it. Yet the Sung founder had also turned his mind to ways of avoiding the dangers that had been fatal to the T'ang and to encourage the success of his dynasty. T'ai Tsu's policies no doubt owed much to his personality, a striking combination of qualities that inspired in his generation and later a multitude of anecdotes about him. Though some of these may include fictional elements, they convey the impression he made on his countrymen. A highly skilled archer and horseman in his youth, Chao survived daredevil equestrian exploits unscathed. As emperor he said that destiny had given him the throne and would determine his life or death; man could not deflect it. Despite remonstrances of his advisers, he persisted in going about incognito to observe conditions among the people. He rejected indignantly the gift of a sword stick for protection in emergency. His tastes were simple; when shown the inlaid urinals captured from the former Szechwan princeling, he had them destroyed. He visited his ministers informally and frankly admitted to them his chagrin over his own errors. In his last year he declined the title of unifier and pacifier that was offered him.

T'ai Tsu's policies and personality

T'ai Tsu was strict in holding his officials to account in important matters; his councillors held him in awe. On the other hand, he accepted minor faults or impertinences with a laugh. He was slow to entertain suspicion. He sometimes acted impetuously, and some have suggested, on rather limited evidence, that he indulged in wine to excess. On occasion, when severely provoked by a presumptuous official or subject, he was given to outbursts of violent rage. At such times, however, his temper cooled quickly, and he then softened penalties he had given in anger and even compensated the unfortunate culprit for abuses suffered.

T'ai Tsu was active by nature. Even as emperor he conducted military campaigns personally from time to time. Rather than simply approving governmental papers in finished form, as T'ang emperors had done, he let his ministers submit rough drafts to him for preliminary criticism.

The functional arrangements of T'ai Tsu's government reflected both his active disposition and his refusal to pretend infallibility. He continued the existing system by which three ministers were directly responsible to him for different aspects of administration (fiscal, military, and general), thus limiting the power of each. By generously granting them consideration and responsibility, however, he encouraged a certain balance between the functions of ruler and minister. The control of the central government over the local was also strengthened. Beginning in 963, the administration of the prefectures was cautiously but steadily transferred from the unruly military to civil officials. Court officials were sent to govern subprefectures. From 965 taxes were remitted directly to the national treasury. The first fiscal intendants—forerunners of the Sung "circuit" system—were established to supervise local functionaries. To counter the military threat to the state's integrity, T'ai Tsu transferred the best troops to the capital and on suitable opportunities induced the most powerful commanders to accept retirement.

T'ai Tsu's policies were clearly directed toward the creation of a bureaucracy based on demonstrated abilities rather than birth or favour. This is evident in his steps to strengthen the examination system. By 963 he had forbidden court officials to recommend candidates and had forbidden graduates to consider examiners their patrons. He ordered re-examinations on the petition of a rejected candidate or on even a hint of favour in the selection of graduates. By 973 he had established the final examination in the Imperial palace to verify the rankings and had ordered the list of successful competitors to be announced publicly. He began to award larger numbers of degrees.

Reform of the examination

A mildness and humanitarian tone pervade T'ai Tsu's policies, which on the whole conform to the Confucian ethos. He extended clemency toward defeated opponents rather consistently. He showed concern for the adherents of the dynasty he displaced. His generals were repeatedly admonished to shun avoidable harm to the citizens of places they occupied and even to spare captured soldiers and leaders; among the latter was the poet-prince Li Yü. His own ministers who lost his favour were treated well. In his legal reforms, though he dealt more severely with corruption and irresponsibility of officials in several measures, he lightened the punishments for violations of the state controls over salt and wine and required a review of all capital sentences by the high court at the capital. His early measures also show a special concern with improving the economic lot of the poorer citizens and easing their burdens of taxation.

When T'ai Tsu died, the construction of the new state was far from finished. The ensuing peace and prosperity would also bring new problems calling for new solutions.

Of the succeeding emperors, none quite matched him in stature or in character. But Confucian ancestral piety reinforced the attraction of his proven policies. The traditions of his active concern in administration and of close association with the bureaucracy's leaders persisted in greater or lesser degree among later Sung rulers. Subsequent developments on the whole moved in directions indicated by T'ai Tsu. Their benefits were scarcely unadulterated; safeguards against the ambitions of military commanders, for example, perhaps hampered Sung armies in meeting powerful foreign invaders. Still, the efforts of his successors to further popular welfare, to find and train the best talent for the civil service, and to defend the state's stability and the unbroken rule of the dynasty for three centuries no doubt owe much to T'ai Tsu's concepts of statecraft. (E.A.K.)

Sun Yat-sen

Sun Yat-sen (in Pin-yin romanization, Sun I-xian, also known as Sun Wen or Sun Chung-shan), early leader of China's Kuomintang (Nationalist Party), played a leading role in the overthrow of the Ch'ing (Manchu) dynasty in 1911 and was the first provisional president of the Republic of China. He is revered by the Communists and is called by the Nationalists the "Father of China."

Early life and influences. Sun was born on November 12, 1866, to a family of poor farmers in Hsiang-shan, in the South Chinese province of Kwangtung. In 1879 his brother Sun Mei, who had earlier emigrated to Hawaii as a labourer, brought him to Honolulu, where, as a student at a British missionary school for three years and at an American school, Oahu College, for another year, he first came into contact with Western influences. Because his brother objected to his penchant for Christianity, Sun returned to his native village in 1883 and went to study at the Diocesan Home in Hong Kong in the fall of the next year. In 1885 he transferred to the Government Central School (later known as Queen's College) and married Lu Mu-chen (1867–1952), the girl chosen for him by his parents. Out of this marriage a son and two daughters were born. In either 1884 or 1885 Sun was baptized by an American missionary. After another trip to Hawaii, he enrolled in the Canton Hospital Medical School in 1886. He transferred later to the College of Medicine for Chinese in Hong Kong and was graduated in 1892.

Education and marriage

Although not trained for a political career in the traditional style, Sun was nevertheless ambitious and was troubled by the way China, which had clung to its traditional ways under the conservative Ch'ing dynasty, suffered humiliation at the hands of more technologically advanced nations. Forsaking his medical practice in Canton, he went north in 1894 to seek political fortunes. In a long letter to Li Hung-chang, governor general of Chihli, he set forth his ideas of how China could gain strength; but all he received from Li was a perfunctory endorsement of his scheme for an agricultural–sericultural association. With this scant reference, Sun went to Hawaii in October 1894 and founded an organization called the Revive China Society (Hsing Chung hui), which became the forerunner of the secret revolutionary groups Sun later headed. As far as it can be determined, the membership was drawn entirely from natives of Kwang-tung and from lower social classes, such as clerks, peasants, and artisans.

Brown Brothers

Sun Yat-sen.

Years in exile. Taking advantage of China's defeat in the Sino-Japanese War (1894–95) and the ensuing crisis, Sun went to Hong Kong in 1895 and plotted for an uprising in Canton, the capital of his native province. When the scheme failed, he began a 16-year exile abroad. In 1896 he was detained for 13 days by the Chinese legation in London. How the incident began is subject to dispute, but it appears likely that Sun ran into a fellow Cantonese who worked for the legation and was found out and caught while visiting him under an alias. The legation planned to ship Sun back to China, but, before this could be done, Sun had converted a British employee at the legation to his side and got a word through to James Cantlie, former dean of Hong Kong College of Medicine. The British Foreign Office intervened, and Sun was released from his captivity. The incident engendered great publicity and gave Sun's career a powerful boost.

Detention in Chinese legation

After spending much of the ensuing eight months reading in the British Museum, Sun travelled to Japan by way of Canada. Arriving in July 1897, he was met by Miyazaki Torazō, an adventurer who had heard of the London incident and who was willing to help Sun in his political activities. Miyazaki introduced Sun to many influential Japanese, including Ōkuma Shigenobu, Soejima Taneomi, and Inukai Tsuyoshi, from some of whom Sun was to receive both political and financial assistance. During the turmoil of 1900, Sun participated in secret manoeuvres involving Sir Henry Blake, the British governor of Hong Kong, and Ho Kai, an influential Chinese in that colony. Their aim was to persuade Li Hung-chang to declare independence from the Ch'ing. Responding to an invitation by Li's staff, Sun journeyed to Hong Kong, but, fearing a trap, he did not go ashore. Instead, he was represented by Miyazaki and two other Japanese at the meeting, which proved fruitless.

Previously, Sun had made contact with bandits and secret societies in Kwangtung. These forces began a revolt in Hui-chou in October 1900. The campaign, the second of ten claimed by Sun between 1895 and 1911, lasted 12 days.

The year 1903 marked a significant turning point in Sun's career; from then on, his following came increasingly from the educated class, the most prestigious and influential group in China. For this decisive change Sun owed much to two factors, the steady decline of the Ch'ing dynasty and the powerful propaganda of Liang Ch'i-ch'ao, a reformist who fled to Japan in 1898, founded a Chinese press, and turned it into an instant success. Liang did not actually oppose the Ch'ing régime, but his attacks on the Dowager Empress, who effectively ruled the country, served to undermine the regime and make revolution the only logical choice. As a consequence, Sun's stock rose steadily among the Chinese students abroad. In 1904 he was able to establish several revolutionary cells in Europe, and in 1905 he became head of a revolutionary coalition, the Alliance Society (T'ung-meng hui), in Tokyo. For the next three years the society propagandized effectively through its mouthpiece, "People's Journal" (*Min pao*).

Founding of the Alliance Society

The rise in Sun's fortune increased many of his difficulties. The Alliance Society was very loosely organized, and Sun had no control over the individual members. Worse still, all the revolts Sun and the others organized ended in failure. The members fell into despair, and outside financial contributions declined. Furthermore, as a result of pressures exercised by the Ch'ing, foreign governments increasingly shunned Sun. In 1907 the Japanese government gave him a sum of money and asked him to

leave the country. A year later French Indochina, where Sun had hatched several plots, banned him completely. Hong Kong and several other territories were similarly out of his reach. In the circumstances, Sun spent a year in 1909–10 touring Europe and the United States. Returning to Asia in June 1910, he left for the West again in December after a meeting with other revolutionaries, in which they decided to make a massive effort to capture Canton. This time Sun raised more money in Canada and the United States, but the uprising of April 27 in Canton (known as the March 29 Revolution, because of its date in the Chinese calendar) fared no better than the earlier plots. The possibility of revolutionary success seemed more remote than ever.

But help was to come from the Ch'ing. If only for the purpose of self-preservation, the court had sponsored reform since 1901. In the next few years it reorganized the army, instituted a school system, abolished the civil-service examinations based on traditional Chinese scholarship, reconstructed many government organs, and convened provincial and national assemblies. The educated class nevertheless remained unsatisfied with the tempo of change, and the regime was rapidly losing its grip over the situation. In 1911 it decided to nationalize all the trunk railways, thus incurring the wrath of local vested interests. Armed rebellion broke out in the province of Szechwan and the court exposed itself to further attacks by failing to suppress it. In October of the same year a local revolutionary group in Wu-han, one of many in China by this time, began another rebellion, which, in spite of its lack of coordination, unexpectedly managed to overthrow the provincial government. Its success inspired other provincial secessions.

The revolution of 1911

Sun Yat-sen learned of the Wu-han revolution from the newspapers while he was in Denver, Colorado. He returned to Shanghai in December and was elected provisional president by delegates meeting in Nanking. Knowing that his regime was weak, Sun made a deal with Yüan Shih-k'ai, an Imperial minister who had been entrusted with full power by the court. On February 12, 1912, the Emperor abdicated; the next day Sun resigned, and on the 14th Yüan was elected his successor.

Later struggles. In September, Yüan appointed Sun director general of railway development. Their entente might have lasted if Sung Chiao-jen, who had reorganized the Alliance Society into the Kuomintang and was serving as its head, had not been assassinated in March 1913, reportedly at Yüan's instigation. This precipitated a second revolution, in which Sun opposed Yüan. When the campaign failed, Sun fled once again to Japan. While there, he unavailingly sought Japanese aid by promising vast concessions in China, and he also alienated many revolutionaries by requiring them to take an oath of personal allegiance to him. He was also criticized for marrying his secretary, Soong Ch'ing-ling (November 1914), without divorcing his first wife.

A combination of internal opposition and external pressures defeated Yüan in 1916. The next year Sun went from Shanghai to Kwangtung to launch a movement against the premier, Tuan Ch'i-jui. Elected generalissimo of a separatist regime in July, Sun had to resign and leave for Shanghai toward the middle of 1918, when he lost the support of Lu Jung-t'ing, the military overlord of Kwangtung.

Earlier, Lu had agreed to Sun's gaining control over 20 battalions of armed guards if the forces would remain outside Kwangtung. Accepting this condition, Sun appointed Ch'en Chiung-ming as the commander and dispatched his men to Fukien. By persuading Ch'en to fight Lu, Sun found his way back to office for another 16 months, at the end of which Ch'en turned against him, and Sun had to leave for Shanghai again. From that sanctuary, he wooed the troops from Kwangsi and Yunnan, and with their help he again returned to Canton. In February 1923 he installed himself as generalissimo of a new regime.

Meanwhile, a new factor had risen in Sun's political life. Unsuccessful at obtaining aid from the West and Japan, he had looked increasingly to the Soviet government, which came to power in Russia in 1917. A Soviet diplomat, Adolf Joffe, visited Sun in Shanghai in both 1922 and 1923. On the latter occasion the two issued a joint manifesto declaring that the Communist system was not suitable for China, that Russia intended to give up its privileges there, and that Russia had no intention of extending its influence over Outer Mongolia. At Soviet prodding, the Chinese Communist Party resolved to cooperate with the Kuomintang. In October 1923, Mikhail Borodin, a representative of the Comintern (Communist International), arrived at Canton and soon gained Sun's confidence. Early in 1924 Sun reorganized the Kuomintang as a tightly disciplined body with authority descending from the top to the lower levels on the model of the Soviet Communist Party. Under his directive a party congress elected three Communists to its central executive committee and approved the establishment of a military academy (of which Sun appointed Chiang Kai-shek president). Part of his party-building efforts were a series of lectures Sun delivered on his own doctrine, the Three Principles of the People.

Ties with the Soviets

Although these actions strengthened the Kuomintang, there was still considerable opposition to Sun's authority when he died of cancer in Peking on March 12, 1925. His coffin remained uninterred in a temple in Western Hills (Hsi-Shan) until 1929, when it was moved to a mausoleum in Nanking.

Assessment. Sun's political doctrines are summarized in his Three Principles of the People (nationalism, democracy, and people's livelihood—the last involving the regulation of private capital and "equalizing land rights") and his Plan for National Reconstruction (*Chien-kuo fang-lueh*), which explained basic parliamentary procedures, attacked the traditional Chinese saying that to know is easier than to do and set forth a grandiose plan for China's industrialization, concocted by Sun without much help from engineers or economists.

Although sanctified by his followers, Sun's doctrine was not his major strength. All contemporary sources attribute to him a magnetic personality, a great capacity for tolerating others' weaknesses, a singular dedication to the pursuit of power, and a knowledge of the West unequalled by any of his political rivals. Perhaps the last factor is the most important, for it is this that set Sun apart and made him the symbol of Chinese modernization. Quite fittingly, the Chinese Communists call him "a pioneer of the revolution."

BIBLIOGRAPHY. An old but still useful biography is LYON SHARMAN, *Sun Yat-sen: His Life and Its Meaning* (1934). A more recent work, *Sun Yat-sen and the Origins of the Chinese Revolution* by HAROLD Z. SCHIFFRIN (1968), is a solidly researched piece, although it covers only the years to 1912. For a sympathetic treatment by a lawyer who knew Sun well, see PAUL LINEBARGER, *Sun Yat-sen and the Chinese Republic* (1925). In *The Japanese and Sun Yat-sen* (1954), MARIUS B. JANSEN analyzes the support Sun solicited and received from the Japanese from the 1890s to 1917. A recent biography is HOWARD L. BOORMAN (ed.), *Biographical Dictionary of Republican China*, vol. 3, pp 170–189 (1970).

(Y.C.W.)

Superconductivity

Superconductivity is a state of matter into which many chemical elements, compounds, and alloys enter on being cooled to exceedingly low temperatures; and while in this state their thermal, electric, and magnetic properties are strikingly different from their properties in the normal state and from those of other materials that do not become superconducting at such temperatures. The unique properties of superconductors have stimulated intensive research and have inspired the development of many new devices (see CRYOGENICS, APPLICATIONS OF).

HISTORY

Superconductivity was discovered in 1911 by a Dutch physicist, Heike Kamerlingh Onnes, who was awarded the Nobel Prize in 1913 for his low-temperature research. Kamerlingh Onnes found that the electrical resistivity of a mercury wire disappears suddenly when it is cooled below a temperature of about 4° Kelvin (—269° C or

Discovery by Kamerlingh Onnes

—452° F; absolute zero is 0° K, a temperature at which all matter theoretically is considered to have lost disorder). Kamerlingh Onnes' discovery was a completely unexpected phenomenon. He soon discovered that a superconducting material can be returned to the normal state either by passing a sufficiently large current through it or by applying a sufficiently strong magnetic field to it. At that time, there was no theory to explain this.

For many years it was believed that, except for the fact that they had no electrical resistance (*i.e.*, they had infinite electrical conductivity), superconductors had the same properties as normal materials. This belief was shattered in 1933 by the discovery that a superconductor is highly diamagnetic; that is, it is repelled by a magnetic field. A ferromagnetic substance easily acquires and then retains strong magnetic properties. A paramagnetic substance is only weakly magnetizable, whereas diamagnetic substances may be said to expel magnetic field that would permeate a magnetizable substance. This phenomenon in superconductors is called the Meissner effect for one of the two men who discovered it. Because such behaviour relates to changes in energy, its discovery made it possible, in the same year, to consider the transition from normal to superconducting states as being thermodynamically reversible. The discovery of the Meissner effect also made it possible to formulate, in 1934, a theory of the electromagnetic properties of superconductors that predicted the existence of an electromagnetic penetration depth (for a definition, see below *The Meissner effect*), which was first confirmed experimentally in 1939. In 1950, it was clearly shown for the first time that a theory of superconductivity must take into account the fact that free electrons in a crystal are influenced by the vibrations of atoms that define the crystal structure, called the lattice vibrations. In 1953, in an analysis of the thermal conductivity of superconductors, it was recognized that the distribution of energies of the free electrons (those not attached to atoms) in a superconductor is not uniform from one extreme to the other but has a separation called the energy gap.

The theories referred to thus far served to show some of the interrelationships between observed phenomena but did not explain them as consequences of the fundamental laws of physics. For almost 50 years after Kamerlingh Onnes' discovery, theorists were unable to develop a fundamental theory of superconductivity. Finally, in 1957, such a theory was presented by physicists John Bardeen, Leon N. Cooper, and John Robert Schrieffer of the United States, which won for them (1972) the Nobel Prize in physics. Now called (for them) the BCS theory, all later theoretical work is based on it. The BCS theory also provided a foundation for an earlier model that had been introduced by the Soviet physicists Lev Davidovich Landau and Vitaly Lazarevich Ginzburg (1950); this model has been useful in understanding electromagnetic properties, including the fact that the internal magnetic flux in superconductors exists only in discrete amounts (instead of in a gradual and continuously changing spectrum of values), an effect called the quantization of magnetic flux. This flux quantization, which had been predicted from quantum-mechanical principles, was first observed experimentally in 1961.

The BCS theory

In 1962 Brian D. Josephson, a physicist in England, predicted that two superconducting objects placed in electrical contact would display certain remarkable electromagnetic properties. These properties have since been observed in a wide variety of experiments, demonstrating quantum-mechanical effects on a macroscopic scale.

The theory of superconductivity has been tested in a wide range of experiments, involving, for example, ultrasonic absorption studies, nuclear-spin phenomena, low-frequency infrared absorption, and electron-tunnelling experiments (see below *Energy gaps*). The results of these measurements have brought understanding to many of the detailed properties of various superconductors. The search for materials that remain superconducting at higher temperatures and in stronger magnetic fields has been pursued on an empirical basis, particularly by Bernd Teo Matthias, a German-born U.S. physicist.

THERMAL PROPERTIES OF SUPERCONDUCTORS

Superconductivity as a property of matter is best understood in terms of atomic structure, specifically of the arrangement of electrons in atoms. Every atom is identified by its nucleus, consisting of two kinds of subatomic particles, positively charged protons and uncharged neutrons. The nucleus is surrounded by electrons equal in number (the atomic number of the element) to the protons and arranged in what are called shells and subshells, or orbitals. Each shell can contain any number of electrons up to a maximum for each shell. In lighter elements the inner shells are filled and only the outermost shell is incomplete; in the heavier elements one or more inner shells, as well as the outermost, may be incomplete. Positions the electrons occupy in the structure are identified on the basis of energy relationships, and electrons can be excited from a normal, or ground state of energy, or energy level, to other energy levels (*i.e.*, to other positions in the structure, or to leave the atom completely). All chemical and most physical properties of the elements —and of the compounds, gases, liquids, and solids they form—are understood in terms of energy changes in the electron structures of atoms. The energy that an electron can absorb or emit in terms of specific units of energy that can be exchanged by electrons or between electrons and radiations such as light is defined by quantum mechanics. As a result of the complex arrangement of electron orbitals in a material when in the superconductive state, there may occur a large interval of unoccupied energy levels assigned to electrons, called an energy gap. Atoms bound into crystals hold their electrons tightly, but atoms of metals release a few electrons, and these free electrons conduct heat and electricity.

Hundreds of materials are known to become superconducting at low temperatures. Twenty-six of the chemical elements, all of them metals, are superconductors in their usual crystallographic forms at atmospheric pressure. Among these are commonly known metals such as aluminum, tin, lead, and mercury, and less common ones such as rhenium, lanthanum, and protactinium. In addition, 13 chemical elements that are metals, semimetals, and semiconductors (nonmetals that are electrically conductive under certain conditions) are superconductors at low temperatures and high pressures. Among these are uranium, cerium, silicon, and selenium. Bismuth, though not superconducting in its usual crystallographic form, can be made superconducting by preparing it in the amorphous (noncrystalline) form, which is stable at extremely low temperatures. Superconductivity is not exhibited by any of the magnetic elements chromium, manganese, iron, cobalt, and nickel.

Superconducting materials

Most of the known superconductors are alloys (homogeneous mixtures of metals) or compounds. It is possible for a compound to be superconducting even if the chemical elements constituting it are not; examples are disilver fluoride (Ag_2F) and a compound of carbon and potassium (C_8K). Some semiconducting compounds, such as tin(II) telluride (SnTe), can become superconducting if they are properly infused with impurities.

Transition temperatures. The temperature below which a substance is superconducting is called the transition temperature (T_c). The vast majority of the known superconductors have transition temperatures that lie somewhere between 1° Kelvin and 10° K. Of the chemical elements, tungsten has the lowest transition temperature, 0.015° K, and niobium the highest, 9.5° K. The transition temperatures of some of the commonly known superconducting elements are indicated in the Table. An alloy of niobium, aluminum, and germanium ($Nb_{12}Al_3Ge_1$) has the highest known transition temperature, 21° K.

Among the transition elements there is a strong correlation between transition temperature and the number of electrons in the outer shell of the atom. When this number is five (vanadium, niobium, and tantalum) or seven (technetium and rhenium) the transition temperature is markedly higher than for other transition elements.

The transition temperature is sometimes unusually sensitive to chemical composition, as in the case of magnetic impurities. A few parts per million of manganese in zinc,

Transition Temperatures and Low-Temperature Values of the Critical Magnetic Field of Some Superconducting Elements

	T_c (° Kelvin)	H_o (oersted)
Zinc	0.88	53
Aluminum	1.20	99
Indium	3.41	282
Tin	3.72	306
Mercury	4.15	411
Lead	7.19	803

for example, lowers the transition temperature considerably. It has already been mentioned that the transition temperature can depend on pressure and crystal structure. The latter is more effective in influencing the transition temperatures of compounds than of alloys, especially of compounds containing at least one transition element. Some types of crystal structure tend to have higher transition temperatures than others, and some types are seldom superconductors, but some types are found in both groups.

Specific heat and thermal conductivity. The thermal properties of a superconductor can be compared with those of the same material at the same temperature in a normal state. (The material can be forced into a normal state at the temperature by a large enough magnetic field.)

When a small amount of heat is put into a system, some of the energy is used to increase the lattice vibration (an amount that is the same for a system in the normal and in the superconducting state) and the remainder is used to increase the kinetic energy of the free electrons. The specific heat (C_e) of the electrons is defined as the ratio of that portion of the heat used by the electrons to the rise in temperature of the system. Figure 1 shows how the

Adapted from *Zeitschrift fur Physik* (1959)

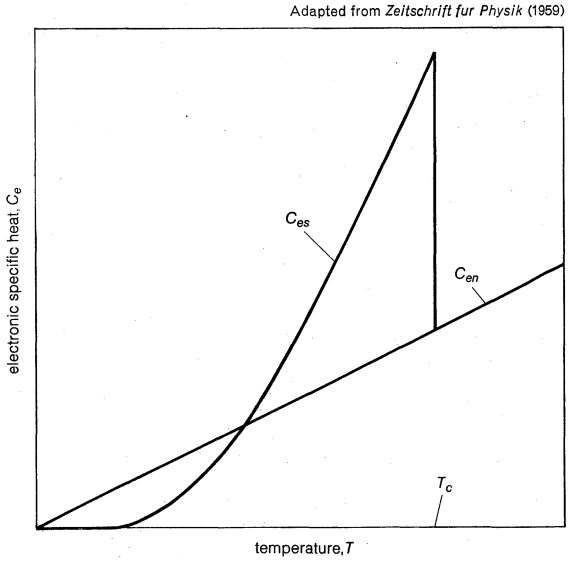

Figure 1: Specific heat in the normal (C_{en}) and superconducting (C_{es}) states as a function of absolute temperature. The two functions are identical at the transition temperature (T_c) and higher.

specific heat of the electrons in a superconductor varies with the absolute temperature (T) in either the normal or the superconducting state. It is evident from the figure that the electronic specific heat in the superconducting state, designated C_{es}, is smaller than in the normal state, designated C_{en}, at low enough temperatures, but that C_{es} becomes larger than C_{en} as the transition temperature T_c is approached, at which point it drops abruptly to C_{en}.

Temperature dependence of electronic specific heat

To a good approximation C_{es} is found to be proportional to the cube of the absolute temperature. Precise measurements, however, have shown deviations from this temperature dependence and have indicated that, at temperatures considerably below the transition temperature, the logarithm of the electronic specific heat is inversely proportional to the temperature.

This temperature dependence, together with certain principles of statistical mechanics (see PHYSICAL THEORIES, MATHEMATICAL ASPECTS OF), strongly suggests that there is a gap in the distribution of energy levels available to the electrons in a superconductor, so that a minimum energy is required for the excitation of each electron from a state below the gap to a state above it.

The heat flow per unit area of a sample equals the product of the thermal conductivity (K) and the temperature gradient ∇T. This may be expressed as $J_Q = -K \nabla T$, the minus sign indicating that heat always flows from a warmer to a colder region of a substance.

It is a fact that thermal conductivity in the normal state (K_n) approaches thermal conductivity in the superconducting state (K_s) as the temperature (T) approaches the transition temperature (T_c) for all materials, whether they are pure or impure. This suggests that the energy gap (Δ) for each electron approaches zero as the temperature (T) approaches the transition temperature (T_c). This would also account for the fact that the electronic specific heat in the superconducting state (C_{es}) is higher than in the normal state (C_{en}) near the critical temperature: as the temperature is raised toward the transition temperature (T_c), the energy gap in the superconducting state decreases, the number of thermally excited electrons increases, and this requires the absorption of heat.

Energy gaps. As stated above, the thermal properties of superconductors indicate that there is a gap in the distribution of energy levels available to the electrons, and so a finite amount of energy, designated as delta (Δ), must be supplied to an electron to excite it. This energy is maximum at absolute zero (designated Δ_0) and changes little with increase of temperature until the transition temperature is approached, where Δ decreases to zero, its value in the normal state. The BCS theory predicts an energy gap with just this type of temperature dependence.

According to the BCS theory, there is a type of electron pairing (electrons of opposite spin acting in unison) in the superconductor that is important in interpreting many superconducting phenomena. The electron pairs, called Cooper pairs, are broken up as the superconductor is heated. Each time a pair is broken, an amount of energy that is at least as much as the energy gap (Δ) must be supplied to each of the two electrons in the pair, so an energy at least twice as much (2Δ) must be supplied to the superconductor.

Cooper electron pairs

The value of twice the energy gap at 0° K (which is $2\Delta_0$) might be assumed to be higher when the transition temperature of the superconductor is higher. In fact, the BCS theory predicts a relation of this type, namely, that the energy supplied to the superconductor at absolute zero would be equal to 3.53 times the product of the Boltzmann's constant, k, and the transition temperature, T_c, in degrees Kelvin; *i.e.*, $2\Delta_0 = 3.53\ kT_c$. Boltzmann's constant is derived from theoretical considerations of the energy distribution among aggregates of particles (it equals 1.38×10^{-23} joule per degree Kelvin, one joule being equal to 0.239 calorie).

The energy gap (Δ) can be measured most precisely in a tunnelling experiment (a process in quantum mechanics that allows an electron to escape from a metal without acquiring the energy required along the way according to the laws of classical physics). In this experiment, a thin insulating junction is prepared between a superconductor and another metal, assumed here to be in the normal state. In this situation, electrons can quantum-mechanically tunnel from the normal metal to the superconductor if they have sufficient energy. This energy can be supplied by applying a negative voltage (V) to the normal metal, with respect to the voltage of the superconductor.

Tunnelling will occur if eV, the product of the electrons' charge, e (-1.60×10^{-19} coulomb) and voltage, is at least as large as the energy gap Δ. The current flowing between the two sides of the junction is small up to a voltage equal to the energy gap divided by the electron's charge ($V = \Delta/e$), and then rises sharply. This provides an experimental determination of the energy

gap (Δ). In describing this experiment it is assumed here that the tunnelling electrons must get their energy from the applied voltage, rather than from thermal excitation.

MAGNETIC AND ELECTROMAGNETIC PROPERTIES OF SUPERCONDUCTORS

Critical field. One of the ways in which a superconductor can be forced into the normal state is by applying a magnetic field. The minimum magnetic field required to cause this transition is called the critical field (H_c) if the sample is in the form of a long, thin cylinder or ellipsoid and the field is oriented parallel to the long axis of the sample. (In other geometries the sample goes from the superconducting state into an intermediate state in which some regions are normal and others are superconducting, and finally into the normal state.) The critical field increases with decreasing temperature toward a value at absolute zero (H_0). For the superconducting elements, values of H_0 range from 1.2 oersted (oersted is a unit of magnetic field intensity) for tungsten to 830 oersteds for tantalum. Values of H_0 are listed in the Table for some common superconductors.

These remarks about the critical field apply to ordinary (so-called type I) superconductors. In the following section the behaviour of other (type II) superconductors is examined.

The Meissner effect. As was stated above, a type I superconductor in the form of a long, thin cylinder or ellipsoid remains superconducting at a fixed temperature as an axially oriented magnetic field is applied, providing the applied field does not exceed a critical value (H_c). Under these conditions, superconductors exclude the magnetic field from their interior, as could be predicted from the laws of electromagnetism and the fact that the superconductor has no electrical resistance. A more astonishing effect occurs if the magnetic field is applied in the same way to the same type of sample at a temperature above the transition temperature and is then held at a fixed value while the sample is cooled. It is found that the sample expels the magnetic field or flux as it becomes superconducting. This is called the Meissner effect. Complete expulsion of the magnetic flux (a complete Meissner effect) occurs in this way only for certain superconductors, called type I superconductors, and only for samples that have the described geometry. For samples of other shapes, including hollow structures, some of the magnetic flux can be trapped, and one has an incomplete or partial Meissner effect. Figure 2 shows a graph of the magnetization of a type I sample with a complete Meissner effect.

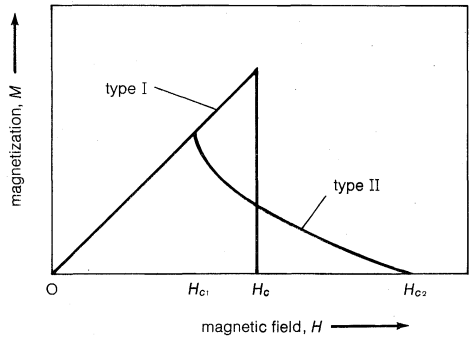

Figure 2: Magnetization as a function of magnetic field for a type I superconductor and a type II superconductor. For type I, magnetic flux is expelled, producing a magnetization (M) that increases with magnetic field (H) until a critical field (H_c) is reached, at which it falls to zero as with a normal conductor. A type II superconductor has two critical magnetic fields (H_{c1} and H_{c2}); below H_{c1}, type II behaves as type I and above H_{c2} it becomes normal.

Behaviour of type II superconductors

Type II superconductors have a different magnetic behaviour. Examples of materials of this type are niobium and vanadium (the only type II superconductors among the chemical elements), concentrated alloys, and superconducting semiconductors. As a sample of this type, in the form of a long thin cylinder or ellipsoid, is exposed to a decreasing magnetic field that is axially oriented with the sample, the increase of magnetization instead of occurring suddenly at the critical field (H_c) sets in gradually. Beginning at the upper critical field (H_{c2}), it is ideally completed at a lower critical field (H_{c1}; see Figure 2). If the sample is of some other shape or is inhomogeneous or strained, its magnetic behaviour may deviate from the ideal behaviour just described; in particular, some magnetic flux frequently remains trapped and some magnetization of the sample remains after the applied field is completely removed. Known values of the upper critical field extend all the way up to 3.5×10^5 oersteds, the value for the compound of vanadium and gallium with formula V_3Ga.

The expulsion of magnetic flux by type I superconductors in fields below the critical field (H_c) or by type II superconductors in fields below H_{c1} is never quite as complete as has been stated in this simplified presentation, because the field always penetrates into a sample for a small distance, known as the electromagnetic penetration depth. Values of the penetration depth for the superconducting elements at low temperature lie in the range from about 390 to 1300 angstroms (1Å = 10^{-8} centimetre). As the temperature approaches the critical temperature, the pentration depth becomes extremely large.

Electromagnetic penetration depth

High-frequency electromagnetic properties. Thus far the discussion has pertained to the behaviour of superconductors in the absence of electromagnetic fields (represented by infrared waves, for example) or in the presence of steady or slowly varying fields, but high-frequency properties of superconductors have also been studied.

The energy gap in a superconductor has a direct effect on the absorption of electromagnetic radiation. At low temperatures, at which a negligible fraction of the electrons are thermally excited to states above the gap, the superconductor can absorb a quantum of energy only if it is at least twice the gap energy (at absolute zero, $2\Delta_0$). In the absorption process, a photon (a quantum of electromagnetic energy) is absorbed and a Cooper pair is broken, exciting both electrons in the pair. The photon's energy (E) is related to its frequency (f) by the famous Planck relation, energy is equal to Planck's constant times the frequency, $E = hf$, in which h is Planck's constant (6.63×10^{-34} joule second). Rearranging the equation gives $f = E/h$. Hence the superconductor can absorb electromagnetic energy only for frequencies at least as large as twice the energy gap divided by Planck's constant, or $2\Delta_0/h$. Data taken in the infrared and microwave regions of the spectrum therefore determine the size of the energy gap for a particular material.

Magnetic-flux quantization. In quantum mechanics, electrons have the properties of waves, and the properties of an electron can be summed up in what is called a wave function. If the wave functions are in phase (*i.e.*, act in unison), they are said to be coherent. The theory of superconductivity indicates that there is a single, coherent, quantum-mechanical wave function that determines the behaviour of all of the superconducting electrons. As a consequence, a direct relationship can be shown to exist between the velocity of these electrons and the magnetic flux (Φ) enclosed within any closed path inside the superconductor. Indeed, inasmuch as the magnetic flux arises because of the motion of the electrons, the magnetic flux can be shown to be quantized; *i.e.*, the intensity of this trapped flux can change only by units of Planck's constant divided by twice an electron's charge.

When a magnetic field enters a type II superconductor (in an applied field between the lower and upper critical fields, H_{c1} and H_{c2}) it does so in the form of quantized fluxoids, each carrying one quantum of flux. These fluxoids tend to arrange themselves in regular patterns that have been seen by electron microscopy and by neutron diffraction. If a current is passed through the superconductor, the fluxoids can be made to move. This motion leads to energy dissipation that can heat the superconductor and drive it into the normal state. In making wire for superconducting high-field magnets, manufacturers thus try to fix the positions of the fluxoids by deliberately making the wire inhomogeneous in composition.

Fluxoids

Josephson currents. If two superconductors are separated by an insulating film that forms a low-resistance junction between them, it is found that Cooper pairs can tunnel from one side of the junction to the other. (This process occurs in addition to the single-particle tunnelling already described.) Thus a flow of electrons, called the Josephson current, is generated and is intimately related to the phases of the coherent quantum-mechanical wave function for all of the superconducting electrons on the two sides of the junction. As a result, several novel phenomena could be predicted, and experiments have demonstrated them. These are collectively called the Josephson effect or effects.

The first of these phenomena is the passage of current through the junction in the absence of a voltage across the junction. The maximum current that can flow at zero voltage depends on the magnetic flux (Φ) passing through the junction as a result of the magnetic field generated by currents in the junction and elsewhere. The dependence of the maximum zero-voltage current on the magnetic field applied to a junction between two superconductors is shown in Figure 3.

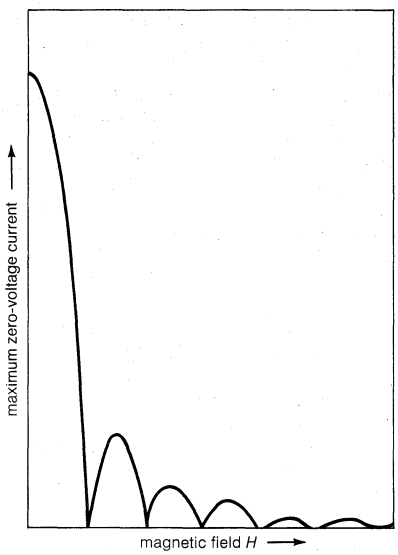

Figure 3: Maximum zero-voltage (Josephson) current passing through a junction by Cooper-pair tunnelling as a function of magnetic field.

Oscillating currents

A second class of Josephson effects is an oscillating current resulting from a relation between the voltage across the junction and the frequency (f) of the currents associated with Cooper pairs passing through the junction. The frequency (f) of this Josephson current is equal to two times the product of the electron charge (e) and the impressed voltage (V) divided by Planck's constant (h); that is, $f = 2eV/h$. Thus the frequency increases by 4.84×10^{14} hertz (cycles per second) for each additional volt applied to the junction. This can be demonstrated in various ways. The voltage can be established with a source of direct current (dc) power, for instance, and the current be detected by the electromagnetic radiation of frequency (f) that it generates. Another method is to expose the junction to radiation of another frequency (f') generated externally. It is found that a graph of the dc current versus voltage has current steps at values of the voltage for Josephson frequencies that are integral multiples (n) of the external frequency ($f = nf'$); that is, the voltage is equal to an integer times Planck's constant times the external frequency divided by twice the electron charge, or in equation form, $V = nhf'/2e$. The observation of current steps of this type has made it possible to measure the ratio of Planck's constant to the charge on the electron (h/e) with far greater precision than by any other method and has therefore contributed to a knowledge of the fundamental constants of nature.

The Josephson effect has been utilized in the invention of novel devices for high-sensitivity measurements of currents, voltages, and magnetic fields.

CONTINUING INVESTIGATIONS OF SUPERCONDUCTIVITY

In addition to the types of tunnelling measurements that have already been described, experiments have been performed in which the single-particle tunnelling process is assisted by energy supplied by phonons (lattice vibrations) or photons (electromagnetic oscillations). These have yielded valuable information on the interactions between electrons and these forms of energy. Experiments in which magnetic impurities are present, either in the insulating layer or in one of the metals at the tunnelling junction, have been used to explore the electronic states of these impurities.

Measurements of the attenuation of ultrasonic waves in an elastic medium have yielded values of the energy gap for electrons moving in particular directions in a crystal. The attenuation of ultrasonic waves in the superconducting state is less than that in the normal state, for frequencies that are less than the gap energy (associated with a Cooper electron pair) divided by Planck's constant ($2\Delta/h$), because a phonon in that frequency range has insufficient energy to excite the electrons that are in unexcited states below the gap.

Extensive measurements have been made of the effect of magnetic impurities on the transition temperature and other properties of superconductors. The effects are sensitive to any spin ordering (orientation of electron spins in a crystal), such as the ordering in nickel and iron, and therefore yield information about this ordering.

The properties of a superconductor never change discontinuously at the transition temperature. The direct-current electrical resistance, for example, decreases continuously as the sample is cooled through a finite range of temperatures. The width of this range is usually small and has been observed to be as small as 2×10^{-5}° K in a pure, unstrained superconductor. (The transition range can be as wide as several degrees, as a result of large inhomogeneities or strains in a sample.) Near the transition temperature, thermodynamic fluctuations between the superconducting and the normal states occur at localized regions of the material. When the width of the transition is mainly a result of these fluctuations, information about them can be obtained by measurements of the properties of the material in the transition region.

Transition range

Surgery

Surgery is identified by the general public as the surgical operation and is defined by some dictionaries as the art and practice of treating injuries, deformities, and other disorders by manual and instrumental means. Surgery actually includes far more than this. The modern surgeon conducts the patient through the diagnostic phase, the preoperative preparation, the operation itself, and the postoperative and rehabilitative period. Thus, it is obvious that the operation takes relatively little of the surgeon's time and thought except in minor injuries. It also should be evident that the surgeon must have an extensive medical knowledge of the working of the body as well as a knowledge of the diseases that can be treated by operative means.

Surgery is fundamentally involved in the management of acute injury as differentiated from chronic, slowly progressing diseases, except when patients with the latter type of disease must be operated upon. Not only does the surgeon take care of the accidentally injured man and the battle casualty but his deliberate violation of the body, as he cuts into it in the elective operation, creates the same sort of damage as is received in an automobile accident. Secondly, there are but three basic acute bodily injuries in the surgeon's province of treatment. These are: loss and disruption of body tissue, as represented by the wound; loss of body fluids, such as blood and gastrointestinal juices, resulting in shock and dehydration; and the invasion of the body by disease-causing pathogenic organisms that produce localized or generalized infection. These three injuries may exist singly or in combination and may result in death if not combatted.

Since the wound is the central happening in surgery, a knowledge of the significance of the wound to the body as a whole and knowledge of wound care make surgery a unique medical specialty. The surgeon's education and knowledge are among the most comprehensive in medicine.

DEVELOPMENT OF SURGERY

Surgery is as old as mankind, and anyone who has ever staunched a wound has acted as a surgeon. In some ancient civilizations surgery reached a rather high level of development, particularly in India, China, Egypt, and, later, in the Hellenistic period of Greek civilization (from the 4th century BC to the 2nd century AD). Medical knowledge and, thus, also surgical knowledge was usually invested in the hands of the priests or the religious orders, particularly in the Western world. It was not until a 13th-century pope interdicted the practice of law and medicine by the clergy that medicine came into the hands of the laymen. The practice of surgery was not taught in most universities, and ignorant barbers wielded the knife. Often they acted on their own responsibility, but frequently they were called in by physicians, who directed their operating. Some barber-surgeons became eminent, wrote treatises on surgery, and were good observers. The Huguenot Ambroise Paré, who lived in 16th-century France, was a barber-surgeon of this type. He used the ligature for blood vessels, for example, instead of cauterizing wounds with hot oil, an Arabic practice. He also used the "kind" treatment of cleansing wounds by washing them with wine and water. The principles of his wound treatments resembled those of the Hippocratic school of Greek medicine (5th–4th centuries BC). Hippocrates stressed that the surgeon should foster and use the healing power of nature rather than interfere unnecessarily. In 1540, in the reign of Henry VIII, organization of the Company of Barber Surgeons of London marked the beginning of some control in qualification for performing operations. This guild, which lasted two centuries, was the precursor of the Royal College of Surgeons of England.

Surgery by barbers

At the end of the 18th and the beginning of the 19th centuries, surgery was firmly established in the medical curriculum. In the period that closed with the public demonstration of anesthesia by the use of ether as an anesthetic, in 1846, the development of surgery was remarkable, despite the lack of anesthesia. Progress at this time was achieved by the application of accurate anatomic knowledge and by the development of skill and rapidity of operating. It was the time of great names in surgery, the cult of the personality. Patients were sedated with opium, made drunk with alcohol, and tied down, so that a leg amputation, for example, could be done in three to five minutes.

Almost simultaneously with the beginnings of modern surgery, which dates from the introduction of ether anesthesia (1846), came the identification of micro-organisms as the cause of infection in wounds. Promulgation of the germ theory of disease by the French microbiologist Louis Pasteur (mid-19th century) and the application of this theory to wound sepsis by the British surgeon Joseph Lister resulted in the technique of antisepsis, which brought about a remarkable reduction in the mortality rate from wounds and elective operations. Before, micro-organisms had been observed in pus from infected wounds, but were thought to be the product of sepsis (putrefaction) rather than its cause. Infection hitherto was considered of biochemical origin. Hospital gangrene, so-called, was so common as to interdict elective surgery at various times in the 19th century. The spread of infection from one patient to another by attendants, including the surgeon, was the cause of the high rate of sepsis. Lister's observation that it was only compound fractures (those in which the skin had been broken and the deep tissue exposed to the environment) that became infected made him sure that the micro-organisms introduced from the environment were the cause of hospital gangrene. Lister's technique of employing antibacterial carbolic-acid spray was instituted gradually in the latter part of the 19th century. It was supplanted by the aseptic technique of sterilizing instruments and materials by moist heat under pressure. This technique is still in use.

20th-century developments

At the turn of the century, the discovery of X-rays by the German physicist Wilhelm Conrad Röntgen added an important diagnostic tool without which modern surgery would not exist. Next, the discovery of blood types in 1900 by the Austrian biologist Karl Landsteiner made transfusions safe. New techniques of anesthesia involving not only new agents for inhalation but also regional anesthesia accomplished by nerve blocking (spinal and local anesthesia) also were introduced. Positive pressure and controlled respiration techniques made chest surgery safe. Ultimately, the intravenous administration (injection into the veins) of anesthetic agents made its appearance. Finally, in the present period, the replenishment of body fluids by intravenous infusion, the introduction of chemicals and antibiotics (in the 1930s and 1940s, respectively) for antimicrobial use and the treatment of the metabolically disturbed body as well as the local wound were additional factors in bringing surgery to its present state, in which every body cavity, system, and area can safely be operated upon.

Today, experimental surgery in animals prepares the way for new and better human application. New operative techniques, such as the application of the laser beam and ultrasonics, have emerged in the experimental and in some cases the practical phases of surgery. These will be discussed in more detail later.

SURGICAL THERAPY OF THE BODY AS A WHOLE

That an injury has a general effect on the body is a most important concept of surgical thought, for an understanding of it as a guide to therapy affects the outcome of serious operations or injuries. The celebrated British surgeon John Hunter appreciated the magnitude of the general effect of acute injury when, in the early 19th century, he wrote: "What does the wound signify to the organism? By what mechanism does the organism safeguard itself against the effect of the wound immediate and remote?" It was not until the late 19th century, however, and more recently that the physiology of bodily response to injury became understood. The dread derangement of metabolism in surgical disease called surgical shock usually results from blood loss but may result from any of the three acute injuries.

The word injury, which formerly was used in surgery to signify trauma, now has an extended meaning that is suggested by the adjective injurious. In other words, it can refer to any action that does harm to the human body. And this extended definition is correlated to a similar development of surgical therapy extending beyond the operation itself.

The bodily response to acute injury protects the organism and preserves its resources, essentially under the control of the entire endocrine system and particularly the adrenal gland, this gland being recognized as the principal organ involved in the immediate response to stress; *i.e.*, triggering the stress reaction (see also the article HORMONE). The physician and physiologist Hans Selye spoke of "the alarm reaction" in describing the events that follow acute injury. Studies of the phenomenon have reached a stage at which the severity of a given injury can be measured in certain respects by the changes in metabolism and particularly by studies of the body fluids—blood, body water, and electrolytes (the salts of body water)—and the excretory function of the kidney.

The relatively new concept that the reaction to injury constitutes a complex homeostatic mechanism has developed from the work of the physiologists Claude Bernard, in the late 19th century, and Walter B. Cannon, in the first part of the 20th century. Cannon coined the term homeostasis for the ordered and coordinated progression of physiologic processes that keep most of the steady states in the body within a small range of variations. Homeostasis holds the body temperature relatively constant, for example, and serves to regulate the quantity and composition of body fluids, including the level of sugar in the blood. The endocrine glands have an active role in homeostatic mechanisms, and there is simultaneous involvement of the heart, brain, lungs, kidneys, and other organs.

Protective mechanisms

Not only complex metabolic reactions but also simple protective mechanisms are brought into play by injury. Present understanding of the way that the body responds to injury sharpens the realization that natural processes can point the way toward proper treatment. Thus an effort is now made to preserve the normal patterns within the body by introducing substances that are in short supply and to correct other abnormalities in the body's metabolism, rather than to employ more drastic surgical measures. One of the greatest blunders during the Middle Ages and the Renaissance was the practice of bloodletting, which killed many people who had already lost much blood and were in shock. The great success that the followers of Hippocrates had in their day rested on this understanding of the ability of the body to restore itself to health. Simple responses to injury can be seen, for example, in the man whose peptic ulcer begins bleeding while he is on a hunting trip and has no help at hand. He does not set out for camp as fast as he can run, as he might if the decision rested with him, but instead he succumbs to involuntary mechanisms that save his life. He goes into the state of surgical shock, usually remaining conscious after a preliminary fainting spell. This manoeuvre is helpful in preserving and maintaining every vital function in the presence of a diminished blood volume. Thus, his vital organs, particularly in the brain, can get enough nutriment (sugar) and oxygen to sustain life until the bleeding stops spontaneously. While his blood pressure remains below normal, his arterioles (small arteries) contract, which makes the circulating vascular system smaller and thus favours the best use of what blood is left to supply vital areas. The deficient oxygen supply to the brain is relieved as the pulse pressure increases. This is nature alone at work, for if the man's brain lacks oxygen for ten minutes he may die from that alone. Other factors favourable to spontaneous stopping of bleeding then begin to operate. If the vessel from which the blood is escaping has sufficient elasticity, it will close its channel spontaneously, and clotting will occur, which eliminates the hazard of continued blood loss. The man's body will adjust to the stress, and, after a period of continued rest, his blood volume may be partially restored from available fluid stored in his tissues outside the cells. Other mechanisms for conserving the body fluids come into play, the most obvious of which is the diminution of the output of urine. But, first, total body rest and rest of a particular part of the body are enforced by nature and must be recognized as homeostatic mechanisms of a high order. These physical homeostatic mechanisms are employed daily in surgical practice; they are called bed rest and immobilization of the injured parts. That is the reason fractures are immediately splinted at the scene of accidents.

Bed rest and immobilization

There is a sameness to all bodily injuries (wounding, blood and fluid loss, and infection) that is expressed by similar endocrine and metabolic responses. Overwhelming infection with septicemia (invasion of the bloodstream by the disease organisms), for example, produces shock similar to that produced by loss of blood. The normal metabolic response to injury is an overlapping interplay among its three basic phases: conservation, degradation, and repair. Study of the conservation phase has given the surgeon insight into how to help the organism that is under the stress of injury. The key to understanding the human body is that it is largely composed of water (approximately 60 percent by weight) and that this water is distributed in three compartments containing salts suitable for cellular function. The first compartment is the circulating blood, which, in addition to its water and salt content, has red blood cells, essential to the oxygenation of vital organs, and white blood cells, concerned in a protective antibacterial function. The volume of blood varies from 4,000 to 5,000 cubic centimetres (four to five quarts), and its loss by extensive bleeding results in surgical shock, the most critical condition engendered by injury. Blood replacement not only is essential to the treatment of shock when it occurs but it is the key to prevention of shock during elective operation. The other two fluid compartments are within the body cells and outside the cells in the tissues. A shift of fluid and salts (electrolytes) among the three compartments occurs in severe injury and changes the electrolytic constituency of blood serum. Such changes can be detected by chemical examination and thereby serve as a guide to fluid and salt replacement. Decreased elimination of water and salts by the kidneys invariably occurs in shock. This reaction, largely under the control of the adrenal glands, tends to preserve the organism, as has been said before. When an injured person cannot eat and drink and may be losing blood or extracellular fluids and salts in excessive amounts, it is the surgeon's job to replace loss quantitatively and qualitatively. This is usually done by intravenous infusions—introduction of fluids into a vein. Cortisone, a product of the cortex (outer substance) of the adrenal gland, is of the greatest importance in regulating water and salt retention and excretion. Measurements of obvious body-water losses and estimations of average known losses of water in exhaled air and sweat are recorded, and the differences between losses and intake of fluid tell whether the person has a subnormal, normal or greater than normal supply of fluid. Examination of blood serum (the blood minus its cells and clotting factors) must be made periodically and often several times daily. The aim of treatment is to keep the internal environment as near normal as possible.

Resuscitation

Resuscitation of the severely injured requires prompt measures to assure a good airway, essential to oxygenation of the blood. It may even be necessary to make an opening through the wall of the windpipe, especially if there are injuries to the chest. Air must be removed that has entered the pleural cavity—the space between the membrane covering the lungs and that which lines the chest—since air in this cavity makes it impossible for the lung on that side to functon and displaces the heart. Other measures that need rapid application include starting an arrested heart and acting to maintain body heat.

MONITORING

At present, surgical therapy is greatly helped by modern technology, particularly by monitoring devices that are used during surgery for the person who is severely in-

jured, during shock, and also during the postoperative period. The surgeon and his assistants, however, are still the best monitors.

Monitoring during the operation consists in obtaining all or part of the following data, depending upon the case. Arterial and venous blood pressure and pulse rate must be monitored. A fall in blood pressure accompanied by a rise in pulse rate is an indication of impending shock, since it gives evidence of critical loss of the volume of circulating blood. Other items monitored are the heart contractions as indicated by electrocardiograms; electroencephalographic records (tracings of brain waves), which reflect changes in brain function and may reveal insufficient oxygenation of this vital organ; the oxygen level in the arteries and veins; carbon dioxide partial pressure in the circulating blood; and respiratory volume and exchange. More extensive monitoring is useful in patients in shock and in the critical postoperative period.

Automatic monitoring

There are, at present, three general areas in which engineering technology can provide monitoring for critically injured patients. The simplest but most useful of such monitoring is that in which machines record heart and respiratory rate, continuous electrocardiographic tracings, urinary-output volume, and similar values. These machines are essentially replacements of human monitors (nurses and technicians) and thus have not gained universal favour, since too great a separation of the patient from human contact might occur from their use. The machines also are expensive. This type of monitoring is of considerable value, however, in patients undergoing open-heart surgery. It allows the simultaneous observation of variation in arterial and venous blood pressure, the filling pressure of the heart, and the resistance to circulation. From these data, plus simpler ones, the output of the heart can be calculated.

The second monitoring installation makes use of automatically obtained data and simultaneously carries out measures to correct observed abnormalities. Intravenous fluid administration for example, can be adjusted to the output of urine. Blood transfusions and drugs can be given as needed in the same manner. This represents a substitution for human performance as well as observation.

The third realm of the use of advanced engineering techniques involves the application of complex computer programming and analyses to clinical investigation of disease. The types of instruments in general use at present are those made for other purposes, although special designs for medical use are being developed. The great obstacle in computer usage is that a considerable amount of modern medicine is still empirical and subjective in nature and thus difficult to translate into objective language for programming.

OPERATIVE SURGERY

Common materials and instruments. The first and essential knowledge for operative surgery is of anatomy and pathology, the structure of the body and the changes wrought by disease; manual dexterity comes second. Next in importance are prevention of bleeding and adequate exposure of the part to be operated upon.

Asepsis, the avoidance of contamination by disease organisms, requires that all instruments and dry goods coming in contact with the surgical field be sterilized. This is done with the autoclave, a device that subjects them to 30 minutes of moist heat at 260°F (127°C) with 20 pounds of pressure. Chemical sterilization of some instruments is also used. The patient's skin is sterilized by chemicals. The surgical teams scrub their hands and arms for at least five minutes, after which hands and arms are bathed in alcohol. Sterilized gowns, caps, and masks that filter the team's exhaled air and sterilized gloves of rubber or disposable plastic complete the picture. Thereafter, attention in avoiding contact with nonsterilized objects is the basis of maintaining the technique. It must be said, however, that disease organisms are ubiquitous in the operating-room air, on the patient's skin, in his gastrointestinal tract, and in the exhalations of all persons in the room. There is an irreducible incidence of wound infection resulting from operations, and more so when the wounds are accidental. The greatest source of wound infection in elective surgery is from the patient himself, since not only his skin but also his gastrointestinal tract harbours a large number and variety of disease organisms. The gastrointestinal tract must be opened in many operations, and this contaminates the operative field. Since the advent of antibiotics, preoperative "sterilization" of the gastrointestinal tract is often done by the use of nonabsorbed agents, particularly in surgery of the large bowel (colon). Before certain operations antibiotics are administered as prophylactics against wound infection, particularly when foreign bodies such as plastic arterial grafts are to be implanted permanently. These measures have greatly reduced septic complications of intestinal surgery.

Aseptic techniques

Hemostasis (the arresting of bleeding) is achieved by use of the hemostat, a clamp with ratchets that grasps blood vessels or tissue; after application of hemostats, suture materials are tied around the bleeding vessels. Electrosurgery (cauterization) can be used to stop bleeding but is not as popular or as secure as the ligature. In a long, bloody operation hundreds of hemostats are used. Absorbent cotton napkins, called sponges, are used for drying the field (at one time marine sponges were used; thus the use of the word sponge). Estimation of blood loss is made by weighing discarded bloody sponges. Deficiencies in the patient's blood-clotting mechanism are sometimes encountered; these can be controlled in some instances. Thus, it is now possible to perform elective operations on persons with hemophilia, an inherited disease involving a defect in the coagulating power of the blood.

Although there is a constant increase in sophisticated surgical instruments, the basic ones have remained little changed since the 19th century. Those most commonly used are the scalpel (knife), scissors, hemostatic forceps, flexible tissue-holding forceps, wound retractors for exposure, crushing and noncrushing clamps for intestinal and vascular surgery, and the curved needle for working in depth.

Suture materials

There are two basic types of suture materials: absorbable catgut, which comes from sheep intestine and which is of varying sizes and strength depending on its chemical treatment, and nonabsorbable materials, made of silk, cotton, steel wire, and synthetic materials.

Catgut is used extensively to tie off small blood vessels that are bleeding, and, since the body absorbs it in time, no foreign materials are left in the wound to become a focus for growth of disease organisms. The nonabsorbable sutures, on the other hand, when buried remain forever in the wound and can harbour micro-organisms. Nevertheless, these materials are needed in wound closure in many instances because of their sustained strength. Personal preference for various suture materials also enters into the selection of one or another type. Suture materials used to close the skin are removed when sufficient healing has taken place. The only important rules that guide the surgeon in selection of suture material are that it is preferable not to use nonabsorbable suture, especially silk, in infected wounds and that monofilament stainless-steel wire of a single strand is the best suture material in situations in which sustained strength is needed over a long period.

Unusual and specialized techniques and instruments. *Stereotactic surgery.* Stereotactic surgery, used in neurosurgery, is the accurate placement of objects, hollow probes or electrodes, by three-dimensional vision using X-ray photography. The apparatus is extremely sophisticated. For brain stereotactic placement the head must be held in a vise, known landmarks visualized by X-ray, and very fine wire electrodes or probes advanced to the desired site under mathematical guidance. The desired site can then be verified by observing that the response to electrostimulation is in accord with the expected response. Diseased tissue can then be destroyed by a variety of agents (cold, chemicals, electrocoagulation). In the case of the brain, only a small burr hole in the skull is needed for the operation. The obvious value of this technique is its avoidance of extensive and difficult dissec-

tion. Also, areas of the brain can be reached by stereotaxis that defy conventional exposure. This field is extremely important in neurosurgery and especially in developing new physiologic surgery (beneficially altering bodily function). The pituitary gland, for example, situated at the bottom of the brain and difficult to expose conventionally, can be reached stereotactically through the nasopharynx (that part of the pharynx, or throat, that is above the soft palate) by electrode or probe and thus destroyed when the procedure is indicated.

Laser. The word laser is an acronym for "light amplification by stimulated emission of radiation." The apparatus, first constructed in 1960, produces high-intensity light or radiation that is monochromatic (of one colour) and emitted in almost perfectly parallel waves. Therefore, much power can be generated in a highly concentrated area. The laser is essentially a cauterizing agent and is absorbed by pigmented lesions. The use of the laser in surgery is still experimental and confined to the hands of experts. Pigmented tumours, freckles, and tattoos have been treated by this method. It has been used palliatively on cancer of the tongue and other superficial tumours. In depth, the laser has been used to destroy brain tumours by special techniques. A number of other experimental uses of the laser are found in the treatment of dental decay and in surgery on the blood vessels. With the development of sophisticated instruments for its application, the laser is expected to be useful in treatment of areas inaccessible by conventional surgery.

Electroencephalography. Electroencephalography, the recording of electrical activity of the brain by tracings, has been in use for a long time. Normal patterns of brain waves are known. Abnormalities in the electroencephalogram, or EEG, as it is commonly called, reflect alterations in the excitability of the brain cortex (the outer substance of the brain). This apparatus is useful in the diagnosis of epilepsy, brain tumours, and hematomas and infections in the brain. Hematomas are masses of blood that have escaped from vessels and press on adjacent tissues.

Ultrasonics. Ultrasonics is the science concerned with sounds too high to be heard by the human ear. These sound waves usually exceed 20,000 vibrations per second. Ultrasonic devices were used extensively during World War II for the underwater detection of submarines (sonar), and in medicine and surgery they have been found to be particularly useful in diagnosis. Ultrasonic waves produce certain characteristic echoes when they strike the boundaries between tissues of different densities. These echoes, or reflections, are then recorded. Since 1956 ultrasonic devices have been used to sterilize surgical instruments. In the treatment of the eye, high-frequency sound waves are being used experimentally to dissolve cataracts (opaque lenses) and practically to diagnose detachments of the retina, the light-sensitive layer in the back of the eye, and in other intraocular conditions. Ultrasonic nebulizers provide humidity to the windpipe and to the bronchioles—small air passages in the lungs—in persons with respiratory diseases. In the field of neurosurgery the ECHO encephalogram uses the reflection of ultrasonic waves to localize structures within the skull. Also in the field of neurosurgery, ultrasonic energy is being used to destroy certain nerve tissue and thereby alleviate disorders involving overactivity or intractable pain. Devices employing ultrasound to produce heat locally are used for treating inflammation in muscles and joints. Ultrasound has been used in studies of fetal growth and of the functioning of the heart valves. Its greatest use in the future will probably be in gathering information of this type and in the general area of diagnosis.

Cryosurgery. Cryosurgery is the destruction of tissue by means of extremely low temperatures rapidly achieved. Liquid nitrogen is the usual agent used. Temperatures of −125° to −130° C (−195° to −200° F) are usually obtained in clinical use. Cryosurgery has several desirable features. It can usually be employed without general anesthesia, and, by the use of special instruments —essentially hollow probes through which the destructive agent is delivered—brain tumours and other diseased brain tissue, difficult or impossible to reach by conventional surgical techniques, can be destroyed. Probes are placed with the aid of stereotactic techniques. Inoperable cancers of the tongue and mouth can be treated palliatively by this method, since it usually relieves pain and reduces the size of the tumour. It is safer than the laser in its application.

Advantages of cryosurgery

Microsurgery. In the mid-1950s the surgical microscope was developed for operations on the eye and ear. The surgical binocular microscope is now extremely complex. Greater visual facility has been gained with the use of colour filters to increase contrast. Multiple eyepieces to fit the eyes of several surgeons and magnification powers of small intervals such as six times, ten times, 16 times, 25 times, and 40 times (the limit of capability of the hand) have been additional valuable features of microsurgery.

Although surgical techniques had to be modified for microsurgery, the needed dexterity can be obtained by most surgeons. Special small instruments have been developed.

Most procedures are performed by the use of finger rather than wrist motions, especially in suturing. The fineness of suturing is limited by the needle diameter, but needles of $\frac{1}{5,000}$ of an inch in diameter have been used.

The microscope has been a particular boon to the surgery of small vessels, structures difficult to see, to dissect, or to suture under ordinary vision; these include the eye, nerves, the ureters, the bile ducts, and structures in the male and female reproductive organs. The surgical microscope has also proved useful in surgery on the coronary arteries.

Closed and open surgery

Basic techniques. There are two general techniques of wound treatment; the closed technique, in which all tissues, including the skin, are closed with suture material after completion of the operation; and the open technique, in which the wound is left open, to be closed later. The open technique is used in badly contaminated wounds in which infection might be anticipated if immediate closure were done. Open treatment allows wound drainage and thus avoids entrapment of micro-organisms, while also permitting observation of the wound. In military surgery, wounds are usually badly contaminated. Such wounds are subjected to debridement. Debridement consists of removing foreign bodies, such as shell fragments, fragments of clothing, and dirt, as well as all dead tissue upon which micro-organisms thrive. The wound is then extensively washed. It is left open for seven to ten days; after this period the wound is closed if it is clean. Serious infection is avoided by this method of treating contaminated wounds. The technique has a place in similarly contaminated civilian wounds; notably, compound fractures—fractures in which bone fragments have penetrated the skin. Infected wounds or tissues are cut into and drained, but drainage is sometimes delayed. The body's antimicrobial forces must be given time to work; during this process, an abscess is formed, which then can be drained. The principles for the treatment of all infection are the same. Drainage is established at the proper time. Resting of the body as a whole and of the part involved, general restoration of the bodily fluids, and the use of antimicrobials—substances to combat infection—complete the picture.

Major categories. There are five major categories of surgery. These are (1) wound treatment, (2) extirpative surgery, (3) reconstructive surgery, (4) physiologic surgery, and (5) transplantation of tissues and organs. The five categories are used in all surgical specialties.

Wound treatment. The technical aspects of wound treatment, already discussed to some extent, revolve around procuring good healing and the avoidance of infection. The elective wound, the wound made in the process of performing an operation, must be large enough so that the area to be operated upon can be seen accurately and injury to other structures can be avoided. In surgical jargon this is called exposure. Instruments called retractors, held by assistants, draw back the sides of the wound and further enhance exposure. Hemostasis not only prevents blood loss and improves visibility but

prevents other complications. In operations on the brain, for example, small, slow leaks of blood can cause serious pressure on the brain and result in unconsciousness. Inadequate hemostasis leaves pools of blood, which promote growth of micro-organisms and encourage wound infections.

Extirpative surgery. Extirpative surgery, one of the earliest types of surgery after wound treatment, involves removal of diseased tissue or organs.

Cancer surgery

Cancer surgery and "radical" operations are of this category. In cancer surgery, not only is the organ or part of the organ containing the cancer removed but so also is a wide margin of adjacent tissue, which might even include adjacent organs. Most importantly, the lymphatic drainage of the organ and its lymph nodes are cut out in one continuous mass (*en bloc*), since it is known that one route of the spread of cancer is by lymphatic channels. Until the present time, surgical excision has had no peer in the cure of cancer, and indeed most of the progress obtained in cancer survival has been made in the extension of the use of operative surgery and in the reduction of operative mortality. Radiation therapy plays some part in "cures" but is most used in palliation. Surgical excision is also palliative when it does not cure. The word radical, applied to surgery, refers to extensive surgical excision and not to heedless abandon in the use of the knife. In radical mastectomy, for example, the operation for cancer of the breast, the breast and the contents of the armpit, including the lymph nodes, are removed.

Reconstruction and replacement surgery. Reconstructive and replacement surgery deals with the consequences of injury—fractures, burns, congenital deformities, and the end results of degenerative-disease processes. To replace lost tissues, grafts, from the patient himself or from a donor, and plastic materials are used. Common examples of this category of surgery are the use of metal in reconstructing hip joints, replacement of diseased heart valves with valves of plastic, and the use of synthetic materials for replacing or bypassing diseased arteries.

Physiologic surgery. Physiologic surgery is a new field. It does not attack the disease but rather alters the body in such a way as to change its function for the betterment of the patient by eliminating the symptoms of the disease or by lessening their impact. An example of this kind of surgery is cutting the vagus nerve in persons who have peptic ulcer (an ulcer in the wall of the stomach or the duodenum). It is known that acid is the principal factor in the production of such ulcers and that the vagus nerve controls one phase of gastric-acid secretion. Severing the vagus nerve, therefore, reduces the secretion of gastric acid and improves the condition of the ulcer, although the fundamental cause of the disease cannot be attacked because its cause is not known.

Transplantation surgery. Grafting of skin from one point on a person's body to another has long been practiced. Grafts of skin from other persons are ultimately rejected but are of use temporarily in the coverage of burn surfaces. Progress has been made in transplantation of organs, including the heart, but the problem of rejection has not been solved. Various methods have been used to reduce the immunologic reaction, but the factor that has the most favourable effect upon the outcome of organ transplantation has been close relationship between the donor and the recipient. The best results are achieved when the two members of the pair are identical twins. Functioning kidney transplants between identical twins, for example, have survived eleven years or more.

Preoperative and postoperative care. *Preoperative care.* The principal work of preparation of patients for major elective operations is to restore them to as near their normal physiologic state as possible. By and large, most preoperative preparation consists of administering blood to the anemic patient with low serum-protein values and giving water and salt by injection into a vein if dehydration be a problem. In some cases antibiotics are given. The bowel, for example, is sterilized by administration of nonabsorbable antibiotics for 24 to 48 hours before an operation for cancer of the intestine is undertaken. Antibiotics are also administered before an operation when any sort of foreign body is going to be left in the body: plastic heart valves, for example. The study of the patient's heart and lung functions and other diagnostic tests are a major preoperative preparatory concern of the surgeon. Digitalis may be given preoperatively to stimulate the heart, for example. An estimation of risk is made, but few persons are denied major surgery on account of age alone, previous "heart attack" (coronary-artery disease), or substantial deficiencies in lung function. Statistical data on life expectancy, the average risk of the operation, and its chance of cure are all known to the surgeon. While concerned relatives of the patient can be informed of risk, type of operation, and other factors, it is finally the patient's own decision for or against surgery that is paramount; that is, if the patient is adult and of sound mind.

Pre-operative use of antibiotics

Preparation for emergency surgery must be done rapidly. Surgical shock, needing much blood replacement, is often a problem. Procuring and maintaining a good airway for breathing is essential. Teamwork and organization of resuscitation procedures have made for a high degree of proficiency in large hospitals and have resulted in saving many lives.

Postoperative care. The only difference between preoperative and postoperative care is quantitative. The objective—the restoration and maintenance of an optimum physiological state in a person who has been severely injured, often deprived of his full respiratory function, frequently dehydrated and anemic (especially if the blood supply is inadequately replenished throughout the operation), and often unable to eat and drink for several days or weeks after surgery—is the same as before the procedure was done. Thus, blood transfusions, intravenous administration of fluids, and the use of measures calculated to prevent common complications such as lung infection and blood clotting in the legs are the principal features of postoperative care. The prevention of postoperative complications with respect to the lungs is done by early but controlled moving of the patient in bed, the encouragement of coughing to expel fluids that have collected in the lung, suctioning of the air passage by use of rubber tubes, and finally, early walking about; walking, by improving the circulation in the legs, helps to prevent formation of blood clots, which can cause death if they migrate to the principal arteries in the lung. One of the most helpful modern postoperative aids is assisted respiration. This is done by machines that, by way of a tube in the bronchus, deliver much more adequate oxygen and ensure more adequate excretion of carbon dioxide in patients with crippled lungs.

Post-operative pulmonary complications

Chemotherapy and antibiotic therapy have a large place in obviously infective diseases. If the disease organism cannot be identified so that an accurate selection of effective drugs can be made, broad-spectrum antibiotics may be used; *i.e.*, antibiotics effective against a wide range of disease organisms.

The surgeon and his assistants are indispensable as monitors; by faithful attendance at the bedside, studying the patient and the charted data of his pulse, blood pressure, respirations, and laboratory data, they do much toward carrying patients through to recovery and rehabilitation. Mechanical monitoring has been discussed in an earlier section.

The increased range of surgical possibilities, not only from new operations but also from the acceptance for major surgery of persons so physiologically crippled as to have been considered unacceptable risks 20 years ago, has made monitoring by precision instruments a necessity today. This is also the case for severely accidentally injured patients who are in shock from blood loss and tissue damage or from overwhelming infection. In large modern hospitals, suitable equipment and trained personnel are available for such special postoperative care.

SPECIALIZATION IN SURGERY

The specialties in surgery are regulated by members of the profession rather than by state action in most parts of the world. In the United States, persons qualify as surgi-

cal specialists by taking graduate medical training of a specified type and for a specified period, by passing oral and written examinations in the specialty, and by presenting evidence of having satisfactorily performed a sufficient number of actual operations in the field. Boards have been established consisting of experts in a given specialty, who in periodic sessions meet candidates personally.

The Royal College of Surgeons of England preceded the United States in recognition of surgical specialties. There are royal colleges in England, Scotland, Ireland, and in many of the Commonwealth nations. In continental Europe specialists serve long apprenticeships in teaching hospitals. The result in Europe has been to limit the number of qualified surgeons. There is also a tendency to hold young men back, since professors often maintain control to an advanced age.

The first year of postgraduate training in the United States is called the internship. It involves a combination of internal medicine and surgery or may consist of exposures to the whole range of surgical specialties. The years beyond the internship are called the resident years, and the person serving them is assistant resident or, on occasion, becomes the chief resident. The chief resident in the United States is equivalent to the registrar in Great Britain and the *chef de clinique* in France.

The situation with respect to placement of a newly qualified surgical specialist in the United States differs from that in Europe. In the United States there are usually openings in community hospitals that are available as soon as a man has become qualified in a surgical specialty. There is a relative dearth of such hospital openings in England and in continental Europe.

The process of specializing within the field of medicine has gone furthest in the United States, where there are 31 medical specialties and subspecialties each governed by qualifying boards. Ten of these specialties involve surgery. A brief look at each of the surgical specialties follows.

General surgery. General surgery is the parent specialty and represents the field with the largest repertoire. It requires the longest training period, since it requires a limited exposure to all of the specialties and often one or two laboratory years in experimental surgery. Essentially, general surgery consists of doing the work that the practitioners of the more recent surgical specialties do not do. The heads of the departments of surgery are traditionally general surgeons, and rightly so. The appellation general surgery is an unfortunate one, for the public thinks of the general surgeon as some sort of general surgical practitioner, and thus general surgery seems a less prestigious pursuit. The principal anatomic and systemic spheres of general surgery are now the stomach and intestines; the breast and, particularly, cancer of the breast; and the peripheral blood vessels, as when the circulation to the extremities is poor. The general surgeon also deals with the endocrine (ductless) glands, such as the adrenal and thyroid glands; with tumours of the soft tissues; and with amputations. He sometimes deals with fractures, although this field has largely been taken over by orthopedic surgeons. When a person has been severely injured, a general surgeon is normally in charge of his case, although a number of other specialists may be involved. Since cancer is a common disease in the general surgeon's domain, and since cancer is more common among older people, much of the general surgeon's practice is among the elderly, although he does perform surgery on infants, also.

Functions of general surgeons

The management of patients at the two extremes of life is not a formal specialty but does require specialized knowledge, particularly with respect to children. Pediatric surgery is not so much a matter of understanding special operative techniques as of knowing the metabolic states in children and of having a background of experience with them. Many congenital anomalies require operations in the first few hours after birth, and the timing of the operation is an important consideration. Fortunately, the newborn tolerate anesthesia and surgery well, except in the case of the prematurely born.

Advanced age itself is not a contraindication to extensive surgery; rather, it is the physical state of the patient, his heart function, and his pulmonary status, in particular, that count.

Plastic surgery. Plastic surgery is largely concerned with the bodily surface and with reconstructive work of the face and exposed parts. The disfiguring facial deformities resulting from warfare gave the greatest impetus to the development of plastic surgery after World War I. Congenital anomalies such as harelip and cleft palate also are operated upon by the plastic surgeon. Removal of lesions on the face, eyelids, and ears with the greatest possible avoidance of functional and visible deformity is best done by these specialists. Skin grafting, particularly the resurfacing of burns, is now largely in the hands of the plastic surgeon. The invention of the dermatome, an electrically or manually propelled drum that can cut large pieces of skin of measured thickness, not only has made the art of the cutting of freehand grafts obsolete but produces larger grafts than free cutting ever could. Sufficient of the underlying skin is left at the donor site to ensure that the skin will grow back. This type of graft is commonly called split-thickness graft. Another development of grafting is the pedicle graft, in which the whole skin and the subcutaneous tissue can be gradually shifted to recipient sites from remote parts of the body where it is not needed. Reconstruction of the nose, eyelids, jaws, and ears is done commonly by the plastic surgeons in cooperation with general surgeons. Some plastic surgeons do the whole job in cancer surgery of the head and neck. The essence of technical plastic surgery is the careful planning of incisions so that they fall in the line of natural skin folds or lines, the use of fine suture material, and the early removal of exposed sutures so that the wound is held closed by buried sutures. Surgery of the hand, restoring function after tendon severance, is a specialty in itself, but much of the work is done by plastic surgeons. The public sometimes identifies plastic surgery with "beauty surgery," but most plastic surgeons are more involved in getting good cosmetic results after burns, removal of tumours, and reconstructive work than in cosmetic or "beauty" surgery for its own sake.

Functions of the plastic surgeon

Cosmetic surgery is largely done by surgeons who confine themselves to this field. Such surgeons usually have their own private hospital facilities, and their numbers are small.

Orthopedic surgery. Orthopedic surgery deals with congenital defects such as clubfoot, congenital dislocation of the hips, and scoliosis (curvature of the spine), but the largest field of orthopedics is in the treatment of fractures of the extremities, which may be either simple (in which there is no open wound) or compound (in which the skin has been penetrated either by the fractured bone or by some object). Compound fractures are more serious because disease organisms can enter and infect the tissues and bones. The basic principle of treating fractures of long bones is to bring the two broken ends into the proper position and hold them there until healing has occurred. Traction on the lower segment of the broken bone is necessary, and, while this can sometimes be done by manipulation, more usually it is necessary to exert traction by a system of weights and pulleys secured to the lower fragment. There are a variety of means of applying traction; usually a heavy wire or pin is driven through the lower fragment, and to this the weights are applied. The next important principle of fracture treatment is immobilization. Plaster-of-paris casts are most frequently used for immobilization of fractures of the extremities.

A direct operative approach to the treatment of fractures, commonly called open reduction with internal fixation, is also a common practice today. By incision the fracture is approached and manually reduced (placed in proper position); a metal plate is used to hold the fragments together. Screws are used to fix this plate to the two segments. Frequent X-ray examination is necessary to verify that the bones have remained in proper position and to observe the progress of healing. Bones heal slowly, and failure to heal is sometimes a problem. Another method of internal fixation of fractures of the long bones

is accomplished by driving a long steel rod down the marrow canal after alignment of the fragments.

Metallic prostheses (artificial parts) are commonly used in orthopedic surgery; useful hip joints can be made of metal. Sometimes metal plates used in the treatment of fractures are left in place permanently, but usually they are removed after healing. Orthopedists also treat back pain and examine patients for insurance claims.

Another field of treatment covered by orthopedic surgery is that of benign or malignant bone tumours. Osteomyelitis, a severe infection of the bone, is less common today than 30 years ago, probably because of the better hygiene now practiced in advanced countries. Since orthopedic surgery includes the treatment of joints, muscles, tendons, and ligaments, athletic injuries are mainly in the domain of this specialty.

Obstetrics and gynecology. Obstetrics and gynecology are combined specialties in the United States as far as board certification goes, but many surgeons confine their practice to just one of the two specialties. The basic operations in gynecology are of two general types. The first is repairing the injuries of childbirth. In all births the vagina is stretched and torn, with varying degrees of damage to the suspensory ligaments of the uterus and bladder; the uterine cervix may be injured, for example. Extirpative surgery of the uterus and ovaries for tumours, benign or malignant, is the second major operation. The diagnosis of the causes of sterility and subsequent treatment by medical means or surgery are a combined obstetrical and gynecological effort that has made significant progress since World War II.

Repair of childbirth injuries

Gynecologists practice medical endocrinology when they treat symptoms of the menopause and abnormal uterine bleeding and when they control ovulation to prevent pregnancy.

Gynecologists make routine examinations of cervical and vaginal secretions to detect cancer of the uterus, fairly common among relatively young women; if these tests suggest the possibility of cancer, specimens of tissue may be taken from the cervix for microscopic examination. These and other periodic examinations and minor office surgery take up much of the gynecologist's and the obstetrician's time. Uterine cancer is often treated by a combined use of radiation and extirpative surgery, surgical removal of cancerous tissue. The application of radium to the cervix for cancer must be done accurately and the dosage carefully calculated by the combined efforts of the radiologist and the surgeon. Cancer of the cervix is more commonly treated by radiation alone, while extirpation is the preferred treatment of cancer of the body of the uterus.

Terminations of pregnancy for social reasons rather than medical are now a substantial segment of gynecologic practice in certain European countries and in some states of the United States (New York State, for example).

The obstetrician's tasks are to bring a woman through pregnancy, to deliver her child, and to give her adequate postnatal care. Prenatal care is important in the detection of possible abnormalities that may complicate delivery, and fetal abnormalities can, in some cases, be diagnosed early in pregnancy. Complications such as premature separation of the placenta require prompt surgery. The recognition of acute abdominal complications, such as intestinal obstruction and appendicitis, is an extremely important aspect of prenatal supervision, since the symptoms of such diseases may simulate labour.

One surgical operation performed by obstetricians, cesarean section, in which the infant is delivered through an incision in the mother's uterus and abdominal wall, is considered necessary in far fewer situations than formerly, and the circumcision of male infants at birth as a hygienic procedure is somewhat less routine than formerly.

Another change in the area of obstetrics has been a shift away from specialized lying-in hospitals to general hospitals, where the services of specialists in all fields are readily available and auxiliary services are complete.

Ophthalmic surgery. Ophthalmologists are trained, for a period of at least three years after an internship, in the medical and surgical aspects of the treatment of diseases and injuries of the eye. Although there is a large field of nonsurgical eye treatment, the surgical field has expanded of late. The correction of certain types of squint (conditions in which the lines of vision of the two eyes are not parallel), the extraction of opaque lenses (cataracts), the relief of high pressure in the eyeball (glaucoma), and reattachment of the retina after it has become detached are among the common operations of the specialty.

New developments in eye surgery include the use of ultrasound in diagnosis. Ultrasound has been tried experimentally for dissolution of cataracts also. The laser is now commonly employed in treating diseases that lead to bleeding in the eye. Occasionally, the laser is used for fixation of detached retinas. Ninety percent of persons who suffer detachment of the retina can now expect restoration of eyesight to some degree. Cryosurgery is often used for lens extraction, treatment of detached retina, and treatment of glaucoma.

Ultrasound and laser in diagnosis and treatment

The transplantation of the cornea from a dead donor to a live recipient is one of the oldest, most successful, and most common of transplantation procedures. The cornea must be implanted soon after death of the donor. Transplantations of the cornea are useful for hereditary corneal diseases of the eye and for corneal burns.

Experiments are being made in the use of synthetic materials to replace corneas. Another new development in eye surgery is the use of special glues as a substitute for sutures. These glues have been highly successful in some instances.

Colon and rectal surgery. Colon and rectal surgery is recognized as a specialty, but only a few surgeons confine their practice to the specialty, and few training centres offer it. Much of the surgery on the colon and rectum is done by general surgeons.

Urology. Urology is concerned with the treatment of diseases of the urinary tract and, in men, of the genital apparatus. The urinary tract consists of the kidneys, the bladder, the tubes between the kidneys and the bladder—the ureters—and the urethra, the tube carrying urine from the bladder to the external opening. Most of the urologist's patients are male, for two reasons: (1) the urinary tract in females is also treated by gynecologists, and (2) much of the urologist's work has to do with the prostate gland, which encircles the male urethra close to the juncture between the urethra and the bladder. The prostate gland is often the site of cancer; even more frequently, it enlarges in middle and old age and encroaches on the urethra, causing partial or complete obstruction to the flow of urine. Prostate enlargement is treated either by total excision of the prostate or by reaming a wider passageway through it. The urologist also may operate to remove stones that have formed in the urinary tract. Surgery performed by the urologist also includes operations for cancers of the kidneys, bladder, and testicles.

Much of the urologist's time is devoted to diagnosis—by X-rays, by use of the cystoscope, and by biopsy. The cystoscope is a tubelike instrument equipped with an electric light on its end. By introduction of the instrument through the urethra, the urologist is able to view the interior of the bladder. In biopsy a piece of tissue is removed for examination under the microscope.

Otolaryngology. Otolaryngologic surgery is performed in the area of the ear, nose, and throat. Previously it was concerned almost entirely with operations upon the tonsils, the sinuses, and the mastoid processes, the bulges in the skull just behind the ears. Much of the surgery for infections in these structures has become unnecessary since the advent of antibiotic therapy. Benign and malignant tumours of the upper air passages, particularly of the larynx, are currently dealt with by the otolaryngological surgeons. Laryngectomy, removal of the voice box for cancer, and the subsequent training of patients to talk are noteworthy accomplishments in the field. More recently, conservative operations for cancer with preservation of the voice have become feasible.

The remarkable progress in surgery for deafness that has occurred since the middle 1950s is one of the most

prominent accomplishments of otolaryngology. Any type of deafness that does not involve the auditory nerve may be within the scope of otolaryngological surgery. Microsurgery has made this ear surgery possible. Cryosurgery has a limited use for palliation of malignant tumours that are inoperable and incurable. Ultrasound, as well as decompression operations, has been used in the control of Menière's disease, a disease of the membranous labyrinth that results in attacks of deafness, dizziness, and other symptoms. At present, eardrums and some of the bones of the middle ear are being transplanted from cadavers with remarkable improvement in the hearing of the recipient. An area now receiving experimental attention is the implantation of suitable electrodes in the inner ear to facilitate the conduction of sounds from external hearing aids.

Neurological surgery. Injury to the brain from skull fractures is the most common disease encountered in the area of neurosurgery. Other lesions treated by the neurosurgeon are tumours of the brain and spinal cord, diseases and injuries of the peripheral nerves, and ruptured intervertebral discs that cause pressure on the spinal cord. The majority of the tumours of the brain operated upon by the neurosurgeon are malignant, but palliation is often obtained. A constantly enlarging field is vascular surgery of the brain. Bleeding from congenital aneurysms (weak spots in blood-vessel walls with resultant dilation or bursting of the vessels) or in patients with high blood pressure frequently requires operation. The great developments of neuroradiology have furthered this field of vascular surgery, and indeed angiography (X-rays of blood vessels) of the cerebral vessels accomplished by rapid X-ray photography after the injection of radio-opaque substance into the large blood vessels of the neck (carotid arteries) has aided greatly in the diagnosis of lesions of the brain.

Neurologic diagnosis

The cerebral vessels have a normal fixed anatomic pattern, and distortion of the pattern by the presence of brain tumours or other lesions shows in the X-rays. Measurement of blood flow is another new, useful diagnostic technique that has greatly added to the accuracy of diagnosis. Most important, stereotactic techniques have been developed by means of which instruments (such as hollow probes) can be accurately placed within the brain. By the use of such techniques, small areas of the brain that are causing abnormal cerebral activity can be destroyed, without the disruption that would be caused by the conventional methods. At present, one of the principal benefits of stereotactic surgery of the brain is the knowledge of brain function that is accumulating, and it is in this experimental area that the future of neurosurgery lies. Microsurgery is being used in the removal of small tumours of the cranial nerves and in surgery on small blood vessels. It promises to have a wider application. The overall operative mortality rate is about 5 percent for all operations on the skull; these cases include a large number of patients who have received irreversible brain damage from accidents. Damage to the brain with or without skull fracture is an associated or principal cause of death in over half of automotive accidents.

Thoracic surgery. Thoracic surgery, an offshoot of general surgery, became broad in scope in the late 1940s. Earlier, the treatment of pulmonary tuberculosis by collapsing the lung, so as to rest it, and emergency operations for bullet and stab wounds of the lung and heart were the principal repertoire. The introduction of the mycin group of drugs (*e.g.*, streptomycin and others) to all practical purposes took pulmonary tuberculosis out of the surgical realm.

Modern thoracic surgery received a great benefit from the development of the endotracheal type of anesthesia. When the chest is open, the lung normally collapses and is unable to oxygenate the blood, a process that is essential to life. When a tube is put in the trachea (the windpipe), pressure from a machine that delivers both anesthetic and oxygen can keep the lung inflated and functioning.

Esophageal surgery, especially resection of the esophagus for cancer, became another new item in thoracic surgery. Removal of all or part of the lung for cancer became successful technically in the 1930s and is now a common procedure. In the 1950s surgery of the heart and the great vessels emerged. It is now a principal field in some clinics; indeed, some thoracic surgeons do nothing else. This work was made possible by a thorough study of congenital anomalies of the heart and the physiologic derangement of such abnormalities. Next, acquired heart disease that results in damaged heart valves was attacked. Cardioangiography—visualization of the heart chambers by X-ray photography—and cardiocatheterization—running small tubes all the way from an arm artery into the heart—have made diagnosis of heart diseases and estimations of operability possible.

A heart–lung machine has been developed that provides artificial oxygenation and pumping of the blood. This has made it possible to open the heart so that abnormalities of the valves and walls of the heart chambers can be corrected. In 1961 replacement of defective valves by metallic and plastic materials was introduced.

An outgrowth of the treatment of congenital heart disease has been the invention of pacemakers, which control the beat of the heart. These electric pacemakers are buried in the patient's body.

Another new and promising field in cardiac surgery is in coronary heart disease, in which heart damage results from inadequate blood flow through the coronary arteries to the heart muscle. The defects in the coronary arteries can now be bypassed with vein grafts taken from the leg (see CARDIOVASCULAR SYSTEM DISEASES AND DISORDERS).

(C.S.W.)

Surinam

Surinam, formerly Dutch Guiana, is a self-governing territory of the kingdom of The Netherlands located on the north central coast of South America between Guyana on the west and French Guiana on the east. The territory covers an area of 63,251 square miles (163,820 square kilometres), extending southward about 310 miles from the 215-mile-long Atlantic coastline to Brazil. Of the territory's population of about 385,000, 102,000 persons live in Paramaribo, the capital district.

Historically, Surinam was a tropical colony with a plantation economy, at first based on slave and then contract labour. In modern times, however, small farms have replaced the plantations, and in the early 1970s Surinam had become one of the world's largest producers of bauxite, aluminum ore. The aluminum industry is fully integrated, processing bauxite into alumina and aluminum. These products account for 92 percent of the country's exports. Other products exported are rice, bananas, sugar, plywood and particle board, citrus fruit, shrimps, and lumber. Surinam, through its ties with The Netherlands, is an associate member of the European Common Market. The country is connected, within the federation of the kingdom of The Netherlands, to such international organizations as the International Monetary Fund, the World Bank, and GATT (General Agreement on Tariffs and Trade).

THE NATURAL AND HUMAN LANDSCAPE

Natural environment. *Relief features.* Surinam consists of a narrow, sea-level coastal zone in which diking and draining are necessary for cultivation, a somewhat higher belt of scattered savannas inland from the coastal zone, and hills rising to low mountains in the south. Geologically, Surinam is a part of the Precambrian Guiana Shield (sometimes also known as the Guiana Highlands), which is more than 570,000,000 years old. In the north the shield is covered by younger sediments, with their largest extension to the west. The greater part of the shield is rather flat, sloping toward the sea. To the south the terrain is slightly undulating, or hilly, with rather low mountain chains (Acarai and Toemak Hoemak Gebergte [Tumuc-Humac Mountains]). Other mountainous regions form the divides between several river systems. The Julianatop in the Wilhelmina Gebergte in the southwest is the highest elevation in Surinam, 4,218 feet (1,286 metres). The rivers have numerous rapids and falls, and along most of them river terraces, or remnants, form conspicuous features.

The natural landscape

The sedimentary deposits in the north produce several distinct landscapes. The flat to slightly undulating savanna belt consists of brown and white sands of Pliocene age (2,500,000 to 7,000,000 years old). To the north the belt is bordered by the old coastal plain, which consists of sands and clays of Pleistocene age (10,000 to 2,500,000 years old). Old rivers and gullies now filled with clay and peat form swampy areas surrounded by slightly higher terrain.

The marine deposits along the ocean form the young coastal plain. The clays, originally supplied by the Amazon River, bear extensive swamps interrupted by old beach ridges, which run mainly east to west and become rarer to the west. Sandy beaches as well as large mud banks tend to creep westward along the coast under the influence of winds and currents. Because of their huge burden of mud, only the larger rivers, with their strong flow, generally empty straight into the ocean, the winds and currents of which deflect the smaller rivers to the west. The seven largest rivers, from west to east, are the Corantijn, the Nickerie, the Coppename, the Saramacca, the Suriname, the Commewijne, and the Maroni (Marowijne).

Climate. Surinam's tropical climate, under the influence of the northeast trade winds, remains warm and moist throughout the year. The day temperature range is between 73° F (23° C) and 88° F (31° C) with an annual mean of 81° F (27° C). The diurnal variation is slight, only about 7° F (4° C).

Temperature and rainfall

Relative humidity is high for most of the year, averaging about 80 percent. Rainfall is highest in the mountains of the interior, and in the coastal areas it varies from east to west, from an annual average of 95 inches in Paramaribo to 76 inches in the west. There are four seasons—a minor rainy season from November to February, a minor dry season from February to April, a major rainy season from April to August, and a major dry season from August to November. In the coastal areas the winds are rather strong but their intensity lessens toward the interior of the country. Surinam lies outside the Caribbean hurricane area.

Vegetation. About 90 percent of Surinam is covered with forests with more than 2,000 varieties of trees. Tropical rain forest covers large areas, but much of it is jungle and inaccessible; and a large percentage of the trees are not commercially useful. Mangrove and swamp forests,

Carl Frank—Black Star

as well as grasses grow along the seacoasts, and various kinds of palms, including coconut, on slightly drier land. Rich stands of baboen (*Virola surinamensis*) in the coastal strip supply the thriving plywood industry. Other commercially important species include greenheart (*Tabebuia serratifolia*, a tree from 30-60 feet high, the wood of which is used to make cogs and rollers in coffee and sugar factories) and wallaba (a valuable timber tree with reddish-brown wood) in the north; mora (a tall, half-evergreen tree, with wood resistant to dry rot and termite injury), and crabwood on swampy sites; and balata and other latex trees, as well as trees yielding handsome cabinet woods in the rain forests and highland forests.

Animal life. There are about 150 species of mammals, including the howler and other varieties of monkey, as well as sloths, anteaters, and armadillos. The largest land mammal is the tapir; deer and pakiras (wild pigs) are hunted by forest dwellers. Jaguar, puma, and ocelot also occur. Rodents include the capybara (the largest living rodent); there are also numerous species of bats. More than 600 different bird species have been observed. Among the reptiles are tortoises and various species of lizard, including the iguana, and caimans. Snakes include the poisonous rattlesnake, the bushmaster, and snakes that strangle their prey, such as the boa constrictor. Among the large variety of frogs and toads are some of incredible size. A large group of insects includes termites and exceptionally large parasol ants, which build canal systems underground.

The landscape under human settlement. *Rural settlement.* With the abolition of slavery in 1863 and later, after having completed their contractual obligations as indentured labourers in the earlier part of the 20th century, a large number of plantation workers settled in the rural areas as small farmers. Types of settlements include plantations exploited by Western methods, government and private settlements of small tenant farmers, and settlements of small farmers who own the land on which they live.

Plantations and small farms

Some small farmers also live at rather great distances apart on their own smallholdings or on rented grounds, especially along the upper parts of the rivers. The economy of the Coronie District, which is comprised of a narrow 50-mile strip along the seacoast west of the Coppename River, and has a predominantly Creole population (of Negroes or persons of mixed origin) is based on the cultivation of coconuts and the production of coconut oil. In all other districts the most important product of the small farms is rice. Other products grown include coffee, citrus fruit, bananas, vegetables, and peanuts. Many small farmers own some cattle. Except in the Coronie District, Asian-Indian and Indonesian farmers predominate.

Urban settlement. By far the largest city, Paramaribo, the chief port, lies about 17 miles inland on the Suriname Rivier and is the seat of government and the main commercial centre. The city is neat and clean with many tree-lined streets; many of its beautiful wooden structures date back to 1835. The marketplace forms a permanent trading centre for tropical produce, Indian pottery, wood carvings, fish, meat products, and other items. In Paramaribo, the early afternoon is siesta time, and many stores and businesses are closed in the afternoons from 1:00 to 4 PM.

Nieuw-Nickerie, the capital of the Nickerie District on the Nickerie Rivier close to the western border with Guyana, has a population of 7,200 and is the second largest city; its port mainly handles rice and banana exports. Many banks and business establishments have branches in the town; there is also a well-equipped hospital. The life-style of the city is much the same as in Paramaribo; the district, however, has a predominantly Asian-Indian population.

THE COUNTRY AND ITS PEOPLE

History. Until the 15th century the only inhabitants of Surinam were Carib, Arawak, and Warrow Indians. Another tribe, the Surinen, who inhabited the country at an earlier time but who were driven away by the Caribs, is considered to be the source of the name Surinam. In 1499, Alonso de Ojeda, a Spanish lieutenant serving the Italian navigator Amerigo Vespucci, landed on the northeast coast of South America, called Guiana by the Indians. In 1593 the Spanish officially took possession of the coast. No actual settlement was attempted, and during the next century several Dutch, British, and French expeditions visited the area.

Derivation of the name Surinam

The first successful settlement in Surinam was founded in 1651 by an Englishman, Francis Lord Willoughby of Parham, Suffolk, who welcomed settlers from other West Indian and South American colonies. Among these were numbers of Jews, mainly from a Dutch colony on the Berbice estuary, west of Surinam, to which they had fled in 1639 from religious persecution in Brazil. They brought capital and skills, and in 1665 erected what is said to be the first synagogue in the Western Hemisphere. The colony developed a prosperous plantation economy based on slave labour imported from Africa, producing sugar, cotton, cocoa, and coffee.

In 1667, after the second Anglo-Dutch War, Surinam was ceded to the Dutch in exchange for Nieuw-Amsterdam (New York). The following century was one of economic decline and political turmoil. Many slaves rebelled and fled to the jungle; banding together, they conducted raids on the plantations. Military expeditions against them resulted in repeated defeats for the army and in the exhaustion of financial resources. In the meantime, as a result of European wars and treaties, the sovereignty of the country shifted between England, France, and the United Provinces of the Netherlands until the Dutch finally gained permanent control under the terms of the Treaty of Paris (1816). When the abolition of slavery in 1863 produced a critical labour shortage, Surinam began to import contract workers (indentured labourers) from China, Java, and India. Many of them stayed—the Chinese mainly as shopkeepers in the rural areas and the Indians and Javanese as independent small farmers.

In 1900, 90 percent of all agricultural products were grown on plantations and 10 percent on small farms. These figures were reversed in the subsequent half century, during which the plantation crops of cocoa, coffee, cotton, and sugar were replaced by rice, bananas, and other fruit. After World War II, the Dutch diverted some of their financial and technical resources from the East Indies to Surinam. In 1950 Surinam obtained some measure of autonomy, and in 1954 it became a self-governing part of the Kingdom of The Netherlands.

Agricultural development in the 20th-century

People and population. *Linguistic, ethnic, and religious groups.* The official language is Dutch, but English is very widely spoken. A lingua franca, known as Sranan (Taki-Taki), is a mixture of English, Dutch, French,

Spanish, and even Hebrew; it is used in interracial communication. Among themselves the Bush Negroes (*i.e.*, those living in the forests) speak variations of African languages; each American Indian tribe has its own language. Hindi, Javanese, Chinese, Lebanese, and other languages are spoken by the various racial groups living in their own communities.

Heterogeneity of the population

One of the most striking characteristics of Surinam is the heterogeneous ethnic composition of its population. The native Indians, or Amerindians, carry on their primordial life almost entirely untouched by outside influence, whereas the Bush Negroes continue their way of life much as their ancestors did in Africa. The Creoles, Asian Indians, and Indonesians, who comprise the three main ethnic groups, maintain their own identities to a large extent. While each retains many of its separate characteristics, the groups nevertheless intermingle in commercial and social activities. There are no minority problems, and assimilation is steadily taking place.

There is complete religious freedom. The Amerindians and Bush Negroes, in so far as they have been converted, as well as the Creoles, are predominantly Christian (either Protestant or Roman Catholic). The majority of the Asian Indians profess Hinduism, and the rest Islām, to which the Indonesians also generally adhere; a small number of both groups is also Christian. Well-known Protestant congregations include the Moravian Brothers Mission, the Netherlands Reformed Congregation, and the Evangelical Lutheran Church. Surinam also has a small Jewish community.

Demography. The 1971 census puts Surinam's total population at about 385,000, consisting of Hindustanis (about 37 percent), Creoles (about 31 percent), Indonesians (about 15 percent), Bush Negroes (about 10 percent), Amerindians (about 3 percent), Chinese (about 2 percent), Europeans (about 1 percent), and others (about 1 percent). In the early 1970s about 45 percent of the population was below 15 years of age; 68 percent was below 30; 6 percent was above 60. The birth rate was 46 per 1,000, while the death rate amounted to 9 per 1,000. The yearly increase is from 3.5 to 4 percent.

ECONOMIC, SOCIAL, AND CULTURAL LIFE

National economy. *Agriculture.* Agriculture is conducted mainly on the coastal plain by a large number of small, independent farmers. The growing of rice occupies about 89,000 acres or 75 percent of the total cultivated area; the largest rice-producing enterprise is the fully mechanized Wageningen project, financed by The Netherlands government, in the district of Nickerie. The sowing periods for rice are from the end of March to May for the major crop and from the middle of October to November for the second crop, each with a growing period of about 142 days. Surinam thus is self-sufficient in rice, its major staple food crop. It also produces sufficient quantities of bananas, citrus fruit, and coconuts for export, in addition to domestic use. As a result of a five-year development plan (1967–71) the production of bananas for export to Europe increased considerably. Citrus production (oranges and grapefruit) is an important factor in Surinam's agriculture, with the bulk of the export going to The Netherlands. Coconut oil is the other principal agricultural export.

Principal crops

Crops grown for domestic consumption include coffee, cocoa, corn, peanuts, soybeans, pulses, sweet potatoes, tomatoes, cabbage, plantains, cassava, and fruits. Sugar, once the principal commodity in Surinam, is now produced on only two plantations.

Industry and finance. The mining of bauxite is the leading nonagricultural economic activity in the country, the bauxite-alumina-aluminum industry accounting for 92 percent by value of 1970 exports. Bauxite is produced at plants at Smalkalden, Moengo, and Paranam; in addition there is an aluminum smelter and an alumina refinery at Paranam. (Alumina, or aluminum oxide, can be reduced by electrolysis to the metal aluminum.) Production of alumina is about 1,000,000 tons annually, and that of aluminum, exceeds 50,000 tons. Surinam is one of the few countries in the world with a fully integrated aluminum industry.

Alumina and aluminum production

To provide the enormous amounts of electricity it requires, the Suriname Rivier has been dammed to create W.J. van Blommestein Meer (lake; 600 square miles), which provides hydroelectric power for installations at Affobakka. Additional large deposits of bauxite in western Surinam are being developed for exploitation.

Surinam has great timber resources, even though many trees are not exploitable. The national forests of Surinam cover more than 37,000,000 acres. The most important potential lies in the so-called high forest. It has the shape of a belt extending from the Maroni to the Corantijn Rivier, running south of the sparsely wooded savannahs and north of the rapids in the rivers and hills region. A large plywood factory produces an excellent product and also manufactures particle board.

Small industries include a shrimp-processing plant, a brewery; shoe, clothing, and paint factories; a cement plant; a flour mill; a packing plant for citrus fruit; and other installations.

The country, with its relatively large export and import trade, has enjoyed a balance-of-trade surplus for many years. Its main trading partners are the United States and The Netherlands. The country has received considerable financial aid from The Netherlands under a ten-year plan (agreed to in 1954) and under subsequent five-year plans; development aid has also come from the European Common Market.

The Centrale Bank van Suriname was established in 1957 as a bank of issue. Surinam also has three commer-

Carl Frank—Photo Researchers

Planting rice, the leading agricultural product of Surinam.

cial banks with branches throughout the country. In addition, some specialized banking institutions handle investing, mortgages, development, credit, and postal savings. A five- to ten-year tax holiday is granted to new enterprises, and other incentives include access to the European Economic Community; all are offered to encourage foreign investment.

The discovery of large bauxite deposits in western Surinam and the plans to develop that region in the 1970s were seen as hopeful signs for the future. The continuation of offshore drillings for natural gas and oil and indications of several mineral deposits, such as copper and nickel, hold promise of accelerated economic growth. An effort is being made to promote tourism. The government has built guesthouses in the interior, some with air-conditioned rooms. Paramaribo has several good hotels and pensions, as well as some first class hotels with casinos and entertainment facilities.

Transportation. Most internal transport is by water over about 750 miles of navigable rivers and canals. Surinam's national steamship line, the Surinam Navigation Company, provides regular service along the coast and on inland waterways, as well as between Paramaribo and New Orleans. Paramaribo, the main port, has custom facilities and modern loading equipment. Other important ports are at Moengo, Paranam, and Smalkalden, all of which handle bauxite.

Roads and highways

There are about 1,500 miles of all-weather roads (300 miles of which are paved) and 810 miles of rural roads. The west–east highway stretches from the Corantijn Rivier, the western border with Guyana, to the Maroni, the eastern border with French Guiana. Excellent highways lead from Paramaribo to Paranam, the centre of the aluminum industry, and from Paramaribo to the international airport at Zanderij. A local airline also operates flights abroad and throughout the country; there are more than 30 airstrips in the interior. A small railroad connects Onverwacht with Brownsweg. Paramaribo's automatic telephone service covers most of the coastal area. International Telephone and Telegraph communications link Surinam with the United States, western Europe, and the Caribbean.

Administration and social conditions. *Government.* Surinam is an autonomous part of the Kingdom of The Netherlands, which also comprises The Netherlands itself and the Netherlands Antilles. This status was established in a constitutional order known as "Het Statuut" in 1954.

The monarch is the head of state and is represented by an appointed governor who presides over the Advisory Council (Raad van Advies) of at least five members, appointed by the governor. Surinam is a parliamentary democracy, with universal suffrage for men and women who have reached the age of 23. By a combination of direct and proportional representation, the voters elect 39 members to the Parliament (Staten van Suriname) for a four-year period. The political party with the majority of seats in Parliament submits to the governor the names of persons to be appointed to the 13-member Executive Council of Ministers, which is headed by a prime minister. Each minister is responsible to the Parliament. The country is divided into nine districts, which are administered by district commissioners who are appointed by the government.

Social conditions. The working population numbers about 100,000, about 26 percent of whom are employed by the government. Agriculture and forestry engage about 24 percent; industry and construction, 17 percent; commerce, banking and insurance, and transportation 12 percent; and mining, 7 percent. The government promotes the hiring of local persons, but grants permission for the engagement of specialists from abroad when they are not available in Surinam. More and more women are being hired by small industries.

The labour union movement in Surinam is young and is responsible in its dealings with management. For the settlement of labour disputes, the law provides for an advisory intermediary council consisting of government representatives, management, and labour. The literacy rate of the country is 70 percent (90 percent in the capital).

Education and public health

Education is compulsory for children up to 12 years of age, and all primary education is free. Denominational schools are subsidized by the government. Of Surinam's approximately 400 schools, 40 educate Amerindians and Bush Negroes living in the interior. In addition, there are high schools, junior colleges, a teacher's college, a university with medical and judicial faculties affiliated with the state University of Leiden in The Netherlands, technical schools, agricultural schools, and an agricultural research centre.

Public health standards are good. Paramaribo has five well-equipped hospitals, and there are other hospitals and various clinics throughout the country.

Cultural life and institutions. Cultural activity generally centres in Paramaribo. Surinam Cultural Centre is active in a variety of fields; it maintains an auditorium with about 400 seats, a reading room, and a library. Theatrical groups perform plays, and classes in ballet, painting, and drawing are held there. The centre also has a film service, which exhibits films in rural areas. The centre also houses a school of music, a chamber music society, a youth orchestra, several choirs and a philharmonic orchestra that has acquired a reputation outside of Surinam. There are several museums in the country, including an open-air one.

Of the country's sports, soccer is the most popular; others include tennis, basketball, volleyball, swimming, and cricket. A modern stadium in Paramaribo is primarily used for soccer, but it has facilities for track-and-field events and bicycle racing.

The one television station is government controlled. Of the five radio broadcasting stations, three are in Paramaribo and the other two in the district of Nickerie. Five daily and three nondaily newspapers and several periodicals are published. Surinam's moviegoers have 16 theatres they can attend, eight of them in Paramaribo, to see films shown from the United States, Europe, and India.

FUTURE PROSPECTS

The development of hydroelectric power resources has resulted in a considerable increase in the gross national product. The discovery and development of new bauxite deposits, coupled with plans for a new hydroelectric power project in western Surinam, point toward continuing activity in the mining sector. Increased exports of rice and bananas, as well as further government efforts to stimulate agriculture, are encouraging signs for the future. If Surinam can maintain the political stability that has hitherto been one of its characteristics and if it succeeds in attracting foreign investors to help develop its resources, the future of the country would appear to be bright.

BIBLIOGRAPHY. The SALZGITTER INDUSTRIEBAN GESELLSCHAFT MBH, *Preliminary Study on the Utilization of Iron Ore Deposits in Surinam* (1966) and *Preliminary Study on Wood Production and Utilization in Surinam* (1965), two studies commissioned by the Surinam government, contain basic information about the country and some of its natural resources. *Investment Factors and General Information About Surinam* and *Facts and Figures About Surinam*, both published by the Economic Division of the Ministry of Trade and Industry (1968), contain valuable information for investors. In addition, *Doing Business in Surinam*, published by the Foundation for the Promotion of Investment in Surinam (1969), provides explicit information about the economy. A.T. VINK (comp.), *Surinam Timbers* (1965), describes the main timber species and deals with the properties and uses of wood as well as with supply. WILLEM VAN DE POLL, *Suriname: een fotoreportage van land en volk* (1949; Eng. trans., *Surinam: The Country and Its People*, 1951) and *Suriname: Foto's en tekst* (1959), give good accounts of the people, vegetation, and animal life. F.E. ESSED, *Opbouw '70* (1971), provides an authoritative analysis of social and economic conditions; a retrospective view is presented by J.H. ADHIN in *Development Planning in Surinam in Historical Perspective* (1961). J. WARREN NYSTROM, *Surinam: A Geographic Study* (1942), is a well-written, informative book. Also of interest are MELVILLE J. and FRANCES S. HERSKOVITS, *Suriname Folk-lore* (1936, reprinted 1969); and MARTHA M. SUMWALT, *Surinam in Pictures* (1971).

(J.G.W.De V.)

Surveying

Surveying is a means of relatively large-scale, accurate measurement of earth surfaces. It includes the determination of the measurement data, the reduction and interpretation of the data to usable form, and, conversely, the establishment of relative position and size according to given measurement requirements. Thus surveying has two similar but opposite functions: (1) the determination of existing relative horizontal and vertical position, such as that used for the process of mapping, and (2) the establishment of marks to control construction or to indicate land boundaries.

Surveying has been an essential element in the development of man's environment for so many centuries that its importance is often forgotten. It is an imperative requirement in the planning and execution of nearly every form of construction. Surveying was essential at the dawn of history, and some of the most significant scientific discoveries could never have been implemented were it not for the contribution of surveying. Its principal modern uses are in the fields of transportation, building, apportionment of land, and communications.

Except for minor details of technique and the use of one or two minor hand-held instruments, surveying is much the same throughout the world. The methods are a reflection of the instruments, manufactured chiefly in Switzerland, Austria, Great Britain, the U.S., Japan, East Germany, and West Germany. Instruments made in Japan are similar to those made in the West.

HISTORY

Egyptian and other ancient devices

It is quite probable that surveying had its origin in ancient Egypt. The Great Pyramid of Khufu at Giza was built *c.* 2700 BC exactly 755 feet long and 480 feet high. It is so accurately square and so perfectly oriented to the cardinal points of the compass that it stands as evidence of the command ancient Egypt had of surveying.

Evidence of some form of boundary surveying as early as 1400 BC has been found in the fertile valleys and plains of the Tigris, Euphrates, and Nile rivers. Clay tablets of the Sumerians show records of land measurement and plans of cities and nearby agricultural areas. Boundary stones marking land plots have been preserved. There is a representation of land measurement on the wall of a tomb at Thebes (1400 BC) showing head and rear chainmen measuring a grainfield with what appears to be a rope with knots or marks at uniform intervals. Other persons are shown, two of high estate according to their clothing—probably a land overseer and inspector of boundary stones.

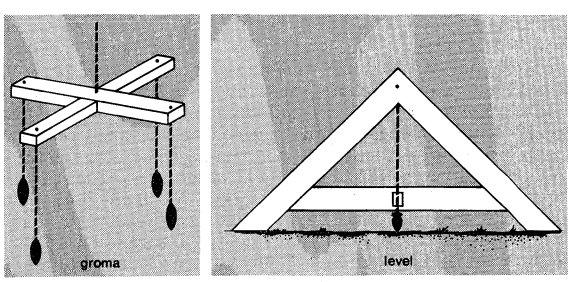

Figure 1: Egyptian surveying instruments.

There is some evidence that, in addition to a marked cord, wooden rods were used by the Egyptians for distance measurement. They certainly had the groma, which was used to establish right angles. It was made of a horizontal wooden cross pivoted at the middle and supported from above (Figure 1, left). From the end of each of the four arms hung a plumb bob. By sighting along each pair of plumb bob cords in turn, the right angle could be established. The device could be adjusted to a precise right angle by observing the same angle after turning the device approximately 90°. By shifting one of the cords to take up half the error, a perfect right angle would result.

There is no record of any angle-measuring instruments of that time, but there was a level (Figure 1, right), consisting of a vertical wooden A-frame with a plumb bob supported at the peak of the A so that its cord hung past an indicator, or index, on the horizontal bar. The index could be properly placed by standing the device on two supports at approximately the same elevation, marking the position of the cord, reversing the A, and making a similar mark. Halfway between the two marks would be the correct place for the index. Thus, with their simple devices, the ancient Egyptians were able to measure land areas, replace property corners lost when the Nile covered the markers with silt during floods, and build the huge pyramids to exact dimensions.

Greek log line and Chinese lodestone

The Greeks used a form of log line for recording the distances run from point to point along the coast while making their slow voyages from the Indus to the Persian Gulf about 325 BC. Still earlier it is said that the Chinese knew the value of the lodestone and possessed some form of magnetic compass, which reached the West from the Arabs in the 12th century. The astrolabe was introduced by the Greeks in the 2nd century BC. An instrument for measuring the altitudes of stars, or their angle of elevation above the horizon, it was in the form of a graduated arc suspended from a hand-held cord. A pivoted pointer that moved over the graduations was pointed at the star. The instrument was not used for nautical surveying for several centuries, remaining a scientific aid only.

During their occupation of Egypt, the Romans acquired Egyptian surveying instruments, which they improved slightly and to which they added the water level and the plane table. About 15 BC the noted Roman architect and engineer Vitruvius mounted a large wheel of known circumference in a small frame, in much the same fashion as a wheel of a wheelbarrow; when it was pushed along the ground by hand it automatically dropped a pebble into a container at each revolution, giving a measure of the distance travelled. It was, in effect, an odometer.

The water level consisted of either a trough or a tube turned upward at the ends and filled with water. At each end there was a sight made of crossed horizontal and vertical slits. When these were lined up just above the water level, the sights determined a level line accurate enough to establish the grades of the Roman aqueducts. In laying out their great road system, the Romans are said to have used the plane table. It consists of a drawing board mounted on a tripod or other stable support and of a straightedge—usually with sights for accurate aim (the alidade) to the objects to be mapped—along which lines are drawn. It was the first device capable of recording or establishing angles. Later, adaptations of the plane table had magnetic compasses attached.

Plane tables were in use in Europe in the 16th century, and the principle of graphic triangulation and intersection was practiced by surveyors. In 1615 Willebrord Snell, a Dutch mathematician, measured an arc of meridian by instrumental triangulation.

In 1620 English mathematician Edmund Gunter developed a surveying chain, which was only superseded by the steel tape in the beginning of the 20th century.

The study of astronomy resulted in the development of angle-reading devices that were based on arcs of large radii, making such instruments too large for field use. With the publication of logarithmic tables in 1620, portable angle-measuring instruments came into use. They were called topographical instruments, or theodolites. They included pivoted arms for sighting and could be used for measuring both horizontal and vertical angles. Magnetic compasses may have been included on some.

17th-century portable instruments

The vernier, an auxiliary scale permitting more accurate readings (1631), the micrometer microscope (1638), telescopic sights (1669), and spirit levels (about 1700) were all incorporated in theodolites by about 1720. Stadia hairs (see Figure 2) were first applied by James Watt in 1771. The development of the circle-dividing engine about 1775, a device for dividing a circle into degrees with great accuracy, brought one of the greatest advances in surveying methods, as it enabled angle measurements to be made with portable instruments far more accurately than had previously been possible.

The start of modern surveying

By the late 18th century modern surveying can be said to have begun. One of the most notable early feats of surveyors was the measurement in the 1790s of the meridian from Barcelona, Spain, to Dunkirk, France, by two French engineers, Jean Delambre and Pierre Méchain, to establish the basic unit for the metric system of measurement.

Many improvements and refinements have been incorporated in all the basic surveying instruments. These have resulted in increased accuracy and speed of operations and have opened up possibilities for improved methods in the field. In addition to modification of existing instruments, two revolutionary mapping and surveying changes have been introduced: photogrammetric, or mapping from aerial photographs (about 1920); and electronic distance measurement, including the adoption of the laser for this purpose as well as for alignment (in the 1960s). Important technological developments benefitting surveying in the 1970s included the use of satellites as reference points for geodetic surveys and computers to speed the processing and recording of survey data.

FUNDAMENTALS OF SURVEYING

The objective of all surveying—whether plane or geodetic—is to determine accurately land or water areas and their boundaries. Related data sought, also determined through surveys, include depths, altitudes, rate of slope (especially useful in mines and tunnel work), and Earth volumes such as required for construction. Thus the surveyor specializes in the measurement of distances and directions, both horizontal and vertical.

Measurements. In contrast to other types of measurement, nearly all those in surveying are made either perpendicular to the direction of gravity (designated as horizontal) or in the direction of gravity (designated as vertical). When not so made, the quantities are immediately reduced mathematically to their horizontal or vertical equivalents. Thus the direction of gravity must be determined whenever a surveying measurement is taken. Surveying measurements are of four types: (1) horizontal lengths or distances, (2) vertical lengths, or differences in height or elevation, (3) horizontal angles measured in horizontal planes, and (4) vertical angles measured in vertical planes.

Horizontal lengths, with few exceptions, are measured in short, straight sections that are together very nearly arcs along the Earth's surface, which again is actually a curved surface because of the spherical nature of the Earth. The surface is calm water, which—because it is continuous everywhere perpendicular to the (vertical) direction of gravity—is a level surface. With a surveyor's level, the difference in height between two points, or the vertical distance between the level surfaces that pass through them (see below *Orthometric Corrections*), can be determined. The level is placed equidistant between the two points, and the graduations are read on a rod held vertically on each point in turn; the difference between the readings represents the difference in height of the two points.

Measuring differences in height

For less accurate results, the instrument need not be placed at the exact midpoint. Variations in the atmosphere affecting the refraction of light restrict the distances permissible from the instrument to the points observed; differences in height between widely separated points, therefore, must be determined by a series of such measurements over temporary points, called turning points. The operation is called levelling, or running a line of levels.

Within any area of the Earth's surface about 12 miles (20 kilometres) square and free of large variations in altitude, the differences between measurements made as described above and the same measurements that might be reproduced on, or from, a truly plane surface would be negligible because the differences caused by the Earth's curvature in a small area are minimal. The results of such surveys can be computed by plane trigonometry; the whole process is called plane surveying.

For surveys covering larger areas, however, the Earth's curvature must be considered. Such surveying is called geodetic; it must be very accurate, and goedetic instruments unusually precise.

Units of measure. The metre is the fundamental unit of length used in surveying throughout the world. In October 1960, the length of the metre was defined as equal to 1,650,763.73 times the wavelength of a specific line in the spectrum of krypton-86 under specified conditions. This stabilized but did not effectively change the length of the metre.

Except in rare instances, the only unit of length used in surveying, in addition to metric units, is the foot, with tenths, hundredths, and thousandths of a foot being used instead of inches and fractions. From 1893 until 1959, the foot used in the United States equalled $1{\cdot}200/3{\cdot}937$ metre or 0.30480061 metre. It was not quite the same length as the foot used in other English-speaking nations, as these were based on the imperial yard, whose relationship with the metre varied slightly from time to time. In 1959 it was agreed by representatives of the English-speaking nations to base the foot on the metre according to the exact ratio: 1 foot = 0.3048 metre. This shortened the foot used in the United States by about two parts in 1,000,000 and lengthened the contemporary British foot by about ⅓ part in 1,000,000.

Setting the exact length of a foot

The U.S. Coast and Geodetic Survey, which maintains the fundamental survey control systems in the United States, measures in metres. Since 1893, this survey has converted to values in feet by the ratio 1.200 : 3.937 in all publications in which the foot appears. To avoid confusion it was necessary to retain this value of the foot until such time as all vertical and horizontal control systems should be readjusted. Accordingly, this foot was named the U.S. Survey Foot.

Two types of angular measure are used throughout the world, the sexagesimal and centesimal:

Sexagesimal system	Centesimal system
1 circle = 360 degrees (°)	1 circle = 400 grads (g)
1 degree = 60 minutes (′)	1 grad = 100 minutes (′)
1 minute = 60 seconds (″)	1 minute = 100 seconds (″)

Directions are given in azimuths or bearings. Azimuths are clockwise angles from the north or occasionally from the south. Equivalent values are the following:

Azimuth from North	50°	120°	200°	310°
Azimuth from South	230°	300°	20°	130°
Bearing	N 50°E	S 60°E	S 20°W	N 50°W

INSTRUMENTS

The fundamental measurements made by the surveyor include distances, angles (both horizontal and vertical), altitudes, and directions. To carry out these measurements, several different types of instruments and supplementary equipment are used.

Distance-measuring equipment. Distances are measured by mechanical devices (chain or steel tape) or by electronic means.

The chain. Gunter's chain, the 300-year-old measuring instrument by which all survey measurement in the English-speaking countries and much of it elsewhere was long done, has been superseded by the steel tape and electronic equipment. Gunter's chain is 66 feet long; 80 chains equal one mile, and 10 square chains equal an acre. The chain is subdivided into 100 links. A rod or perch was 25 links. Each link was a short section of wire connected to the next link by a loop. At each end of the chain was a brass handle. The 66-foot unit is still called a chain and is still in use in property descriptions and in the public land systems.

The steel tape. A graduated steel ribbon, or a flat wire, with handles at each end, is the basic modern means of measuring distance. Its length is taken as the straight-line distance between the two end marks at 68° F (20° C) because the tape's actual length varies with different types of support, different tensions, and different temperatures. In the field, if extreme accuracy is desired, the type of support, the tension, the temperature, and the difference in height of the two end marks are recorded and the measured length corrected accordingly.

In most routine surveys the tape is held by hand at the

ends, kept high enough to clear ground objects, made horizontal by estimation, and placed in the direction of measurement by eye or with an instrument. The desired tension is estimated, and the positions of the graduations are brought to the ground marks by plumb bobs. Sometimes the air temperatures are recorded. For higher accuracy, tripods or other supports are employed, or the tape is fully supported on smooth surfaces. The slopes and temperatures of the tape are determined. Tension is regulated with a spring balance.

Eliminating temperature problems

When especially accurate measurements are necessary, particularly for base lines in a triangulation system, a steel tape must be used at night or when the sky is overcast; otherwise radiant heat would make it impossible to determine tape temperature. Tapes made of Invar avoid this difficulty. Invar is a steel alloy with an extremely low coefficient of thermal expansion (about 0.00000045 foot per foot per degree Fahrenheit). With such a tape, a temperature difference of 10° F (5.6° C) from the design temperature would result in an error of only about 1/20 of an inch (1.3 millimetres) in 1,000 feet (305 metres). Unfortunately, Invar tapes are too easily damaged for general use. Before the introduction of Invar, iron bars immersed in melting ice were used for daytime measurements.

Electronic instruments. Sir Robert Watson-Watt, a Scottish physicist working in England, introduced an electronic pulse-type instrument in 1935. Called hiran, it measures distances over water between land survey stations obscured from each other by the Earth's curvature. An airplane flying high enough to be visible from both stations crosses over the line between them while sending out a series of pulses. These are automatically relayed back to the plane from each station. The minimum sum of distances represented by the timed returns is chosen, and the nearby sums are corrected to be averaged with it. The result is corrected for the altitude of the plane and refraction of the atmosphere, and the final value is taken as the distance between the two stations.

The phase-shift type of system was first developed in 1948 and gives very accurate results. The process is comparable to conventional radio transmission, in which the carrier frequency is modulated by the audio frequencies that the receiver makes audible.

In phase-shift devices, the carrier frequency is either light (generated by a laser or an electric light beam) or an ultrahigh-frequency radio beam. The light beam requires a clear line of sight; the radio beam can penetrate fog, haze, heavy rain, dust, sandstorms, and some foliage. Both types have a transmitter-receiver at one survey station. At the remote station, the light type uses a set of corner mirrors; the high-frequency type utilizes a retransmitter (requiring an operator) identical to the transmitter-receiver at the original station. A corner mirror has the shape of the inside of a corner of a cube. It returns light toward the source from whatever angle it is received, within reasonable limits. A retransmitter must be aimed at the transmitter-receiver.

In both types of instrument, the distance is determined basically by the length of time it takes the radio or light beam to travel to the target and back (see also RADAR; SONAR). The elapsed time is determined by the shift in phase of the modulating signal during its travels. Electronic circuitry detects this phase shift and converts it very accurately into the exact fraction of a small unit distance. By using several frequencies for the modulator signal the total distance can be computed.

Shift in phase of modulating signal

Angle-measuring equipment. The theodolite is the basic instrument for measuring horizontal and vertical angles. It consists essentially of a sighting tube in the form of a telescope, and horizontal and vertical scales so set up that horizontal and vertical angles of the object sighted in the telescope can be read from the scales.

Theodolites and transits. There are two general types of theodolites: direction theodolites (also called simply theodolites) and repeating theodolites (also called American transits). In the direction theodolite, the graduated horizontal circle remains fixed while the telescope is pointed at several objects in turn and the direction to each is read on the horizontal scale. In the repeating theodolite, the same angle is measured a number of times on the horizontal scale, which is rotated by as much as the arc of each measurement. The successive values of each measurement are accumulated on the horizontal circle, the final reading representing the total arc of all the measurements taken. The desired value is then obtained by dividing the final reading by the number of repetitions. The repeating theodolite, or transit, is used in the U.S., Canada, and, to some extent, in Central and South America.

The theodolite is basically a more accurate instrument than the transit, measuring angles to five seconds of arc or less; the transit only measures to about 20 seconds of arc. The transit's repeating characteristic, however, permits the angle to be measured several times and an average reading obtained, in about the same time that it takes to measure once with a theodolite, and the end result is equal accuracy. When angles are established by one setting from one fixed station, as in placing marks for construction, the theodolite is more accurate.

Modern transits and theodolites nearly all have stadia hairs (see Figure 2). When the vertical angle is observed, along with the distance on the rod (staff) intercepted by

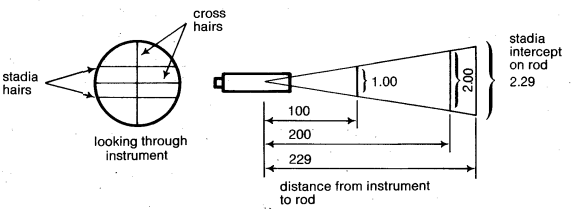

Figure 2: Principles involved in the use of telescope stadia hairs and a staff to determine distance (see text). In the example illustrated, the distance to the rod is equal to 100 times the stadia intercept on the rod.

two of the horizontal stadia hairs, the surveyor can determine approximately the horizontal distance and the difference in height between a point in the telescope and the point on the rod or staff (see below) where the cross hair falls.

Vertical circle attachments. Except in astronomical observations, vertical angles seldom need be measured with the accuracy required for horizontal angles. In all instruments, the vertical circle is attached to the end of the horizontal axle and turns with the telescope. In American transits, it is read with a vernier attached to a standard and thus depends on the accuracy of the levelling of the instrument. In modern European instruments, the vertical circle is read with an optical device governed by a pendulum and therefore is independent of any inaccuracies in the hand levelling of the instrument. The accuracy of the setting of the reading device in both instruments can be tested by reading the same vertical angle with the telescope both direct and reversed.

Testing accuracy of the setting

Plane-table alidades. Modern plane-table alidades consist of a telescopic sight of about 13–16 power equipped with stadia hairs and mounted on a metal graduated straightedge called a blade, with which survey data can be plotted on the supporting drawing board (see below *Maps and charts*). The telescope, on horizontal bearings, does not reverse, and it measures angles of elevation and depression up to as much as 20° to 30°, as indicated on a vertical circle. A prismatic eyepiece makes it possible to observe when looking down into the telescope to avoid the interference of the plane table. Also mounted on the blade are a circular spirit level for levelling the plane table and a trough compass that operates when the alidade is aimed nearly along the magnetic meridian.

Plane-table surveying has been nearly eclipsed by photogrammetry. It is still used, however, for mapping small areas, for filling in where the lack of detail prevents the proper orientation of aerial photography, or where detail is concealed on the photograph. It is sometimes used for finding the position and elevation of photo-control points.

Measurement of direction. There are two major techniques for measuring direction—by means of compasses and by celestial observations.

Compasses. Two needle-types are used: box compasses and circular compasses. Box compasses must be used with angle-measuring instruments, as the compasses operate only when the line of sight points toward magnetic north. The bearing desired must then be measured from this direction.

Circular compasses can be mounted on theodolites and are often permanently mounted on transits. When provided with open sights, they can be used alone, either mounted on light tripods or held in the hand.

Magnetic declination, called variation by mariners, is the angle from the direction of true north to the direction of the needle. This angle varies from place to place, and at any place it changes slowly through large, little-understood swings. This is called the secular change. The diurnal change is a more or less regular swing as follows: quiescent at its mean position from 9 PM to 3 AM, then easterly to 2 to 5 minutes at 8 or 9 AM, and then westerly to 2 to 5 minutes at 1 or 2 PM, thence to mean at 9 PM. There is also an annual swing in the order of one minute, varying according to locality.

Secular and diurnal changes

Celestial observations. Astronomic north, the direction of the celestial North Pole, is determined by observations of the sun or stars with transits or theodolites. The most accurate method of determining direction is to observe the North Star (Polaris) in latitudes where it is visible and not too high to give accurate results. In southern latitudes there are six bright stars about 30° from the Pole, well enough distributed so that one is usually above the horizon. These are observed in the same way as Polaris.

As the first step, the horizontal direction of the star is measured from a mark on the ground. The precise time is recorded at the moment the instrument is pointed at the star. With these values and the latitude and longitude of the instrument, the bearing of Polaris or other star with relation to an Earth station can be computed. If any of these data is unavailable further observations are required.

A second method is sometimes used. The altitude, direction, and the time of observation are noted for a star in the east and one in the west at about the same elevation. By referring to astronomical tables the resulting bearings of the mark are obtained. These are averaged and thus observational errors in the vertical angles are reduced.

Vertical measuring equipment. Theodolites and transits measure vertical (as well as horizontal) angles. Surveying levels and barometric-pressure devices measure vertical levels, or elevations, exclusively.

Surveying levels. There are three types of surveying levels: (1) the wye, or the dumpy, level; (2) the tilting level; and (3) the self-levelling level. The first type consists of a telescopic sight, like that of a transit but usually of slightly higher magnification, to which a long spirit level is attached and adjusted so that the bubble centres when the line of sight is horizontal. The whole is mounted on a vertical spindle in a levelling head so that it can be turned in any direction. The telescope of the wye level can be rotated and changed end for end in the wyes (Y-shaped supports) for adjustment.

The tilting level is similar, but the telescope with the main bubble attached can be separately tilted up or down by means of a micrometer screw, giving it greater accuracy. The spindle is first set nearly vertical with a circular spirit level, and the main bubble is centred with the micrometer screw.

The self-levelling level is similar to the tilting level except that it has no micrometer screw. Instead, it contains an optical part that is operated by a pendulum in such a way that the line of sight is automatically made horizontal. Some types are extremely accurate, and the pendulum eliminates the operation of centring the main bubble, which is especially time-consuming.

Coincidence-reading bubbles

For very accurate work, tilting levels are equipped with coincidence-reading bubbles. By an optical device the elongated bubble appears to be split into two sections, with a central portion apparently removed. As the telescope is levelled, the sections of the bubble are brought closer together until their ends coincide; then the bubble is precisely centred. Often tilting and self-levelling levels have three horizontal cross hairs so that three readings of the staff (rod) can be taken and averaged. Optical micrometers also yield greater accuracy in rod readings; they consist of thick glass disks with parallel, optically flat surfaces usually mounted in front of the telescope. When the micrometers are rotated on a horizontal axis, they move the line of sight up or down and parallel to itself. A graduated drum indicates the distance moved from their normal position, so that when the line of sight is placed exactly on a rod graduation, they read the very small additional quantity to be applied.

The level rod (staff). The rod is used to measure the vertical distance between the point on which it stands and the line of sight. It is made of wood with graduations, and large, clear numbers usually printed on it. It is divided either into centimetres or half-centimetres or into hundredths of a foot or yard. Between divisions it is alternately black and white, so that the exact values occur where the colour changes. For routine levelling, the American rod is made in two sections. The rear section slides upward until, when fully extended, the face reads continuously up to 12 or 13 feet. It has a target that may be set where desired.

For accurate levelling the graduations are painted on a steel or Invar ribbon fastened at the bottom and held taut by a spring at the top. A special thermometer is held with its bulb against the ribbon, and a circular spirit level is attached to aid in keeping the rod vertical.

Aneroid barometers. Vertical measurements can be approximately determined by finding the difference in barometric pressure at the two elevations. Aneroid barometers and hypsometers measure such differences. Aneroid barometers are devices in which changes in atmospheric pressure cause a needle to move over a scale. Instruments of this type designed for surveying are called altimeters. A type that records time along with pressures is usually placed at a known elevation (the base) and the second instrument is taken to the points where measurements of elevation are desired. When the second instrument is read, the time is recorded, so that the simultaneous reading of the base instrument can be selected. The difference of the two readings must be corrected for the unit weight of the air, which is estimated from the barometric pressure, temperature, and humidity.

Two-base method

More accurate results, independent of the unit weight of the air, can be obtained by the two-base method. Recording aneroids are placed at two bases, preferably one higher and one lower than the elevations to be determined. In effect they weigh the air. Each field reading is adjusted in proportion to the relative height above and below the two bases and so that the sum of the two heights equals the known difference in height between the bases. Within a radius of ten miles (16 kilometres), this method gives elevations within about two feet (0.6 metre).

In Australia, some effort has been made to use three bases over a large area and to compensate according to the barometric pressures shown on a weather map.

Hypsometers. The hypsometer is a device that measures barometric pressure by determining the temperature required to boil distilled water. By means of suitable tables, this temperature can be converted to barometric pressure. The bulb of an accurate thermometer is immersed in a very small container of water that is brought to a boil. The results can be handled as described for the aneroid barometer, but usually the boiling point is again determined at the starting point, and if there is a difference in the measured altitude there, the field elevations are corrected in proportion to elapsed time.

CURRENT SURVEYING PRACTICES

Survey control. The accuracy of survey measurements can be improved almost indefinitely but only at increased cost. Accordingly, control surveys are used; these consist of a comparatively few accurate measurements that cover the area of the project and from which short, less accurate measurements are made to the objects to be located. The simplest form of horizontal control is the traverse, which consists of a series of marked stations connected by

measured courses and the measured angles between them. When such a series of distances and angles returns to its point of beginning or begins and ends at stations of superior (more accurate) control, it can be checked and the small errors of measurement adjusted for mathematical consistency. By assuming or measuring a direction of one of the courses and rectangular coordinates of one of the stations, the rectangular coordinates of all the stations can be computed.

Superior horizontal control. A system of triangles usually affords superior horizontal control. All of the angles and at least one side (the base), of the triangulation system are measured. Though several arrangements can be used, one of the best is the quadrangle or a chain of quadrangles. Each quadrangle, with its four sides and two diagonals, provides eight angles that are measured. To be geometrically consistent, the angles must satisfy three so-called angle equations and one side equation. That is to say, the three angles of each triangle, which add to 180°, must be of such sizes that computation through any set of adjacent triangles within the quadrangles will give the same values for any side. Ideally, the quadrangles should be parallelograms. If the system is connected with previously determined stations, the new system must fit the established measurements.

When the survey is of an area where the Earth's curvature is a factor, an imaginary mathematical representation of the Earth must be employed as a reference surface. A level surface at mean sea level is considered to represent the Earth's size and shape, and this is called the geoid. Because of gravity anomalies, the geoid is irregular; however, it is very nearly the surface generated by an ellipse rotating on its minor axis—*i.e.*, an ellipsoid slightly flattened at the ends, or oblate. Such a figure is called a spheroid. Several have been computed by various authorities; the one usually used as a reference surface by English-speaking nations is the (Alexander Ross) Clarke spheroid of 1866. This oblate spheroid has a polar diameter about 27 miles less than its diameter at the equator.

The imaginary Earth, or geoid

Because the directions of gravity converge toward the geoid, a length of the Earth's surface measured above the geoid must be reduced to its sea-level equivalent—*i.e.*, to that of the geoid (see Figure 3). These lengths are assumed to be the distances, measured on the spheroid, between the extended lines of gravity down to the spheroid from the ends of the measured lengths on the actual surface of the Earth. The positions of the survey stations on the Earth's surface are given in spherical coordinates (*i.e.*, geodetic latitude and longitude).

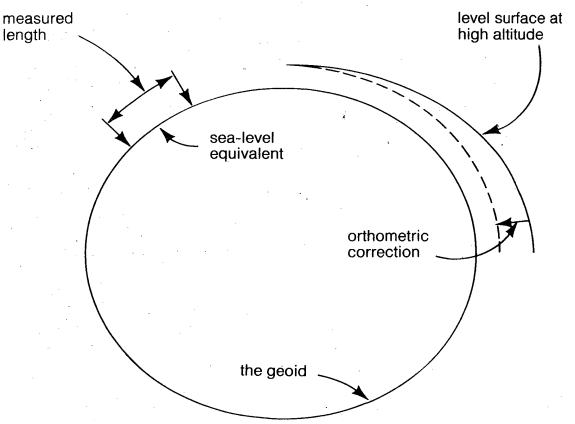

Figure 3: Measured length corrected to its sea-level equivalent (on the geoid) and the orthometric correction for high altitude measurements (see text).

Vertical control. Bench marks, or marked points on the Earth's surface, connected by precise levelling constitute the vertical controls of surveying. The elevations of bench marks are given in terms of their heights above a selected level surface called a datum. In large-level surveys the usual datum is the geoid. The elevation taken as zero for the reference datum is the height of mean sea level determined by a series of observations at various points along the seashore taken continuously for a period of 19 years or more. Because mean sea level is not quite the same as the geoid, probably because of ocean currents, in adjusting the level grid for the U.S. and Canada all heights determined for mean sea level have been held at zero elevation.

Orthometric corrections. Because the level surfaces, determined by levelling, are distorted slightly in the area toward the Earth's poles (because of the reduction in centrifugal force and the increase in the force of gravity at higher latitudes), the distances between the surfaces and the geoid do not exactly represent the surfaces' heights from the geoid. To correct these distortions, orthometric corrections (see Figure 3) must be applied to long lines of levels at high altitudes that have a north–south trend.

Trigonometric levelling often is necessary where accurate elevations are not available or when the elevations of inaccessible points must be determined. From two points of known position and elevation, the horizontal position of the unknown point is found by triangulation, and the vertical angles from the known points are measured. The differences in elevation from each of the known points to the unknown point can be computed trigonometrically.

Maps and charts. The most familiar, everyday experience with surveying for most persons is the use of maps. A complete map or chart shows the horizontal size, position, and elevation of natural and man-made topographic features according to a scale or, if the Earth's curvature is considered, according to a mathematical projection. The shape of the ground in elevation is shown by contour lines that connect points of equal elevation; water depths are shown by spot depths and sometimes by lines of equal depth. Small-scale maps and charts show lines of latitude and longitude; large-scale maps show an indication of geodetic, astronomic, or magnetic north and often the lines of a rectangular coordinate system. Maps or charts made for special purposes omit many of these features.

A drawing of a line that shows to scale the elevation of the ground or other features along a selected route is called a profile. Frequently the profiles of several features are shown on the same drawing.

Taking a profile of surface features

Large areas of the Earth have been surveyed, mapped, and charted, with the results published by government agencies. Government triangulation systems cover most of the world and are connected over oceans by observations of moon occultations, ordinary astronomical observations, and satellite triangulation; the systems are coordinated temporally by radio signals. Smaller bodies of water, but large enough for the Earth's curvature to prevent ground triangulation, are crossed by trilateration—the measurement of the sides of a system of triangles—with electronic devices or triangulation by simultaneous observations of flares dropped from an airplane. Level nets (interconnecting networks of level circuits) based on mean sea level give elevation control as points of reference. Secondary triangulation and levels are established where the mapping will be carried out. Photogrammetry (see below) is used almost exclusively for supplying detail.

The plane table, with its drawing board and alidade mounted on a tripod, is a basic tool of map making. When plotting a distant point, the map maker keeps the rear end of the table's straightedge at the point where he is stationed and aims the front end at the rod held at the distant point to be located. Once it is aimed, he reads the stadia intercept and the vertical angle and records the direction by drawing a line along the straightedge onto paper on the plane table. Points are so located, and a map can be drawn as the work progresses.

Surveys for smaller maps usually are based on traverse and sometimes triangulation with a rudimentary level network to control elevations. Detail is filled in by transit stadia on the plane table. Where elevations are important, the area is laid out in squares and the elevations of the intersections are determined with a level.

When large areas must be mapped but accurate control is lacking, positions are determined astronomically, and elevations are measured by barometric pressure, usually

determined by sensitive aneroid barometers or by hypsometers. Elevations are measured from aircraft by determining the height of the aircraft above the ground with electronic devices and the elevation of the aircraft above sea level by altimeter or trigonometric levelling.

Photogrammetry. Photogrammetry is the measurement of photographs for certain engineering and other purposes. Applied to surveying, it is used to supply detail

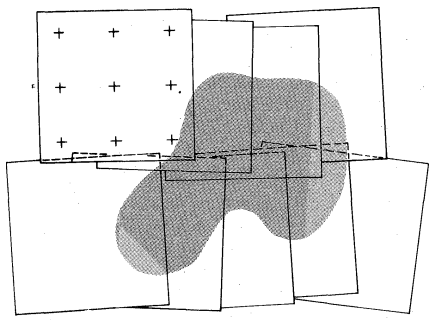

Figure 4: Photogrammetric photographs from two short, overlapping flight strips arranged for supplying mapping details. Photo-control points are shown on only one photograph; shading indicates a typical terrain feature such as a lake (see text).

for mapping. Sometimes it is used for planimetric maps, but usually for topographic maps that show contour lines. Whereas it is possible to map from photographs taken from high ground elevations, the greatest use of photogrammetry is the construction of maps from aerial photographs taken from points almost directly overhead.

Flight strips with 10 percent overlap

Trained pilots fly the airplane or helicopter along previously planned flight strips that are straight, parallel, and so spaced that they overlap by about 10 percent. In each strip the camera automatically changes the film and makes an exposure that causes the photographs to overlap about 60 percent. Thus every ground point appears on at least two and sometimes six pictures (see Figure 4). Ideally, each strip should contain many photo-control points—*i.e.*, three per photograph. The control points that are chosen on the photographs can be precisely determined and are uniformly spaced. The photographs are converted into maps by plotters, of which there are many types of varying accuracy. All of the better ones work on the same principle, which is best illustrated by the multiplex projector (see Figure 5).

That instrument consists of a row of projectors, each with a two-inch by two-inch diapositive (transparency), made from an aerial photograph. The projectors aim downward to the future manuscript map on which the horizontal positions of the photo-control points have been plotted to the desired map scale. Supported on the map surface is a movable tracing table consisting of a white surface about six inches in diameter with a tiny white light at the centre. The table can be raised or lowered as required. Directly under the light and almost on the map surface is a pointer that can be interchanged for a pencil that rests on the map.

The tracing table is placed on each photo-control point in turn and adjusted in height, to the map scale, according to the elevation of the photo-control point. The projector containing the diapositive is adjusted in height, azimuth, position, and aim until the image of each photo-control point falls on the white light, adjusted to the control point position. This reproduces, to scale, the exact geometry that existed when the photograph was taken. A second diapositive is adjusted in the same way.

To create contour lines, the tracing table is set at the elevation of the desired contour. A blue-green filter is placed on one projector and a red filter on the other, and the operator wears coloured glasses arranged in the same way. With the tracing table at the desired elevation of a contour line and placed at B, point C is projected as shown, as the original geometry has been recreated. The operator sees the projection of C at one point with his left eye and at another point with his right eye, as though C were at A. Because B is a white light, he sees it with both eyes in its actual position. Thus the apparent depth of C below B is greatly exaggerated. He moves the table to D where the white light appears to strike the ground. He lets down the pencil and by following the ground surface traces the desired contour. When plotting an actual object he raises or lowers the plotting table so the light appears to follow the ground surface.

Procedure for conducting a survey. The second principal function of surveying after mapping, as has been mentioned, is the establishment of marks to control construction or to indicate land boundaries. A complete survey consists of four steps: (1) reconnaissance; (2) a preliminary survey; (3) a map; then a plan is prepared based on steps 2 and 3; and (4) a location survey based on the plan. Each of these steps may be rudimentary or intricate, depending on the data available, the field conditions, and the project for which the survey is carried out.

Basic steps in surveying

Reconnaissance. A reconnaissance is a study of an area to determine where the preliminary survey or surveys must be made, the extent of the survey, and the information it must obtain. The reconnaissance might be merely a look at the ground, the study of existing maps, a crude survey, or a study of a pieced-together set of controlled aerial photographs. When triangulation is to be used for control, the location of the stations must be determined and the necessary heights of the towers noted.

Preliminary survey. The preliminary survey measures the relative positions in three dimensions of existing objects that control the plan. It usually consists of a horizontal survey control system of triangulation and traverse with connecting survey stations and a vertical control system of precise levelling with connecting bench marks. From these control points, measurements are made to existing objects by tape, plane table, stadia, or photogrammetry, depending on the accuracy required.

Mapping the details. If an office building is to be planned, for example, the architects will need a map that shows such data as (1) property lines, easements, and encroachments with their bearings and lengths; (2) the exact positions and floor elevations of any existing buildings that may be connected with the new building; (3) trees and other objects in the area; (4) contours with a contour interval of one or two feet; (5) any streams or ponds; and (6) the elevations of the low points on the property lines in order to plan the surface drainage system. In addition, the architects will need to know the positions of the adjacent public roads or streets, the eleva-

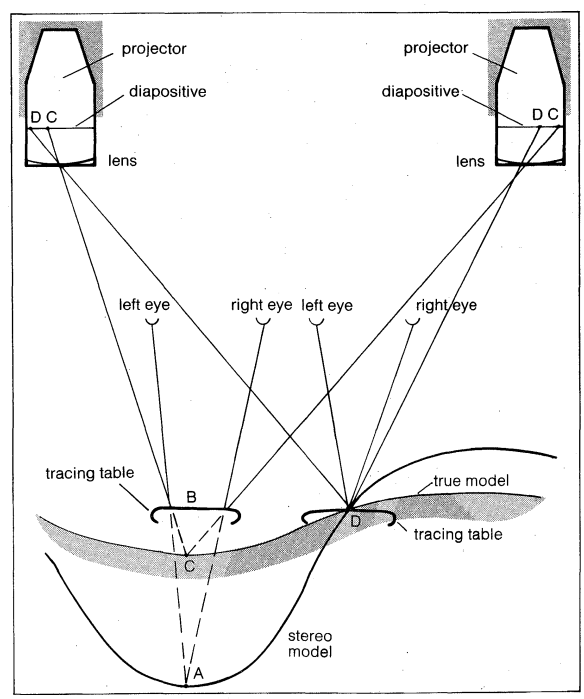

Figure 5: Multiplex projector system of mapping contours and other details from aerial photographs. Only two projectors are shown (see text).

tions of their centre lines and their gutters, the tops of curbs, all at 25- or 50-foot intervals, and facilities, like poles, that might interfere within the street rights-of-way.

Underground facilities must be shown. These include the elevation, position, size, and water pressure of water mains, gas mains, and electric conduits, and the exact elevations of storm and sanitary sewers and their manholes. Frequently, test borings must be made and located.

A land surveyor must be employed to mark the property corners, the easements, and encroachments. His survey usually serves as the control survey. If the project is in a town, levels must be run in from the nearest municipal bench mark to permanent bench marks, preferably three, established in or near the property and safe from disturbance by construction. If the area is fairly large, supplementary control by traverse and levelling is often necessary to reduce the length of measurements to details. Ties to control points are often made with tapes, stadia, hand levels, and by ordinary levelling.

The map is plotted according to the survey measurements. The architect gives dimensions from the property lines and states elevations from which the basic building lines and elevations can be laid out.

Property boundary surveys. Surveys to establish property boundaries constitute a large, highly specialized branch of surveying known as land surveying. Not only must a land surveyor be thoroughly versed in surveying techniques but he must understand real property law, be familiar with property lines within the area where he works, and be able to make decisions that he can justify in court when appearing as an expert witness.

Land surveying

Monuments. In general, property boundary lines must be shown by marks on the ground (landmarks), often called monuments. These marks usually consist of ridges, streams, blazed lines, ditches, walls, fences, trees, fieldstones, stakes, iron pipes or rods, or prepared square concrete or stone posts sunk into the ground.

Land surveying as it is now known was first used to determine acreage. The directions of the boundary lines were determined by compass, and their lengths were determined usually by a Gunter's chain. With the introduction of the transit and tape, it became possible to locate land boundaries accurately by measurement from any monumented line, resulting in an increase in recorded measurements and fewer monuments.

Because the cost of a survey increases with its accuracy, surveys of low-priced land are seldom very accurate. Surveys of parcels of such lands often contain errors, omissions, and inconsistencies. In localities where land is increasing in value, these defects must be eliminated. Whereas the power of decision rests with the court, the land surveyor must reach a solution based on his experience, his estimate of the accuracy of the work of the previous surveyors, his familiarity with the property lines in the vicinity, and his knowledge of the law.

Metes and bounds. A land description in which the boundaries are described by the directions and length of successive boundary lines that the land adjoins is called a metes-and-bounds description. The term derives from measurements and boundaries. A typical good metes-and-bounds land description for the parcel of land shown (see Figure 6) reads as follows:

Beginning at a concrete monument in the northerly line of Day Street distant 896.34 feet westerly from the intersection of the northerly line of Day Street and the westerly line of Main Street, thence: (1) N 75° 55′ E 416.00 feet along the northerly line of Day Street to a concrete monument at the southwesterly corner of John Doe, thence: (2) N 19° 45′ W 285.68 feet along the westerly line of John Doe to an iron pipe at the southeasterly corner of Richard Roe, thence: (3) S 61° 47′ W 187.15 feet along the southerly line of Richard Roe to an iron pipe, thence: (4) N 81° 02′ W 184.32 feet, still along the southerly line of Richard Roe to an iron pipe at the southwesterly corner of Richard Roe and in the easterly line of Mary Jones, thence: (5) S 7° 21′ E 312.92 feet along the easterly line of Mary Jones to the place of beginning. An area of 2.26 acres.

(The adjoiners are named to show that there is no gap between the holdings and to serve as a description by bounds. Also, many other data are often listed.)

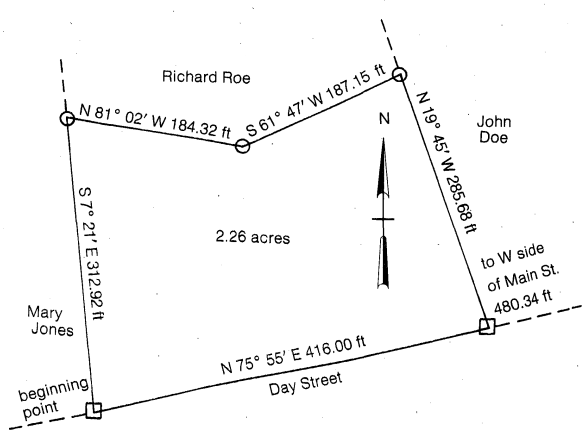

Figure 6: Plot or plat of the metes-and-bounds description (see text).

Special types of surveys. Special surveys for transportation routes, nautical charts, and mine surveying frequently require specialized techniques. All routes of transportation require surveys; particularly accurate must be those for canals, railways, pipelines, and highways. A strip map is made of the most probable route, which is controlled by a traverse and a single line of levels. Photogrammetry usually fills in details. For small surveys, profiles are measured at right angles to the traverse, and contour lines are drawn connecting them. Other details are located by right-angle distances (offsets) from the traverse and by the distance along the traverse to the foot of the perpendicular.

Surveying for transportation routes

The centre line of construction is laid out on the map where the required limits of rate of grade and curvature can be met with the greatest economy. Changes in rate of grade are connected by vertical curves, which are parabolas with vertical axes. Occasionally, in the final layout, spirals are used to connect curves with tangents or other curves. Detailed construction usually is laid out on the ground by measurements from the centre line and the original line of levels. Often the centre line is represented by a base line parallel to it.

The computation of earthwork volumes and the complicated computations required for highway interchanges are nearly always handled by electronic computers.

Nautical charts. Horizontal control for a chart usually consists of triangulation established on land and on stationary positions in the water, such as lighthouses. Traverse is frequently carried out on land, and usually special land targets are built to mark ranges from which the positions of soundings can be determined. These targets, the shoreline, and other objects used for navigation or construction are located from the control.

Mine surveying. Mine surveyors map mine workings, measure the quantities of material excavated, lay out mine tunnels and shafts, and transfer the limiting boundaries on the surface down into the workings.

The fundamental control is almost always located on the surface and is carried out as in ordinary surveys. Wherever possible, ordinary survey methods are also practiced inside the mine. For levelling, shorter than normal rods are used, illuminated by the rodman's flashlight. Where the workings slope, slant measurements are made and their vertical angles recorded, so that horizontal distances and elevation differences can be computed.

Transits are usually equipped with an auxiliary telescope that can be attached to the end of the telescope horizontal axle and adjusted so that its line of sight is parallel to that of the main telescope so that highly inclined sights can be observed.

To measure a downward slant distance, the tape is held at the centre mark of the end of the telescope axle and the other end of the tape at the lower point aimed at by the transitman. Thus the vertical angle of the tape itself is determined. The horizontal angle is measured with the telescope direct and reversed. The average eliminates the effect of the eccentricity of the side telescope.

Because each mine level requires, in effect, a separate survey, it is essential to interconnect these surveys and especially to connect them wherever possible with the surface ground control. When an adit is available, or even a shaft that is not vertical, there is no difficulty. Plumb lines can be used in vertical shafts; a heavy weight, supported on a wire from the top of each shaft, is immersed in oil at the bottom of the shaft to steady it. The greatest difficulty arises when only one vertical shaft is available for surveying operations. In such an event, the azimuth, or bearing, of the surface control must be carried down step-by-step to establish control points at each level. To provide two control points (with only one shaft), two wires with weights are hung as far apart as possible but clear of any contact with the sides of the shaft. Their azimuth is determined as accurately as possible at the surface. At the bottom of the shaft they tend to swing like pendulums, and they are seriously affected by air currents. It follows that many continuous observations are necessary to determine their average position and fix their azimuth with relation to the surface ground control.

The operation can be carried out from the top of the shaft with a transit with an auxiliary telescope by aligning a wire below, so that the line of sight will sweep the wire as far as the shaft permits. The telescope can then be raised and the line of sight to a distant point established.

Suvorov, Aleksandr Vasilyevich

Aleksandr Suvorov was the most celebrated and original of all Russian military commanders and the most successful instrument of Russia's territorial expansion in the 18th century. His ability to exploit to the full the patriotism and endurance of Russian peasant soldiers, to fire them with enthusiasm and dash, made him a legend in his lifetime and a national hero who is still held up as a model to inspire the Soviet soldier.

Born in Moscow of a noble family on November 13, 1729, Suvorov was educated at home, joined the Semyonovsky Guards regiment at the age of fifteen, and was commissioned a lieutenant of infantry in 1754. Having gained varied experience during the Seven Years' War (1756–63), in 1763 he became colonel of the Suzdal

Suvorov, portrait by J. Schmidt, 1800. In the State Hermitage Museum, Leningrad.
By courtesy of the State Hermitage Museum, Leningrad

Regiment, for which he wrote a comprehensive manual notable for its realistic emphasis on battle training at a time when the prevailing fashion was for parade-ground manoeuvres in the Prussian style.

His successes during the Russo-Polish conflict of 1768–72 earned him a reputation as a self-willed subordinate and a boldly unorthodox tactician—a reputation that was confirmed when, in 1773, he joined Count P.A. Rumyantsev's army fighting the Turks on the Danube. His two successful descents on Turtukai, his brilliant defense of Hirsov, and, above all, his successful direction of the Battle of Kozludji (1774) showed him to be an incomparable commander of the field, but after he helped to suppress the Russian peasant revolt led by Yemelyan Pugachov in the same year and subsequent service in the Crimea, his career seemed to founder.

A mission to Astrakhan to prepare an expedition into Persia proved abortive, and, even after he returned to a more active posting in the Caucasus in 1782, the establishment repeatedly passed him over. His marriage to Varvara Prozorovskaya, contracted ten years before, broke down in 1784, Suvorov refusing to recognize her child, Arkady, as his son, though he remained devoted to his daughter, Natalya. Returning to St. Petersburg and the court, Suvorov felt consistently ill-at-ease—conscious of his scrawny appearance, rough manners, and inability, as he put it, to "endear myself to my superiors," to which he attributed the slow progress of his career. But in 1787, after almost 15 years, he was at last promoted to the rank of general.

Victories over the Turks

In the Russo-Turkish War of 1787–91, he successfully defended Russian territory on the north shore of the Black Sea from Turkish attack. His victory over the Turks at Kinburn (October 1787) restored him to the limelight, and though his alleged rashness and drunkenness at the siege of Ochakov, in 1788, earned him official displeasure and exclusion from fighting commands, in 1789 he was sent to Moldavia (in present Romania) to conduct joint operations with Russia's Austrian allies. The ensuing victories at Fokshany (now Foçsani, Romania), and his brilliant and bloody storming of the stronghold of Ismail (1790), confirmed his popularity in the army, but his sense of frustration was revived when he was transferred to Finland in 1791. Hostile rumours circulated against him at court, and, as younger, less deserving men overtook him in rank, his embitterment deepened, and he became noticeably more eccentric.

Then, in 1794 he was recalled to crush the nationalist-revolutionary movement in Poland—which he did with ruthless efficiency. The slaughter involved in his storming of the Warsaw suburb of Praga (which he justified as shortening the war and saving lives) shocked Western opinion, but it earned him a reward of 7,000 serfs and the promotion to field marshal he had long coveted.

Subsequently appointed commander in chief of the

southern army, Suvorov set about molding it according to principles he set out in his celebrated military treatise, *Nauka pobezhdat* (*Science of Victory*)—remarkable for its clipped, colloquial style, its novel emphasis on speed and mobility, and the use of the bayonet and accuracy of fire. But on the accession of the Emperor Paul I (reigned 1796–1801), the old Prussian parade-ground emphasis was reimposed, and, refusing to hide his opposition to it, Suvorov was dismissed.

Suspected of treason, he was kept under close surveillance, but a thorough investigation produced no evidence against him, and the emperor restored him to favour. But Suvorov continued to show his dislike of the way the army was being managed and soon retired again.

Italian campaign

Fiercely antirevolutionary, he responded with enthusiasm when he was recalled in February 1799 to command a Russo-Austrian army against the French in northern Italy. A series of rapid victories (April–August 1799) resulted in his capturing Milan and almost completely expelling French forces from Italy. These successes made him a hero to those opposed to the French Revolution but also aroused Austrian misgivings about Russian ambitions in the west. Suvorov had wished to invade France, but was ordered across the Alps to join a Russian force under Aleksandr Rimsky–Korsakov that was being threatened by the French in Switzerland.

Fighting his way across the mountains, he reached Altdorf, only to hear that Korsakov had already been defeated and that the Austrian divisions in Switzerland, intended to support him, had retired. Surrounded by the enemy, short of ammunition and supplies, and with the first snows of winter falling, Suvorov set out to extract his army from an apparently hopeless position. Though old and sick, he succeeded in arousing his starving and dispirited troops, broke out to reach Glarus, and, repulsing a pursuing French force, succeeded in escaping with three-quarters of his men, achieving one of the most remarkable exploits in the annals of war.

Though disillusioned with the Austrians, Suvorov still envisaged fighting another campaign, but in January 1800, having been promoted to the unprecedented rank of generalissimo, he was recalled. He arrived at St. Petersburg, exhausted and gravely ill, only to find that, on account of a petty misdemeanour, the hero's welcome planned for him had been cancelled and that he was excluded from the court. He died on May 6, 1800.

(P.L.)

Swamps, Marshes, and Bogs

Swamps, marshes, and bogs are commonly considered together as wetlands, distinct from lakes, ponds, and streams. Wetlands combine characteristics of both aquatic and terrestrial areas. They are covered with emergent vegetation of higher plants and mosses, rather than only algae, which are typically found growing in open water. The soil or root mat from which the plants grow is usually saturated with water for at least a major portion of the year and may be covered with water most of the time.

The distinction between swamps, marshes, and bogs varies from place to place. Bogs are often thought of as places that look dry but that wet the feet of walkers, whereas marshes are places with visible standing water. A useful distinction used in this article is that marshes and swamps are characterized by plants that grow on mineral soils. The area is a swamp if the plants are principally trees, and a marsh if they are principally grasses. Examples are mangrove swamps, cypress swamps, cedar swamps, cattail marshes, and salt marshes. Bogs, often called moors, are wetlands with organic soils or peats. The vegetation in bogs of temperate regions is rounded in outline and cushion-like, in contrast to wet woodlands that are swamps or wet prairies that are marshes.

Swamps and marshes occur on river floodplains behind various sorts of dams and along sheltered intertidal seacoasts in tropical regions. Bogs are characteristically more stagnant areas dominated by the growth of mosses; these usually belong to the genus *Sphagnum*.

Swamps and marshes are found throughout the world wherever there is shallow stagnant water in which higher plants can grow. Bogs are also found throughout the world, although they are much more abundant in temperate and colder regions, including the mountains in tropical climates. Wetlands are frequently formed as a result of the filling in of ponds and lakes, by erosion from the surrounding land or by the accumulation of various organic sediments.

Importance of wetlands

Swamps, marshes, and bogs have been traditionally thought of as undesirable features of the landscape. To a large extent this is because they are breeding grounds for mosquitoes and are thus associated with diseases such as malaria and yellow fever. Wetlands have always been objects of large numbers of drainage projects in an effort to convert them to farmland and sites suitable for construction. It is now recognized that these wetlands are of value to man, the remaining ones especially so because many have been destroyed.

Wetlands, lying in depressions, hold large quantities of freshwater by retarding the rate at which it can run off into rivers and so eventually to the sea. This retardation allows water to percolate into the ground and thus recharge the groundwater. This is of particular importance in countries such as the United States, where highly mechanized industry and farming are threatening to exhaust groundwater supplies in many areas.

The retardation of runoff is also important in the prevention of flooding. Preservation of inland wetlands is a less expensive flood-control measure than the construction of dams and gives added benefits in the field of conservation.

Coastal salt marshes and mangrove swamps, when allowed to remain as a barrier between the sea and human construction, provide a self-repairing protection against damaging storm waves.

Commercial uses of wetlands can be direct or indirect. Peat is mined from bogs in various parts of the world and then dried and used as fuel. Peat fires, used to smoke malt, give the characteristic flavours to Scotch and Irish whiskies. Peat is also mined for horticultural purposes, as is *Spaghnum* moss itself.

Peat production in the United States is between 500,000 and 600,000 tons a year and about half that in Canada. East and West Germany combined produce 2,000,000 to 4,000,000 tons a year, Ireland produces 5,000,000 to 6,000,000 tons a year, and the Soviet Union from 150,000,000 to 200,000,000 tons a year. The large Soviet production is used partly in the generation of electricity.

Swamp forests are sources of timber. Although cypress can grow in upland soils, it is found in large stands only in swamps to which this tree is particularly well adapted. Marshes support fur bearers such as muskrat, mink, and otter.

Coastal marshes are of indirect commercial value because they provide nursery grounds for many species of commercially valuable fish and shellfish. Wetlands are of commercial value also to industries connected with some aspects of recreation. Marshes, both coastal and inland, furnish nesting and feeding areas for waterfowl. Salt marshes support many species of sport fish.

The Florida Everglades region, in spite of widespread drainage, is still one of the world's largest combinations of marshes and swamps, and it makes an important contribution to Florida's tourist industry. Finally, wetlands have a purely recreational value in preserving variety in the landscape and in preserving species of animals and plants that cannot survive elsewhere.

This article treats the physical and biological characteristics of swamps, marshes, and bogs and contains a discussion of wetlands of the geological past. In the latter regard, see COALS and articles on the CARBONIFEROUS PERIOD for relevant information. See also COASTAL FEATURES; LAGOONS; and ESTUARIES for additional coverage of nearshore environments.

BOGS

Types and characteristics

Bogs are spongy, poorly drained, wet areas with peaty soils in which drainage typically gets worse as the bog grows. This results from the water-retaining nature of the plants that grow in bogs or of the peat that accumulates there.

Bogs can be divided into three types: (1) typical bogs of cool regions, dominated by the growth of bog mosses, *Sphagnum*, and heaths, particularly *Chamaedaphne* (northern bogs with trees growing on them are often called muskegs); (2) fens, dominated by grasslike plants, grasses, sedges, and reeds; and (3) tropical tree bogs, in which the peat may be formed almost entirely from tree remains. Typical, or *Sphagnum*, bogs are highly acid with a pH (index of acidity–alkalinity) of less than five (seven being neutral) and are associated with waters containing no more minerals than are contained in rainwater, often the only source of water for a bog. Fens are watered with groundwater that has some dissolved minerals and that has a pH above five; that is, it is only moderately acid. Fens and bogs are often associated in one area that usually is called a bog. Tropical bogs occur only in areas where the water is very low in minerals. They are less common than swamps but still cover extensive areas in Malaya, Indonesia, tropical South America, and Africa.

Typical bogs have simple floras. Other than the *Sphagnums* and heaths, there are a few sedges and grasses, such as cotton grass; insectivorous sundews; pitcher plants; and many orchids. Desmids, a group of unicellular green algae divided into symmetrical halves, are characteristic of bogs. Animals are not common on bogs.

Sphagnums are large mosses with large empty cells with pores opening to the outside that lie between the chlorophyll-bearing cells of the leaves. These empty cells readily absorb and retain water, giving a spongelike quality to the moss. *Sphagnum* absorbs minerals (cations) from the water, replacing them with acid (hydrogen ions), and thus makes the water around itself more acid. *Sphagnum* also possesses mild antibiotic properties. (These characteristics made *Sphagnum* popular as a wound dressing; it was used extensively in World War I.)

The saturation of the moss with water retards passage of air, so that parts of a mass of *Sphagnum* more than a few inches from the surface are usually anoxic. The combination of lack of oxygen, lack of minerals, and highly acid condition greatly retards the action of bacteria and fungi, the usual decay organisms. With the retardation of decomposition of the dead moss, a *Sphagnum* peat develops under the living plants. This is particularly the case in areas where there is a mean annual temperature of below 10° C (50° F), which also retards decay.

Bogs are most common in parts of the world glaciated during the Pleistocene Epoch (10,000 to 2,500,000 years ago). They cover vast areas in the tundra and boreal forest regions of Canada, northern Europe, and the Soviet Union. Areas of high rainfall farther to the south, such as the wetter parts of the British Isles, also contain extensive bogs. Glacial ice created many local depressions by scouring underlying rocks and spreading an uneven deposit of till on the ground. With the melting of the ice, these depressions filled with water. If the mineral content of the water was low, the ponds so formed were colonized by *Sphagnum*, which converted them to bogs.

Once bogs are formed, they retard the development of efficient drainage by inhibiting water movement and slowing erosion of the soil or rocks on which they rest. Thus, bogs tend to be long-lived if temperatures remain low and sufficient excess of rainfall over evaporation exists to prevent their drying out. If they do dry out, upland plants will colonize the former bog.

In some areas in Alaska, an unstable equilibrium between bog and forest exists. Bogs that begin by filling ponds tend to spread as the water that collects around their edges is warmed by the sun and causes the permafrost under the surrounding forest to melt. This undermines the forest, which then falls into the bog. The bog then spreads outward and gradually fills both with peat and with depositions of silt from river flooding, until finally it becomes high enough for trees to grow on the surface. As the trees grow, the ground is shaded, the peat compacts, water movement through it slows, and the ground becomes permanently frozen again. The expansion that occurs with the formation of ice elevates the ground to complete the cycle.

Development from lakes

Small lakes in glaciated regions have also often developed into bogs if they were not drained by headward erosion of stream beds or completely filled with terrestrial sediments. The lake begins to fill by the development of a floating mat of vegetation next to the shore. This may become a fen, with grasses and sedges principally involved, if the lake water has sufficient mineral content. A lake on resistant rocks, poor in minerals, will develop a floating bog mat wtih *Sphagnum* and *Chamaedaphne*. In larger lakes, wave action will not allow such floating mats to develop.

As the mat grows into the water, it floats at the surface supported by air in the plant tissues. Upward growth shades the lower parts and these die, forming an increasingly thick floating mat, the top of which remains only a few inches above the level of the lake surface. Slow decay and mechanical disturbances break off waterlogged bits from the bottom of the mat. These sink and collect on the lake bottom so that the lake is filled both from the bottom up and the top down. The material collecting on the lake bottom is very fine, only a little denser than the water. It does not compact into a firm layer but forms a false bottom layer through which heavy objects fall to the solid original lake bottom.

From the surface down, the layers are (1) floating bog, (2) clear water, (3) false bottom, and (4) true bottom. With the continued thickening of the mat there is less influence of the lake water on plant growth, and *Sphagnum* usually begins to invade the surface of the mat even if it was previously dominated by grasses. With the growth of the moss a true bog is formed and various heaths invade the mat, especially *Chamaedaphne*. With continued thickening, trees may begin to grow, the first usually being larch (*Larix*). Black spruce may invade in the last stages of bog development. From a distance it may be difficult to detect the original boundary between the upland and the now filled lake.

During much of this process the vegetation is floating. The bog is called a quaking bog to indicate the instability of the surface, which will sink slightly beneath a weight. It is even possible to break through the vegetation into the water beneath. Both men and animals have drowned this way. Nonfloating bogs may also quake if the peat is thick and spongy.

Creation of raised bogs

Ultimately, by upward and centripetal growth, the bog fills the lake completely. The original glacial basin will then contain a bottom layer of inorganic sediment combined with organic debris derived both from lake production and from terrestrial sources surrounding the lake. On top of that, a layer of false-bottom material, compacted by the weight of overlying peat, may be visible. Bog peat fills the remainder of the basin. Growth of the bog does not necessarily stop at this stage for, if rainfall is sufficient, the water-retaining properties of *Sphagnum* are sufficient to maintain a wet, stagnant environment above the original water table represented by the lake surface. Thus, continued upward growth of the bog plants creates a raised bog. The raised bog is similar to the ordinary bog except that it does not lie in a depression but is raised above the surroundings. A moat containing some open water typically surrounds a raised bog where water drains from the raised bog and surrounding upland. Because the moat receives upland drainage it may be a fen. The raised bog itself receives only rainwater. Because rain is very low in mineral content, the raised bog is more completely dominated by the characteristics of *Sphagnum* than that of the floating bog. Heaths, larches, and black spruce, which grow fairly well on the floating bog, survive only as stunted specimens around the edges of the raised bog.

Raised bogs can develop elsewhere than in old lake basins. They may even exist atop hills. A moister climate is needed than that necessary to support a bog in a basin, but, given enough rain and mist and a drainage sluggish enough for bog mosses to start growth, a bog may result.

Here again, the water-retaining ability of the mosses, and their effect in removing minerals from the environment, favour their own growth and inhibit the growth of taller plants that might shade the mosses and take over the site. These bogs, perched on the tops and sides of hills, full of water, and very poorly anchored to the underlying substratum, are not stable landscape features. Bog slides, which most often occur after heavy rains, do considerable damage in such places as Ireland.

Properties and accumulations of peat

The peat underlying a *Sphagnum* bog is composed largely of partly decomposed moss. There may be some inclusion of windblown particles, pollen, and dust. The water content of peat may be as high as 90 percent. The ash content of dried peat varies from 2 to 20 percent, with lower values more usual because the higher ash amounts come from sand and clay blown into the peat when it was at the surface. Other chemical characteristics of peat underlying bogs are the absence of free oxygen; the presence of carbon dioxide at high pressure, though in small amounts; low electrolyte concentration; and high acidity.

Plant nutrients, or electrolytes, are too low to support the growth of most higher plants. This is the principal reason why few higher plants can grow on bogs. Peat is commonly used as a medium for growing seedlings, but its suitability lies in its ability to hold water and its freedom from weed seeds. Nutrients have to be added to the medium if the seedlings are to be grown in it. The properties of *Sphagnum* in inhibiting growth of fungi have led to the use of *Sphagnum* for germinating seeds because it prevents the fungus attacks known as damping off.

In general, temperatures in lowland tropical areas are high enough for organic decay to be too fast for large quantities of peat to accumulate. But in areas with very high rainfall and with groundwater of very low mineral content, bogs may occur. As is the case in colder regions, the bogs may fill low basins, or they may develop into raised bogs. The plants of these bogs are mainly broad-leaved evergreen trees, which may be as tall as 100 feet (30 metres). Palms and screwpines may also occur. The number of kinds of plants of these bogs is very limited in comparison with the surrounding forests, just as is the case in colder bogs. Toward the centre of the raised bogs, trees are shorter or absent. Grasses and sedges cover more of the ground and open pools of water may occur. *Sphagnum* does not grow in tropical bogs to any extent, and the peat is composed of the remains of seed plants. The limited number of species is caused entirely by the lack of any groundwater supply of minerals and the rapid removal, by heavy rainfall, of those that arrive in dust.

SWAMPS AND MARSHES

Swamps and marshes, wetlands with mineral soils vegetated principally with trees or grasses, respectively, are found throughout the world. They exist in areas with poor drainage and sufficient water supply to keep the ground waterlogged, and they have a high enough supply of minerals in the water to stimulate decay of organisms and prevent the accumulation of organic materials. They are often found in regions of low relief associated with rivers that supply the water. Marsh and swamp soils do not usually develop into peat, although the salt-marsh peats are a notable exception to this rule. In salt marshes the seawater supplies enough minerals to compensate for the lack of a mineral soil, and it supports the growth of grasses. Swamps and marshes also differ from bogs in that they typically grow from the bottom up. Floating mats are less common than in bogs.

Relations to rivers and river deltas

Freshwater restriction. Marshes are common at the mouths of rivers, especially where extensive deltas have been built. The river brings a steady supply of water. The gradient of the river approaches zero at the sea, where flow is sluggish. Because the delta is deposited by sediment settling from the river water, the land that is built will be poorly drained at its driest and will often be underwater. Sediment supplied by the river has often been eroded from the surface soils of the drainage basin and is thus very rich. The combination of water supplied steadily at a low rate over a waterlogged but rich soil creates a perfect environment for marsh grasses.

Fibrous-rooted grasses bind the muds together and further hinder water flow, thus encouraging the spread of both the delta and the marsh. Marshes occur in the deltas of most of the world's great rivers. In Europe well-known river-mouth marshes include those of the Camargue in the Rhône Delta, the Guadalquivir in Spain, and the Danube in Romania, all of which are famous as bird sanctuaries. In the Middle East, both the Nile Delta and the delta of the Tigris–Euphrates have extensive marshes of historical importance. The marsh dwellers of the Iranian marshes have developed a unique culture adapted to life in the wetlands.

Marshes and extensive mangrove swamps occur in the deltas of the Mekong in Vietnam and the Amazon in Brazil. In the United States, the most extensive delta marshes are those of the Mississippi River. Other than building delta marshes, rivers in mature valleys frequently have extensive marshes and swamps along their sides. Floodplains elevated only a few feet above river level, abandoned river channels, and oxbows may have standing or sluggishly flowing water for appreciable parts of the year and thus support swamps and marshes.

River swamps are abundant along the coastal plain in the southeastern United States. They are delightfully described in their primeval condition by William Bartram in his account *Travels through North and South Carolina, Georgia, East and West Florida* written in 1791. These were the swamps that Francis Marion used so successfully to escape the British forces during the Revolutionary War and the source of his nickname, "the old swamp fox."

The great Dismal Swamp, of North Carolina and Virginia, actually a mixture of waterways, swamps, and marshes, is a coastal-plain swamp although it is not associated with a large river. The Mississippi and its lower tributaries, such as the Red River and parallel rivers in eastern Texas, have extensive swamps along the slugggish portions that flow through the coastal plain. The Paraná and Paraguay rivers in South America have extensive swamps and marshes along their courses.

Some low-lying areas with poor drainage at the heads of more extensive drainage patterns contain wetlands. The vast swamps of the Rio Negro, which drains into the Orinoco and Amazon, is one such. Another is the Pripet Marshes and fens that historically have served as the natural boundary between Poland and Russia. In the United States a mixture of swamps and marshes in Georgia called the Okefenokee Swamp is the source of the Suwannee River.

Drainage basin depressions

In some places basin-like depressions in the Earth's surface trap waters and make wetlands. Most such areas are drained someplace along their rim by a river that is impeded at that point sufficiently to dam water at times of high flow and create marshes and swamps. The world's two largest rivers, the Amazon and the Congo, fall into this category. Both of the great basins named after these rivers have extensive wetlands. The papyrus marshes of the upper Nile in southern Sudan lie above dams of resistant rocks of the cataracts. The marshes along the Danube lie above a natural dam called the Iron Gate, at which point the river flows between the Transylvanian Alps and the Balkan Mountains. Marshes adjacent to the Sahara surround Lake Debo on the upper Niger River in Mali. They were formed by a similar natural obstruction in that river.

The Okavango Marshes east of the Kalahari desert in Botswana are perhaps the best example of marshes formed in an interior, closed basin that has no drainage. Other basins without outlets like that of the Great Salt Lake in Utah have accumulated too much salt for marsh growth.

The Florida Everglades constitutes a unique marsh–swamp combination growing on a limestone base. Because the region is near sea level the water from the abundant rains does not drain but remains on the surface. The Everglades is similar to a huge, shallow, slowly flowing river. The area is an ideal marsh habitat but the Everglades is different from usual marshes. The soils are alkaline because of the limy base, and the water is clear.

Large cypress swamps occur to the northwest of the Everglades.

There are also enormous numbers of small swamps and marshes. Some areas, such as the northern Great Plains of the U.S., have so many small marshes that they are a characteristic of the landscape. These small marshes formed because the landscape left by the retreat of glacial ice was so irregular and so poorly drained that countless little depressions were filled with water each spring. As snow melted, the depressions supported the growth of temporary marshes, which then dried up during the summer. Larger depressions were occupied by ponds. These gradually became marshy as they filled in with sediment.

The succession of plants in these marshy areas is similar to that of bogs except that there is no floating mat. The ponds fill from the bottom up and have marsh plants rooted in bottom muds. The same filling in converts beaver ponds and abandoned stream meanders to small marshes.

Many of the small marshes of the Great Plains have been destroyed as a result of agricultural drainage schemes. Now, in some areas, they are being revived by destruction of the drainage systems. This has been undertaken for waterfowl and shorebird conservation. These birds depend on small marshes as nesting places. Destruction of drainage systems also aids in the conservation of water, as water can now enter the ground supply rather than run off in the drainage structures. Topography and water supply are the two most important features in determining the distribution of freshwater swamps. The nature of soils and bedrock is of importance in determining the drainage in a region, but wetlands may exist locally on any base from sands to impervious rock.

Plant occurrence and accumulation

The flow of water through wetlands is slow because of low gradients and retarding effects of the vegetation. Dead plant matter settles rather than being washed away. The slow replacement and lack of turbulence in the water results in a low rate of oxygen supply. Decay of the dead vegetation quickly uses up what oxygen is supplied, so that the mud and bottom waters are low or lacking in oxygen content. Under these conditions, the decay of organic matter is incomplete. This causes an accumulation of the more resistant fraction (humates and tannins) in the substratum. The familiar swamp water, varying from yellow to such a deep brown that it resembles strong tea or root beer, is the result.

Many species of plants grow in freshwater marshes and swamps, but relatively few are dominant. The number of species is few compared to the numbers that grow on well-watered but not waterlogged land. Grasses, grasslike sedges, and reeds or rushes are of major importance. Cattails (*Typha*) and common reeds (*Phragmites*) are familiar swamp species around the world. Papyrus, a sedge, is widespread in the tropics. Wild rice is of some commercial importance, but true rice is undoubtedly by far the most important marsh plant and supplies a major fraction of the world's grain. Bald cypress is an example of a tree adapted to growth in swamps, but gums, willows, alders, and maples are also common. Tropical swamps have many tree species including palms.

Flooding by seawater. In the foregoing discussion of swamps and marshes, the structure of the land has been noted as a factor that restricts the drainage of freshwaters, thus causing a wetland to be formed. Salt marshes and swamps, however, are formed by seawater flooding and draining, which exposes flat areas of intertidal land. Where flooding is irregular, such areas may become too salty for higher plants to grow.

Salt-marsh grasses will not grow on permanently flooded flats, although mangroves may grow in water up to a few feet deep. Growth is also prevented where the flooded land is subject to strong currents and is therefore unstable. But regularly flooded, protected areas develop salt marshes in temperate regions and mangrove swamps in tropical and subtropical regions. Mangroves will grow in pure sand at the edge of the sea. Extensive swamps develop mainly where land runoff is sufficient to bring a supply of sediments that accumulate and extend the swamp. The deltas of the Mekong, Amazon, Congo, and Ganges and the north coast of Australia and of Sumatra have notable and extensive mangrove swamps. Salt marshes, which are particularly extensive along the east coast of the United States, formed after the retreat of the last continental ice sheet. They are also common in the Arctic, northern Europe, Australia, and New Zealand and to some extent throughout the world.

Salt marshes and sea-level change

Salt marshes are covered with species of grass. In eastern North America, coarse-leaved *Spartina alterniflora* grows at midtide level and the fine-leaved *S. patens* (salt hay) at high-tide level. *S. townsendii* occupies a similar place in northwestern Europe, along with other grasses, *Puccinellia* species. The latter are also important in Arctic salt marshes. Species of *Suaeda*, *Atriplex*, and *Salicornia*, all members of the Chaenopodiaceae, are among the other important marsh plants particularly in saltier, less well drained parts of salt marshes.

On the Atlantic coast of the United States, salt marshes began to form about 4,000 to 5,000 years ago when the rapid postglacial rise in sea level slowed. *Spartina* began to grow at midtide levels in sheltered areas. The grass stems retarded water movement. Sediment accumulated along with roots, which raised the level of the marsh. By this means, coupled with the addition of new sediments from land erosion, marshes grew out into the water and up to high-tide level.

The accumulation of peat composed largely of dead *Spartina* occurred only where the peat was anoxic, which depended on its being waterlogged. The marsh did not grow above high-tide level unless river-flood or windborne sediments were deposited. At high-tide level the marsh supported mainly *S. patens* north of Cape Lookout, North Carolina, and a dwarf form of *S. alterniflora* to the south. As sea level rose marshes grew by spreading out over neighbouring uplands and into the bays and coves in which they had formed.

The sea level in Massachusetts has risen about eight metres (27 feet) in 5,000 years. Peat in the oldest parts of the marshes is about eight metres deep, the amount of rise in sea level. Primary drainage patterns developed on the flats on which the marshes grew.

Secondary patterns result from processes within the marsh. Most water-borne sediment settles out at the edge of the marsh, where water first meets resistance to movement from the grass. Levees tend to form along the creeks and dam up water in interior parts of the marsh. When an area retains standing water continuously between tides, the marsh grasses die and pools are formed. These may subsequently be drained, with the formation of secondary drainage patterns by erosion of the levees or headward erosion of the primary drainage creeks. The same general patterns of water depth tend to occur also in river marshes and swamps with times of flood and drought corresponding to high and low tide.

The creeks in a mature salt marsh are in hydrodynamic equilibrium, maintained by the currents necessary to flood the surface of the marsh. Strong currents occur just before high-tide water. At this time the area being flooded increases from the area of the creeks to the entire marsh. There is a similar strong flow in the reverse direction when the marsh is being drained on the ebb. Whereas the flow in freshwater marshes and swamps tends to be unidirectional and sluggish, the flow in salt marshes is back and forth and varies from strong in the marsh along the creeks to sluggish in portions far from them.

In regions with appreciable rainfall, land drainage is impeded by salt marshes so that there may be a progression from the salt marsh through brackish marshes to freshwater marshes and swamps. Among the most characteristic species of plant in the brackish marshes in the United States are the black rushes, *Juncus gerardii* in the north and the larger and stiffer leaved *J. roemarianus* in the south.

WETLANDS IN THE GEOLOGICAL PAST

It is logical to assume that ever since there have been land plants there have been bogs, swamps, and marshes. The deposits of coal, the remains of those preceding wetlands, prove the point. Coal has been formed in every geological

Association with coal deposits

period since the spread of land plants in the Devonian Period (345,000,000 to 395,000,000 years ago), but, during the Late Carboniferous, some 250,000,000 years ago, the first significant amounts of coal were deposited. It is from those deposits that the world's most valuable coal comes.

Carboniferous coals occur in the British Isles, France, Germany, the Soviet Union, China, and North America. There is very little coal known in Africa, South America, or Oceania. In the United States the coal was largely deposited in the east central part of the country in three main fields slightly separated from one another: the Appalachian, which extends from Pennsylvania to Alabama; the Illinois Field; and the Mid-Continent Field, extending from Missouri to North Texas. The coal swamps lay in a basin with the Appalachian Highlands on the east and the Canadian Shield on the north. The basin sloped toward the sea to the south with a very gentle gradient of only one or two feet to the mile. The entire basin was apparently only a few feet above sea level and was submerged at intervals, so that coal seams alternate with sandstones, shales, and marine limestones that were deposited when the swamps were destroyed by river sands or flooding by the sea.

Under the coal seams are clay deposits that appear to be the soils in which the coal swamp plants grew. In some areas, remains of trees are still in position extending up through the coal that represents the accumulation of remains of plants growing in the swamp. These plant remains are preserved in the coals in sufficient abundance to permit determination of the appearance of the swamps.

These remains have no indications of annual or seasonal growth rings, thus indicating that the climate must have been tropical or at least subtropical. The trees had widely spread roots and often aerial roots, both of which are typical of swampy conditions. The alternation of marine and coal deposits, as well as the small slope, indicates that water movement must have been very sluggish. If there were a very rainy climate as well, conditions would have been like those found in the bog forests of the tropics where, under conditions of very low mineral water, peat is accumulating today from the remains of partly decomposed trees.

The sulfur content of much of the Mid-Continental coals is high. When the coal is burned, sulfur is put into the air and forms one of the irritants in air pollution. Sulfur is believed to have been deposited with the coal, pointing to the fact that most of the coal swamps were brackish rather than completely fresh. Sulfur is not common in freshwater but sulfate is one of the common constituents of sea salt. The coals of Nova Scotia and New Brunswick and of eastern Pennsylvania are low in sulfur; this is an indication that the swamps in those particular regions were probably fresh.

Plants of the former swamps

The Carboniferous coal swamps, more correctly called coal bogs, were vegetated with primitive vascular plants related to modern club mosses, horsetails, and ferns. These are spore-bearing plants whose spores accumulated in parts of the bogs in almost pure deposits. The deposits formed cannel coals, a very fine coal that burns with a bright flame.

Though their modern relatives are usually small plants, the swamp-forming species were trees up to two metres (six feet) in diameter and 30 metres (100 feet) in height.

As well as the Carboniferous coal swamps, extensive deposits of coals were formed in the Jurassic Period (136,000,000 to 190,000,000 years ago), the Cretaceous Period (65,000,000 to 136,000,000 years ago), and the Paleocene Epoch (54,000,000 to 65,000,000 years ago). By Cretaceous time, coal swamps were inhabited by modern types of plants, often belonging to the same genera that occupy swamps today.

Things that occurred during the times the coals were being formed can often be determined by examining the sequence of rocks in the coal beds. In a similar manner it is possible to look at the sequences of deposits laid down in modern bogs and other sediments, such as lake muds, in which organic matter is preserved and determine the history of the bog and its vicinity by noting changes in plant parts and pollen preserved in the peat. This method is subject to uncertainties, however, because the abundance of a particular type of vegetation does not correspond exactly to the abundance of its pollen in peat.

Pollen of pines and grasses is wind-borne and overrepresented compared to plants with heavy insect-borne pollens. Herbaceous-plant pollen may be largely excluded from a bog by a surrounding ring of bushes. Relative changes in any one type of pollen with depth in the peat, however, will yield information about changes of climate and plant cover with time.

Peat formation in Massachusetts

Studies of some peat deposits and radiocarbon dates from Boston, Massachusetts, show that the earliest remains are from a freshwater swamp growing on glacial clay, 7½ metres (25 feet) below present sea level. This was followed about 5,700 years ago by a reed swamp (*Phragmites*), covered in turn by a short-lived salt marsh. Above this are remains of Indian fish weirs from 4,500 years ago.

Cores from a salt marsh on Cape Cod, Massachusetts, were taken to nine metres (29 feet) below sea level in an upland soil. The first definite saltwater peat was found at a depth of eight metres (27 feet) and was laid down about 5,000 years ago. The climate was that of a postglacial warm, dry period, judging from pollen from oak, hickory, birch, and grasses. At a depth of about five metres or 17 feet (1,900 years ago) these pollens became less abundant. Those from pine and hemlock increased, indicating a change to a colder, moister climate. At a depth of about 53 centimetres or 21 inches (400 years ago) there was an enormous increase in grass pollen, a decrease in pine, and an increase in oak, all a likely result of the deforestation of Cape Cod by settlers during the colonial period. Finally, at a depth of 30 centimetres (12 inches), corresponding to the middle of the 19th century, there was a decline in grass and oak pollen and an increase in pine pollen. This represents the time farms on Cape Cod were abandoned as new farmlands were opened in the Midwest. Pine colonized the former fields.

In regions that escaped being covered by ice during the last stages of Pleistocene glaciation, the pollen records in bogs extend much further into the past and give a record of conditions in the vicinity of the ice. One such bog, Humptulips Bog on the Olympic Peninsula in Washington, was only two to eight miles from the edge of the ice at various times. The record extends back more than 50,000 years. Sediments in the core show intervals during which the present bog was filled with silt, lake sediment, fibrous peat, and peat formed from *Sphagnum*. This reflects the great changes that took place in climate and erosion near the edge of the ice.

During most of the period represented by this core, vegetation around the bog was that of tundra or tundra interspersed with trees of types that grow in colder climates. By comparing the fossil pollen in the core with pollen presently being deposited at successively colder temperatures along the Pacific coast, a temperature record was made to correspond with the pollen record in the core. Throughout the 50,000 years, it was colder than at present. The July average was 6° C (11° F) colder during the ice maximum. During an interglacial period, from 20,000 to 30,000 years ago, climatic conditions approached that of the present, but the temperature was still about 2° C (3° to 4° F) lower than at present. The postglacial warm period referred to in relation to the Massachusetts bogs appeared to have been about 1° C (2° F) warmer than the present.

For a more detailed discussion of the utility of pollen studies in such interpretive problems, see POLLEN STRATIGRAPHY.

LIFE IN WETLANDS

Relatively few species of organisms have adapted to the special conditions of wetlands. Raised bogs impose the most rigorous conditions and have the fewest species of both plants and animals. Salt wetlands are next, with highly saline inland-basin marshes having fewer species

than wetlands flooded by ocean tides. Permanent freshwater wetlands are more favourable, but the greatest variety of inhabitants are found in temporary freshwater wetlands where the soil dries out for a part of the growing season.

Influence of the substrata. In all wetlands, plants must contend with substrata low in oxygen and usually completely anoxic. The substratum is also typically soft and offers relatively poor support or anchorage. Plant roots survive by getting a supply of oxygen from the aerial parts of the plant and by being able to metabolize without oxygen, producing ethanol as an end product rather than carbon dioxide. The oxygen-transport mechanism depends on air spaces within the tissues (aerenchyma) through which oxygen passes by diffusion to the underground parts and carbon dioxide returns. The air spaces in grasses communicate with the air through the leaves, but in many swamp trees the roots send up special pneumatophores into the air. The knees of cypress are such, as are the striking fingerlike projections from black mangrove roots.

Effects on plant roots

In nonarboreal marsh plants, the air spaces that typically occupy the entire centre part of the roots are also mechanically important to the plants. With a large empty space in the centre, root tissue is more spread than it could otherwise be, and provides more friction with the soft soil that holds the plant in place. The hollow plant is also more resistant to bending, which in turn, lessens damage by water movement.

Tropical swamp trees often develop buttresses that apparently help support them, though buttresses are also common on many upland trees in the tropics. Generally, all swamp trees lack deep-growing roots. Roots tend to stay near the surface, probably because of the lack of oxygen in the soil. Being near the surface gives a large lateral spread to the root system which also gives the tree support against lateral stresses from winds or water flow. The shallowness of the roots also often produces the appearance of buttresses in temperate swamp trees because the beginnings of the roots usually hidden in the soil are visible at the surface.

Different species of trees that grow in temporary swamps differ considerably in their resistance to submersion—*i.e.*, to lack of oxygen. This is serious during the submersion period but is not a problem in drier periods, at least in the shallow layers of the soil. In North American swamps alders and willows will survive or even thrive on land immersed for periods as long as one month, whereas red gum survives only about two weeks. Cottonwood begins to show the effects of submergence after only two days and survives only one week.

Animal adaptations

Animals have adapted to the limited supplies of oxygen in somewhat similar ways. Rat-tailed maggots (*Tubifera*), for example, survive in shallow marshes by means of a telescoping, tail breathing tube that they extend to the water surface for air. Some larvae of shore flies (Ephydridae) and some nematodes take advantage of the air spaces in plants and obtain oxygen from that source. Many small marsh animals have great resistance to lack of oxygen; for example, many nematodes can live indefinitely in the complete absence of oxygen. This ability is essential for such minute animals that would otherwise be limited in distribution to a thin layer a fraction of an inch deep at the mud surface.

The soft substratum is a problem for large animals whose weight may not be adequately supported. It is also unsuitable for sessile animals. These are rare in freshwaters in any case. In salt wetlands, sessile animals are restricted by the substratum, with the exception of such animals as mussels, which can move their position slightly to avoid being covered by mud.

Effect of salt concentration. High salt concentrations make the soil physiologically dry, and salt marshes and swamps are thus difficult habitats for species (halophytes) that grow there. In many cases these plants grow better in well-watered upland soils than they do in salt wetlands, but they cannot compete and are crowded out by upland plants. Upland plants cannot withstand high salt concentrations and leave such areas to the halophytes by default. All halophytes can concentrate salts in their cells. This enables them to resist the wilting action of saltwater.

Halophytes lose water by transpiration (evaporation from the leaves). In the process, salt is left behind. Some halophytes exclude most of the salt at the roots by means of semipermeable membranes. The excess salts that do get into the plant are secreted by special salt glands on the leaves. Other halophytes do not exclude the salts at the roots but secrete them or store them in leaves and stems. At the end of the growing season, the leaves and stems are dropped and with them the salt.

Salt-marsh animals living at or in the ground are largely derived from marine ancestors and have a problem in resisting freshwater from rains rather than salt. Some, such as the worms, merely hide in the mud until the freshwater has run off the marsh surface. Others, such as fiddler crabs, have developed the ability to control their osmotic concentration in freshwater for periods of up to several days. Insects are the principal land animals found on marshes. Although they can withstand short periods of saltwater immersion, they often avoid saltwater by moving up the plants or flying away.

The tops of mangrove trees shelter a diverse group of animals that are unaffected by seawater, because they never contact it. In general, swamp animals are little affected by wetland conditions except as those conditions affect the species of trees growing in the swamp. Whereas the diversity of plants is limited by the stresses that the presence of water entails, the animal diversity is more a reflection of the plant diversity than the nature of the water supply.

Other physical factors. Physical factors of the environment are important in determining the relative distribution of trees and grasslike plants in both fresh and salt swamps and marshes. The growing tips of grasses, sedges, and rushes are at or just under the soil level. In this position they are protected from certain kinds of damage. The tops of the grasses can be bent or even broken off without permanent damage to the whole plant. Fire is an event that may damage grasses but fires are relatively rare on wetlands. Water movement may damage plants by breaking their upper parts. Trees and shrubs will suffer more from such damage than grasses that have flexible upper parts. Grassy plants also have an advantage in regions where large masses of ice form in winter, especially if the ice is moved by currents or tides. Moving ice can completely destroy seedlings and even large trees. Winter ice prevents the evolution of a tree that could form salt swamps. Grasses, however, are not destroyed even though sheered off. The rhizomes, protected by the frozen mud in winter, put up new stalks with the commencement of the growing season.

Water and ice movement, nutrients, and temperature

Wetland plants in bogs suffer from low concentration of plant nutrients (minerals). In bogs that lie on sloping land there may be regular courses of water flowing from areas with exposed mineral soil. These tracks are clearly evident in the growth of trees. The presence of alders along such tracks is especially significant because alders fix nitrogen by means of symbiotic bacteria existing in nodules on their roots. Nitrogen fixed by these plants is then available for other species that cannot fix it themselves. The conditions that favour the tree growth also favour the growth of fungi and bacteria. Peat under these tracks is thinner than elsewhere in the bog. The relatively good growth along these tracks emphasizes the nutrient-poor environment.

Bogs are also colder than the surrounding environments. Open bogs growing only bog mosses are colder than bogs that support higher plants as well. In a central Massachusetts open bog, the frost-free season is only two months long, whereas in the surrounding spruce forest it lasts four months. Most of the plants are limited by lack of nutrients, however, rather than by the shortness of the growing season.

Animals are also rare in bogs. A few insects live in and on *Sphagnum* and on other bog plants, but in general bogs are as impoverished in animals as they are in plants. In some cases animals may affect bogs. Deer taking shel-

ter in white-cedar swamps in northern Wisconsin break up and compact peat, reducing its water-holding capacity. This makes the site more suitable for some varieties of upland trees and accelerates the change from wetland to dry forest. In the process the wintering yards for the deer are destroyed.

Wetland productivity. The productivities of various types of wetlands range from poor to good. Productivity is low in bogs where plant growth is limited by a meagre supply of nutrients. Organic matter accumulates relatively rapidly in bogs because the rate of decay is slow. Productivity has been measured in bogs in Alaska in which the *Sphagnum* grows at the rate of 150 to 280 grams per square metre per year (1,340 to 2,500 pounds per acre). This is about the same productivity as occurs on uncultivated short-grass prairies.

Few measurements exist of the productivity of swamps or freshwater marshes. Values will vary depending on the nutrient supply and should fall between the bog values and those of the most productive natural systems. The latter are well represented by salt marshes. Productivities of more than 3,000 grams per square metre per year have been reported for the most productive parts of salt marshes, the tall *Spartina alterniflora* stands growing along tidal creeks.

Role of the tides in weeding and feeding

These values correspond to nearly 30 tons per acre per year and are equal to the highest values that have been achieved in agriculture. Agricultural productivities have been maximized in subtropical areas where the growing season lasts throughout the year by the use of fertilizers and by means of careful cultivation and weed control. Natural production in salt marshes comes about without human effort. Tides accomplish weeding by keeping all but a few well-adapted plants out of the marshes. Tides also provide fertilizer in the form of nutrients dissolved in the water and nutrients absorbed in particles of silt and clay transported by tidal flow. Although salt marshes occur in areas that have a cold winter, the growing season extends throughout the year. Grasses do not grow during the winter, but unicellular algae, which live on the surface of the marsh and in the water that floods it, grow throughout the year.

(J.M.Te.)

Swaziland

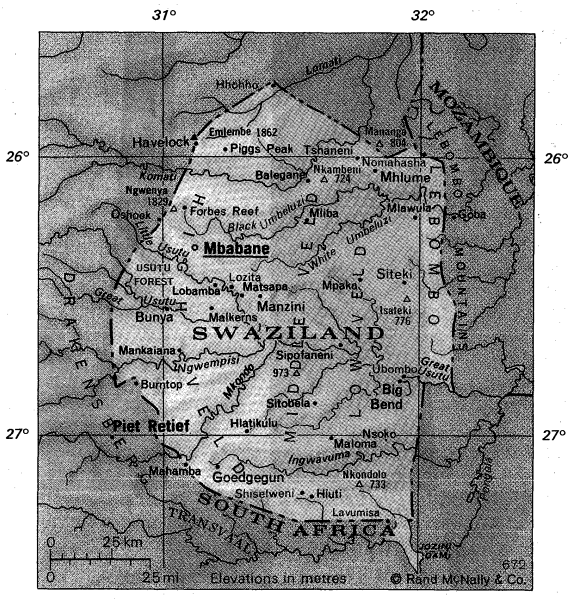
Swaziland is a landlocked, independent kingdom wedged between South Africa to the north, west, and south and Mozambique to the east. It has a total area of 6,704 square miles (17,364 square kilometres). Small and compact, the oval-shaped country is less than 120 miles from north to south and 90 miles from east to west. It is named for the Swazi nation, which comprises almost all of the country's 446,000 people. The national capital is at Mbabane.

Formerly a British High Commission Territory, Swaziland gained its independence in 1968 under the leadership of its king, Sobhuza II. Surrounded by white-ruled countries, the small black nation is faced with delicate problems of economic development. It is rich in agricultural land and mineral resources, but its mines are controlled by foreign interests, and its commercial agricultural operations remain in the hands of Europeans. Economic progress has, however, been steady. For an associated physical feature, see VELD; for historical aspects, see SOUTHERN AFRICA, HISTORY OF.

The natural landscape. Despite its small size, Swaziland has a rich variety of relief features and soils. There are four well-defined topographic regions, extending longitudinally from north to south in roughly parallel belts. From west to east they are Highveld, the Middle Veld, and Lowveld, and the Lubombo escarpment.

Relief features and soils

The Highveld, which covers an area of 2,000 square miles, is a continuation of the Drakensberg range of South Africa. Locally known as Inkangala (meaning A Cold Treeless Place), it is a granite massif (mountainous mass) with quartzite ridges that are broken up into rugged terrain. The average elevation is between 3,500 and 4,500 feet; the highest elevations are the summits of Emlembe (6,100 feet) and Ngwenya (6,000 feet). The rocks on gentle gradients are covered by deep red, orange, and yellow acidic soils of medium texture.



SWAZILAND 31° 32°

The Middle Veld covers an area of 1,900 square miles and has an average altitude of 2,000 to 2,500 feet. It is a region of hilly country and well-watered valleys. Its foundation is mainly dolomite (limestone rich in magnesium carbonate) and gneiss (coarse-grained rocks containing ponds of minerals). Dolerite (coarse basalts) and quartzite also occur. The principal soils are deep and friable red and clay loams; gray-brown sands and sandy loams rest on mottled, sandy clay or iron concretions.

The Lowveld, or Bushveld (locally known as Lihlanze a Swazi name meaning A Warm Place with Trees) covers 2,200 square miles. It is a gently undulating region with hills that rise from an average of 500 to 1,000 feet to a height of 2,300 feet reached by the isolated hill of Nkambeni and the isolated ridge of Nkondolo. The complex geology of the region ranges from the acidic rocks of the west to the basalt and dolerite of the east. The soils are similar to those of the Middle Veld.

The Lubombo, covering 600 square miles, is an escarpment along the eastern fringe of the Lowveld. It rises from an average height of 2,000 feet to the two highest points of Isateki hill (2,500 feet) and Mananga Beacon (2,700 feet), which is on the border with South Africa. The scarp is intersected by the gorges of the Ingwavuma, Usutu, and Black Umbeluzi rivers. The plateau's foundations are composed of acidic and intermediate volcanic lavas, such as rhyolite, lava-formed granite. Soil is virtually absent in some areas, while in others it is fairly deep, reddish, and medium to heavy in texture.

The country is one of the best watered in southern Africa; major rivers flow through all four regions. From the Highveld—where most streams are perennial—the Lom-

The rivers

ati, Komati, Black Umbeluzi, Usushwane (Little Usutu), Usutu, Ngwempisi, and Mkhondvo rivers flow in a generally easterly direction toward the Indian Ocean. The Usutu, which carries the greatest volume of water, flows into the Pongolo to form the Maputo River of Mozambique.

The environment. The climate varies from almost tropical and subhumid conditions in the Lowveld, where the average annual rainfall amounts to between 20 and 35 inches, to the humid, near temperate climate in the Highveld, which receives between 40 and 90 inches of rainfall. The Middle Veld and Lubombo region are subtropical and drier, receiving only 30 to 50 inches of rain. Rains occur during the summer from October to March. The mean annual temperature is 59° F(15° C) in the Highveld and 72° F (22° C) in the Lowveld.

More than 2,600 species of ferns and flowering plants have been recorded. Among these are 25 species of aloe (members of the lily family), *arum lilies*, Cape primroses, begonias, gladioli, and a rich variety of orchids. Cape heath (*Erica*), a large sturdy shrub, with red, pink, green, yellow, and white flowers, grows in the mountains. Trees include the crimson-flowered Hottentot's bean, the scarlet-flowered umsini, umvangata or kiaat (a leguminous tree that yields durable wood), and umbrella trees.

Although the animal population has been greatly reduced (earlier by hunting, but now by the expansion of agriculture), there are still numbers of hippopotamus, blue wildebeest, zebra, and antelope (including the koodoo, impala, reedbuck, duiker, klipspringer, and waterbuck). Lions, baboons, monkeys, and galagos (small African lemurs known as bush babies) are less numerous. There are crocodiles in the Lowveld rivers. Birdlife is abundant and includes a few rare species with northern affinities, such as the European stork, the sacred ibis and hadedah. Other more conspicuous species are the hammerhead, the gray heron, the lisakabuli (widow bird), the hornbill, and the lilac-breasted roller.

The landscape under human settlement. Nine-tenths of all Swazis live in villages that are divided into family homesteads, or *umuti*. Each village is led by a headman, who is the village patriarch. A unique feature of Swazi life is the role of the headman's mother, who acts as village "mother" and is in control of everything affecting the homestead. Each such homestead, at the minimum, consists of a great hut, the cattle kraal (enclosure), and the bachelors' quarters. Flask-shaped pits for storing grain are built into the wooded palisades surrounding the kraal.

Rural life

The pattern of village life is strictly set by the seasons. With the onset of the rains in spring (August to October), women plant small gardens along the riverbanks; later, when the heavy rains come in summer (November to January), with some help from the men, they hoe and sow maize (corn) and millet in larger fields; at this time all able women and children abandon their homesteads for the fields, and the men also join in the planting and weeding. The summer months are, on the whole, the hungry months.

Autumn (February to March) is the time of harvest; in winter (April to July) the last of the crops are brought in. Activity then moves to the homesteads, where women and men thresh the grain, the best of which is stored and the remainder consumed at once. Winter is a time for relaxation; the men hunt and entertain from their full food bins and the women visit their parents.

The central points of Swazi political life are the royal villages of the king at Lozita, with a population of 50, and the queen mother at Lobamba, which had 75 to 100 inhabitants in the early 1970s and was to become the new legislative capital. The two principal commercial centres are Mbabane and Manzini. Mbabane, attractively situated on wooded hills, contains both modern and colonial-style buildings. It is the country's largest town, with 17,850 inhabitants, of whom 2,000 are Europeans. Manzini is a growing industrial and agricultural service centre; its population of 7,580 includes 500 Europeans.

The Swazi nation

People and population. The Swazi nation of 382,000 people is composed of over 70 clans, of which 70 percent are Nguni and 30 percent Sotho. The Dlamini, the dominant clan, forms the nucleus of the nation and constitutes the royal family. Its customs, laws of property and person, and dialect, known as Siswati, prevail.

The Swazis comprise about 90 percent of the total population of about 446,000. Other Africans, mainly Shangane from Mozambique, number about 25,000. Europeans, largely English- and Afrikaans-speaking South Africans, total less than 10,000, and Eurafricans (persons of mixed European and African descent) and Asians number about 5,000. Eurafricans and Asians are mainly in commerce and industry as shopkeepers, clerks, and artisans. Most Europeans are either large-scale farmers, miners, technicians, teachers, public officials, or traders. The majority of the Europeans speak English, which is one of the official languages, together with Siswati.

A majority of Swazis are Christians. About 43 percent hold strongly to their traditional animist religious beliefs.

The population, which totalled about 446,000 in 1972, was expected to double by 1985. The birthrate is 48 per 1,000 and the mortality rate 22 per 1,000. Life expectancy is 40 to 45 years of age. Population varies from 37.9 in parts of the Lowveld to 572 persons per square mile in the Ezulwini Valley of the Middle Veld.

Swaziland, Area and Population

	area		population	
	sq mi	sq km	1966 census	1972 estimate*
Districts				
Hhohho	1,378	3,569	96,000	110,000
Lubombo	2,296	5,947	82,000	117,000
Manzini	1,571	4,069	101,000	112,000
Shiselweni	1,459	3,780	96,000	95,000
Total Swaziland	6,704	17,364†	375,000‡	446,000§

*Resident African population only. †Figures do not add to total because of rounding. ‡Includes 126 persons in transit through the country at the time of the census. §Includes an estimated 12,000 non-Africans.

The national economy. Swaziland is principally an agricultural country, with 90 percent of the population engaged in subsistence agriculture. Mixed farming is carried out on the Middle Veld, where rice and fruits, such as bananas and citrus, are grown under irrigation; maize, cotton, beans, tobacco, and pineapples are raised on dry lands. The Lowveld is ideally suited to cattle raising, which is little developed commercially; this region is under irrigation, and there is intensive cultivation of cash crops such as sugarcane, rice, tobacco, and citrus fruits, which are mainly grown by European farmers for export.

The nation's main export wealth derives from forestry and mining. The largest man-made forest, the Usutu afforestation estate, covers 100,000 acres of pine and eucalyptus trees planted in the Highveld. It supplies the wood pulp factory, near the town of Bunya, the products of which are a major export earner. Although not extensive, mineral resources are rich. Iron ore and asbestos deposits are located in the Highveld region, and there are also important coal deposits near Mpaka.

Mining operations

Three major mines were in operation in the early 1970s. The most important is the iron-ore mine at Ngwenya, owned by the Swaziland Iron Ore Development Corporation and controlled by South African and British interests. The British-owned Havelock Asbestos Mine exports asbestos fibre. Third in importance are the Mpaka coal mines, mainly owned by a South African firm. Smaller mines, also foreign owned, produce kaolin, barite, and pyrophyllite.

Industry is mainly confined to the processing of agricultural products and to providing small-scale services. Manufactured products include clothing, edible oils, soap, canned fruit, and ginned cotton. There are also a slaughterhouse and a small engineering industry. Handmade woven and wooden articles are also produced.

Less than one-third of the working population is engaged in paid employment. Of these, more than 25 percent are employed in agriculture and related services. It

was formerly traditional for Swazi labourers to engage in migratory labour in South Africa's mines and farms, but by the early 1970s the proportion that still did so had dwindled to about one-quarter of all male workers. Annual recruitment for the South African mines was about 6,000.

The bulk of all wholesale and retail trade is traditionally controlled by white South Africans. All commercial banking is foreign owned.

The country maintains a favourable balance of trade. The need for budgetary assistance ended in 1970, but the country still depends on foreign aid—mostly from the United Kingdom—for capital and development needs. Imports of machinery, fertilizer, clothing, fuel, and vehicles largely come from South Africa. Exports—including iron ore, sugar, wood pulp, asbestos, and agricultural products—are sold to the United Kingdom, Japan, and South Africa.

The main sources of national income are taxes, mining royalties, and customs revenues. Income tax is payable on all incomes derived inside the country. A personal tax is paid by all non-Swazi adult males, and Swazi adult males pay a graduated tax based on the number of their wives. Company taxes are paid at a fixed rate, and mining taxes are on a variable scale.

The country's future economic prospects are mostly encouraging. With improved education and training, the Swazis can be expected to increase their levels of agricultural productivity and to play a much larger role in private industry and commerce.

Transport and communications. Good all-weather roads link the main population centres. The transterritorial highway runs from Oshoek, on the western frontier, to Nomahash, on the eastern border. The road network consists of more than 900 miles of main roads and 1,000 miles of feeder roads.

A railway line running from Kadake to the port of Lourenço Marques, in Mozambique, opened in 1964, is linked to the Mozambique Railways network at Goba across Swaziland's northeast border. There is no rail link with South Africa.

The only airport is at Matsapa, five miles from Manzini. South African Airways operates scheduled services to Johannesburg and Durban, and Mozambique Airways flies to Lourenço Marques. There are more than 20 landing strips.

The government operates postal, telephone, and telegraph services. An international teleprinter service is routed through South Africa.

Administration and social conditions. Executive authority is vested in the king and exercised through a cabinet, which is presided over by the prime minister, who is appointed by the king. The cabinet advises the king and is responsible to a bicameral parliament. The House of Assembly is composed of 30 members—24 of whom are elected by adult franchise and 6 appointed by the king and the attorney general. There is universal franchise for all men and women over the age of 21 who are citizens of Swaziland and who are not insane and who have not been convicted of serious crimes. The Senate has six members elected by the House of Assembly and six nominated by the king. Parliament has no power to legislate in respect of Swazi law and custom, which is the prerogative of the Swazi National Council, consisting of the king, the queen mother, and all adult male Swazis. The civil service is controlled by a public service commission appointed by the king on the advice of the Judicial Service Commission.

The governmental structure

Local urban government operates through town councils and urban area advisory committees. A majority of the council and committee members are elected and a minority appointed by the Minister of Local Administration. Rural administration is conducted in the four districts of Shiselweni, Lubombo, Manzini, and Hhohho by district commissioners responsible to the Minister of Local Administration.

The judicial system comprises a court of appeal, a high court, subordinate courts, and Swazi (traditional) courts. The court of appeal comprises a judge president and three justices of appeal appointed by the king. The high court, presided over by the chief justice, hears appeals in civil and criminal matters from subordinate courts and the Higher Swazi Court of Appeal. Subordinate courts, presided over by magistrates, have wide criminal jurisdiction but not over murder, sedition, or treason. There are 14 Swazi courts, two courts of appeal, and the Higher Swazi Appeal Court; these may hear cases only if all those involved are Africans and if the charges fall within a restricted list of criminal and civil offenses.

Land ownership is the most sensitive issue in Swazi national life. Under the British colonial administration about 44 percent of the land was either sold as concessions to Europeans or alienated by the government. Traditionally, however, all land is vested in trust in the king as Swazi national land, and all Swazis are entitled to a share, which is allocated by the king through the chiefs. The Swazi National Council adopted a policy in 1946 of repurchasing for the nation as much as possible of the 1,873,000 acres still held out of communal ownership by Europeans.

Educational services

Half of the school-age children, numbering about 71,000, attend the 366 primary schools, of which 322 are mission (primarily Protestant) schools. About 9,000 students attend the 54 secondary schools. Schooling is free except at the Waterford School at Mbabane, which is a multiracial institution for pupils from all over southern Africa. Two teacher-training colleges produce 170 teachers annually. Higher education is provided at the University of Botswana, Lesotho, and Swaziland (UBLS), which is situated at Roma, in Lesotho.

Medical services are provided by the government, missions, industrial concerns, and private practitioners. In the early 1970s, the country had 11 hospitals and 44 rural clinics. Chief causes of illness are schistosomiasis (a parasitic infestation of the bladder or intestines), food-deficiency diseases, typhoid and paratyphoid, and respiratory diseases. Malaria has been virtually eliminated.

Major national celebrations

Cultural life. Traditional ceremonies and music play an important part in Swazi social life. The two major cultural events are the *Incwala* (National Ceremony) held in December or January, and the reed dance (*umhlanga*) held in June or July; both are held at the royal village of Lobamba. The *Incwala,* the most sacred of the ceremonies, represents the king as the source of fertility and the symbol of power and unity. It lasts for six days and is a highly ritualized festival of song, dance, folklore, and martial display. The reed dance, which lasts for one week, encourages girls of the same age-group to work in harmony under discipline and to preserve their virginity.

Traditional music accompanies the Swazi from birth to death, beginning with the first lullaby. There are songs for children and adults; for courting, weddings, and mourning; for working; for specific tribes and clans; and for insult. The main musical instruments are rattles, which are tied to the wrists or ankles or shaken by hand. The shield is used for percussion; buckhorn whistles and long red flutes are the principal wind instruments.

The Swaziland Broadcasting service in Mbabane, which is commercial in character, broadcasts in English and Siswati. Radio programs are also received from South Africa and Mozambique. The *Times of Swaziland* is a privately owned English-language weekly. *Umbiki* is a government fortnightly published in Siswati. Both are published in Mbabane.

Prospects for the future. Swaziland is one of Africa's more politically stable countries. With the promise of economic development, based on adequate resources, its future appears assured. Long-term problems arise from the country's sensitive location between Mozambique and South Africa. National policy is to protect the country's independence by not becoming too closely dependent on the political systems of either of its neighbours.

(Co.L.)

Sweden

In area the fourth largest nation of Europe—after the U.S.S.R., France, and Spain—Sweden lies in the Scandinavian Peninsula bounded by Norway on the west, Finland on the northeast, and the Gulf of Bothnia, the Baltic Sea, and the North Sea on the east, southeast, and southwest, respectively. A narrow sea channel separates it from Denmark to the southwest. Most of the 8,000,000 inhabitants live in dense clusters in a relatively small portion of its 173,649 square miles (449,750 square kilometres), but in the years since 1815, during which Sweden has remained at peace, the Swedish people have achieved a remarkably stable and democratic way of life. In form, Sweden's government is a constitutional monarchy, with its seat in Stockholm.

Location and general character of the nation

The popular image of Sweden includes such features as the prototype it has provided of the modern welfare state, a "middle way" that is Socialist but non-Communist, and its traditional nonalignment in peace and neutrality in war, which has allowed its people to assume a unique leadership in the world community.

Although more than 90 percent of Sweden's trade and industry is in private hands, its labour movement chose, at the time of industrialization in Sweden (at the end of the 19th and the beginning of the 20th century), to follow national traditions that combined firm and efficient public administration with a keen sense of justice, independence, and loyalty. These qualities perhaps in some way reflected the high degree of homogeneity that the Swedish people had achieved in ethnic, linguistic, and religious identity. Thus, the movement found its place within—or, in the view of many, conquered—the newly evolving social and economic forms by the relatively slow processes of democratic, parliamentary action rather than by upheaval and force. Today, the nation's standard of living is perhaps exceeded only by that of the United States.

As a country that in many ways has had good luck, including a peripheral but in-between location and vast resources of iron ore and timber, Sweden long ago disavowed the military aggressiveness that once made its armies bulk large during Europe's centuries of dynastic warfare. It chose instead to play a balancing role among the world's conflicting ideological and political systems. It is no coincidence that Swedish statesmen have often been sought out to fill major positions of leadership and mediation within the United Nations.

For information on Swedish history, see the article SCANDINAVIA, HISTORY OF. For the nation's place in the larger physical and cultural pattern, see EUROPE and articles on the various arts, such as LITERATURE, WESTERN; MOTION PICTURES, HISTORY OF; and VISUAL ARTS, WESTERN; see also the article STOCKHOLM.

THE NATURAL AND HUMAN LANDSCAPE

The natural environment. *Physical features.* Sweden's four main physical regions are, from the north, the northern mountain and lake region known as Norrland; the lowlands of central Sweden known as Svealand; the relatively low Småland highlands and the small but rich plains of Skåne, the two last areas in Götaland.

From the ancient mountain range with its crest along the Swedish-Norwegian border, the land descends southeast and south. The mountain, or *fjäll*, region has a most dramatic scenery. The highest peaks of Sweden are found in Lappland: Kebnekaise, at 6,926 feet (2,111 metres), and Sarektjåkko, at 6,854 feet (2,089 metres), the latter situated in a national park of great and lonely magnificence. Åreskutan, Helagsfjället and Sylarna peaks lie amid favourite sporting locales in a more southerly location; they are especially popular during the spring and summer.

The four physical regions

The big rivers, or *älvar*, of Norrland flow from the mountains to the sea in the southeast. Many are linked to long, narrow lakes made by dams of moraine, and often they have rapids and falls, many of which have power stations. Several of the larger rivers have huge flows and fall great distances in their course to the sea.

The metallic-ore deposits are found mostly in the lower parts of the highlands, both in the north and farther south. These highlands were not below sea level during the glacial period, and the soil is meagre. Most of the central lowlands were then pressed down below sea level by the glaciers, creating fertile plains of clay, with many lakes. The gravel ridges that are characteristic features of the landscape of the whole region are remains of the last glacial period. In ancient times they were used as highways, but today they serve as gravel and water deposits. Many lakes, big and small, are typical of the central lowlands. Lake Vänern, 2,156 square miles in area, is the largest of Sweden's 90,000 lakes and the largest in Scandinavia. The Göta, which drains Lake Vänern into the Kattegatt section of the North Sea at Göteborg, is the only major river of southern Sweden. It is famous for its falls in Trollhättan, located in a region of fertile plains, forests, industries, and numerous small towns.

South of Lake Vättern the plains are transformed into a new but lower mountain area, the Småland highlands, seldom over 500 feet above sea level. The soil is stony; the agriculture is small in scale; and the people depend upon small industries that utilize forest products.

The plains of Skåne are the most densely populated agricultural areas of Sweden. The ground consists of rocks from later geological periods, and the soil has been enriched by recent marine deposits. Some clay beds in the northwest contain coal, and the clay itself is used for making fireproof materials.

Typical of Sweden is a rocky coastline with hundreds of small, sometimes wooded islands. Ground by the glacial ice in the same direction, they have a common rounded shape. This type of coast, known as *skärgård*, is found both in the east and west, especially around Stockholm and Göteborg. Other parts of the coast are sandy, and the island of Gotland has limestone rocks.

Climate. The Scandinavian countries profit from the warm Gulf Stream, which allows forests and agriculture farther north than anywhere else on the globe. About 15 percent of the country lies within the Arctic Circle, and the climatic differences between northern and southern Sweden are vast. The temperate west winds of the stream produce a continental climate similar to that of the Soviet Union, which is very cold in winter and very warm in summer. Mean February temperatures range from 7° F (−14° C) at Karesuando in the far north to 27° F (−3° C) in Stockholm and 30° F (−1° C) in Lund in the far south; comparable July figures are 57° F (14° C), 64° F (18° C), and 63° F (17° C).

Interaction of geography and climate

The regions covered by the high mountain range have a more continental climate than the west coast, where the prevailing winds dump heavy rains that diminish as the winds approach the east coast. Also there, precipitation is sufficient for agriculture. Annual precipitation ranges from 15 inches in the far north to 22 inches in Stockholm and 23 inches in Lund.

Snow lies in the mountains of Norrland for eight months, whereas three months is the average length of winter in the highlands of Småland, and one month or less in Skåne. Ice seldom covers the waters of the west coast, but the northern Baltic is usually unnavigable from the end of November to the beginning of May.

The shorter growing period in the north, about three or four months as compared to eight in Skåne, is partly compensated for by the long period of constant daylight. In Karesuando, above the Arctic Circle, the sun remains over the horizon between May 26 and July 18. At the summer solstice on June 21, daylight lasts 23 hours at Haparanda, at the northern end of the Gulf of Bothnia, and in Skåne 17 hours. Long twilight hours are typical of Sweden.

Vegetation and animal life. Latitude and altitude produce many local variations. In descending order of altitude and latitude, general vegetational zones are Alpine regions, birchwoods, a coniferous forest region, and a beech wood region.

The alpine region, down to 1,600 feet in the north and 3,000 feet in the southwest, begins with mosses and lichens at the highest points where growth occurs. Dwarf birches become a more extensive belt of alpine birches in the north, together with rowans, bird cherries, willows, and aspens. The undergrowth is rich in herbs. Lichens, especially reindeer moss, prevail in dry areas.

The coniferous forests that cover 57 percent of Sweden are especially abundant in the north and the Småland highlands. Some farms currently are being converted back to forest. Scotch pines and spruces are often mixed with lowland birches, rowans, and aspens in the north and central parts of Sweden and with oaks, ashes, lindens, maples, and elms in the south. The beech forests are found in Skåne.

The wolf, almost extinct, is protected by law, as are bear and lynx, which are only found in the deep forests of the north. Large domesticated herds of reindeer are common in the northern mountains, while the elk, the most valuable game animal, is common throughout the country. Badgers, foxes, hare, and otters are also hunted, as are the roe deer, which are common in southern and central Sweden.

Birds are numerous, with some migratory species breeding in spring and summer. Songbirds, game birds, and forest birds of prey are found, as are cranes in northern marshy clearings; gulls, terns, and eider ducks are found at the coast. The viper is the only poisonous snake. Salmon, trout, char, pike, and perch are common in rivers and lakes. Both freshwater and marine fisheries are important, especially on the west coast, where shrimp, herring, cod, flatfish, mackerel, and sprat are taken. The crayfish, a favourite among Swedes, is found in many lakes of southern Sweden.

The human imprint. *Traditional regions.* Götaland, Svealand, and Norrland are considered the traditional regions of Sweden. The first two take their names from the small, prehistoric clans of Götaland and Svealand who inhabited central Sweden. The Svear and Götar were united into one state about AD 1000. The Götar lived in Västergötland and Östergötland and Småland, the Svear around Lake Mälaren. Certain differences remain in the dialects of these two regions. Skåne and the surrounding regions were taken from the Danish crown in the 17th century, and Skåne is still looked upon as a special region in both language and customs. The food is richer, and the people are said to be warmer and more easygoing than the taciturn northern people.

Variations in cultural character

The vast Norrland was colonized later. It is looked upon as somewhat less important than the old cultural centre of the southern and central regions, and its vast distances are often overlooked. These tendencies have become stronger, with the modern industrial concentration in the southern and central parts.

Rural settlement. Generally, the traditional patterns of villages in the old agricultural areas were broken up in the 19th century to get larger field units and more productive cultivation. In Värmland and Dalecarlia, the traditional red-painted wooden houses still lie side by side in the village centre. In Skåne, a square house with brick and clay applied over a stick frame is the most common form.

Houses built in modern Sweden are basically the same throughout the country. Many small rural holdings have been annexed to neighbouring areas and the empty houses converted to vacation homes. To have homes in both urban and rural surroundings is the dream of many Swedish families, especially those who have had to abandon their rural milieu.

The relatively few castles and manors are found only in southern and central Sweden. The old industrial centres were often concentrated near waterpower and water transportation facilities; the newer ones are situated near railway stations and along the highways.

Urban settlement. The process of urbanization has been rapid during recent decades. About 90 percent of the population lived in the countryside 100 years ago, whereas today less than 20 percent do so—and only about seven percent of the economically active population are farmers.

This shift in concentration has occurred not only in the central cities but also in the areas surrounding them. This is especially true of regions around Stockholm, Göteborg, Malmö, and the cities and towns in the central lowlands. The population has diminished in the interior regions of Norrland, the northwestern portion of Svealand, southeast Götaland, and the isle of Gotland. Often the population shift has been a two-step process, shifting first from the rural areas to small towns and from there to the cities.

THE PEOPLE OF SWEDEN

Nearly 90 percent of Sweden's population, small in relation to its land area, live in the southern half of the country and about 80 percent in towns or other densely populated areas.

Linguistic, ethnic, and religious groups. Although different groups of immigrants have influenced Swedish culture through the centuries, the population is unusually homogeneous in language, ethnic stock, and religion. The language, which belongs to the North Germanic (Scandinavian) subgroup of the Germanic languages, is closely related to the Danish, Norwegian, Icelandic, and Faeroese languages. It has been influenced at times by German, but it has also borrowed some words and syntax from French, English, and Finnish. The written language showed the influence of Latin as late as in the early 20th century, especially in formal usage. A common standard language has been in use more than 100 years, though

Homogeneity of the populace

dialectal intonation is often retained. The traditionally varying dialects of the provinces are being homogenized rapidly through the influences of education and the mass media.

The Lapps form a special linguistic group, though they usually understand and speak Swedish as well and are taught both Swedish and the Lappish language at school. There are approximately 10,000 Lapps living in Sweden. From time immemorial, they have inhabited the northern parts of the Nordic countries, retaining their own culture and language, the latter belonging to the Uralic group of languages. Immigration to Sweden after World War II created new language groups, such as Finnish, Serbo-Croatian, Turkish, and Greek. Efforts are being made to make these immigrants and their children learn Swedish, while keeping their mother tongue.

The new immigrants have little diminished the ethnic and religious homogeneity. About 90 percent of the Swedish people belong to the established Swedish state church, Evangelical Lutheran. Even most of those who profess to different "free churches" in Sweden still belong to the state church. The Swedish state church is organizationally and economically tied to the state, but it is independent in religious matters. Infants are "born into" the state church unless the parents have withdrawn, and later must withdraw if membership is not wanted. The 10 or so free churches are all Evangelical Lutheran; the two largest each have about 90,000 members. The Roman Catholic Church has almost 35,000 members, but only 8,000 of these are Swedes. The rest are foreigners, some living only temporarily in Sweden. The Jewish faith is practiced by about 16,000 adherents.

Demography. Sweden's birthrates and death rates are among the lowest in the world, and it has had one of the lowest infant mortality rates for many years. The 14.1 births per 1,000 inhabitants in the early 1970s were just over one-half those of the period from 1871 to 1910, while deaths fell from 16.6 per 1,000 to 10.2. As a consequence of these declining rates, the percentages of the population in the age groups below 15 and above 65 have, respectively, dropped and risen markedly during the 20th century; the proportion in the "working ages" 15–64 has remained relatively stable.

Historic patterns of migration

Emigration during the latter part of the 19th century—more than 1,000,000 Swedes emigrated between 1860 and 1910, most of them to the New World—has left its special mark on the Swedish people in respect to population movements across the frontiers. Since 1910, Sweden has had an increasing surplus of immigration over emigration. This indicated a return to an older tradition, when different groups of people moved to Sweden: Hanseatic merchants during the Middle Ages; German, English, French, and Dutch officers and government officials during the 16th and 17th centuries; and German, English, and Dutch merchants and industrialists during the 18th and 19th centuries. After World War II, immigration consisted mainly of refugees from the Baltic states—about 30,000—and later of workers from Italy and other countries in which wide unemployment existed. During the 1960s more unskilled labour was allowed to enter Sweden.

Sweden's high rate of emigration, approximately one-half the rate of immigration, continues, but the bulk of this is made up of immigrants returning to their home countries or moving on to other states. A very small percentage of native Swedes emigrate.

The large internal population movements that have taken place since the beginning of industrialism have accelerated during recent decades. As elsewhere in the world, these movements have increased concentration of people in the larger towns as well as in Sweden's three major metropolitan areas—Stockholm, Göteborg, and Malmö. Between 1910 and 1970, the population of Stockholm grew from 342,000 to 747,000; of Göteborg, from 168,000 to 451,000; and of Malmö, from 88,000 to 265,000.

Projections for the future include the fact that the growing number of educated people who will begin gainful employment at a later age probably will alter the percentage of youth and workers. The labour reserve may be maintained partly by continued immigration and partly by increased participation of married women. The percentage of married women who are gainfully employed already has increased from 25 in 1950 to 50 in 1970.

THE NATION'S ECONOMY

Exports make up a bit over 20 percent of Sweden's gross national product, which is the highest per capita in Europe. The greatest proportion of trading, both export and import, is with member nations of the European Free Trade Association (EFTA) and the European Economic Community (EEC). The formation of multinational enterprises has been a traditional part of Sweden's international economic relations. In the early 1970s about 230,000 persons were employed in Swedish companies abroad, while about 70,000 persons were employed in foreign enterprises in Sweden.

Minerals and forest products

Basic economic resources. Sweden's important raw materials are iron ore and lumber. The iron ore now being mined is concentrated largely in the Bergslagen district and in Kiruna-Gällivare-Pajala, an area rich in ore. Kiruna boasts the largest ore deposit in the country and one of the richest in the world. Until about 1960, mining in Kiruna was done by open-pit workings, but today all mining is done underground.

Of great importance also are the sulfide ores, which often contain important metals. The Skellefteå field completely dominates the production of such metals as gold, silver, copper, and iron pyrite (the last important for the pulp industry). Smaller deposits of zinc, lead, manganese, tungsten, and copper exist elsewhere. Exploitation of coal deposits in southern Sweden has ceased because of the low quality of the coal.

Productive forest area covers more than one-half of Norrland, Svealand, and Götaland. Harvesting and reforestation are regulated by law. Corporations and other private owners control at least three-quarters of the nation's forest land and timber value.

The forest industry today is concerned not only with the supply of such traditional products as lumber, pulp, paper, and board but also with such products as rayon, plastics, dyes, resins, and turpentine. The latter require more complex technology and consequently pump more "value added by manufacture" into the economy.

Its many rivers with large waterfalls make Sweden one of the greatest exploiters of hydroelectric power. The total development of this potentiality is expected to be completed by the mid-1970s. Some waterfalls, however, will be kept undeveloped to preserve the natural environment. A series of thermal power plants complement the waterpower, producing about 20 percent of all energy. They are run almost exclusively by imported oil. A number of nuclear power stations are being built. The state is in charge of approximately 45 percent of the total power production.

Sources of income. In the early 1970s the production of power and goods contributed just under, with services contributing just over, 50 percent of Sweden's GNP, representing a slight rise in the role of services over the two preceding decades. Manufacturing remained the major factor during this period, but the agricultural and fishing shares declined precipitously, while public services, trade, and transportation and communications topped the list of services.

To a great extent, Sweden is dependent on foreign trade for its economic growth and development. About one-half its industrial production is sold abroad. The old domination of iron and forest products has decreased gradually in favour of different kinds of manufactured commodities, especially machinery and transportation equipment. Mining products and fabricated metals make up about 50 percent of the Swedish export, while forestry and forest-based industries contribute another 25 percent.

The private and public sectors. In addition to the 90 percent of Swedish industry that is privately owned, cooperative enterprises account for about one-half of the rest; the remainder is publicly owned, either by the state or by local authorities. Cooperative activity is relatively greater in the retail area. By combining the more impor-

tant publicly owned industries into one concern, Statsföretag AB (State Enterprise Ltd.), the state has, however, increased its importance and influence in Swedish industry. Mixed enterprises, with half-public and half-private ownership, also exist.

Patterns of taxation and public expenditures

The role of government, however, cannot be measured only by its direct management of industrial or business enterprise: a large percentage of the GNP goes into the public sector in the form of taxes and social charges, and much of this is returned to the private sector through insurance payments of different kinds. Taxes and social charges paid to the state and to the local authorities constitute slightly more than 40 percent of the GNP, the largest amount of any nation, and this figure is likely to approach 50 percent during the 1970s. About one-third of this money returns to the private sector, especially to private households.

About one-fourth of Sweden's GNP finances public activities—of which about one-half goes to local authorities—and a good deal of this money is returned indirectly to the citizens in the form of services, the largest of which in terms of expenditure are education, health, defense, and welfare.

The taxes are charged partly as a strongly progressive national income tax, partly as a local proportional income tax, partly as a tax on net wealth and as inheritance and gift taxes. To this should be added the profit taxes on businesses and the indirect taxes, particularly the value-added tax. For the corporations the tax is about 50 percent of net profits, in addition to which a tax on dividends to shareholders is imposed.

Labour and management. Sweden has been called the most thoroughly organized country in the world. Approximately 80 percent of all wage earners belong to a trade union.

The workers' trade unions, united in the Swedish Confederation of Trade Unions (LO), have 1,733,000 members; the Central Organization of Salaried Employees (TCO) has 720,000; and the Swedish Confederation of Professional Associations (SACO) has 120,000. Employers are united in the Swedish Employers Confederation (SAF) covering about 24,100 companies with 1,250,000 employees.

The Swedish labour market long has been known as peaceful, with a good mutual understanding between employers and employees and with a tradition of negotiation that has guaranteed the proper functioning of agreements. The extended wildcat strike that broke out at the state-owned mining company, Luossavaara-Kiirunavaara AB (LKAB) in 1970 shook the Swedish labour market rather roughly, though the direct economic losses were quite modest.

Economic policy making and outlook. Since World War II, Swedish economic policy has remained in the liberal tradition in the sense that the government intervened only in general matters and has tried to keep regulation to a minimum. The theory has been, as far as possible, to allow companies independent economic responsibility and then, through the growing public sector, to provide increasing resources for social expenses and other forms of public consumption. In recent years, however, the Social Democratic government has begun a policy involving more detailed regulations, bringing about strains in the formerly cooperative relation between government and industry.

Symptoms of economic change

The long-range outlook for the Swedish economy in the early 1970s seems somewhat less bright than earlier. Certain Swedish advantages in the world marketplace are no longer so pronounced. The LKAB conflict hurt the peaceful image of the Swedish labour market, while Sweden's long lead in welfare is being diminished by several nations, such as France and West Germany. Growing research-and-development costs make it more difficult to pioneer on the world market. The Swedish refusal to join the EEC as a full member, which, it was felt, might impeach its neutrality, could produce further unfavourable consequences. Overall, the Swedish economy is not in a bad position, but the advantages of yesterday no longer can be expected to pertain as strongly as before.

TRANSPORTATION

Trucks are the main means of transporting heavy goods, while the private automobile accounts for about 85 percent of all passenger traffic. As a result, demands for expressways are increasing.

By the middle of the 19th century, the railways had begun to compete with older means of transportation. Three main principles ruled the construction of the railways: they must not follow existing shipping routes, whether coastal or canal; they should, except for terminal points, be built through sparsely populated or poor districts rather than through rich areas that often could support their own transportation networks; and a connected and coordinating network of railways should be constructed. Through this policy, new towns grew up at the junctions.

The present national traffic policy, dating from 1963, requires that every kind of transport or communications bear its own expenses. This policy has affected the railways in particular: they have suffered from low profits followed by long-term shutdowns and have been able to maintain themselves only by the movement of goods, yet with a reduced share of even this market.

Domestic shipping along the coasts and on lakes and canals has been extremely important throughout Swedish history. Today, intranational shipping has a limited share of all transports. International shipping, on the other hand, is very lively, with at least nine ports engaged in large-scale commerce with foreign nations.

State ownership of airlines and railways

The air services are dominated by the Scandinavian Airline System (SAS), which is owned chiefly by the states of Sweden, Denmark, and Norway. The interests of SAS are concentrated on international aviation, but a few domestic scheduled services are maintained in Sweden. The rest of the domestic traffic is run by Linjeflyg (LIN), half of which is owned by SAS. The most important airports are in Stockholm, Göteborg, and Malmö.

The interests of the state in transportation and communications are wide. The railways are 95 percent owned and run by the state, which maintains bus traffic on a large scale and has two subsidiaries that dominate the trucking industry.

Local transportation consists mainly of buses, though Stockholm has a subway. Streetcars were abolished in several cities in connection with the switchover to right-hand traffic that took place in 1967, but Göteborg and Norrköping retained trolley service. Generally, local traffic is controlled by local authorities.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. The crown of Sweden is inherited in straight lineal descent on the male side. For decades, however, the monarch's position has been almost exclusively symbolic, a status to be confirmed by fundamental law among other far-reaching constitutional reforms that have been in preparation since the 1950s. These reforms already have led, through partial implementation, to important changes concerning the parliament, or Riksdag, and the electoral system. Other changes in the basic Instrument of Government of 1809 are anticipated.

The national level. Since January 1971, Sweden has had a unicameral parliament with 350 members elected for three-year terms by direct universal suffrage. The parliamentary system, in use during most of the 20th century, is now constitutionally established. The Riksdag can, by a vote of "no confidence" by a minimum of 176 members, force the resignation of the government or dismissal of a Cabinet minister, unless the prime minister appeals to the country within a week for a new election. The terms of office after such an election last only for the remainder of the original parliamentary period.

Interactions of administrative and parliamentary bodies

The government, under the leadership of the prime minister, is administered by 12 departments, each headed by a Cabinet-level minister; there are, in addition, six consultative ministers, or ministers without portfolio. This parliament-appointed government has taken over, in large measure, the former prerogatives of the monarch, though formally they function as his advisers. Although through

this arrangement the government often was able to act independently of the Riksdag, the formal prerogatives of the latter have been strengthened by bestowing the right of initiative on the parliamentary committees, which formerly could only discuss propositions from the government. The work of the committees, including constitutional, finance, and 14 other permanent committees, usually is regarded as the most important part of parliamentary activity. The committees are not open to the public, but their reports are published. In many questions, however, the parliamentary-party groups or conferences between party leaders may play an even greater role than the committees.

Certain characteristics of the former dualism between the king (the government) and the Riksdag have been kept. The latter alone has the right of taxation.

Power to enact laws is jointly vested in the Riksdag and in the King in Council, which under the contemporary constitutional practice is the Cabinet appointed in observance of parliamentary principles. Power to institute ordinances and regulations in matters concerned with administration and economic policy is reserved by the Instrument of Government for the King in Council alone, which gives it a wide range of independent action. In practice, however, many of the principles for these so-called economic laws are put before the Riksdag, the decision of which is regarded as binding. So the dividing lines are, on the whole, uncertain.

All lawmaking takes place on the national level—local lawmaking does not exist, because Sweden is a unitary and not a federal state. Ordinances and regulations are of a lower power than laws; they are easier to enact and easier to change. Certain ordinances and regulations of a local character—e.g., parking regulations—can be established by local authorities.

Different rules pertain as to how Swedish laws may be changed. Alterations in the constitutional laws—the Instrument of Government (1809), the Act of Succession (1810), the Parliament Act (1866), and the Freedom of the Press Act (1949)—may be instituted only by the approval of two successive parliaments, between which elections must occur. The civil and criminal laws, on the other hand, may be instituted or changed by the combined agreement of government and parliament. The government itself has authority to change ordinances and regulations.

County and local government. Implementation of administrative decisions is, in part, the responsibility of the 24 county (*län*) administrations, which represent the national government in regional administration. Each of these is headed by a governor appointed by the government.

Parallel to the county–state administrations are 23 county councils and 270 municipal councils, elected locally to provide local administration. One county, Gotland, comprises a single municipality and thus has a municipal council but no county council. Health and medical care are primarily the responsibility of the county councils, while the local school system and almost all other social services are the responsibility of the municipal councils.

Administration of law and justice. Swedish law is the result of a long historical development marked by continuity rather than by abrupt changes. As the result of extensive collaboration with the other Nordic countries, a significant degree of legal uniformity exists throughout Scandinavia, especially in the field of civil law. The Swedish judicial system is built upon written law; practice, customary (or common) law, and judicial precedent retain a strong influence, but the following of precedent is not obligatory. The voluminous body of printed matter—generated by the traditionally careful and prolonged lawmaking process—in which reasons and intent of the law are formulated, is an important source of interpretation for courts, authorities, and individual jurists. Judges and high-ranking administrators—as well as prosecutors, senior police officers, and attorneys—have the same academic training. Moreover, the majority of law graduates serve in one of the courts of first instance for two and a half years to gain experience before taking an appointment in the civil service or embracing other careers.

The primary responsibility for the application of legal rules lies upon the courts and the different administrative authorities. The difference between adjudicative and administrative authorities is less in Sweden than in most European countries: their organization and the division of powers between them have both evolved in response to historical trends rather than to deliberate government planning. Administrative authorities are not partisan representatives of those holding political power at any one time; apart from matters of internal organization and procedure, the lower authorities do not take orders from the higher but follow the generally prevailing rules under their own responsibility. Their decisions may be challenged under appeal provisions resembling those in force for the court system, though in most cases, administrative decisions are not subject to review by a regular court.

Three-tiered hierarchy of courts

Sweden has a three-tier hierarchy of courts: the courts of first instance (*tingsrätter*), the intermediate courts of appeal (*hovrätter*), and the Supreme Court (Högsta Domstolen). In addition to the regular courts of justice, there are also a number of special courts and administrative tribunals.

After a reorganization effective in 1971, which merged the former rural and city courts and considerably reduced their number, Sweden now has just over 100 courts of first instance. These courts, in addition to their primary concern with civil and criminal cases, perform many duties of an administrative nature related to conveyancing, land development, guardianships, probate, and the like. An unusual feature of courts of first instance is the *nämnd*, or panel of lay assessors, who take part in the main hearings in most criminal and some civil cases. Assessors (*nämndemän*) are elected for six-year terms by local representative councils from among eligible local citizens; often they are reelected for successive terms. The *nämnd*, which has medieval traditions and has constituted a significant element of democracy in Swedish public life, is not to be confused with the Anglo-American and Continental jury. Its members are concerned not only with verdicts but also with such matters as the sentences to be imposed in criminal cases. A qualified majority of the lay assessors prevails over the contrary opinion of the judge.

Of the six courts of appeal, or of second instance, the oldest and largest is the Svea Hovrätt in Stockholm, established in 1614. Besides serving as appellate bodies, these courts also are responsible for the administration of the court system within their respective areas and for the further training of judges. In their adjudicative capacity, courts of appeal operate in divisions. No limits are imposed on the right of appeal, and about 5 percent of the total number of cases tried by lower courts pass on to a higher court.

The Supreme Court, that of third and last instance, has 24 justices (*justitieråd*), but it works in three sections. Because of the great value attached to its decisions as precedents, however, the entire court also can meet in plenary session—if, for example, there is cause to depart from previously applied principles on any point. The Code of Judicial Procedure defines the classes of cases that may be considered by the Supreme Court after their trial in courts of appeal. A separate section of the court, comprising three justices, determines whether to accept a case for review, and about one-seventh of all appellate decisions are reviewed by the Supreme Court. Like the courts of appeal, the Supreme Court need not confine itself to points of law but may also consider new evidence. Its decisions are final.

Among the special courts, the Court of Impeachment (Riksrätten), empowered under the Instrument of Government to try Cabinet ministers, has not been convened since 1854. Of greater importance is the Labour Court (Arbetsdomstolen), established in 1928, which has exclusive competence in controversies concerning the interpretation and application of collective bargaining agreements. Of its seven members, two represent labour and

two management. There are also, for example, first instance special water courts (with Svea Court of Appeal and the Supreme Court as appeal instances), special courts for cases relating to land ownership, boundaries and expropriation, a special insurance court, and a court to deal with such matters as undue clauses in standard contracts.

As already noted, the decisions of administrative authorities are not appealable to an ordinary court of justice. Instead, a complainant can take his grievance to the next highest authority or to a specialized tribunal. In theory, a complainant may appeal the decision of a lower administrative authority to the local county administration or to a specialized agency attached to it. From there, two channels are available. In certain cases—of which dissatisfactions with tax assessments are the most numerous—an appeal against the ruling on county level is lodged with one of Sweden's oldest and most notable administrative tribunals, the Fiscal Court of Appeal (Kammarrätten) in Stockholm. The highest instance in the tribunal system is the Supreme Administrative Court (Regeringsrätten). Cases falling within the competence of this court are enumerated by special statute: generally speaking, these are cases in which the legal element prevails, as in taxation or in the institutionalization of the insane, alcoholics, delinquent youth, and the like. The Supreme Administrative Court is also the final court of appeal against the decisions of local representative councils and authorities in those cases in which such decisions are appealable. The second channel, applicable in all other cases, has the King in Council as its highest instance. Like their counterparts in the regular court system, the higher instances in the tribunal system of adjudication are empowered to review questions of both fact and law.

The institution of the ombudsman

The control system—of great importance to guarantee against injustice from either the judiciary or the administrative authorities—is handled to a large extent by the three *justitieombudsmän* appointed by the Riksdag. Their principal task is to oversee the observance of laws and constitutions and to prosecute officials and civil servants who have committed illegal acts. Consequently, the duty of the ombudsman is aimed especially at controlling the ways in which the authorities execute their power and guaranteeing that the rights of the individual are not violated. The Swedish institution of the ombudsman has served as a model for other nations, including the United Kingdom, Denmark, Norway, and Finland, and it has been instituted at various levels of local government throughout the country.

The political process. Sweden's triennial elections result in proportional representation: *i.e.*, each political party receives the same proportion of seats as it receives votes in the general elections. To avoid a proliferation of small parties, however, a party must get either 12 percent of the votes in one constituency or 4 percent of the votes nationwide to be represented in parliament. Of the 350 seats, 310 are elected directly, while the remaining 40 are distributed among the parties so as to achieve proper proportionality.

Proportional representation and citizen participation

Five parties are represented in the Riksdag. With the exception of 100 days in 1936, the Social Democratic Labour Party has formed the government since 1932. At two periods it has formed a coalition with the Centre (former Agrarian) Party. The parties receive financial support from the state in proportion to the number of seats they hold.

All Swedish citizens are eligible and may vote at 20 years of age. In elections, between 80 and 85 percent of the voters usually participate, and about 30 percent of the voters are members of one or another party. During the 1960s these parties endeavoured to broaden their inner democracy by encouraging different conferences of members and holding primary elections to select candidates.

National defense. Sweden's defenses, based entirely on its own financial resources, devolve from its traditions of non-alignment and neutrality. Military and civil defenses, as well as economic and psychological defenses, work closely together—the last two concepts referring, respectively, to the stockpiling of essential goods and materials for wartime and to the maintenance of domestic morale. Service in Sweden's military is compulsory for all able-bodied men between 18 and 47 years of age. Most conscripts have ten months of basic training, which later is followed by five refresher courses. Roughly 50,000 conscripts are called up every year.

Since World War II, Sweden has expended about 4–5 percent of its GNP on defense. Outside its own territory, Sweden takes an active part in the United Nations' peace-keeping operations: since 1956, about 32,000 members of its armed forces have served in different UN missions, particularly in the Gaza Strip, the Congo, and Cyprus.

The social milieu. Peace, economic prosperity, and a tradition of social and political stability are among the factors that allowed Sweden to emerge in the 20th century as the prototypal image of a nation ideally combining free electoral practice with a pronounced socially oriented concern for the well-being of its citizens. Incomes and standards of living generally are looked upon as the highest in Europe, but these have tended to decline relative to other countries in recent years.

Income and other social differentials

Internally, however, differences in level of income and, consequently, of social status and of educational and other attainments are not radically different from the same phenomena in other advanced industrialized nations. Rises in the cost of living have paralleled rises in income, and employment among the young, especially women, tends toward irregularity or the low-income brackets. Social conditions in various regions of Sweden also restrict choice of work, education, or access to types of social service from the state.

Welfare and health. Sweden long has been regarded as a leader in social welfare, and, in spite of inequities, the rights of the citizen for social assistance are manifold. Compulsory health-insurance programs reimburse all but small portions of doctors' fees, hospital treatment, and medicines. The national pension system is paid, beginning at 67 years of age, to all citizens and to foreigners resident in Sweden for a certain period. A supplementary pension, introduced in 1960 and based upon average yearly income, will be paid in full to all persons born after 1914.

Children's allowances are paid for each child under 16 years of age, and every mother receives a stipend at each childbirth. Unemployment insurance is based on voluntary premiums, but it is subsidized by the state. Between 1965 and 1970, state expenditures for social security were doubled.

The relatively excellent health conditions of the Swedish people can be attributed to the rugged but basically healthy climate and to the many factors that have made it possible to offer free medical care to every citizen. Medical practitioners of all kinds are able to remain in the vanguard of research, and hospital facilities have been kept among the most advanced in Europe. Preventive medicine, in terms of information to the public and early diagnosis, is in an advanced state. Tuberculosis, the disease that once claimed the most lives, is far down on the scale of causes of death. The main causes of death are, today, those of the other advanced nations: circulatory diseases, cancer, and the like. In the more remote areas, health care is provided mainly through a system of smaller hospitals and of provincial doctors, nurses, and midwives employed by the county councils, each covering a specific area.

Enrollments in the six medical faculties—which, like all faculties of higher education in Sweden, are supported by the government—swelled during the 1960s, promising a significant increase in the number of registered doctors. Students are eligible to apply directly for medical training after completion of their course in the gymnasium, or pre-university school. There is no entrance examination or requirement of a premedical course, but competition is severe. A new system of medical education introduced in 1969 shortened the basic curriculum of undergraduate training, mainly by doing away with the nine-month internship period. The basic curriculum is followed by

postgraduate training, the first part of which provides for a compulsory "general service period" lasting 21 months. After that the doctor takes either specialist training, usually embracing residencies totalling four to five years, or a three-year period of training for general practice.

Housing. The average Swedish household consists of about three persons. Most of them live in densely populated areas and about one-third of them in one of the three biggest cities and their metropolitan areas. Fewer than one-half of them reside in individual houses. Swedes spend an average of 17 percent of their income on housing. In spite of large-scale construction, a shortage of dwellings exists around the largest cities: Stockholm, for example, had more than 100,000 people waiting for homes in the early 1970s.

Housing shortages

About one-half of Sweden's housing is privately owned, one-quarter owned by housing cooperatives, and most of the remainder owned by semipublic bodies. Since about 1950, however, private ownership has fallen sharply, due in large measure to the fact that state assistance for housing is not equal for all types of investors: private builders of apartment houses get, at most, 85 percent state loans, whereas cooperative and semipublic bodies may receive up to 95 or even 100 percent.

Education. School attendance is compulsory for nine years, beginning at age seven. The nine-year comprehensive school is divided into three-year stages: lower, middle, and upper. All pupils follow the same curriculum for six years. The first foreign language, English, is introduced in the third year. In upper classes, training in German and French can also be chosen, while in the gymnasium, for example, Russian, Spanish, Finnish, and Italian can be chosen as well. From the seventh year the curriculum is divided into different lines chosen by the pupils themselves from subjects or groups of subjects. Special education is given to all pupils suffering from physical or mental handicaps.

An important principle in Swedish education is that everyone who wants to continue studying after the comprehensive school shall have the opportunity. About 30 percent of pupils choose courses that will qualify them for university study. Other, less theoretical curriculums offer a vocational training.

Sweden's five universities are in Stockholm, Göteborg, Uppsala (the oldest, founded in 1477), Lund, and Umeå (the youngest, founded in 1963). The first four have branches in other cities. Other institutions for higher education offer training, for example, in technology, medicine, art and music, and journalism. More than 120,000 students were studying at universities and other institutions in the early 1970s; the corresponding figure in 1951 was 21,000.

Adult-education programs

Strong emphasis is given to adult education. Since 1968 free evening and daytime classes have been sponsored and administered by both local authorities and state government. The instruction follows the same curriculums as the ordinary school, and the adult pupils can either follow classes in separate subjects or choose the entire alternative. The number of students is increasing, though irregularly, hovering around 100,000 per year in the early 1970s.

The folk high schools (*folkhögskolorna*) also offer adult education for those 18 years of age and above. Radio and television courses and instruction by correspondence are forms of education with a large geographical range. Study circles arranged by a number of "study societies" cover a large group of subjects from hobbies to purposeful school or university studies.

Retraining courses for new jobs, funded by the state, attracted about 92,000 students during 1968–69. Training in Swedish for immigrants also is paid for by the state and arranged by study societies.

CULTURAL LIFE AND INSTITUTIONS

In the pre-industrial period the cultural manifestations of the small upper class were different and separated from the popular ones. The upper classes took their patterns from the European currents and passed them down to ordinary people. In the other direction, inspiration from popular songs, art motifs, and handicraft work enriched the higher culture.

The changing cultural milieu

Today, popular and upper class cultures are no longer separate in this way. The popular political movements of the 20th century advanced the notion that education and the understanding of the arts were the rights of every man, but this idealistic hope has not been met fully. New forms of entertainment—television, weekly magazines, and popular music of the international type—have taken their places. Poetry, avant-garde literature, and classical music still belong to small specialized groups.

Improved means of communication—both of such media as television and of the greater travel of foreigners to Sweden and of Swedes abroad—have had other effects. As in many other Western nations, differences between rural and urban life-styles are growing smaller as the population becomes more homogeneous and more internationally influenced. Foreign foods appear increasingly alongside traditional Swedish dishes, and wine has tended to decrease the consumption of hard liquor. The Swedish youth culture has its "pop" music and musicians and its contemporary international mode of dress. Drugs have posed a problem in the growing number and decreasing age of addicts, though under Swedish law many substances—*e.g.*, amphetamines—are prohibited as narcotics that are not so classed in most other countries. Since World War II, however, Swedish youth have tended to lead the way toward greater awareness of, and participation in, national and international political activities, solutions to the problems of the world's developing nations, and similar areas of concern—often in response to the atmosphere created by the informative reports and documentary materials widely available through public media, but often, also, with a consequent lessening of interest in the traditional fine arts.

The movement for equality between men and women is of long duration in Sweden. Positive results include greater female participation in the labour market, in higher education, and in politics; broader access to the professions (including the clergy); and more equality in wages and salaries. The traditional male–female relations likewise have moved toward greater equality, accounting in part, perhaps, for the reputation of sexual permissiveness on the part of the Swedish women—an image created in large measure through misunderstanding and exaggeration. Related to this diminution of double standards of morality is the production and sale of allegedly pornographic materials, which is probably no larger in quantity than elsewhere but which is covered by liberal legislation except in such matters as window display.

The state of the arts. The postwar period has been lively: the "Monday group" of composers was inspired by the antiromantic Hilding Rosenberg in the 1920s and drew also upon leading modern composers from abroad. Their repertoire includes orchestral, operatic, and religious works. The vital Swedish folk song has been developed further by a number of musicians, while Swedish jazz became another phenomenon. A number of Swedish opera singers gained renown throughout the West.

Since the 1920s, Harry Martinson has been a favourite poet in Sweden. His motifs range from the romantic Swedish countryside to global and cosmic visions. Among novelists, Vilhelm Moberg is widely known for the epic and dramatic force in his novels of the Swedish emigrants in the United States and of the farmer-soldiers of old Sweden. Younger novelists tend to treat the social and moral aspects of society.

A multifacetted theatre, opera, and ballet life is found in Sweden. Contemporary international plays are staged throughout the country, and the premieres of several of the posthumously performed plays of the American Eugene O'Neill took place in Sweden. Birgit Cullberg has attained international fame as director of the Swedish Royal Ballet in Stockholm. The Swedish stage and film director Ingmar Bergman gained critical acclaim outside Sweden with his film *Wild Strawberries* (1957). Subsequently, his earlier and later films have been shown throughout the world, and he has been hailed as one of the major film makers of all time.

Modern Swedish art was inspired by early-20th-century romantic nationalism, originating with such painters as Carl Larsson, Anders Zorn, and Bruno Liljefors. Carl Milles, who dominated monumental sculpture in the 1920s, is as famous abroad. At the Paris World's Fair in 1925, an important connection was established between Swedish industry and designers who had both academic art education and popular handicraft tradition. Since then, this combination has been vital, and superb results have been achieved in glassware, ceramics, woodwork, textiles, furniture, silver, and stainless steel.

Folk culture. The genuine rural folk traditions are disappearing with settlement in urban areas. Among those remaining in Gotland, Dalarna, and other areas are special national costumes, dances, folk musicians, and the like, and many traditions are found even in urban settlements. Spring is celebrated on the last night of April with big fires across the country. May 1 is the day of workers' demonstrations. The bright Midsummer Night is celebrated with a big cross placed into the ground and laid with flowers and leaves; children dance around it. Some celebrations have a religious background: Advent, Lucia, Christmas, Easter, and Whitsuntide. The Lucia candlelights are a rather new but very popular custom performed on the dark morning of December 13.

Traditional festivals

Cultural institutions. The traditional cultural institutions were initiated and protected by the king. The Drottningholm Theatre; the Swedish Royal Opera; the Royal Dramatic Theatre; the Royal Academy of Music; the Swedish Academy; the Royal Academy of Letters, History, and Antiquities; the Royal Library; and the Royal Academy of Sciences, all in Stockholm, date from the 18th century. The universities in Lund and Uppsala have traditions from the Middle Ages, when those cities were major European centres of learning.

In modern Sweden organizations and institutions for cultural activities usually can depend upon state and municipal contributions. The state theatre, the state concerts, and the state exhibitions travel around the country. Idealistic organizations collaborate with the labour groups in establishing the 240 *folkets parker* ("peoples' parks"), a type of out-of-doors entertainment hall for dancing, theatre, shows, and concerts in the summer. These organizations and others, for religious or temperance purposes, have educational branches concerned with adult educational programs involving the folk high schools and evening classes. Such activities are financed by government.

The Nobel prizes

Of special note are the Nobel prizes, initiated in 1901 through a bequest by Swedish millionaire Alfred Nobel. Awarded annually in the fields of chemistry, physics, physiology or medicine, literature, peace, and (since 1968) economics to persons throughout the world for specific or general achievements in their fields, they are administered and bestowed by various Swedish academies and institutes. The peace prize is under the aegis of the Norwegian parliament.

Press and broadcasting. Swedish radio and television are owned and run by a company consisting of different organizations, including those of the press. The company, licensed as a monopoly by the government, is regulated in accordance with a special radio law. Three radio networks present contrasting programming. Television operates as two independent stations, each with its own manager and supposedly in competition with each other. Commercial advertising is forbidden in both media, which are supported by annual license fees paid by owners of receivers.

The formal conditions of the Swedish press are good. The Freedom of the Press Act of 1949 regulated working conditions and outlawed all forms of censorship or administrative intervention. Only special courts can accept cases pertaining to the act. The press has a special ombudsman and an honour committee to assure that ethical norms are followed in the industry.

The greatest problems for the press are economic. Since the early 1930s the number of daily newspapers has decreased from some 230 to about 115. This decrease has meant that many areas and towns have only one paper. Measures to prevent further declines have been started by political parties, which use some of their state financing to support the press, and by the state itself, which has made special grants to second and third papers in various areas.

The political affiliations of the daily press are in almost inverse relation to the strength of the parties. The trade-union movement also has weekly magazines, copies distributed to all members—about 1,500,000—functioning largely as a Social Democratic Party newsletter.

A number of political and cultural magazines also play a role in the general debate. They probably have less importance in Sweden than corresponding magazines in many other countries, since the larger daily newspapers cover the cultural and political fields quite well.

BIBLIOGRAPHY. General materials include fact sheets and booklets on various subjects, published by the Swedish Institute, which are both informative and comprehensive; the NATIONAL CENTRAL BUREAU OF STATISTICS, *Statistical Abstract of Sweden* (annual), a comprehensive statistical reference; and the ROYAL MINISTRY FOR FOREIGN AFFAIRS AND THE SWEDISH INSTITUTE, *Sweden in Europe* (1971), articles on Sweden and on its relation to Europe.

Landscape: AXEL SOMME (ed.), *A Geography of Norden* (1968), an informative introduction to Nordic geography.

The people: EDMUND DAHLSTROM (ed.), *The Changing Roles of Men and Women* (1967), a discussion of a subject of current interest led by a major Swedish sociologist; ROBERT MURRAY, *A Brief History of the Church of Sweden*, 2nd rev. ed. (1969); ISRAEL RUONG, *The Lapps in Sweden* (1967), descriptions of an ethnic minority with interesting traditions and culture.

Economy: MARIE and CHRISTIAN NORGREN, *Industrial Sweden* (1971), a good account, with an up-to-date introduction; and MARTIN SCHNITZER, *The Economy of Sweden: A Study of the Modern Welfare State* (1970), on the Swedish economy, with American comparisons.

Administration and social conditions: MINISTRY OF EDUCATION AND CULTURAL AFFAIRS, *Adult Education in Sweden* (1970), a brief report on an important issue; NILS ANDREN, *Modern Swedish Government* (1968), a well-known work on the Swedish political system, mainly its formal construction; ALFRED BEXELIUS, *The Swedish Institution of the Justitie-Ombudsman* (1965), coverage of the Swedish ombudsman system; SWEDISH BOARD OF EDUCATION, *The Comprehensive School in Sweden* (1970), a description of the basic educational system; and PIERRE VINDE, *Swedish Government Administration* (1971), a lucid description of how the government works in practice.

Cultural life and institutions: NIKLAS BRUNIUS, GORAN ERIKSSON, and ROLF REMBE, *Swedish Theatre* (1967), a descriptive review; LEIF FURHAMMAR and BERTIL LAURITZEN, *Film in Sweden* (1966); AKE STAVENOW and AKE H. HULDT, *Design in Sweden* (1961), on the wide range of Swedish design and handicraft; BENGT PLEIJEL (ed.), *Swedish Music: Past and Present* (1967); and ROLF SODERBERG, *Modern Swedish Art* (1963), a good introduction to Swedish 20th-century art.

Swedenborg, Emanuel

Emanuel Swedenborg, a significant Swedish scientist, mystic, philosopher, and theologian, has exerted a considerable influence on modern literature and religion, though the church (Church of the New Jerusalem) and the Swedenborgian societies based on his thought are small in membership. His scientific theories, though novel during his lifetime, were soon surpassed by the rapid developments in science in the 18th and 19th centuries.

Early life and works. Swedenborg was born on January 29, 1688, at Stockholm. His father, Jesper Swedberg, was a prominent member of the Swedish clergy, court chaplain, professor of theology in the University of Uppsala, and later bishop of Skara. When the family was ennobled in 1719, it took the name Swedenborg. In his memoirs Swedberg appears to be an egocentric of the first order, with a remarkably naïve belief in guardian angels and spirits. Emanuel Swedenborg thus received from his psychical heritage as well as his childhood environment a predisposition for the supernatural experiences that occurred in his adult life.

After graduating from the University of Uppsala in 1709, Swedenborg spent five years abroad. Early in his

Scientific studies and interests

education he had become fascinated by mathematics and natural science, and for that reason he first travelled to England in order to meet some of the representatives of the new natural sciences and to learn practical mechanical skills. These studies, which were continued in France and Holland, gave him an initiation in modern science that surpassed that of his compatriots. He returned to Sweden in 1715 and soon began to publish that country's first scientific journal, called *Daedalus Hyperboreus*, in which he wrote numerous reports of his projects and discoveries and of the inventions of Sweden's foremost mechanical talent of the time, Christopher Polhem. King Charles XII made the young scientist an assistant to Polhem by appointing him assessor *extra ordinem* ("extraordinary") at the Royal Board of Mines. In this capacity he worked for the next five years publishing several reports and treatises on various scientific and philosophical problems; *e.g.*, cosmology (the order of the universe), corpuscular philosophy, mathematics, and human sensory perceptions. Now and then Swedenborg also found time to write poems in Latin, some of which were published in his lifetime.

Development of a philosophy of nature. His favoured position came to an end when Charles XII died in 1718. Though he was ennobled in 1719, such practice was mere routine in the case of children of a bishop. After a second journey abroad in 1721–22, during which he published two Latin volumes on natural philosophy and chemistry, Swedenborg wrote little or nothing for more than ten years. When he set out for a third European journey in 1733, it became obvious that these years had been filled with reading and reflection in addition to his ordinary work as a civil servant. In 1734 he published in Leipzig his *Opera Philosophica et Mineralia* ("Philosophical and Logical Works") in three folio volumes, the first of which, the *Principia Rerum Naturalium* ("Principles of Natural Things"), contains Swedenborg's mature philosophy of nature. As a student at Uppsala, he had studied philosophy and physics according to the theories of René Descartes, a major French philosopher, and his years with Polhem increased the influence of the great French thinker. In fact, the three main themes of Swedenborg's philosophy of nature were inspired by Descartes: (1) matter consists of particles that are indefinitely divisible; (2) these particles are in constant vortical (swirling) motion; and (3) the Earth's planetary system sprang from the solar mass. The third theme, the nucleus of Swedenborg's cosmology, was strongly influenced by the English writer Thomas Burnet's *Telluris Theoria Sacra* (1681; "Sacred Theory of the Earth") and is a precursor of the Kant–Laplace nebular theory (*i.e.*, the Sun and planets come from a common nebula).

According to Swedenborg, the planetary system marks the end of the particle series. The beginning of the series is described with the aid of a metaphysical concept *i.e.*, the mathematical point in which the Creator introduced a conatus (an effort). This mathematical point is multiplied to ever greater powers in a universal system of series and degrees. Because the concept was an abstraction, it did not satisfy Swedenborg. For the next few years he eagerly looked for a language (symbolic or scientific) in which the relations between the Infinite and the finite creation could be expressed with mathematical exactitude.

Physiological and psychological investigations. After he published the *Principia* and a small work on the Infinite in 1734, Swedenborg returned home. His father died in 1735, and in the next year he was granted a new leave of absence from his office as assessor. This time he went to France, Italy, and Holland. In Amsterdam he completed and published a new work in two great volumes, called *Oeconomia Regni Animalis* (1740–41; *The Economy of the Animal Kingdom*, 1846), and in November 1740 he was back in Stockholm.

Psychological interests

The *Oeconomia Regni Animalis* represents a new stage in Swedenborg's scientific career. The term "animal kingdom" in Swedenborg's thought is to be understood as the human body; *i.e.*, "the kingdom of the soul (*anima*)." Here Swedenborg made a thorough study of human anatomy and physiology, with special attention to the blood and the brain. He had been interested in anatomical matters ever since his youth, but now this study had become a real passion to him. The title, however, indicates that Swedenborg was not studying the human body as a subject *per se*, but as the "kingdom of the soul." What he intended was to fulfill a program that he had formulated in 1734; *i.e.*, to prove the immortality of the soul to the senses themselves. He believed the soul to be the inmost life of the blood and located in the brain, specifically in the cellular cortex.

Swedenborg's method as a researcher consisted mainly in collecting facts from microscopists and experimentalists and drawing his own conclusions from them. His energy and his erudition were overwhelming, and he has been given credit for some contributions to the localization of the mental processes. His anatomical works, however, remained almost unnoticed by contemporary science; and when they were discovered by some 19th-century scholars, science had moved beyond them. They did, however, play a decisive role in Swedenborg's personal development.

Oeconomia Regni Animalis was followed by a whole series of sketches and small treatises in which Swedenborg attempted to fulfill his psychological investigations. Some of these became a part of the three volumes of the *Regnum Animale* (*The Animal Kingdom*, 2 vol., 1843–44)—planned to be 17 volumes—that Swedenborg himself published in 1744–45. One of the most interesting elements in this prolific and chaotic production of ideas was the problem of a universal language. Ever since the *Principia*, Swedenborg had been complaining about the lack of linguistic instruments capable of describing psychic phenomena with mathematical exactitude. In the beginning of the 1740s he made several attempts at a universal language based on the model of Descartes and Gottfried Wilhelm Leibniz, an important German philosopher of the 17th and 18th centuries, but at last he made up his mind to present a substitute for it. This substitute was the famous doctrine of correspondence, *i.e.*, Swedenborg's vision of the universe as a system of symbols permeated by divine light in different degrees, which, since the 19th century, has fascinated many poets. Its earliest systematic presentation was called *Clavis Hieroglyphica* (1784; *A Hieroglyphic Key*, 1792), in which the linguistic origin of the doctrine of correspondence becomes evident. Swedenborg wanted to demonstrate how to transform propositions from the natural sphere into its correspondence in the spiritual sphere and from there to the divine sphere by changing a few central terms in otherwise identical sentences. Later, the doctrine of correspondence was given a very wide range, becoming a kind of universal symbolism according to which everything outward and visible in nature had an inward spiritual cause. But the linguistic origin of the doctrine is reflect-

ed in its function as an instrument for revealing the spiritual meaning of the sacred Scriptures.

Religious crisis and theological concerns

The years of preparation, as Swedenborg in his old age called this period, were concluded by a painful religious crisis from which there exists a unique document. It is usually called the *Journal of Dreams* (1743–44) and was obviously meant to be a journal of his new travels beginning in July 1743; but the rather trivial notices were suddenly interrupted. There follows instead a list of various dreams recalled from earlier years and a detailed report on his spiritual experiences, mostly at night, from March to October 1744. He began to write the journal in The Hague when he prepared the second part of the *Regnum Animale*, and the journal comes to a sudden stop while he was in London, where he was writing his drama of creation, *De Cultu et Amore Dei* (1745; *On the Worship and Love of God*, 1801). His scientific and literary work determined to a great extent both his dreams and interpretations of them. Some of the dreams were of a grossly sexual character and caused many pious readers quite a shock when the journal was published in 1859. Swedenborg himself was obviously not ashamed of these dreams. His feeling of guilt was concentrated on his intellectual pride, his burning ambition to be recognized as a great man of science. On April 7, 1744, he had his first vision of Christ, which gave him a temporary rest from the temptations of his own pride and the evil spirits he believed to be around him.

A definite call to abandon worldly learning occurred in April 1745, Swedenborg told his friends in his later years. The call apparently came in the form of a vision of the Lord when he was awake. Swedenborg left his last work as a secular writer unfinished. It was his drama of creation, *De Cultu et Amore Dei*, that is the synthesis of his scientific writings. The creation of the Earth and its inhabitants, concluded by the birth of the first human couple, is the theme of this modern hexaemeron (creation poem). It is written in a style that wavers between the poetically sublime and the minute concerns of the scientist.

Theological thought. For the remainder of his long career, Swedenborg devoted his enormous energy to interpreting the Bible and to relating what he had seen and heard in the world of spirits and angels. From 1749 to 1771 he published some 30 volumes, all of them in Latin and the major part anonymously. He gave an admirably clear summary of his theological thinking in his last work, the *Vera Christiana Religio* (1771; *True Christian Religion*, 1781), which was written when he was 83.

Briefly, the *esse* ("being") of the Lord cannot be described since it is substance and form itself, but his *essentia* ("essence") can be understood in two of its primary qualities, love and wisdom. In the world of spirits that corresponds to nature, this *essentia* of the Lord is represented by the spiritual sun, the warmth of which is love and the light is *sapientia*, or "wisdom." But the Lord also has manifested himself in other forms, and foremost in his Word. During the ages, mankind has removed itself so far from its origin that the Lord allowed himself to be born into the human world through a mortal woman. Swedenborg thus rejected the doctrine of Christ as the Son of God, as well as the doctrine of the Trinity (*i.e.*, the one God revealed in the Persons of Father, Son, and Holy Spirit).

The maintenance of creation proceeds according to the doctrine of series and degrees. This is one of the many theories and doctrines that Swedenborg kept more or less unaltered in form from his scientific period. Everything in the universe belongs to a series, and in each of these there are three discrete degrees interrelated in terms of correspondence as end, cause, and effect. Each effect becomes an end in the next series at a lower level. The ultimate end of creation can be achieved only through man, and in Swedenborg's anatomist version of the *De civitate Dei* (*The City of God*) by St. Augustine, the great 4th–5th-century North African theologian, the final goal of creation is formed by innumerable angelic societies making a *maximus homo* ("greatest man").

His view of ultimate end of creation

This true order of creation, however, has been disturbed by man's misuse of his free will. He has diverted his love from God to his own ego, and thus evil has come into the world. The ultimate fate of an individual is determined in the intermediate stage immediately after the death of his body. The inner man (*i.e.*, his soul) at that time chooses a society of spirits with which he feels an inner kinship. His social position on Earth will be of no importance when his true affections are revealed in the spiritual world. Instead, new relationships, including marriages, will be established there.

On March 29, 1772, Swedenborg died in London where he was buried in the Swedish Church. At the request of the Swedish government, his body was removed to Uppsala Cathedral in 1908.

Influence. Swedenborg never acted as a preacher but rather relied totally on the effect of his huge Latin volumes. The first Swedenborgian societies appeared in the 1780s and the first independent congregation, the origin of the various Church of the New Jerusalem organizations, was founded in London by the end of the same decade. Swedenborg's influence is by no means restricted to his immediate disciples. His visions and religious ideas have been a source of inspiration for a number of prominent writers, including Honoré de Balzac, Charles Baudelaire, Ralph Waldo Emerson, William Butler Yeats, and August Strindberg. His theological writings have been translated into many languages, and there is a constant flow of new editions.

BIBLIOGRAPHY. The greater part of Swedenborg's manuscripts, preserved in the library of the Royal Swedish Academy of Science in Stockholm, were lithographically published in 10 vol. in 1869–70, and in an 18-volume edition in 1901–16. Unfortunately, these editions cannot stand up to the demands of modern scholarship. Most of the biographical sources were collected, translated, and annotated by R.L. TAFEL in *Documents Concerning the Life and Character of Emanuel Swedenborg*, 2 vol. (1875–77). His letters have been published in English translation in A. ACTON (ed.), *Letters and Memorials*, 2 vol. (1948–55).

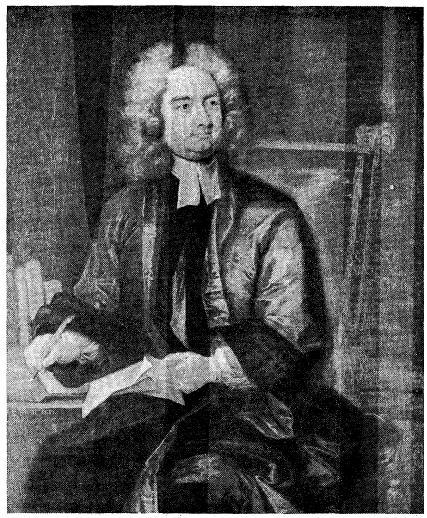
HYDE, *A Bibliography of the Works of Emanuel Swedenborg* (1906); I. JONSSON, *Emanuel Swedenborg* (Eng. trans. 1971); M. LAMM, *Swedenborg* (1915), in Swedish; CYRIEL O. SIGSTEDT, *The Swedenborg Epic* (1952); and SIGNE TOKSVIG, *Emanuel Swedenborg, Scientist and Mystic* (1948).

(I.Jo.)

Swift, Jonathan

Generally acknowledged as the foremost satirist in the English language and one of the satiric masters of all time, Jonathan Swift was many other things as well: a wit, a social personality, a clergyman and churchman, an eminent public figure. He wrote prose satires widely different in theme and execution; he was a distinguished minor poet in an age of great minor poetry; and he was a political journalist of unsurpassed power. His genius and achievement as a satirist have always been recognized, but in other respects he has been a controversial figure—sometimes provoking severe judgments on his personality, various aspects of his career, and on the intent and effect of his satiric writings, especially his most famous work, *Gulliver's Travels*. There are episodes in his private life that, for lack of full and certain factual information, cannot be wholly understood; but these fascinate all the more for that reason and have given rise to endless conjecture—often of a sensational nature and frequently to his discredit. Even quite generally accepted facts about his birth and parentage have, from time to time, been called in question by persons persuaded that the true circumstances were concealed from the world.

Early life and education. Swift was born on November 30, 1667. His grandfather, the Rev. Thomas Swift, had been vicar of Goodrich, Herefordshire, and was remembered for his unswerving loyalty to the Royalist cause during the English Civil War (1642–51). Swift's father, Jonathan the elder, along with three of his brothers, settled in Ireland after the Restoration and became steward of the King's Inns, Dublin. In 1664 he married Abigail Erick, who, though she may have been



Swift, oil painting by C. Jervas (1675?–1739). In the National Portrait Gallery, London.

born in Ireland, was the daughter of an English Leicestershire clergyman. Their daughter, Jane, was born in May 1666. In the spring of 1667, however, Jonathan the elder died suddenly, leaving his wife, baby daughter, and an unborn son to the care of his brothers.

Unsettled youth

As a result of growing up fatherless, dependent on the generosity of his uncles, with no settled home, it may be that Jonathan Swift suffered from a sense of insecurity. His education was not neglected, however, and at the age of six he was sent to Kilkenny School, then the best in Ireland. In 1682 he entered Trinity College, Dublin. In a fragment of autobiography, written many years later and first published in 1755 as "Family of Swift" (edited by H. Davis, *Miscellaneous and Autobiographical Pieces*, 1962), he represents himself as so discouraged and sunk in spirit by "the ill-treatment of his nearest relatives" that he neglected his studies and was therefore only granted his bachelor of arts degree in February 1686 *speciali gratia* ("by special favour"). In fact, his career as an undergraduate seems to have been neither distinguished nor disgraceful; the manner of his degree being a device often used when a student's record failed, in some minor respect, to conform to the regulations, it was not the "discreditable mark" against his name that he himself called it.

He continued in residence at Trinity College as a candidate for his master of arts degree until February 1689. But the disorders that had begun to spread through Dublin after the Revolution of 1688 caused the college authorities to permit students to withdraw to safety. Swift sought security in England, and, after visiting his mother (who had earlier returned to Leicestershire), he became a member of the household of Sir William Temple, at Moor Park, Surrey, where he was to remain off and on until Temple's death in January 1699.

Years at Moor Park. Temple, a man of wide culture, was engaged in writing his memoirs and preparing some of his essays for publication, and he needed someone to act as a kind of secretary. Swift's residence at Moor Park was an interrupted one; he twice returned to Ireland (from May 1690 to December 1691 and from May 1694 to May 1696), a fact that points to some uneasiness about his career. During the second of these visits to Ireland, Swift took orders in the Anglican Church, being ordained priest on January 13, 1695. At the end of the same month he was appointed vicar of Kilroot, near Belfast.

It may be said that Swift came to intellectual maturity at Moor Park, with Temple's rich library at his disposal. Here, too, he met Esther Johnson (the future Stella), the daughter of Temple's widowed housekeeper. She was a dark-haired child of eight when Swift first came to Moor Park, and his friendship with her began by his taking a share in her education. In 1692, through Temple's good offices, he received the degree of M.A. at Oxford, after incorporation as a member of Hart Hall. It was probably in 1693 that he went to Kensington on a mission from Temple and there had a conference with William III, who had asked Temple's advice on a constitutional problem.

Between 1691 and 1694 he wrote a number of poems, notably six odes. His early verse, which at one time provoked only the harshest of judgments, has come to be much more favourably regarded, perhaps because of William Butler Yeats's expressed admiration. Clearly, however, his true genius did not find expression until he turned from verse to prose satire and composed, mostly at Moor Park between 1696 and 1699, *A Tale of a Tub*, one of his major works. Published anonymously in 1704, this was made up of three associated pieces: the *Tale* itself, a satire against "the numerous and gross corruptions in religion and learning"; the mock-heroic "Battle of the Books"; and the "Discourse Concerning the Mechanical Operation of the Spirit," which ridiculed the manner of worship and preaching of religious enthusiasts at that period.

Early satire

In the "Battle," Swift displayed his loyalty to Temple, who, through an essay entitled "Upon the Ancient and Modern Learning" (1690), had taken part in a long-standing dispute about the relative merits of ancient and modern learning. The essay supported the cause of the ancients and was severely criticized by William Wotton, a defender of contemporary culture, and by Richard Bentley, a distinguished scholar. Swift allegorized this attack on Temple, ridiculing Wotton and Bentley; in the famous episode of the bee and the spider, with which the symbolic battle opens, he expresses his own and Temple's tenets regarding the right and universal standards in taste and literature as first set forth by the ancients: the spider feeds wholly on itself, producing nothing at last but flybane and a cobweb, whereas the bee in its wide flights visits all the flowers of the field and brings home honey and wax, "thus furnishing mankind with the two noblest of things, which are sweetness and light." But the *Tale* itself is the most impressive of these three compositions, outstanding for its exuberance of satiric wit and energy and marked by an incomparable command of stylistic effects, largely in the nature of parody. Swift saw the realm of culture and literature threatened by zealous pedantry, while religion—which for him meant rational Anglicanism—suffered attack from both Roman Catholicism and Dissent. He proceeded to trace all these dangers to a single source: the irrationalities that disturb man's highest faculties—reason and common sense.

Career as satirist, political journalist, and churchman. With Temple's sudden death in January 1699, Swift entered on a period of varied experience and considerable uncertainty. In the summer he returned to Dublin as chaplain and secretary to the Earl of Berkeley, who was then going to Ireland as a lord justice. During the immediately ensuing years he was in England on some four occasions—in 1701, 1702, 1703, and 1707–09—and won wide recognition in London for his personal charm and his wit as a writer. Otherwise, his position remained unchanged. He had resigned his position as vicar of Kilroot while still at Moor Park, but early in 1700 he was preferred to several posts in the Irish church, of which the most important was the vicarage of Laracor, not far from Dublin. His public writings of this period show that he kept in close touch with affairs both in Ireland and England. Among numerous compositions, the most notable are the "Discourse of the Contests and Dissensions between the Nobles and the Commons in Athens and Rome" (a forcible statement of Whig principles and an appeal to both political parties for moderation); "A Project for the Advancement of Religion, and the Reformation of Manners"; and "The Sentiments of a Church of England Man with Respect to Religion and Government." In London he was increasingly well-known. His religious and political essays, serious and ironic; the publication in 1704 of *A Tale of a Tub*, anonymous but generally attributed to him; certain impish works, including the well-known "Bickerstaff" pamphlets of 1708–09, which put an end to the career of John Partridge, a popular astrologer, by first prophesying his death and then describing

it in circumstantial detail; and several amusing pieces in a minor key, such as the short poem "A Description of the Morning," printed by Richard Steele in *The Tatler* in 1709—these brought him to the attention of the general public as well as to a circle of Whig writers led by Joseph Addison. It is apparent, however, that Swift was uneasy about many policies of the Whig administration. He was, on the one hand, a Whig by birth and education, and the political principles that he had been setting forth in his writings were in the 17th-century Whig tradition. But, on the other, he was also passionately loyal to the established church, and he came to view with apprehension the Whigs' growing determination to yield ground to the Dissenters. He was increasingly aware of this conflict of loyalties.

Political alliance with the Tory party

Another momentous period began for him when, on September 7, 1710, he once again found himself in London. A Tory ministry headed by Robert Harley (later earl of Oxford) and Henry St. John (later Viscount Bolingbroke) was replacing that of the Whigs. The new administration, bent on bringing hostilities with France to a conclusion, was also assuming a more protective attitude toward the Church of England. Swift's reactions to such a rapidly changing world are vividly recorded in his famous *Journal to Stella*, a series of letters written between his arrival in England in 1710 and 1713, which he addressed to Esther Johnson and her companion, Rebecca Dingley, who were now living in Dublin. The astute Harley had already befriended the satirical poet and pamphleteer Daniel Defoe, thereby gaining the valuable political services of this writer. Now he made overtures to Swift and, by assuring him that the grant of Queen Anne's Bounty would be extended to the church in Ireland, won him over to the Tories. But though Swift was thus placing church above party, he was not renouncing his deeply fixed and essentially Whiggish convictions regarding the nature of government. The old Tory theory of the divine right of kings had no claim upon him. The ultimate power, he insisted, derived from the people as a whole and, in the English constitution, had come to be exercised jointly by king, lords, and commons, between whom it was most important that a balance be maintained lest any form of tyranny arise.

Swift quickly became the Tories' chief political writer and, by the end of October 1710, had taken over the Tory journal, *The Examiner*, which he continued to edit until June 14, 1711. He then began preparing a pamphlet in support of the Tory drive for peace. This, "The Conduct of the Allies," appeared on November 27, 1711, some weeks before the motion in favour of a peace was finally carried in Parliament. His services were not underrated by his friends in the ministry, but his reward was slow to come. When it did—in April 1713—it proved to be the deanery of St. Patrick's Cathedral in Dublin, not one of the English deaneries then vacant. The Queen and many persons of influence are believed to have regarded *A Tale of a Tub* as irreligious, and it may be that they were instrumental in blocking Swift's way to preferment in England. In any event, English deaneries and bishoprics were not being bestowed on those who were, like Swift, of Anglo-Irish birth.

Dean of St. Patrick's, Dublin

Withdrawal to Ireland. But with the death of Queen Anne in August 1714 and the accession of George I, the Tories were a ruined party and Swift's career in England was at an end. He withdrew to Ireland, where, except for two later visits to England in 1726 and 1727, he was to pass the remainder of his life. At first he was the object of scorn and abuse on the part of the Anglo-Irish Whigs, and, bitter over the turn of events and emotionally exhausted, he retired to the seclusion of his deanery. Only gradually did he regain his full energies, but by 1720 he was showing a renewed interest in public affairs and was also returning to verse, which he continued to write through the 1720s and early 1730s. In his Irish pamphlets of this period he came to grips with many of the problems, social and economic, then confronting Ireland. His tone and manner varied from direct factual presentation to exhortation, humour, and bitter irony. He was moved by his perception of the realities of the Irish situation and by his desire to strike at the all-powerful Sir Robert Walpole, and his Whig administration. Ireland's backward state he chiefly blamed on the blindness of the English government; but he also insistently called attention to the things the Irish themselves might do in order to better their lot. Of the Irish writings, the "Drapier's Letters" (1724–25) and "A Modest Proposal" are the best known. The first is a series of letters, purportedly written by M.B., a Dublin linendraper, attacking the English government for its scheme to supply Ireland with copper halfpence and farthings; the latter is a grimly ironic letter of advice in which a public-spirited citizen suggests that economic conditions could be alleviated if the children of poor parents were used as food for the rich.

Mention should be made of certain events in Swift's private life and the theorizing to which they have given rise. The bare events are these. Stella continued to live with Rebecca Dingley after moving to Ireland in 1700 or 1701. Another woman, Esther Vanhomrigh—named Vanessa by Swift—appeared in his life during his London sojourn of 1707–09; in 1714, despite Swift's admonitions, she insisted on following him to Ireland. Her letters to Swift reveal her passion for him (though before her death in June 1723, she apparently turned against him, for he is not mentioned in her will). What lies behind these facts? Were Stella and Swift secretly married? According to one story, long in circulation, there was a marriage, though in name only, in 1716. One version makes Stella Sir William Temple's illegitimate daughter, for which reason Swift was reluctant to marry her openly. Sometimes it is said that Stella, deeply disturbed by Vanessa's presence in Ireland, finally insisted on a marriage. A more sensational variant makes Stella Swift's half sister, each fathered by Temple—a fact obligingly revealed to them immediately after their marriage. And what was the nature of the relationship between Swift and Vanessa? Did Swift remain merely her friend, or did he become her lover? One report affirms that they were the parents of a boy who—add others—was in time taken in and cared for by the compassionate Stella. Denis Johnston's *In Search of Swift* (1959) effects the ultimate turn of the screw: Swift's father was not Sir William Temple but Sir William's father, thus making Swift and Stella uncle and niece; there was no marriage between them, but Swift and Vanessa were more than friends. The point must be made that there is almost no evidence likely to stand up in a court of law to support any of these theories. The actual events, clear to the participants, may very well have been more commonplace.

Stella died in January 1728. Swift's greatest satire, *Gulliver's Travels*, had already been published, the original edition having appeared late in October 1726. It is uncertain when Swift began this work, but it appears from his correspondence that he was writing in earnest by 1721 and had finished the whole by August 1725. He had not been to England since 1714, but in 1726 he returned, carrying with him in manuscript the work—designed, as he said in a letter (September 29, 1725) to Alexander Pope, to "vex the world rather than divert it." He visited Pope at Twickenham, where other friends of former days joined them and where he completed arrangements for publication. *Gulliver's Travels* appeared on October 28, after its author had left again for Dublin. Its success was immediate. Then, and since, it succeeded in "vexing" (but also diverting) all classes of readers. To what extent is it a political allegory, hinting at the story of the Tory ministers Oxford and Bolingbroke, their fall, and Walpole's policies? Is it essentially comic, or is it a misanthropic depreciation of mankind? How seriously is one meant to take Lemuel Gulliver's utopian sketches? Its matter-of-fact style and its air of sober reality confer on it an ironic depth that defeats oversimple explanations.

Publication of *Gulliver's Travels*

Last years. The closing years of Swift's life have been the subject of some misrepresentation, and stories have been told of his ungovernable temper and lack of self-control. It has been suggested that he was insane. From youth he had suffered from what is now known to have been Ménière's disease, an affliction of the semicircular

canals of the ears, causing periods of dizziness and nausea. But his mental powers were in no way affected, and he remained active throughout most of the 1730s—Dublin's foremost citizen and Ireland's great patriot dean. In the autumn of 1739 a great celebration was held in his honour. He had now, however, begun to fail physically and later suffered a paralytic stroke, with subsequent aphasia. In 1742 he was declared incapable of caring for himself, and guardians were appointed. He died on October 19, 1745. He was buried in St. Patrick's Cathedral, and on the wall was affixed a Latin epitaph that he had himself composed and that may be translated thus:

> The body of Jonathan Swift, Doctor of Sacred Theology, dean of this cathedral church, is buried here, where fierce indignation can no more lacerate his heart. Go, traveler, and imitate, if you can, one who strove with all his strength to champion liberty.

MAJOR WORKS

POLITICAL WRITINGS: "A Discourse of the Contests and Dissensions between the Nobles and the Commons in Athens and Rome" (1701); "The Conduct of the Allies, and of the Late Ministry, in Beginning and Carrying on the Present War" (1711); "Some Remarks on the Barrier Treaty, between Her Majesty and the States-General" (1712); "The Importance of the Guardian Considered" (1713); "The Publick Spirit of the Whigs" (1714).

POLITICO-RELIGIOUS WRITINGS: "A Project for the Advancement of Religion, and the Reformation of Manners" (1709); "A Letter . . . Concerning the Sacramental Test" (1709); "Argument Against Abolishing Christianity" (1711); "The Sentiments of a Church of England Man with Respect to Religion and Government" (1711); "A Letter to a Young Gentleman, Lately Enter'd into Holy Orders" (1721).

ON IRISH QUESTIONS: "A Proposal For the Universal Use of Irish Manufacture" (1720); "Drapier's Letters" (1724–35; concluding with "An Humble Address to both Houses of Parliament," 1735); "A Short View of the State of Ireland" (1728); "A Modest Proposal For preventing the Children of Poor People From being a Burthen to their Parents, or the Country, and For making them Beneficial to the Publick" (1729); "An Examination of Certain Abuses, Corruptions, and Enormities in the City of Dublin" (1732).

OTHER: *A Tale of a Tub . . .* (1704), including the *Tale*, "The Battle of the Books," and "Discourse Concerning the Mechanical Operation of the Spirit"; Bickerstaff pamphlets (1708–09); *Journal to Stella* (letters 1 and 41–65 published 1766; 2–40, 1768); *Travels into Several Remote Nations of the World . . . By Lemuel Gulliver* (1726, known as *Gulliver's Travels*).

VERSE: "A Description of the Morning" (1709); "A Description of a City Shower" (1710); "Cadenus and Vanessa" (1726); "The Grand Question Debated" (1729); "On Poetry: A Rapsody" (1733); "Verses on the Death of Dr. Swift" (1739).

BIBLIOGRAPHY. The Swift bibliography in *The New Cambridge Bibliography of English Literature*, vol. 2 (1971), covers both Swift's writings and Swift criticism through 1969. For Swift's works, see also H. TEERINK, *A Bibliography of the Writings of Jonathan Swift*, 2nd ed. rev. and corrected by A.H. SCOUTEN (1963). For Swift criticism, see L.A. LANDA and J.E. TOBIN, *Jonathan Swift: A List of Critical Studies Published from 1895–1945* (1945); and J.J. STATHIS, *A Bibliography of Swift Studies, 1945–1965* (1967).

Major collected editions, editions of separate works, and selections: *The Prose Works*, ed. by H. DAVIS, 14 vol. (1941–68), is the standard edition, though still useful is the older *Prose Works*, ed. by T. SCOTT, 12 vol. (1897–1908). *The Poems of Jonathan Swift*, ed. by H. WILLIAMS, 2nd ed., 3 vol. (1958), is of first importance. The useful one-volume *Poetical Works*, ed. by H. DAVIS (1967), is based on the Williams edition. H. WILLIAMS' editions of the *Correspondence*, 5 vol. (1963–65), and of the *Journal to Stella*, 2 vol. (1948), have superseded all earlier editions. Modern editions of separate works include *A Tale of a Tub . . .*, ed. by A.C. GUTHKELCH and D. NICHOL SMITH, 2nd ed. (1958), which is notable for its scholarly introduction and notes; *Polite Conversation*, ed. by E. PARTRIDGE (1963), with most interesting commentary; and *A Discourse of the Contests and Dissentions Between the Nobles and Commons in Athens and Rome*, ed. by F.H. ELLIS (1967), valuable both for its textual scholarship and for its critical and historical notes. Selections include *Swift: Gulliver's Travels and Selected Writings in Prose and Verse*, ed. by J. HAYWARD (1934); *The Portable Swift*, ed. by C. VAN DOREN (1948); *Gulliver's Travels and Other Writings by Jonathan Swift*, ed. by R. QUINTANA (1958); *Jonathan Swift: Selected Prose and Poetry*, ed. by E. ROSENHEIM, JR. (1959); *Jonathan Swift: Gulliver's Travels and Other Writings*, ed. by L.A. LANDA (1960); *Jonathan Swift: Gulliver's Travels and Other Writings*, ed. by M.K. STARKMAN (1962); *Poetry and Prose by Jonathan Swift*, ed. by H. DAVIS (1964); and *Selected Poems of Jonathan Swift*, ed. by J. REEVES (1967).

Biography and criticism: H. CRAIK, *The Life of Jonathan Swift*, 2nd ed., 2 vol. (1894), for many years the standard biography, is still useful. Of more recent biographies, the most detailed and in many respects the best is I. EHRENPREIS, *Swift: The Man, His Works, and the Age*, vol. 1 (1962), vol. 2 (1967), vol. 3 (in prep.). There is also J.M. MURRY, *Jonathan Swift: A Critical Biography* (1955). *In Search of Swift* by D. JOHNSTON (1959), professing to reveal the nature of the relationship between Swift and Esther Johnson, has proved convincing to some but has been repudiated, either openly or silently, by the majority of Swift scholars and critics. S. LE BROCQUY, *Cadenus: A Reassessment in the Light of New Evidence of the Relationships Between Swift, Stella and Vanessa* (1962) and *Swift's Most Valuable Friend* (1968), the latter concerned principally with Esther Johnson, and both heavily influenced by Johnston's speculations, have won little assent. Swift's personality, aspects of his daily life, and some of the particulars of his career as a public writer are treated in the following: R.W. JACKSON, *Jonathan Swift, Dean and Pastor* (1939) and *Swift and His Circle* (1945); L.A. LANDA, *Swift and the Church of Ireland* (1954); M. FOOT, *The Pen and the Sword* (1957), concerning Swift and the Duke of Marlborough as public antagonists; I. EHRENPREIS, *The Personality of Jonathan Swift* (1958); B.A. GOLDGAR, *The Curse of Party: Swift's Relations with Addison and Steele* (1961); O.W. FERGUSON, *Jonathan Swift As a Tory Pamphleteer* (1967). Reactions to Swift by his contemporaries and by later writers are the subject of D.M. BERWICK, *The Reputation of Jonathan Swift, 1781–1882* (1941); and K. WILLIAMS, *Swift: The Critical Heritage* (1970), the latter reaching to 1819. Modern criticism of Swift has been extensive. Some studies have a broad, general approach to Swift and his writings: R. QUINTANA, *The Mind and Art of Jonathan Swift* (1936; reprinted with additional notes and bibliography, 1953) and *Swift: An Introduction* (1955); K. WILLIAMS, *Jonathan Swift and the Age of Compromise* (1958); D. DONOGHUE, *Jonathan Swift: A Critical Introduction* (1969). More specialized studies, scholarly and critical, include M.O. JOHNSON, *The Sin of Wit: Jonathan Swift As a Poet* (1950); M.K. STARKMAN, *Swift's Satire on Learning in A Tale of a Tub* (1950); J.M. BULLITT, *Jonathan Swift and the Anatomy of Satire: A Study of Satiric Techniques* (1953); M. PRICE, *Swift's Rhetorical Art: A Study in Structure and Meaning* (1953); W.B. EWALD, *The Masks of Jonathan Swift* (1954); J.P. HART, *Swift and Anglican Rationalism: The Religious Background of A Tale of a Tub* (1961); E.W. ROSENHEIM, *Swift and the Satirist's Art* (1963); H. DAVIS, *Jonathan Swift: Essays on His Satire and Other Studies* (1964); and G.P. MAYHEW, *Rage or Raillery: The Swift Manuscripts at the Huntington Library* (1967). M. VOIGT has reviewed the body of modern scholarship and criticism in his *Swift and the Twentieth Century* (1964). The Swift tercentenary, observed in 1967, called forth several collections of essays both old and newly composed: *Jonathan Swift, 1667–1967: A Dublin Tercentenary Tribute*, ed. by R. MCHUGH and P. EDWARDS (1967); *Fair Liberty Was All His Cry: A Tercentenary Tribute to Jonathan Swift, 1667–1745*, ed. by A.N. JEFFARES (1967); *Swift Revisited*, ed. by D. DONOGHUE (1968), consisting of lectures broadcast in Ireland; *The World of Jonathan Swift: Essays for the Tercentenary*, collected and ed. by B. VICKERS (1968). Also to be noted are several studies more closely analytical and focussed upon Swift's stylistic characteristics: R. PAULSON, *Theme and Structure in Swift's Tale of a Tub* (1960); L.T. MILIC, *A Quantitative Approach to the Style of Jonathan Swift* (1967); W.B. CARNOCHAN, *Lemuel Gulliver's Mirror for Man* (1968); A. ROSS, *Swift: Gulliver's Travels* (1968); KATHLEEN WILLIAMS, *Jonathan Swift* (1968), consisting of extracts from Swift's work accompanied by commentary and analysis; and J.R. CLARK, *Form and Frenzy in Swift's Tale of a Tub* (1970).

(R.Q.)

Swimming and Aquatic Sports

Swimming is the action of self-support and propulsion in the water. As a pastime it has few equals, can be enjoyed year round either outdoors or indoors during cold weather, and is reputed by physical educators to be the best exercise for the symmetrical development of the whole body. It is enjoyed by millions and is often a means of protecting and saving lives.

This article is intended for the general reader who may have no knowledge of the activities described. The article traces the history and development of swimming and covers methods of instruction, basic strokes, and growth of competition, along with sections on diving, channel and open water (marathon) swimming, water polo, water skiing, surf riding (surfing), and skin diving. For information on specific rules of competition or finer points of performance the reader should consult the works listed in the bibliography.

SWIMMING

History. The ability to swim was valued in many ancient civilizations, including Egypt, Assyria, Greece, and Rome, where it was practiced widely and stressed in the training of warriors. During the Middle Ages, however, swimming fell into almost complete disuse throughout Europe because of the general belief that outdoor bathing helped to spread the epidemics that so often swept across the continent.

Not until the second half of the 19th century was this medieval prejudice overcome sufficiently for aquatic activities to be resumed. Competition was revived, first in Great Britain, then elsewhere. Swimming was one of the sports included in the first modern Olympic Games at Athens in 1896. Diving events were added in 1904, and women's swimming and diving in 1912.

There have been cases where beginners have been able to swim upon first entering the water, but generally speaking swimming is an acquired skill. With the increased acceptance of swimming as recreation and healthful physical activity, it has grown by leaps and bounds. More and more swimming pools or baths (Great Britain) are found in schools, colleges, communities, and private homes and clubs throughout the world. Teaching of swimming has long been part of the curriculum in many schools. Learn-to-swim campaigns have been fostered by the Red Cross and by national athletic and youth organizations in most countries. During World War II almost all nations included swimming instruction as part of the training of all military personnel. After the war, the gains made in swimming instruction and promotion were consolidated further by national organizations, such as the United States Council for National Cooperation in Aquatics, which is made up of several different organizations and meets annually to further the cause of swimming in all phases.

Instruction. Many methods of instruction have been tried, some more successfully than others. In the main there have been two predominant schools: the American, whose coaches insist that the crawl should be taught first; and the European, where emphasis has been on teaching the breaststroke. In the past twenty years, however, teachers in most countries have stressed learning the crawl first. With children being taught at ever younger ages, learning to swim presents few problems.

The greatest handicaps in learning are failure to relax and haste in performing swimming movements. Fear of the water, experienced by almost all nonswimmers, is overcome to a large degree by playing games in shallow water, ducking the head and looking for objects on the bottom, and learning the fundamental skills of kicking, arm stroke, and floating. Recent innovations aiding the nonswimmer to learn more quickly are swim fins, rubber fins attached to the feet like shoes to help the beginner learn proper kicks; the snorkel, a breathing tube that helps the beginner learn stroke technique without worrying about the breathing cycle; and swim buoys, egg-shaped floats that are attached to the torso by means of an adjustable belt and supply the buoyancy needed to keep the nonswimmer afloat while concentrating on the swimming stroke being taught.

During World War II, when great numbers of men had to be taught and speed in training was necessary, a method of starting a pupil on his back was developed by U.S. Navy personnel. In this position floating was facilitated, breathing made easier, thus developing confidence in the water more quickly. A very simple propulsive stroke was taught, a frog kick synchronized with a short arm stroke, the arms remaining underwater throughout.

Another simplified approach called drown proofing emphasizes breathing and relaxation. This method was adopted by the U.S. Marine Corps for its survival-training program. Eschewing the safer techniques of learning in shallow water, beginners are introduced directly into deep water. By the use of natural buoyancy, breath control, and a minimum of effort, beginners are able to stay afloat as well as propel themselves slowly in the water. Drown proofers with little instruction can stay afloat for hours.

Drown-proofing approach

Swimming strokes. The most popular strokes or styles of swimming are the crawl (freestyle), sidestroke, backstroke, and butterfly. In the early years sidestroke and breaststroke were most frequently used, but the thirst for speed in swimming led to the development of the faster, more efficient crawl. The older strokes remain, however, the basic strokes in most lifesaving courses.

In early competition the most effective racing stroke was sidestroke, originally swum with both arms submerged. The first advance was made when swimmers conceived the idea of minimizing water resistance by recovering (bringing forward) one arm above the water. This was called the single overarm. The double overarm soon followed, with each arm recovering above the surface and the body rolling from side to side on its long axis. This stroke was made famous in the 1890s by an Englishman, J. Arthur Trudgen, who told of learning it in South Africa. The stroke took his name and eventually became the basic action of the crawl.

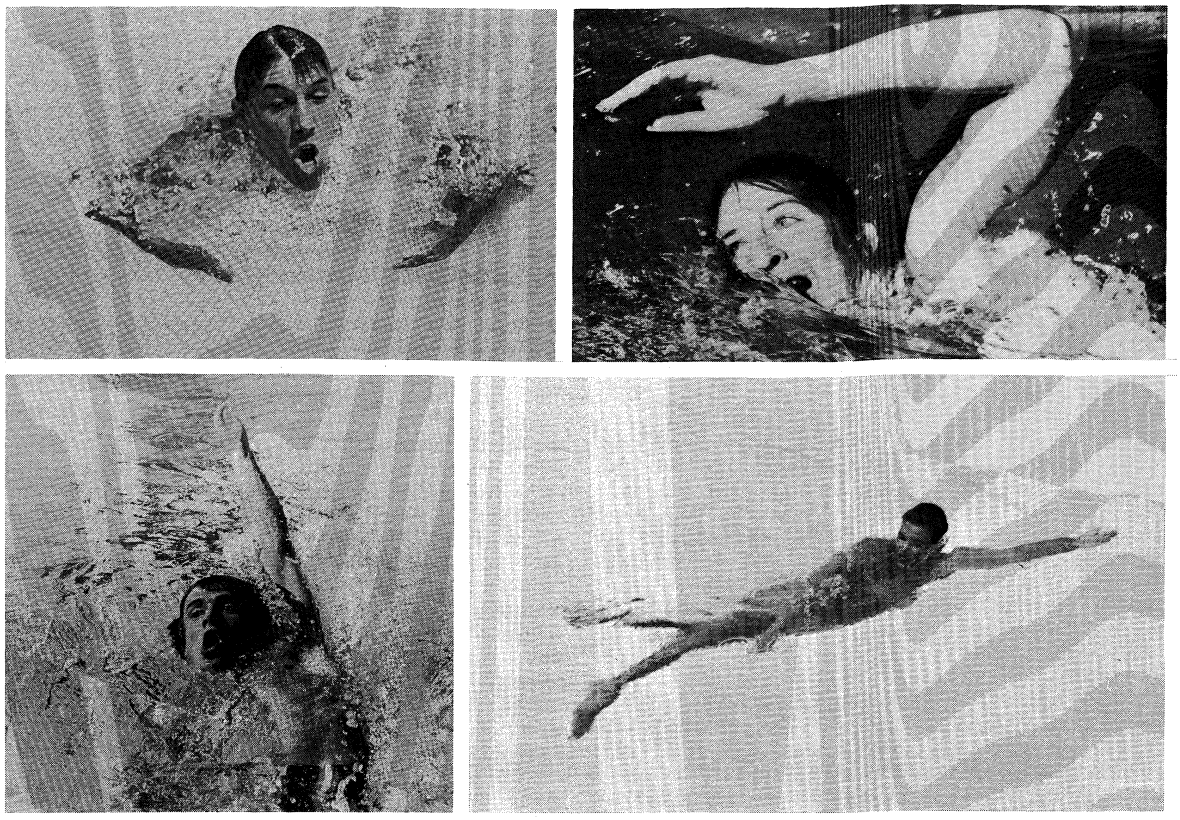
Sidestroke. The sidestroke is valued today chiefly for lifesaving purposes, since it is the most efficient of all in rescue situations. It is also preferred by the average untrained person for open-water pleasure swimming, since it is faster and more easily learned than breaststroke, and the face remains at or near the surface at all times for ease in breathing. The body stays on its side, as the name implies, and the arms propel alternately. The lower arm starts from a comfortably extended position overhead, pulls straight down below the body to waist level, then bends upward and extends again. The topmost arm pushes somewhat outside the body line with a sweeping movement from a point slightly beyond the head all the way to the thigh and recovers either over or under the surface. The kick used in sidestroke is called the scissors kick. It is performed by opening the legs slowly, the underleg moving backward and the upper leg forward, both knees bent a little and toes pointed. The scissoring action of the legs coming smartly together after opening creates the forward propulsion of the kick.

Scissors kick

Breaststroke. The breaststroke is believed to be the oldest of strokes and is of great practical value in lifesaving and recreational swimming, as well as being ideal for swimming in rough water. The French writer M. Thevenot in his book *Art de Nager* (Art of Swimming) of 1696 described the stroke as a wide lateral pull of the arms combined with a symmetrical action of the legs, simulating the swimming movements of a frog. This stroke is now known as the orthodox breaststroke to differentiate it from the newer butterfly breaststroke, or butterfly, a racing adaptation introduced by a German swimmer, Erich Rademacher, in 1926 and later popularized by the American swimmer Henry Myers in 1933.

The breaststroke and the butterfly stroke are both performed lying face down in the water and are primarily distinguished by differing arm actions. In butterfly the arms are brought forward above the surface, whereas in the orthodox breaststroke the arms always remain under water. In breaststroke the two hands are extended together and start their pull about six to eight inches under the surface, with the hands and arms pressing backward and to the sides in an arclike pattern of about 100 degrees. When they reach their maximum spread, the hands are brought together under the breast, completing the arc, and are then extended again quickly, palms down, to start another stroke.

The leg action for the breaststroke, known generally as the frog kick, may be of two types—wedge kick or whip kick. The older wedge is characterized by a very wide



Four basic swimming strokes.

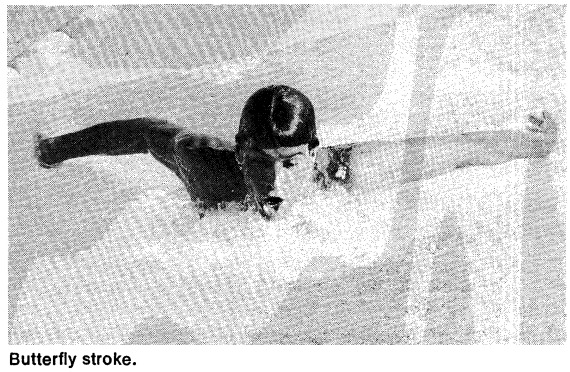
Wedge and whip kicks

action in which the feet are drawn up, knees bent, and the kick produced by a vigorous rounded and outward sweep of the legs in a fully extended position, until the feet come together again. The wedge kick is often described as "squeezing" the water. The more efficient whip kick features a much narrower action. The knees are kept much closer together, yet the feet reach out to engage the water by rotation of the upper thigh.

Formerly, breaststroke swimming featured a momentary glide at the completion of the leg thrust. Modern techniques eliminate the glide entirely, aiming to maintain continuous propulsion. This results in keeping the body high in the water, reducing resistance, and helping to produce more speed. Breathing techniques also have changed. In the old breaststroke, inhalation came at the beginning of the arm stroke. Inhalation now comes at or near the end of the arm pull, just before the hands come together under the shoulders.

Don Wilkinson



Butterfly stroke.

Butterfly. The butterfly stroke is a refinement of the orthodox breaststroke. It was brought to the attention of the United States officials in 1933 in a race that included Henry Myers. He insisted that his method of swimming breaststroke (bringing the arms forward over the water) conformed to the rules of breaststroke as then written. This precipitated much discussion and consternation in the U.S. and abroad, the eventual result being international recognition of a new competitive stroke called breaststroke butterfly in 1953. In its short history it has become, next to the crawl, the fastest competitive stroke and can be considered a double freestyle or crawl. It is definitely a crawl-like stroke in that the arm stroke contributes most of the forward motion and each arm executes a pattern similar to the crawl arm action. Instead of pulling alternately with the arms as in crawl, however, the butterfly swimmer pulls and then recovers both arms simultaneously.

When the butterfly stroke was first swum the frog kick was used. The effect of combining this kick with the simultaneous movement of the arms was a series of jerky forward movements. This was eliminated as the up and down movement of the fishtail (dolphin) kick was perfected, mainly through trial and error by the swimmers themselves. Present butterfly-stroke rules demand up and down movement of the legs only, whereas breaststroke rules still require the rounded outward sweep of the legs in the lateral plane.

Fishtail (dolphin) kick

In the early stages of development of the fishtail (dolphin) kick, excessive undulation of the body was thought necessary to provide speed. This was replaced by a kick that reduces undulations of the torso to necessary reactions to the movement of the arms and legs in certain phases of the stroke. The kick is actually a double crawl kick. Most swimmers execute two dolphin kicks to one arm pull.

In breathing, inhalation usually takes place when the arms are in the final stages of the propulsive action. Exhalations come immediately afterward during the overwater recovery of the arms and the initial part of the down stroke. In sprint competitions (100 metres or less) it is common to inhale every second or third stroke to develop more speed. Lifting the head too often and too high when breathing creates unnecessary drag.

Backstroke. There is indication in the 1903 edition of *Swimming* by Archibald Sinclair and Willam Henry that a backstroke similar to the trudgen, and therefore similar to modern backstroke, was then in use. The style of backstroke then in vogue, however, was aptly described as inverted breaststroke, since it consisted of a simultaneous arm action combined with a frog kick performed while swimming on the back. To U.S. Olympic champion (1912) Harry Hebner goes the major credit for revolutionizing the stroke that first became known as back crawl. The stroke featured alternate arm pulls, as in the crawl stroke, and was so revolutionary that Hebner was almost disqualified for swimming improperly. Intervention by American officials citing the rule that required the swimmer to remain on his back throughout the race preserved his Olympic victory. The new back crawl, now called backstroke, was much faster and far more efficient and drove the old stroke into discard. Since then the stroke has undergone subtle changes, all for the better, if improvement in race times is the criterion.

In the backstroke the body position remains as flat and streamlined as possible. A pronounced bend at the hips creates a "sitting" effect, a common error that produces too much resistance to make the stroke effective. The arms reach alternately above the head and enter the water at a point directly in line with the shoulder, palm facing outward and little finger entering the water first. After the hand enters the water the arm is pulled to the thigh. The first third of the pulling action is done with a straight arm, the middle third with a flexed arm, and the last third with a final thrust or push to full extension. Authorities differ slightly on how much elbow flexion is desirable during the middle third of the pull as well as the degree to which the shoulders and body should roll. Most agree, however, that body roll is necessary for efficient backstroking but should not be more than 45 degrees. At the completion of the pull, the arm is raised in a straight position from the water directly overhead with no lateral deviation. The hand is then ready to start the next pull.

The kick has seen many changes, the most important of which was the switch from the frog kick to alternating up-and-down movements of the legs, as in the crawl. Some swimmers favour continuous kicking; others prefer a broken tempo.

The head should remain still throughout the stroke. Breathing presents few problems, since the face is almost always out of water. Breathing, however, is cyclical as in all other strokes, inhalation usually coming as one arm reaches the high point of its recovery.

Crawl stroke. Crawl, often called freestyle, has become the fastest of all known strokes. In its infancy crawl swimming was considered fit only for sprinting, as it was thought too physically exhausting for the longer competitive distances. Presently, crawl is the almost unanimous choice of swimmers the world over for any distance. Many marathon swims, including crossings of the English Channel, are accomplished using crawl exclusively.

There is evidence that a type of crawl was practiced in the Solomon Islands of the South Pacific and elsewhere before the Cavill brothers of Australia, Syd and Charles, popularized it in Europe in 1902 and in America a year later. The introduction of the crawl in Australia, however, is generally credited to Harry Wickham. When demonstrating it in Australia around 1893, Wickham's alternating arm action was described by coach George Farmer as crawling through the water. The name crawl gained immediate favour, later becoming the Australian crawl, since the Cavill brothers, along with their countryman Cecil Healey, became most proficient after learning it.

Australian crawl

The chief difference between the crawl and the older trudgen is in the leg action. Trudgen relied on the wider scissor- or breaststroke-type kick, creating drag. The crawl kick eliminated the wide lateral movements by fluttering up and down.

The earliest knowledge of the crawl obtained in the United States was derived from hazy newspaper accounts and descriptions of the Cavills' stroke. In attempting to imitate the action, United States swimmers unwittingly developed a faster leg drive, executing four kicks per stroke instead of the two performed by the Cavills. Further experiments led to the belief that the four-beat leg thrash was more effective when composed of one comparatively wide and three very narrow scissoring motions. This style, termed the four-beat trudgen crawl or the four-beat single-rhythm crawl, became the accepted racing stroke. This combination of movements led to such an improvement in average performances that experts conceived the idea of obtaining still greater speed from a six-beat drive set to a double rhythm—two major and four minor kicks—which would minimize resistance and afford more even distribution of propelling power.

Six-beat crawl

Late in 1917 two young swimmers of the New York Women's Swimming Association, Charlotte Boyle and Claire Galligan, determined to give the six-beat kick a trial, and by the summer of 1918 they broke records with it over the longer regulation courses, 800 yards and one mile. The six-beat crawl immediately won favour. Within a few years it had become the recognized stroke the world over, not only for racing but for all-around purposes as well. A great many women and some men used an eight-beat kick successfully in the early years of crawl swimming, notably the Japanese Olympic swimmers in 1932.

Despite the fact that the six-beat crawl is the almost universal choice of sprinters, present-day distance swimmers use a variety of kicks, some six-beat, some four-beat, some scissor, some a combination of scissor and flutter. Others practically drag their legs, using a minimal crossover movement primarily to maintain balance, it being well established that the arm stroke is the major propulsive force in crawl swimming. Debbie Meyer (U.S.), 1968 Olympic champion in three events and then women's world record holder at all freestyle distances 200 yards and over, and Mike Burton (U.S.), 1968 Olympic 400 and 1,500 metre freestyle champion, demonstrated wide differences of leg action in their respective strokes. Miss Meyer swam a strong, classic six-beat crawl, while Burton, particularly in distance racing, used his arms predominantly and a minimal drag kick.

Developments in crawl swimming in the 1950s and 1960s were dramatic, due largely to more and better facilities, both indoor and outdoor, increased technical knowledge, and improved instruction, coaching, and training methods. It became increasingly difficult to predict ultimate limits. In the men's 1,500 metre race, the 1956 world record was 17 minutes 52.9 seconds set by George Breen (U.S.); by 1970 the world record for the same race stood at 15 minutes 57.1 seconds, set by John Kinsella (U.S.), a drop of almost two minutes. Comparable times for women at the same distance show a drop of over three minutes: 20 minutes 34.6 seconds in 1958 by Sylvia Ruuska (U.S.) to 17 minutes 19.9 seconds in 1969 by Debbie Meyer (U.S.).

The correct position in crawl swimming is that of a streamlined whole, the body lying flat on the surface, the legs kept slightly under the water. Raising the head high results in an exaggerated arch in the lower back, which increases body resistance. Lateral movements of the body must also be avoided. The arms move alternately, so timed that one will start pulling just before the other has finished its pull, making propulsion continuous. Most crawl swimmers complete about one-half of the arm pull before the recovering hand next enters the water. The hand enters the water with the elbow held high and slightly bent. Throughout the pull, the shoulder is always above the elbow, and the elbow above the wrist and hand. Bending the elbow affords greater strength in pulling. The force of the arm stroke can be thought of as pressing downward and backward during the first third of the stroke, pushing during the middle third, and pushing through and backward but not upward during the final third of the action, completing an arc of roughly 180 degrees in the vertical plane. The direction of pull should be on a line from the shoulder moving under the body and out past the thigh on recovery. On recovery the elbow is bent and carried high. The forearm circles quickly out and around until the hand extends toward the point of entry. The elbow is then extended, although not fully, for the catch of the hand on a line with the shoulder.

Stroke and kick basics

In kicking, the legs remain fairly straight but fully relaxed. The legs whip up and down alternately in an undulating action, so that in both the up kick and down kick there is a backward push directed against the water by the lower leg and more so by the foot. The scope of the thrash varies somewhat according to the individual length of leg and the number of beats used per stroke.

When a swimmer is viewed head on from an underwater window, a distinct roll from one side to the other is apparent. This newer technique has completely outmoded the previous no-roll style.

Breathing is effected by turning the head to either side during recovery of the arm on that side. Inhalation is quick, and the head is then returned to the face downward position, exhaling through the nose and mouth. Normally one breath is taken for each full cycle of the arms. In short-distance sprinting however, breathing may take place after two, three, or even four cycles of the arms. The skilled swimmer can breathe equally well on either side.

Competitive swimming. While swimming was not a part of the ancient Olympic Games, the sport was not unknown to the Greeks and Romans and other early civilizations. In Japan competition is known to have taken place as early as 36 BC, during the reign of Emperor Sujin; an imperial edict in AD 1603 made swimming an integral part of the school curriculum. By 1810 Japanese swimming competition had reached the level of a three-day meet.

Anglo-Saxons, however, are responsible for organizing the modern sport. The first championship meet of modern times was held in Sydney, Australia, in 1846. A group of London clubs met in 1869 and formed the Metropolitan Swimming Club Association, which later changed its name to the Amateur Swimming Association. The United States Amateur Athletic Union, formed in 1888, included swimming along with other sports under its supervision. Soon other Western nations founded similar governing bodies.

Controlling national groups met in London in 1908 and organized the Fédération Internationale de Natation Amateur (FINA), its purpose to establish programs and rules for Olympic Games and other international competitions and to supervise and register world records. From ten original members the FINA had grown to almost 100 by the 1970s. With few exceptions, notably China, practically all national swimming organizations are FINA-affiliated. Aquatic sports over which the FINA assumes authority are swimming (women's competition was recognized in 1921), diving, and water polo. Synchronized swimming (*i.e.*, swimming with music) was formally added for the 1955 Pan-American Games. Major competitions operating under the FINA code in addition to the Olympic Games, include the Pan-American Games, the Maccabiah Games, the European Games, the Asian Games, and more recently the World Student Games.

While most countries adhere to FINA rules, the United States, with its tremendous emphasis on club, interscholastic, and intercollegiate swimming, competes under rules of the Amateur Athletic Union (AAU) and National Collegiate Athletic Association (NCAA) for the simple reason that American swimming traditionally emphasizes short-course competition (pools 25 yards long), while FINA recognizes world standards set in 50-metre pools only.

Ever since Olympic competition was revived in 1896, freestyle (crawl) races have been more predominant than races using any other stroke. This also holds true for NCAA and interscholastic competition in the United States. Only in the past ten years have races in backstroke, breaststroke, butterfly, and individual medley (all four strokes) challenged the popularity of the crawl.

Olympic swimming

A study of Olympic competition reveals that excellence in performance follows no one pattern or nation, as Hungary, Denmark, Australia, Germany, France, Great Britain, Canada, Japan, and the United States have been leaders at different times. Since 1920, however, with the exception of the 1932 and 1956 Olympiads, the swimmers of the United States have won the largest share of Olympic honours. They were particularly strong in the 1960s, winning 50 of 74 Olympic events. (For complete lists of Olympic swimming champions, see ATHLETIC GAMES AND CONTESTS: *Olympic champions;* for world records see SPORTING RECORD in the *Ready Reference and Index.*)

Many factors contributed to the United States' rise to preeminence in swimming, the most important of which was the start of the age-group swimming programs in the late 1940s. Age-group swimming is a program sponsored by the AAU whereby boys and girls compete on local, sectional, and national levels in all competitive strokes at specific age levels: ten and under, 11–12, 13–14, and 15–17 (originally 15–16). Other countries have instituted similar programs. Unselfish help has come from coaches and editors of such swimming periodicals as *Swimming World* (U.S.) and the *Swimming Times* (London). These programs have provided youngsters with the stimulus necessary to reach local and international proficiency. In the United States alone, over 1,000,000 age-group swimmers enjoyed racing annually in the 1970s. In 1970, 500 swimmers representing 12 countries swam in the Seventh Annual Darmstadt (Germany) International Junior Gala.

Other factors contributing to the elevation of swimming to a place of eminence in world sport include increased construction of standard 50-metre pools featuring such technical innovations as wave-killing gutters, racing lane-markers that further reduce surface turbulence, the use of movie cameras to study strokes from underwater viewing windows, large-faced electric clocks that enable swimmers to observe and regulate their own performance in training, and electrically operated automatic judging and timing equipment.

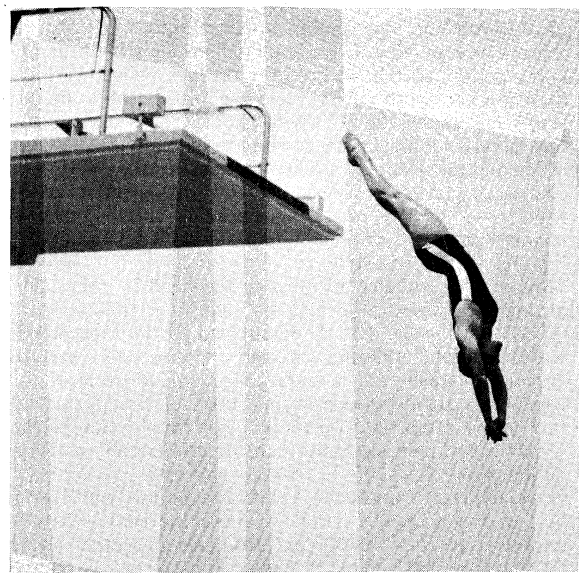
All aspects of swimming are being explored continually. The World Swimming Coaches Association, formed at the 1968 Olympic Games, has as one of its goals the exchange of technical information on swimming. Out-of-water exercises, both in and out of season, body building, running, the use of both heavy and light weights to develop specific muscle groups, and isotonic and isometric exercises are some of the many methods used to increase strength, muscle tone, and endurance.

Before interval training and repeat training came into prominence in 1956, swimmers trained mainly by swimming as much distance as they could in any given workout regardless of stroke quality or speed. Interval training consists of a series of swims of the same distance with controlled rest periods. In slow interval training the rest period is always shorter in time than it takes to swim the prescribed distance. Fast interval training permits longer periods of rest with consequently greater recovery of the heart rate to normal. Slow interval training is used primarily to develop endurance, while fast interval training develops speed, with endurance a secondary goal. Repeat training is a type of swimming in which rest periods between swims are long enough to permit almost complete recovery of the heart and respiratory rate. The emphasis in repeat training is on speed and quality. All competitive swimmers, from age-group to Olympic champions, use both interval and repeat training methods.

DIVING

To dive means, most simply, to plunge into the water head first from a pool deck, a float, raised platform, or springboard. In competition dives are executed in a prescribed manner and consist of a takeoff from springboard or platform, a movement or series of movements performed in the air, and a smooth entry into the water either head first or feet first. Diving contests are a part of most aquatic meets.

When diving first became part of the Olympic program in 1904, it was little more than plain high diving from five- and ten-metre fixed platforms. The combination of acrobatic and gymnastic manoeuvres with diving, first called variety diving and later fancy diving, made a uniform method of judging the competitors necessary. An international committee in 1904 composed a table of dives, listed a description of each, and assigned a value for each based on its relative difficulty of performance.



Two types of dives.
(Left) inward dive in pike position from a 3-metre springboard; (right) back dive in layout position from a 10-metre tower or platform.
(Left, right) Swimming World Publications, (left) Fort Worth *Star-Telegram*, (right) R.F. Lewis

Original tables listed but 20 springboard dives and 14 platform dives. By 1970 there were 77 springboard and 59 platform dives recognized in international competition, governed by the FINA.

Types of dives. Competitive dives, both platform and springboard, are separated into different groups: (1) forward dives, in which the performer, facing the water, dives out from the board and rotates ½ to 3½ turns before entry; (2) backward dives, in which the performer stands with his back to the water and rotates backward ½ to 2½ turns; (3) reverse dives, in which the performer begins in a forward position but changes the direction of his rotation from forward to backward after takeoff, making ½ to 2½ turns; (4) inward dives, in which the performer stands with his back to the water and, after a backward takeoff, rotates inward ½ to 2½ turns toward the board; (5) twisting dives, in which the performer spins about the long axis of his body, twisting ½ to 3½ turns while performing any dive from the other four categories. A sixth category, used only in platform contests, includes the armstand dives, in which the performer must maintain a perfectly balanced handstand at the edge of the platform before executing his dive.

Straight, pike, or tuck

The majority of dives in the FINA diving tables can be performed in three different positions: straight, pike, or tuck. In the straight position the body remains perfectly in line, with no flexion at the hips or knees permitted. In the pike position, there must be a distinct flexion at the hips, but none at the knees. In the tuck position, the body is gathered tightly into a ball with the hands grasping the shins firmly. In all three positions the toes must be pointed.

An indication of the advances made in diving during the 20th century is the report of the IV Olympiad (1908), which suggested the elimination of the double somersault from the tables because it was believed too difficult to control and a possible cause of injury. Modern divers, however, perform up to 3½ somersaults forward, 2½ somersaults inward or backward, and add complicated twisting movements while somersaulting—all with grace and beauty.

Judging and scoring. Winners are determined by a panel of judges—three in dual meets, five in international, and seven in Olympic competition. Judges score each diver from 0 to 10 points in ½ point increments, taking into account the run, the takeoff, the technique and grace of the dive during the passage through the air, and the entry into the water. The panel is supervised by a referee assisted by secretaries and an official scorer who records the award of each judge. When five judges officiate, the scorer eliminates the highest and lowest awards, multiplies the sum remaining by the degree of difficulty of the dive, and enters the result on a scoring sheet. Example: 5 judges (8)-7-7-7-(6) = 21 × 2.0 (degree of difficulty) = 42 (score). When seven judges are used, the score, obtained as before, is divided by 5 and multiplied by 3 to establish a comparable score: 7 judges (8)-7-7-7-7-7-(6½) = 35 total; 35 × 2.0 (degree of difficulty) = 70 ÷ 5 = 14; 14 × 3 = 42 (score). The winner of the contest is the one totalling the greatest number of points for all dives. Should two or more score the same number of points, a tie is declared.

Equipment. The popularity of diving is partially the result of improvement in equipment, most notably the invention of the Duraluminum springboard. A previous invention, the movable fulcrum, enabled the diver to adjust the flexibility of the board to his own liking.

Equipment for diving is defined by rules made by the FINA International Diving Committee, the most important of which follow.

Springboards may be 1 metre or 3 metres (10 feet) above the surface of the water; the board itself must be at least 4 metres long and ½ metre wide. Minimum depth of water is 3 metres beneath the 1-metre board and 3.5 metres (12 feet) beneath the 3-metre board. Originally springboards were made of wood, covered with cocoa matting to prevent slipping, later of fibreglass-sheathed laminated wood. The Duraluminum board, with its built-in nonskid surface, was first used in the Olympic Games at Melbourne in 1956 and has made the wooden board practically obsolete. Regulation springboards must be provided with a movable fulcrum easily adjusted by each diver.

Fixed boards (platforms or towers) may be 7.5 metres or 10 metres (33 feet) above the surface of the water. Platforms 2 metres wide and not less than 6 metres long must be rigid, accessible by stairs, covered over their entire length with rough cocoa matting, and the back and sides surrounded by a handrail. Minimum depth of water under the 7.5-metre (intermediate) tower is 4 metres (13 feet) and 4.5 metres (15 feet) under the 10-metre tower.

Competition. Men's springboard competition at the most proficient levels comprises 11 dives: 5 required (forward, backward, reverse, inward, and forward with ½ twist) and 6 voluntary dives selected from the diving tables. Dual meet diving at the interscholastic and intercollegiate levels consists of contests of 6 dives, 1 required and 5 voluntary. Men's tower diving competition comprises 6 dives, 1 from each category, with a total degree of difficulty that does not exceed 11.2; and 4 voluntary selections, again from different categories but with no limit on the degree of difficulty.

Women's championship springboard contests require

the same 5 required dives as the men, but only 5 voluntary dives. In women's tower competition there are 4 required dives, specifically named (forward, backward, reverse, and inward), and 4 voluntary dives.

In international competition, when there are more than 12 contestants, each contestant performs the required dives and three voluntary dives in a preliminary event. The 12 highest scorers then compete in the finals, in which they perform three voluntary dives. The United States national championship diving contests consist of three parts: preliminaries, semifinals, and finals, because the size of the field has become so unwieldy. Trials for the 1968 U.S. men's Olympic tower diving team alone saw more than 100 divers competing, while 75 or more divers are not unknown at the national intercollegiate championships. This far exceeds the numbers competing in European, Asian, Pan-American, or Olympic competitions.

The tremendous growth of diving in the United States has resulted in the separation of diving from its parent sport swimming, with increasing strength in all phases of the program. The American Diving Coaches Association, organized in 1969 with more than 150 members, has the power through its own Olympic Diving Committee to select divers and coaches for Pan American and Olympic diving teams, as well as for other international events. The committee has also organized age-group, regional, and zone competitions in greater numbers than ever before and has revitalized women's intercollegiate championships.

More frequent contests between divers from various countries at all levels have resulted in dramatic improvements everywhere. Recent Europe-versus-United States team-diving contests, exchange programs with Canadian, German, Swedish, and English divers, and the establishment of diving camps in various areas to give younger divers first-class coaching indicate future strength.

The dominance of U.S. divers grew out of the efforts of outstanding coaches. Both the American and World Diving Coaches Association (formed in 1968) have contributed to the standardization of all equipment and the spread of diving expertise. Their success is born out by the fact that Klaus Dibiasi (Italy) won the 10-metre tower Olympic title in 1968, breaking an unprecedented string of United States victories that began in 1920, complete except for the 10-metre win of U.S.-trained Joaquin Capilla (Mex.) in 1956. The record in ladies' diving is almost identical, with U.S. women winning most springboard and tower Olympic gold medals until 1960 when Ingrid Kramer (Germany) won both events. (For lists of Olympic diving champions, see ATHLETIC GAMES AND CONTESTS: *Olympic champions.*)

OTHER WATER EVENTS

Channel and open-water (marathon) swimming. Long before the advent of swimming pools, distance swimming was practiced by swimmers everywhere. It was not until 1875, however, that Matthew Webb, a 27-year-old Englishman, captured the fancy of the world by being the first person successfully to swim the English Channel, covering the distance from Dover to Calais in 21 hours and 45 minutes. English Channel swimming received its greatest publicity in 1926 when Gertrude Ederle, U.S. world-record holder, became the first woman to conquer the Channel, using the crawl the entire distance and finishing in 14 hours 31 minutes. Webb swam breaststroke.

The Channel has been conquered hundreds of times since then, the fastest crossing belonging to Barry Watson of England in 9 hours 35 minutes. The best time for women, 9 hours 59 minutes, is credited to the Australian professional Linda McGill. Florence Chadwick, (U.S.) was the first woman to swim the Channel in both directions, in 1950 and 1951. Undoubtedly the greatest feat is that of the Argentine professional Antonio Abertondo, who swam the Channel both ways in 1961, 18 hours 50 minutes from England to France and 24 hours 25 minutes for the return, a total of 43 hours 15 minutes. The Channel has even been conquered underwater by Fred Baldasare, an American frogman, using aqualung equipment and swimming in a towed submerged cage.

While the English Channel has received the most popular attention, there are other challenging long distance, or marathon, swims. Most of them are in the 15- to 37-mile (24- to 59-kilometre) range, although some are longer, notably the Lake George marathon (42 miles, or 67 kilometres), and the Lake Michigan Endurance Swim (50 miles, or 80 kilometres), both in the United States.

Marathon swimming

Since the FINA is concerned with amateur swimming at distances up to 1,500 metres only and since marathon swimming is largely professional in nature, an international group of amateurs and professionals met in 1954 to form the Fédération Internationale de Natation de Longue Distance (FINLD). Since the FINLD permitted amateurs to compete with professionals, problems were bound to arise, and in 1963 the professional distance swimmers founded the World Professional Marathon Swimming Federation (WPMSF) to set the standards for the conduct of marathon swimming. Eight sanctioned championship races are usually held each year. Countries sponsoring championship marathons include Canada, Egypt, Italy, Argentina, and the United States. During 1969, 10 international professional marathon races were held, 8 of which were sanctioned by the WPMSF, with 107 swimmers from 21 different countries participating.

Water polo. Water polo was first conceived in England in the 1870s. At first the game was an attempt by British gentlemen to emulate the polo played on horseback while in the water. "Horses" were made from wooden barrels, decorated with horseheads and fancy tails. Double-bladed paddles served both to strike the ball and to provide propulsion and balance. The game eventually gave way to one wherein all players remained in the water as swimmers.

The swimming game was introduced in the United States in 1890, at which time teams of six men played with a partially inflated ball. This "soft ball" game was characterized by very rugged underwater tackling and was called by some the roughest sport on Earth. Its popularity had diminished greatly by 1935, when it was succeeded by the international (hard ball) game in which underwater tackling was prohibited. This made the hard-ball game a surface rather than an underwater game, and swimming, ball handling, passing, and throwing skills became prime requisites.

Hungary has dominated the sport since that time, winning Olympic titles in 1932, 1936, 1952, 1956, and 1964, with Italy winning in 1948 and 1960, Yugoslavia in 1968, and the U.S.S.R. in 1972, also supplanting Great Britain, the Olympic winner four times in the early years of the sport. Hungary's strength was due in large part to the play of Dezső Gyermarti, who at 37 helped his country win a gold medal in his fifth Olympic competition (1964). (For Olympic water polo champions, see ATHLETIC GAMES AND CONTESTS: *Olympic champions.*)

Water polo has grown by leaps and bounds during the past 25 years, especially since the disproval of a superstition that a world class swimmer would lose his swimming form by playing polo. Due in part to the 1964 Olympic exploits of Roy Saari (U.S.) then world 1,500 metre record holder and a water polo player of international class at the same time, and Charles Bittick (U.S.), national collegiate backstroke champion and member of the 1960 U.S. Olympic water polo team, swimming coaches throughout the world at last permitted swimmers to play the game. The rapid growth of the sport is indicated by the fact that in the United States alone there is organized water polo competition at age-group, secondary school, club, collegiate, and national levels. Many swimming coaches urge their swimmers to engage in water polo as training to improve not only their swimming skills but their endurance as well.

Swimmers and water polo

International water polo is governed by the FINA. The game is played in a pool 20–30 metres (65–100 feet) long and 8–20 metres (25–65 feet) wide, by two teams of seven men each, using a rubber fabric composition ball, 68–71 centimetres (27–28 inches) in circumference, fully inflated. The depth of the pool may vary, except in championship play, when at least 1.8 metres (6 feet) is required. Players on one team wear numbered white caps; oppo-

nents wear a contrasting colour. The use of plastic ear guards is also recommended.

The game, four periods of five or seven minutes each with a two-minute interval between periods, is officiated by two referees, a timekeeper, a recorder, and two goal judges. Teams change sides after each period. A goal, scored as 1 point, is made by throwing the ball between the goal posts, which are 3 metres (10 feet) apart and 0.9 metres (3 feet) high, by dribbling the ball through them, or by a penalty throw, an unimpeded shot at a goal guarded only by a goalkeeper. Penalty throws are awarded by the referee for serious fouls or infractions of rules. Fouls may be technical, personal, or major. Technical fouls result in loss of the ball to the opposing team. A penalty throw is awarded to a team after its opponents commit ten personal fouls or one major foul. Any player committing five personal fouls must leave the game, although he may be replaced by a substitute. (K.B.M.)

Water skiing. Water skiing evolved in the 1920s and early 1930s in Europe and the United States concurrently with the rising popularity of motorboats capable of speeds over 20 miles per hour (32 kilometres per hour). Today it is practiced in nearly every country in the world wherever a stretch of calm water is available. Its popularity with people of all ages stems from the thrill of speed enjoyed without its usually attendant dangers.

General purpose and jumping skis are about 68 inches (1.7 metres) long by 6½ inches (16.5 centimetres) wide, with wooden fins on the bottom for stability. The resilient rubber foot binding is put on like a rubber overshoe and releases without injury in case of a fall. For slalom competition, a single ski is used that is tapered toward the rear, where a large metal fin is mounted. It uses two foot bindings in tandem. Trick riding is best done with skis 48 inches (1.2 metres) long by 10 inches (25 centimetres) wide, slightly rockered and without fins of any kind. The standard tow line is about 75 feet (23 metres) long with a wooden handle on a triangular bridle. Minimum boat speed is about 15 miles (24 kilometres) per hour.

The American Water Ski Association, with headquarters in Winter Haven, Florida, sanctions upward of 100 tournaments each year in the United States. Australia, France, Canada, Italy, Great Britain, and other countries have similar organizations. World competition is regulated by the World Water Ski Union in Geneva. All competition is open; no discrimination is made between amateur and professional.

Competition under a rigid set of rules is in three categories: jumping for distance at up to 35 miles (56 kilometres) per hour boat speed from a 6-foot (1.8-metre) high, sloping wooden ramp; slalom through a winding course of buoys at progressively higher boat speeds up to 36 miles per hour; and trick riding, where as many tricks as possible are performed in two 20-second runs at a speed selected by the contestant. Trick riding involves variations of turning from front to backwards on the water and in the air from wake or ramp jumps and holding the tow line with the foot as well as the hands.

Spectacular variations of water skiing include barefoot skiing, where boat speeds of 35 to 40 miles (56 to 64 kilometres) per hour are required to enable the rider to "ski" on his feet on the surface and do many of the manoeuvres including ramp jumping, that normally are performed on skis.

Ski kiting is done with a large fabric kite on a 100-foot (30-metre) or longer line. The kite is attached to the tow line and the skier, using light skis, holds a trapeze-like bar attached to the kite. Lift-off in still air is at 25 to 30 miles (40 to 48 kilometres) per hour. Elevation is controlled by boat speed and, in some kites, by the flyer. Competition on kites includes slalom and trapeze tricks. Some types of kites can cut loose from the tow line and do free flights to a landing. (For lists of water skiing world records and champions, see SPORTING RECORD in the *Ready Reference and Index*.)

Surf riding (surfing). Surf riding, or surfing, was practiced by the Polynesian islanders when the first European explorers visited the Pacific Ocean. Capt. James Cook reported at length on his observations of the sport when he reached Hawaii in 1778. For many years it was regarded as an exotic pastime, practiced only by Pacific islanders, some of whom demonstrated it for tourists, by a few adventurous visitors, and by a few mainlanders in Australia and Southern California who had seen demonstrations. The real growth of the sport came with the growth of other water sports after World War II, and it is now practiced around the world wherever wave action permits. Ideal conditions occur where the open ocean bottom slopes very gradually to depths of not over 10 feet (3 metres) at distances from 100 to 1,000 yards (90 to 900 metres) from the shoreline.

All competitive and most recreational surfing is done in standing position on hollow, light wood or foam-filled fibreglass boards about 2 feet (60 centimetres) wide and 10 to 12 feet (300 to 360 centimetres) long, tapered and rounded on ends and edges with a stabilizing fin on the bottom near the rear end. It is also done in prone position with narrower boards, 3 to 5 feet (1 to 1.5 metres) long; on air mattresses; or with the body itself in a prone position ("body surfing").

The rider first paddles or swims his board out from shore to the area where the ocean rollers peak up, but have not yet broken at the crest. As a suitably shaped wave approaches him, he lies prone on his board and paddles toward shore to gain speed so that when the wave reaches him he will slide down its forward face as it breaks and continue toward the shore. After catching the wave, he climbs to his knees and then to his feet. By banking the board he can steer it; by riding diagonally across the wave as it advances to shore, he can increase his speed and the distance travelled. Breaking waves from 2 to 20 feet (0.6 to 6 metres) in height can be ridden for distances up to 900 metres (1,000 yards).

Competitions are held nationally and internationally both for individual surfers (men and women) and two on a board (mixed). Points are awarded for ability to catch the wave, wave selected, distance travelled, skill in manoeuvring, form, and acrobatic tricks and lifts done.

Surf boards are also ridden in calm water on the large stern wakes of a slowly driven powerboat (not to be confused with aquaplaning, where a board is attached by a rope to the boat and driven at higher speeds). On some inland lakes, surfing is performed on waves produced by special machines.

Skin diving. Skin diving has been practiced throughout history as a means of fishing and salvage of shipwrecks. As a popular sport, it started in the 1930s with the use of glass and rubber face masks that allow a diver to see clearly underwater; foot fins to greatly increase mobility; and a J-shaped breathing tube or "snorkle" to permit breathing while lying face down on the water and watching below. Somewhat later, "wet" suits of cellular rubber material were developed for use in cold water or for prolonged diving.

A great majority of the approximately 3,000,000 modern skin divers do not dive very deep or very often. They prefer to swim with mask, snorkle, and flippers on the surface and enjoy the underwater scenery. The coral reef areas of the tropical zone around the world are generally considered the most rewarding for this purpose, but any shallow sea, pond, spring, or river has interest.

To dive, the body is bent at the waist, the head ducked downward and the feet raised straight up in the air. The weight of the feet plus a breast stroke with the arms will propel the diver down if he is weighted for near neutral buoyancy. On descending, the pressure in the ears must be neutralized by swallowing, yawning, or holding the nostrils while blowing gently. With practice, dives of 35-foot (11-metre) depth and a full minute duration can be achieved by most nonsmokers.

The development and marketing of the scuba (Self Contained Underwater Breathing Apparatus), starting in the 1940s, gave great impetus to sport diving. Using bottles of highly compressed air that gave the diver up to two hours submergence time, the scuba allowed him to live like a fish and explore or work without coming to the surface for air. Valid instruction in the use of scuba is imperative for safety.

For spear fishing, scuba is not used by sportsmen. The spear guns used are powered by rubber tubing, springs, compressed gas, or gun powder. The spear is generally about 4 feet (1.2 metres) long with a hinged barb at its point. Since the range of the gun is 6 feet (1.8 metres) or less, the fish must be closely stalked by the diver to shoot it. For conservation purposes, only fish that will be eaten or stuffed as trophies should be shot.

Spear-fishing, salvage, and photography

Diving to investigate shipwrecks, hunt treasure, and explore archaeological finds has another group of devotees. Salvage involves a great deal of underwater and surface equipment and is more complex and expensive than imagined by most amateur divers.

One of the most popular facets of diving is underwater photography. By means of the great variety of still and movie cameras available to the sport diver, the beauty of the underwater world can be captured on film. Photography is also widely used by naturalists and marine biologists to record in detail the fantastic variety of life in the sea.

Competitions in diving and spear fishing are held at irregular intervals under varying rules specifying hours of diving and species of fish to be taken. Diving for record depths or duration is extremely dangerous and is not encouraged by any sporting organization. (J.A.)

Switzerland

Landlocked amid the mountains of central Europe, Switzerland is a nation the people of which have no unity of ethnic heritage nor of language or religion and the land of which is splintered by barriers of rock and river; but it is a nation that nonetheless is united and prosperous. Officially known as Schweizerische Eidgenossenschaft, or Swiss Confederation, Switzerland is a republican federation of 22 cantons, or states, three of which (Basel, Unterwalden, and Appenzell) are divided into half cantons. It is a *mater fluviorum* ("mother of rivers"), situated at the hydrographic centre of Europe and bordered on the west by France, on the north by West Germany, on the east by Austria and the Principality of Liechtenstein, and on the south by Italy. Two-thirds of its borders follow the natural contours of mountain ridges and crests, lakes, and rivers. Except for minor adjustments, Swiss borders have remained stable since their establishment at the Congress of Vienna in 1815, a stability from which the economy of the nation often has benefitted.

Switzerland's small area of 15,941 square miles (41,288 square kilometres; about one-half the size of Scotland or of Maine) and population of nearly 6,270,000 (1970), give no indication of the country's character or significance on the international scene. Switzerland's geographically imposed role as guardian of Europe's natural trans-Alpine routes has been both a reason for and a basic tenet of its existence—a role expressed in its traditional neutrality in time of war that was sanctioned by the Treaty of Westphalia in 1648 and confirmed in 1815 in Vienna, by the Treaty of Versailles in 1919, and again in 1920, when the Council of the League of Nations acknowledged it as "conditioned by a centuries-old tradition explicitly incorporated in international law." The tradition was upheld even while war raged around Switzerland's borders during 1939–45.

Traditional neutrality

Switzerland owes its existence, however, no less to the will of its inhabitants than to the exigencies of geography. With one-quarter of its area comprising high Alps, lakes, and barren rock and with no seaboard and few natural resources other than waterpower, Switzerland has managed to impose unity on diverse races, religions, and languages: for almost 700 years it has maintained the world's oldest and the European mainland's most virile democracy, achieving an almost unrivalled standard of living. It has become a financial centre and headquarters of more than 300 international institutions, including the International Committee of the Red Cross in Geneva and the Universal Postal Union in Bern. (For information on related topics, see SWITZERLAND, HISTORY OF; special features are covered in ALPINE LAKES; ALPS MOUNTAIN RANGES; JURA MOUNTAINS; GENEVA; and ZURICH.)

THE NATURAL AND HUMAN LANDSCAPE

Geographical regions. Switzerland's small area contains an unusual diversity of topographic elements, which are divisible into three distinct regions: the Jura, the Alps, and the plateau area known as the Mittelland.

The Jura (Celtic: "forest"), a bleak and rolling mountain range in the northwest, occupies about 10 percent of the country. The region was formed under the extended impact of the general Alpine folding, particularly of two phases of that folding. Limestone and marl with rich fossil content are the characteristic rocks. The ridges, covered with meadows and only sparsely forested, receive greater amounts of rainfall than do the valleys, the slopes of which are wooded. Between Val St. Imier and the Doubs, a river that forms part of the border with France, mountains have been reduced by denudation to an undulating plateau, or peneplain. This plateau Jura, which extends into France, is known geographically as the Franches-Montagnes (Free Mountains), a name acquired in 1384 when the Bishop of Basel freed the inhabitants from taxation to encourage settlement of the remote area. The unfolded plateaus of the Jura tableland, atop which mixed agriculture is practiced, rise slightly toward the north and northwest, and their steep edges are forested.

Diversity of natural relief

In origin, the Alps were built of large complexes of massed overthrusts of extremely varied rocks. Especially well-known for its scenery is the Valais (a canton),

site of the Dufourspitze (15,200 feet [4,634 metres]), the highest point in Switzerland, and the Matterhorn (14,691 feet [4,478 metres]). The northern and southern Swiss Alps are separated by the trough formed by the Rhône and Upper Rhine valleys. The narrowest portion of the trough, the Urseren Valley, lies between two crystalline central massifs, the Gotthard and the Aarmassif.

The Alps' role as the European watershed is most apparent in the central Alpine region of Switzerland, where the different chains meet; from there, the Rhône River flows west, the Rhine River east, the Ticino River south, and the Reuss River north. The fundamental Alpine source point, however, is located in the Upper Engadine at Piz Lunghin, from which streams flow toward the North, the Adriatic, and the Black seas.

In the central Alpine region lies the Gotthard route, the first and shortest north–south passage through the mountains and an important European connection; it was opened around 1225 with the construction of a bridge in the Schöllenen Gorge. The gorge traverses the northern chain, while the southern range is crossed by the St. Gotthard Pass at an altitude of 6,916 feet. The 9.3-mile-long St. Gotthard Tunnel through the mass was opened in 1882.

Between the Jura and the main Alpine ranges lies the hilly Mittelland accounting for 30 percent of the country and enclosed by the two mountain ranges and the two largest lakes, Lake Geneva (Lac Léman) in the west and Lake Constance (Bodensee) in the east. The Mittelland, where the greatest part of the population is concentrated, supports Swiss economic life and guarantees the country's industrial and international importance. As a result, it is becoming highly urbanized, although even in urban Switzerland the feeling of security and rootedness remains alive, symbolized by the mountain peaks that can be seen on the horizon from every point on the plateau.

Climate. The waters may flow away from the Alps in all directions, but the climates of Europe converge upon the Swiss mountains. The Alps are essentially the dividing line between the different climates of central Europe, but Switzerland as a whole combines the four main European climatic types to form a single transitional climate, influenced on the west by the Atlantic climate, which is affected by the Gulf Stream; on the east by that of the eastern European continent; on the south by the Mediterranean climate; and on the north by the middle European cyclonal climate.

Wind systems. Prevailing winds are from the west, but, in the valleys, air currents are channelled into particularly frequent or violent local winds such as the Bise, the northeast wind characteristic of Geneva. The Föhn, a brisk south wind that occurs in the large transverse valleys of the northern Alps, makes it possible to grow sweet

chestnut, laurel, and tobacco on the northern slopes of the Alps.

Precipitation. Since rainfall tends to increase in direct proportion to altitude, the precipitation map corresponds very closely to the relief map; and, because of the marked variation in reliefs, differences in precipitation within short linear distances are often very great. For example, Sankt Gallen, at 2,180 feet, has an average annual precipitation of 52 inches (1,318 millimetres), while that of the Säntis, 8,200 feet but only 32 miles away, is 114 inches (2,904 millimetres). The average annual precipitation of three-quarters of the country exceeds 40 inches, varying amounts of which fall as snow, which, in turn, characterizes and explains the dense variety of weather phenomena. In the southern town of Lugano (905 feet), which has a Mediterranean climate, only 5 percent of the precipitation is in the form of snow; in Zürich (1,620 feet) 11 percent is snow; and on the Säntis 72 percent is snow. At altitudes above 11,500 feet, all precipitation consists of snow, which becomes impacted into perpetual snowfields and glaciers; the snow line is at about 9,200 feet in the northern Alps and at 10,800 feet in the southern Alps of the Valais.

Dry areas

In the mountains of the interior, distinct dry pockets occur, the most famous being the Rhône Valley in the Valais, closely encircled by the highest (13,000-foot) mountain groups. Precipitation is also slight on the slopes with southern exposure near the cantonal capital of Sion (1,800 feet), but extensive irrigation is possible since the area is surrounded by large snowfields and by glaciers that extend far down into the valleys. The rarefied, germ-free, and unexpectedly dry air of such high-altitude towns as Davos (5,121 feet) and Arosa (5,987 feet) permits a more intense, broader spectrum solar irradiation, thus producing a radiant climate long famous in tuberculosis cures. At altitudes of 13,000 feet, precipitation levels rise to 160 inches, and the Mönchsgrat (13,460 feet) in the Jungfrau group has the highest average annual precipitation (163 inches, or 4,141 millimetres) in Switzerland, while Stalden in the encircled Valais has the minimum (21 inches, or 530 millimetres).

Skies and temperatures. The stable high-pressure weather conditions prevailing over central Europe and the Alps during the winter create cold air masses that often are covered by thick, gray layers of fog, a climatic phenomenon with widely varying consequences. The mouths of the northern Alpine valleys, the basins of the Jura Mountains, and the villages and cities of the low areas of the Mittelland are blanketed with fog for days and, often, for weeks on end, while towns located at high altitudes enjoy warm, brilliant, high-pressure conditions and the view of the glistening sea of fog below them. Temperature inversions between mountain and valley locations in close proximity can be quite pronounced, with the higher point having the higher temperature reading. Frequent temperature inversion is a primary reason why high-altitude Swiss sanatoriums remain occupied even during the winter and why, in the present century, the Alpine winter season has gained popularity in Europe for sports as well as for health cures.

Avalanches

With the increase in winter tourism, the study of avalanches has developed as a branch of Alpine climatology, and during threatening weather the research station near Davos publishes daily avalanche bulletins, mainly as a warning for tourists. The Alpine cantons have about 10,000 avalanches annually, more than 8,000 of them in February, March, and April. For centuries, village communes have used *Bannwälder* ("protective forests") on the mountain slopes as protection from these slides, since a 20- to 30-year-old forest can usually stop avalanches. Costly artificial structures protect the villages, highways, and Alpine paths.

Vegetation and animal life. The vegetation is derived from that of the four European climatic regions converging in Switzerland and from the varied relief. It includes the beeches and oaks of the Atlantic west; hornbeam and larch trees in the more continental east, predominantly in the Engadine and the dry Valais; extensive spruce forests in the northern sub-Alpine region; and chestnut groves in the south. The vegetation boundaries are several hundred metres higher in the south than in the north because of the generally southern exposure.

Crop cultivation at high altitudes

The Alpine pastures of the Monte Rosa region reach an altitude of 10,800 feet, and until recently the highest Alpine grainfields, which have fallen victim to the decline in Alpine agriculture, lay above Zermatt at an altitude of 6,900 feet. The highest vineyard of central Europe, at an altitude of 3,900 feet, is still located near Visperterminen in the Valais, although the largest vineyards are on the southern-exposed shore of Lake Geneva, on the sunny slope of the Rhône valley, along lakes Neuchâtel and Biel at the foot of the Jura, and in the northern Alpine valley of the Rhine, which is affected by the Föhn. On the western Mittelland, a considerable grain-producing area has developed on the sheltered side of the Jura Mountains, an area of scanty rainfall, while in the more humid eastern region, mainly in the cantons of Thurgau and Sankt Gallen, grass cultivation is combined with fruit growing.

Swiss animal life is mainly Alpine, but a mixture of species familiar to southern and north central Europe is also found. Animal life is protected, except during a brief annual hunting season. The Alpine tourist may be pleasantly surprised by the sight of the marmot, which lives near the snow line, and the chamois; large herds of the proud ibex, which had died out in the Swiss Alps and has since been carefully re-introduced, have again developed in several areas, especially in the Bernina region of Graubünden (canton). In the forests there are rabbits, foxes, badgers, squirrels, and numerous varieties of birds, while the lake and river trout are especially famous. Snakes and lizards are concentrated in the south, but insects, in profuse variety, are diffused throughout the country.

Patterns of human settlement. The diversity of geomorphology, climate, and plant distribution in Switzerland provides a wide variety of bases for the formation of settlements, a variety further enhanced by the country's central European location. Switzerland supplies more varied material for the study of the geography of settlements than does any other European country. Even the types of houses vary from one region to another, especially well-known examples being those of the Engadine, the Ticino, the Bernese region, the Jura, and northeastern Switzerland. In atmosphere, too, there are distinct variations: the German-speaking cantons and large cities, such as Bern, Zürich, and Basel, express an earnest and stern efficiency, whereas in the west, especially in Geneva and the canton of Vaud, the Latin influence prevails and life becomes less thrifty and more graceful. In the south, the Ticinese enjoy a more luxuriant climate, and this, too, is perhaps reflected in an easier life-style.

Rural communities. The valleys are the residential areas of Switzerland. Alpine villages extending along the base of slopes are a characteristic sight. Since the extensive river diversions made chiefly during the second half of the 19th century, villages often have expanded into the valley plains, where intensive farming is carried on. The isolation of portions of many valleys, such as those of the Rheinwald, Poschiavino, and Urseren, by barriers of resistant rock or by prehistoric landslides was an impetus to the formation of communes and of the early *Alpgenossenschaften* ("Alpine cooperatives").

Self-sufficiency of the rural communes

The modern network of communes, small but politically important units, stands out in the parallel relief of the Jura and the Alps, since the communes are generally laid out with their boundaries drawn from one mountain crest to the next. Every commune has all the basic living requirements, including pasture, forest, fertile valley bottom, and water. Terraced slopes characterize the sites of villages that serve as bases for "Alpine nomadism," the seasonal moving of livestock to or from the mountains.

Some villages, such as Guarda in the lower Engadine, have a reputation for picturesque beauty, while others, such as Montana in the Valais or Wengen in the Bernese Oberland, have developed into famous resorts and spas. Valley forks, where the traffic from two valleys combines, are attractive sites for settlement, as are places in the Alps such as Amsteg (canton of Uri), Silvaplana (the

upper Engadine), and Gordola (near Locarno), where the entrance into an adjacent valley of higher altitude is made gradually. In the Mittelland, with its abundant lakes, delta villages are especially closely related to the environment; in recent decades villages have expanded toward each other and merged, creating population belts all along the lakes. Unfortunately, uncontrolled property speculation has permitted many characteristic, substantial village settlements to spread into the surrounding areas with very little architectural planning. The goals of local environmental protection are clashing with large-scale financial interests, a conflict that is becoming a matter of concern throughout Europe in the important case of Sankt Moritz (Graubünden).

Urban Switzerland. In the early 1970s, about 100 Swiss communities had more than 10,000 inhabitants and thus were classed as cities. Some had developed around monasteries, as did Sankt Gallen, or around Roman settlements, as in the case of Zürich; many developed from villages into market cities. Some, such as Fribourg (1157) and Bern (1191), were founded on a plan; their old sections, located within the protected areas formed by looped river bends, present a fascinating vision with their unified urban architecture. Each city is geographically unique, particularly those lying at the head of a lake, such as Zürich, Geneva, and Luzern, which were essentially harbour towns until the opening of the railroads (a status to some extent regained with the lakes' new importance to the tourist industry). A lake inlet, or the mouth of a river such as the Limmat, Rhône, or Reuss, and moraines and rings of mountains combine with the cities' houses and scenically situated cathedrals and minsters to form composite landscapes of nature and art. Many towns have sprung up around the site of a bridge; as a rule, these have two sections separated by the narrows of a river. Hill towns such as Regensberg and Gruyères, which were medieval fortified settlements with castles and the architecture of which developed through the late Gothic period, have a natural dominance that rather gives them the appearance of scenic ornaments, of crowns gleaming in the distance.

In Switzerland, isolated from Europe by mountainous barriers, location in relation to the traffic pattern has played an important role in urban development. Chur, Martigny, and Bellinzona are keys to a series of Alpine passes. Lugano, which, along with Locarno and Ascona, forms an extensive resort area benefitting from the abundant sunshine of the Mediterranean climate, is a gateway from the south to the Alpine region. Basel's location at the head of Rhine navigation has been of particular significance, since this was the basis of its early prominence as a city of scholars and of its present international importance as an industrial centre. Switzerland's eight largest cities in order of size in the early 1970s were Zürich, Basel, Geneva, Bern, Lausanne, Winterthur, Sankt Gallen, and Luzern.

THE PEOPLE OF SWITZERLAND

Etruscans, Raetians, Celts, Romans, and Germans have left their mark on Switzerland in the course of its historical evolution. The present population mainly shows traces of the Alpine, "Nordic," and southern Slav, or Dinaric, peoples. To survive as a cohesive unit, the disparate elements of the Swiss people have had to learn a mutual cooperation to protect the neutrality that has been their safeguard. Their outlook has been shaped largely by economic and political necessity, which has made them realistic, cautious, and prudent in accepting innovation and ingenious in the use of what resources they have. Their lives exhibit acumen, discipline, and thrift and a somewhat Germanic love of order and thoroughness allied with a Latin independence of spirit and an admiration for quality and craftsmanship that makes their products highly valued throughout the world.

Mixed character of the Swiss

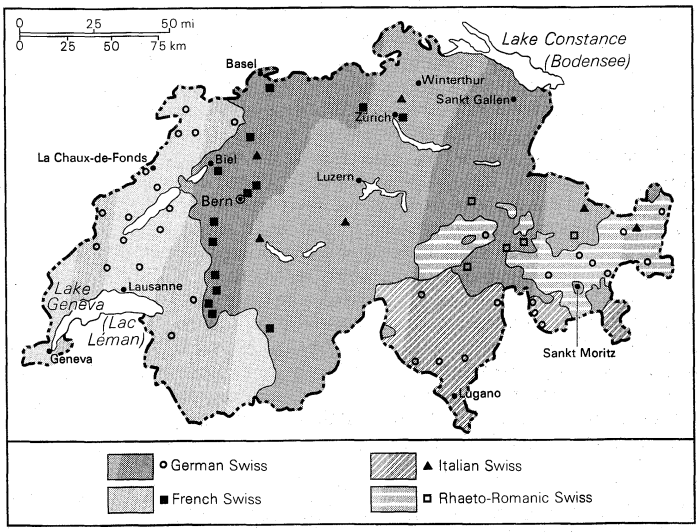
Bern. The prison tower (centre) is a remnant of the medieval city walls.



Ethnic composition of Switzerland.

Language and religion. One of the distinctive features of the Swiss Confederation is the variety of its languages. About two-thirds of the total population speak German, one-fifth French, one-tenth Italian, and 1 percent Rhaeto-Romanic. Switzerland encompasses the area in which the major cultural regions of western continental Europe—the German, the French, and the Italian—come into contact. Its fourth language, Rhaeto-Romanic, is a linguistic relic preserved amid the mountainous regions between the Gotthard and the East Alps; it is subdivided into even smaller dialect regions. In 1938, a federal popular vote indicative of Swiss sentiment recognized Romansh as a fourth official national language, which was tantamount to a political declaration in favour of federalist diversity and in opposition to centralized power.

Switzerland also exhibits diversity in the area of religion, although conflicts over faith are rare and there are even churches in which Protestants and Catholics worship together. The great internal population shift caused by industrialization has also resulted in a greater mixture of the religions. The Swiss are divided almost equally into Protestants and Catholics, with a tiny Jewish community. The constitution of 1874 guaranteed full religious liberty but repeated the 1848 constitution's prohibition of settlement by Jesuits (members of the Roman Catholic Society of Jesus) and their affiliated societies in Switzerland. Such discrimination had become a point of controversy by the early 1970s and seemed likely to be abandoned in any revision of the constitution.

Demography. The doubling of the Swiss population over 100 years, to 5,000,000 in 1955, contributed to considerable emigration, especially from the economically unproductive Alpine regions, to places such as the United States. Of the more than 300,000 Swiss residing in foreign countries in 1971, nearly one-half possessed dual citizenship. Switzerland has 393 inhabitants per square mile, a high density in view of the large proportion of the country occupied by high mountains; if density is calculated for only the permanently settled territory, it reaches 628 inhabitants per square mile. The population has increased by about 15 percent during the 1960s, and future planning projects the population at 7,500,000 in the year 2000, with some projections rising as high as 10,000,000. Between 1965 and 1970 the Swiss birth rate dropped from 18.8 to 15.8 per 1,000 inhabitants, while the death rate remained almost constant at 9.1, reducing the excess of births over deaths, and consequently the rate of natural increase.

Population shifts in Switzerland are highly complex. In the less mountainous cantons the population has increased greatly, rising in the half canton of Basel-Landschaft, for example, by 38 percent since 1960; some communities near Zürich have increased to an unwholesome extent, as much as 535 percent. In contrast, the figures reported by the mountain cantons remain unchanged, with Glarus reporting a 5 percent decrease. Hundreds of mountain communes reported population losses, which result from the decline of agriculture and the shift to an industrial economy. The business boom since 1950 has created a labour shortage in spite of the presence of almost 700,000 foreign workers in the country.

THE NATIONAL ECONOMY

The Swiss economy has been molded by several specific factors: a paucity of raw materials; the pressure of urbanization on the limited amount of cultivable land; precipitation, which to a large extent determines the type and size of cultivation; the advantage of being centrally located on international trade routes; scenic beauty; and the inability of the domestic market to absorb the total output of a skilled and efficient population. Factors shaping the economy

These factors have given rise to industries such as shipping, freighting, banking, and insurance and to export industries requiring skill rather than large imports of raw materials, resulting in high-value, small-bulk industries such as precision-instrument manufacture. An important consequence of the traditional Swiss neutrality has been economic stability even in times of European war.

Between 1888 and 1970 the percentage of the population involved in basic raw-materials production dropped from 37 percent to 8 percent; that involved in manufacturing rose from 41 to 48 percent; and that involved in the services sector rose from 22 to 44 percent.

Components of the economy. *Agriculture.* Agriculture, which employs perhaps 4 percent of the total population, is characterized by fodder crops and grazing, which occupy nearly one-half of the total area. Grain, occupying only 6 percent of productive land, satisfies barely one-half of the domestic demand. The variation in soil quality within small areas produced by geological conditions and by the relief makes large-scale, single-crop farming impossible; instead, a particularly varied assortment of crops is grown in a limited space. Two-thirds of all farms combine grass and grain cultivation. The Valais, with its abundant sunshine and artificial irrigation, specializes in cultivating fruits, vegetables, and berries. In the southernmost canton of Ticino, a mixed Mediterranean agriculture has been attained, although it is endangered by the disruptions of oversettlement. Viticulture characterizes slopes along many lakes.

The primary agricultural pursuit, however, is cattle raising, for which Switzerland has become important throughout Europe. The income from dairying and cattle raising amounts to about one-half of all agricultural income.

Since the importance of forest to the ecology of large areas was recognized early, an exemplary forestation law forbids reduction of woodlands, which amount to nearly one-quarter of the total area of the country. Forests have become a main feature of the recreational areas located near cities.

Industry. Switzerland's transformation into an industrial state began during the second half of the 19th century; now, some 90 percent of exports consist of manufactured goods and chemicals, with some companies exporting 97 percent of their production. Lacking its own mineral and agricultural raw materials, however, Switzerland is forced to import raw materials, foodstuffs, and manufactured goods by costly land routes; raw materials, food, vegetable oils, and fuel account for nearly 25 percent of the imports. Only the outstanding quality of its products, ranging from motors, generators, and turbines to the atomic clock, enables Switzerland to remain competitive. The operations of the first European factory to produce aluminum by electronic methods have remained a model for Europe. The chemical–pharmaceutical industry, centred in Basel, is also a prime competitor in world trade. The chemical industry alone spends great sums on research, and many other industries also collaborate with the country's seven universities and with the Federal Institutes of Technology at Zürich and Lausanne. Many large firms are merging under the pressure of international competition, although the typical Swiss traits of diver-

sity and division into small units still make it possible for firms in small towns and villages to continue to supply products of worldwide importance.

Hydroelectric power

Although Switzerland lacks mineral power sources to run its industries, the extensive Alpine precipitation, glacial water storage, and the great range of altitudes make hydroelectric power widely available. The electrical industry has become an essential branch of the Swiss economy as a whole, with 400 large hydroelectric power plants currently in operation and numerous low-pressure plants situated on the lower courses of the rivers in the Mittelland. Major electrotechnical progress has occurred in the Alps, where large systems of tunnels and subterranean powerhouses have been constructed in suitable valleys. The highest dams in Europe, Mauvoisin (777 feet) and Grande Dixence (932 feet), have been erected in the Valais, where, on the Rhône, the highest rate of hydroelectric power consumption in Europe has been attained. By 1971, 95 percent of the hydroelectric energy worth harnessing for power plants was utilized, and Switzerland had begun to operate thermal power plants. In addition, several nuclear power plants were in the planning stage, under construction, or already in operation.

International trade. Switzerland has trade relations with 80 countries and is outranked only by Belgium–Luxembourg in total per capita imports and exports among the trading nations of the world. Its most important trading partners are the Federal Republic of Germany, France, Italy, the United States, and Great Britain.

Banking and insurance. Its central location has been a vital factor in making Switzerland one of the most important of the world's financial centres, with 475 banks, in 1969, on its territory financing the enormous freight stream that flows through the country. In the same context a large industry has grown up, specializing in reinsurance.

Tourism. The deficit in the balance of trade is to a large extent covered by income from tourism. During the Middle Ages, healing spas such as Baden, Bad Pfäfers, Leukerbad, and Rheinfelden flourished, while mountain-pass hospices were the predecessors of Alpine hotels. Since World War II, travel has increased at an explosive rate: hotels, guesthouses, and high-altitude sanatoriums counted 16,800,000 overnight stays in 1951, a figure that more than doubled by 1970, with 23,000,000 additional overnight stays in vacation apartments, youth hostels, and on campgrounds. Of the tourists, about 80 percent come from European countries, one-half of these from Switzerland itself. In 1971 the tourist industry as a whole employed almost as many as were engaged in farming.

Management of the economy. The long-standing tradition of direct democracy and federalism in Switzerland and the country's heavy dependence on foreign trade have given rise to an equally traditional suspicion of state intervention and to strong and constant support for worldwide free trade. Apart from the post office, telegraph, telephone, and main railway network, all utilities are privately owned or municipal enterprises, in some cases subsidized by cantonal governments. Even the hydroelectric plants are owned by private companies under federal or cantonal grants.

Areas of governmental involvement and restraint

Taxation. In matters of taxation, federal regulations extend mainly to customs duties and sales and defense taxes. Income taxes are cantonal responsibilities, and rates are fixed by decision of the voters of communal or cantonal parliaments.

Trade unions. Employer–employee relations have generally been good in recent years. The more than 30 trade unions have a combined membership of over 900,000. The Swiss Federation of Trade Unions, with almost 450,000 members, has Social Democratic tendencies. Since the Depression of the early 1930s, the unions have gradually denounced the use of strikes as economic and political weapons, and disputes are usually settled by arbitration.

Contemporary policies and problems. Although the Swiss have tended to reject state intervention in their free market economy, since World War II such intervention has been unavoidable, particularly in relation to the labour market. The sustained boom of the 1950s and later, with its very low rate of inflation, was only possible because the Swiss labour market was augmented by large numbers of foreign workers. By the 1970s, every third worker in industry was a foreigner. Social tensions became unavoidable, particularly where foreigners threatened to displace the Swiss, and the government was forced to restrict the inflow, thus for the first time breaching the liberal doctrines of Swiss economic policy.

This restriction of an important factor in an otherwise fast-expanding economy intensified inflationary pressures. Contemporary policy thus was directed to the difficult job of damping down the expansionary forces. Just as centralized bureaucracy was distrusted at home, so, in relation to European integration, the Swiss, though seeking a special arrangement with the European Economic Community, preferred the first type of integration offered by the European Free Trade Association, of which Switzerland was already a member.

TRANSPORTATION

Control of the most important Alpine passes and the ancient routeway through the Mittelland between the Rhône, Rhine, and Danube waterways has given Switzerland a key position in European transit traffic. The main artery of European trans-Alpine traffic, the St. Gotthard route, runs through Swiss territory.

Roads. In 1960 construction of a national highway network 1,143 miles in length was begun at Lake Geneva. In 1964 the 3.6-mile motor tunnel under the Great St. Bernard Pass was opened and, in 1967, the 4.1-mile San Bernardino Tunnel, thus ensuring important north–south Alpine connections to traffic throughout the year. Work was also started on a St. Gotthard highway tunnel.

Railways. The large-scale technical undertakings of highway construction were preceded by those of the railway system, which has a total track length of 5,833 miles and includes 608 tunnels, among them the 12.3-mile Simplon Tunnel, the longest in the world, and the famous winding tunnels of the Gotthard railway, by means of which altitude differences between valley levels are overcome. The entire Swiss railway system has been electrified, thus saving the country from dependence on coal imports. The Swiss Federal Railways, which constitute over half of the system, are operated by the federal government, while the remainder, including the numerous mountain railways, is distributed among over 75 private railroads, partially owned by the cantons and municipalities. The Vitznau-Rigi-Bahn, the first cogwheel railway in the world, was built in 1871 by Nikolaus Riggenbach of Basel and achieved early fame. Automobiles have not displaced rail traffic: in 1970 the Swiss Federal Railways carried 104 percent more passengers than in 1938, as well as 235 percent more freight.

Shipping. In 1970 the Rhine harbours of Basel handled a record tonnage; 1969 figures were lower. Heating and motor fuels were the major items. Since World War II, Switzerland has also maintained its own small "oceangoing fleet" of 31 ships, with a total tonnage of 200,000 metric tons. The popularity of the steamers on Lake Geneva has never flagged since they were inaugurated in 1823. Regular summer services are provided on several lakes by more than 120 vessels, which include a few paddle-wheelers.

Airlines. Swissair ranks 20th in number of passengers (1969) among the world's commercial airlines. The largest airports are in Zürich–Kloten and Geneva. The total number of motor-powered planes in Switzerland is over 1,000—including helicopters, which play an increasingly important role in mountain rescue operations.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. The Swiss Confederation consists of almost 3,000 communes that, like the 22 cantons, are largely autonomous and that range in size from Bagnes, with an area of 110 square miles (282 square kilometres), to Rivaz, with an area of 0.1 square mile (0.3 square kilometre). From the multiplicity of small communal republics stems a special quality and,

paradoxically, a basis of the inner strength of the entire nation, for each citizen treasures and supports the freedom of the commune, a shared conviction that unites him with the rest of the population in a way that transcends differences of language and of party.

Constitutional bases of the confederation

The Swiss Confederation's main body of laws rests upon the Federal Constitution, adopted in 1848 and revised in 1874; its 123 articles established the rights and duties of the citizen and of the governing bodies. Although in the 1960s there were discussions throughout the population, in numerous professional associations and societies, and in the press concerning a proposed overall revision of the Federal Constitution, no future version was expected to deviate from the basic political concepts derived from the Bundesbrief (document of confederation) signed in 1291 by the three original cantons on Lake Lucerne.

The federal government supervises external and internal security, all transportation affairs, forestry, water conservation, and the like and deals with foreign policy and customs, the postal, telephone, and telegraph systems, the monetary system, and the military organization, as well as with the extensive social insurance programs. It may take steps to adjust the course of the economy and provides for uniform administration of justice in the areas of criminal and civil law.

The organizational units of the federation are the people and the states, or cantons, the Federal Assembly, the Federal Council, and the Federal Supreme Court. Legislative power resides in the bicameral Federal Assembly, comprising the National Council, with 200 deputies elected by a system of proportional representation, and the Council of States, in which each canton is represented by two deputies. The administrative Federal Council is a seven-member collegial board, an organization of equals with a rotating presidency, with each councillor presiding over a federal department. Supreme judicial power is vested in the Federal Supreme Court, the seat of which is in Lausanne (Vaud).

The Swiss Civil Code of 1912 has furnished a model for the administration of justice in many countries, and parts have been adopted verbatim. The difficult task of creating and preserving a uniform judicial system within so diverse a national structure has produced a number of great jurists and international law experts in Switzerland. Each canton elects and maintains its own magistracy for ordinary civil and criminal trials. Capital punishment was abolished by the unified federal penal code of 1937, except under circumstances of martial law, general mobilization, or war.

Sovereign power rests with the people, however, who vote on proposed legislation several times a year and elect representatives every four years. In 1971 a popular vote for the first time gave women the right to elect officials and to vote on issues of national concern.

The principal political parties are the Swiss Social Democratic Party, the Liberals, and the Conservative Christian Socialist Catholics, who in the 1967 election to the National Council won 51, 49, and 45 seats, respectively.

Security. *Police.* Police authority is generally exercised by the cantons, but larger communes also maintain police forces. A small federal police corps enforces special federal laws concerning such crimes as treason and forgery (mainly in collaboration with cantonal police).

Defense. In accordance with confederation neutrality, which dates back to the 16th century and in 1815 became international law, the army serves solely to preserve the independence of the country. Defense is based on a system of universal conscription under which every Swiss male is liable for military duty between the ages of 20 to 50 years and, for officers, to 55 years. The training of recruits is followed by eight annual three-week refresher courses and later by shorter supplementary courses. Swiss women may serve as volunteers in the Women's Auxiliary Force. The Swiss is the only soldier in the world who keeps his equipment, including arms and ammunition, at home and who performs his obligatory gunnery duty each year in civilian clothes, a manifestation of the extraordinary degree of trust between citizen and government.

The citizen army

The social milieu. *Education.* The 1874 constitution stipulates that each canton or half canton is sovereign in education, that elementary education is compulsory and free, and that all public schools must be state directed. The confederation financially assists public elementary schools, vocational training, and the cantonal universities, and, by regulating examinations for the professions, it also influences the curriculum of the secondary schools. The only institutions of higher education maintained by the confederation itself are the Federal Institutes of Technology at Zürich (founded 1855) and Lausanne (federalized 1969). The interior department in Bern administers education, and there is an education department in every canton.

The combination of Alpine scenery and the pedagogic reputation of the country of educational theorists Jean-Jacques Rousseau and J.H. Pestalozzi forms a common attraction, and approximately 10,000 students annually receive their schooling during a sojourn in healthful surroundings, thus combining the useful with the beautiful. In addition, more than 8,000 foreign students per semester attend the ten cantonal and federal institutes of higher education, where they comprise approximately 25 percent of the total number of students.

Social insurance. The law stipulates that assistance to the poor is primarily the concern of the family. Public welfare services were developed in a typically federalistic way: first in the communes, then in the cantons, and later in the confederation. Social insurances that were introduced by amendments to the federal constitution already existed in some communities. The most important was compulsory old-age insurance (introduced in 1948, extended in 1960 to cover chronic illness), which provides annuities and rent allowances to all men over 65, all women over 62, widows, orphans, and invalids; it is financed by contributions from every worker under 65 and his employer and by smaller contributions from the cantons and the confederation. The old age subsidy does not cover the cost of living: communes, cantons, and the confederation provide additional support for the destitute out of general revenues. Compensation for loss of earnings due to military service is similarly financed by contributions.

Federal-local interaction in public welfare

The national income. The national income has been increasing constantly since 1945. As extremely high individual incomes are rare, the repartition of the national income appears tolerably balanced. In spite of a growing inflation, the average income of a Swiss worker showed an increase in buying power of more than 30 percent in the 15 years after 1949.

Leisure. Surrounded as they are by scenic splendour and always within one-half-hour's journey of mountains, pastures, lakes, and rivers, the Swiss have become extremely sports conscious and have encouraged the growth of skiing, tobogganing, and mountaineering as tourist attractions. Other sports include Swiss-style wrestling, gymnastics, regular Sunday-morning shooting, Hornussen (a kind of Alpine baseball), tennis, golf, ice hockey, soccer, sailing, and swimming. The fishing is good in the lakes and rivers, and when the lakes freeze over, they are used for curling and even horse racing.

CULTURAL LIFE

Although Switzerland may not rank foremost among the centres of European culture, the country can yet boast an impressive list of contributors to the arts and sciences. Perhaps because their country has presented too fine a view with too little challenge, some of Switzerland's creative minds have chosen to live elsewhere. This has been especially true of architects. On the other hand, Switzerland's traditional neutrality and its laws of political asylum have made the country a magnet for many creative persons during times of unrest or war in Europe. The mid-19th century was such a period, as were the 1930s and 1940s, when the rise of Fascism caused a number of German and Austrian and Italian writers such as Thomas Mann, Stefan George, and Ignazio Silone to seek harbour in Switzerland.

If a "Swiss culture" can be spoken of in its broader

implications beyond the arts, distinctive French, Italian, and German cultural circles must be recognized, as well as a robust Rhaeto-Romanic culture. In a real sense the four parts of the country represent a definite resistance to levelling or homogenizing influences, political or cultural. In addition, Switzerland's geographical centrality in Europe can be seen reflected in the notion of *Helvetia mediatrix*—Switzerland the mediatress. The Swiss Henri Dunant, founder of the International Red Cross, lives on in the continued sense of many Swiss in a distinct mission of cultural union, a mission revealed not only in the foreign assistance programs toward self-help being carried out in several small and developing nations but also in the unusual number of literary translators within the country.

Architecture. The 12th-century Romanesque style found particularly rich expression in the cathedrals of Geneva, Basel, Lausanne, Sion, and Chur and in the many castles and fortresses; and the Gothic style was expressed in the cathedrals of Zug, Zürich, and Schaffhausen. But in the Renaissance period many architectural masters, especially from the Ticino, gave their talents to Italy: Antonio da Ponte built the Prisons near the Doge's Palace and the Rialto Bridge in Venice; Antonio Contino built Venice's Bridge of Sighs; Domenico Fontana (1543–1607) designed the whole of Lateran Palace, and the facade of St. John Lateran Church, and the Royal Palace in Naples; his nephew Carlo Maderno became architect to Pope Paul V; Francesco Borromini built San Carlino, the gallery of the Spada Palace, and the Filippini Monastery and modified the Falconieri and Barberini palaces; Carlo Fontana built the facade of San Marcello al Corso and the Montecitorio Palace; Baldassare Lenghena, from Maroggia, built the Church of Santa Maria de la Salute, the Rezzonico, Pesaro, and Widmann palaces, the Ospedaletto, and the interior of Scalzi. In a later period, G.B. Gilardi rebuilt the Kremlin in Moscow and his son Domenico the Moscow University and a number of the Soviet capital's palaces. In the 20th century Le Corbusier (Charles-Édouard Jeanneret) was one of the major creative forces behind the International school of architecture that dominated most building trends throughout the West.

Visual arts. The Protestantism of 16th-century Switzerland had a strongly inhibiting effect on Swiss painting and sculpture in general. The peculiar lack of either French or Italian Renaissance influence left Swiss artists in a limbo from which they showed signs of recovery only in modern times. Artists of international renown have included Alberto Giacometti and Paul Klee. The arts are championed by renowned museums not only in cities such as Basel, Zürich, and Genf but also in small towns such as Winterthur and Schaffausen, which pride themselves as cultural bastions far beyond the usual provincial standards.

Literature. In the field of literature, Switzerland has produced Jean-Jacques Rousseau, the historian and critic Jacob Burckhardt, Madame de Staël, whose home at Coppet became a centre of European literary life during the 18th century, Gottfried Keller, and Nobel Prize winners Hermann Hesse and Carl Spitteler. The contemporary dramatists Friedrich Dürrenmatt and Max Frisch have been widely produced outside Switzerland. By the great number of dialects in all the four languages, a living dialect literature is comprehensible. It is an expressive cultural characteristic of nearly each valley.

Music. Although Switzerland is not a leading musical nation, in the 20th century such composers as Arthur Honegger, Othmar Schoeck, and Frank Martin have gained international renown. An annual international music festival is held in Lucerne.

Science. Swiss men of science have included Paracelsus (Theophrastus Bombastus von Hohenheim), who in the 16th century brought chemistry into the field of medicine; the Bernoulli family of Basel, who made significant contributions to mathematics over three generations; the innovative mathematician Leonhard Euler; the naturalist and pioneer Alpine scholar Horace Bénédict de Saussure; and the Nobel Prize-winning chemist Alfred Werner. Zürich's Federal Institute of Technology has produced more Nobel Prize winners than any other scientific school in the world.

Folk arts. Since Switzerland remains largely a nation of small rural communities, folk arts have continued to flourish, although sometimes for the sake of the tourist industry. Survivals include yodelling, alphorn blowing, weaving, wood carving, and ceramics and metalwork.

Communications. Radio and television in Switzerland are largely noncommercial, but, because of the separate language channels, efforts are somewhat dissipated. Journalism is of a high standard, and the *Neue Züricher Zeitung* is regarded as one of the finest of the world's newspapers.

PROBLEMS AND PROSPECTS

Switzerland in the early 1970s continued to enjoy an economic boom. It was a member of the European Free Trade Association, the General Agreement on Tariffs and Trade, the Organization for Economic Cooperation and Development, and the United Nations Conference on Trade and Development. In addition, it participated in several other United Nations organizations, such as the Economic Commission for Europe and the UN Industrial Development Organization. With all this and a policy that advocated ultimate participation in a European common market, Switzerland still remained outside the European Economic Community (EEC). Stumbling blocks to entry included the country's traditional neutrality, the federalist and directly democratic political structure, the sensitivity of this small nation's specialized economy, and difficulties in maintaining its agriculture under the community's agricultural policy. Although negotiations were under way for the establishment of special relations with the EEC in 1972, it appeared that Switzerland might be entering a period of political and economic transition to fit it for closer association with its more powerful neighbours, who themselves hoped to emulate Swiss success in forging unity out of diversity. In 1972 a special arrangement with the EEC was concluded and signed in Brussels.

Relations with the European community of nations

Switzerland, History of

The frontiers of Switzerland have remained almost unchanged since 1815. This stability is relatively modern. The history of this area was for centuries that of a small part of the Holy Roman Empire; changes were frequent, and the emergence of a coherent community in the absence of a common race, language, or religion was long in doubt.

SWITZERLAND TO C. 1300

Before the Christian Era there were sporadic settlements of hunters, fishermen, agriculturalists, and armed warriors in caves along the rivers and occasionally on piles beside the lakes, much as elsewhere in the West. A Tène civilization was followed by growing numbers of Celts. By the time of Julius Caesar, Helvetia (as the region was then called) was known as strategically important to Rome, if only because of the Alpine passes. A Roman invading army asserted its superiority at Bibracte in 58 BC, and Roman colonies or garrisons followed at Nyon (Julia Equestris), Augst (Augusta Raurica), Avenches (Aventicum), and near Windisch (Vindonissa), bringing Roman ideas and civilization to the inhabitants.

North of the Rhine were the Germanic "barbarians." In AD 259 the Alemanni began to penetrate the Roman defensive barrier, and during the 5th and 6th centuries they had become permanent residents east of the Aar, with the less numerous Burgundians to the west of it.

These were followed by Ostrogoths, who were in transit only, and by Franks, whose rulers by 639 had secured recognition as kings, thus ensuring permanent connection with the France of the future. All these invaders were pagans; survivors of Roman converts to Christianity had practically disappeared by the 6th century, when missionaries like St. Columban and St. Gall arrived. Five rather inconvenient dioceses were set up—Chur, Sion, Basel, Constance, Lausanne—and Benedictine monasteries, forerunners of many more, were settled and endowed at St. Gall (modern Sankt Gallen), Zürich, Disentis, Romainmôtier, and elsewhere.

Arrival of missionaries

Such political authority as remained was exercised by the counts, who accepted the Frankish monarchs after Clovis as their overlords. Charlemagne crossed this remote corner of his empire more than once, but such unity as his reign implied was broken at the partition of Verdun (843). This left the land west of the Aar in the hands of Lothair, while that to the east was assigned to Louis the German. Thus, these separate influences, along with local devolution, were fused with the Latin traditions of the Roman Church to shape the future.

In the 10th century both Muslim and Magyar marauders reached Swiss territory, but in each case they were too far from their base to have anything more than nuisance value. By 1033 dynastic accident and deliberate policy had brought the whole of what is now Switzerland into the orbit of the Holy Roman emperor Conrad I, and it remained part of the empire until the end of the Middle Ages. With the re-establishment of imperial authority in the 11th century came conflict with the papacy. Switzerland was divided between the supporters of Emperor Henry IV and those of Pope Gregory VII. The Emperor was supported by the counts of Lenzburg, the bishops of Basel and Lausanne, and the abbot of St. Gall, while the Pope could rely on help from the counts of Rheinfelden, Toggenburg, Kyburg, and Zähringen. It was the counts who gained most. Switzerland was by now thoroughly feudalized. The dukes and counts exercised local jurisdiction practically unchecked. From their castles they dominated and also protected the peasants of the countryside, as did the great abbots and bishops also. Only in walled cities such as Basel, Zürich, Solothurn, Bern, and Schaffhausen was there hope of independence.

Its assertion came, however, not from thence but from the peasant communities of inaccessible mountain valleys, the members of which had learned economic cooperation to avert starvation and were determined to secure freedom from forced labour services or feudal payments in cash or kind.

Towns and dynasts. Many towns were deliberately set up by the ruling feudal families as centres of defense, trade, and administration, Bern most obviously so. Fribourg, Thun, Burgdorf, Laupen, and Morat illustrated the power and extent of the Zähringen dynasty, which died out in 1218. The Zähringen authority reverted in part to the emperor, from whom it had derived. The surviving families—Kyburg, Habsburg, and Savoy—pursued much the same policy of territorial aggrandizement. The Kyburgers, with great possessions in Thurgau and Aargau, came to an end in 1264; and after a struggle with the House of Savoy, Rudolf IV (later Rudolf I of Germany) of Habsburg obtained most of the Kyburger territory, thereby becoming the most powerful ruler with whom the Swiss were in contact. Rudolf was already in control of a sizable part of Alsace and of much of the route from the Rhine to Schwyz and Nidwalden, either as protector of the abbeys of Muri and Murbach or as representative of the emperor.

Foundation of towns

At about the same time, the opening of the St. Gotthard Pass greatly increased the value of the north–south route to Italy and therefore of the communities of Uri, Schwyz, and Unterwalden (Obwalden and Nidwalden). There the peasants had long enjoyed a large measure of freedom from the interference of any feudal overlord and had limited rights to choose their own magistrates, although "high justice" rested with the representative of the feudal lord. In 1231 the men of Uri became directly subject only to the distant Holy Roman emperor, with the right of appointing their own magistrate; and in 1240 Schwyz and Nidwalden obtained a similar privilege from the emperor Frederick II, the validity of which was promptly challenged by the Habsburg overlords. Such uncertainty as there was, however, was largely removed when Rudolf of Habsburg became German king in 1273. The crown meant that he could assert imperial rights in Uri and hereditary family claims in Schwyz and Unterwalden. The heart of Switzerland was at his mercy when he died on July 15, 1291.

The league of 1291. In 1291 Schwyz, Uri, and Nidwalden (Obwalden followed that December) formed the Everlasting League, a perpetual alliance for the settlement of disagreements among themselves by arbitration, for the punishment of crime, for resort to law rather than to violence, and for mutual defense. They would accept only natives as judges, and these must not have paid for their office. All this was confirmed by oath and by a sealed document, which marks the traditional inauguration of the Swiss Confederation (an even earlier union is clearly implied, but its exact nature is unknown).

The traditional inauguration of the Swiss Confederation

Rudolf's son, Albert I of Austria, who obtained the German crown in 1298, forced Zürich to abandon its attempt to be comprised within the union. The successive German rulers—Adolf of Nassau (reigned 1292–98), Albert of Austria (reigned 1298–1308), Henry VII of Luxembourg (reigned 1308–13, Holy Roman emperor 1312–13), and Louis IV the Bavarian (reigned 1314–47)—were far too busy elsewhere to intervene in Switzerland, although the Habsburgs relinquished none of their hereditary claims.

THE DEVELOPMENT OF THE SWISS CONFEDERATION FROM C. 1300 TO C. 1530

The struggle for independence and subsequent expansion. In 1314 the men of Schwyz attacked the abbey of Einsiedeln, which enjoyed the protection of Frederick III of Austria, who was challenging the claims of Louis the Bavarian to the empire. The Waldstätte (the three forest cantons, Uri, Schwyz, and Unterwalden) supported the latter claimant, and this led to an armed invasion by Leopold, Frederick's brother, in 1315.

Morgarten and the league of 1315. Ships from Luzern attacked Schwyz by water, and Unterwalden was threatened from Entlebuch. Meanwhile a force of mail-clad horsemen advanced toward Lake Egeri (Ägerisee). At Morgarten on November 15, 1315, their passage was blocked at a point where they were unable to charge and were vulnerable to boulders hurled from the mountain slopes, and the attackers were completely defeated. consolidate their gain, the three allies reaffirmed in a German document (December 9, 1315) their defensive alliance, rejected Habsburg rights, and agreed to make no separate peace. The Habsburgs agreed to a long truce, which lasted, with occasional intermissions, until the end of the century, neither side accepting any permanent renunciation of its claims.

Alliances with Luzern and Zürich

A notable advance was made on November 7, 1332, when Luzern entered into a perpetual alliance with Uri, Schwyz, and Unterwalden, while at the same time maintaining the Habsburg link. It was an alliance and not absorption, but it was advantageous to both sides.

Zürich and Bern. More important was a similar arrangement made with Zürich in 1351. Zürich had secured "immediate" status as a free imperial city in 1218, politically within the Habsburg orbit. It was a flourishing market and manufacturing centre with good defenses, where the nobles were depressed and the artisans were organized into craft guilds. In 1336 an internal revolution enabled the artisans to secure parity with the aristocrats and wealthy merchants; this, in practice, enabled the artisans to exercise supreme power. The dispossessed nobles returned to their castles or to neighbouring Rapperswil; they failed to regain power by a coup d'etat in 1350.

The Habsburgs failed to reduce Zürich to submission, and the city's alliance with Luzern and the three interior communities followed as a natural defensive measure (May 1, 1351). Zürich, besieged or threatened by Austria in 1351, 1352, and 1355, resisted at great expense.

Bern escaped Habsburg domination and Savoyard protection, and after 1218 it asserted its freedom as an imperial city and administrative centre. The predominating influence was military and patrician, not artisan, and accident and design enabled its governors to expand steadily over the neighbouring countryside. During the first half of the 14th century, Bern had sometimes been anti-Habsburg without any long-term commitments and had received help from the Waldstätte in successfully defending Laupen against a coalition including Fribourg and Austria in 1339. At other times—in 1342, 1351, 1352, and later—Bern enjoyed Habsburg friendship. For greater security, and to ensure that Unterwalden did not support hostile peasant movements, Bern agreed to a perpetual union with Uri, Schwyz, and Unterwalden in 1353, although this did not prevent Bernese–Habsburg cooperation when it was advantageous to both sides.

Expansion of the confederation. An unsuccessful attack on Solothurn by Rudolf II, count of Kyburg, in 1382 enabled Bern to secure Thun and Burgdorf. This meant direct collision with Leopold III of Tirol, who was opposed by a Swabian League (founded 1377) and by Zürich, Bern, Solothurn, and Zug. At the end of 1385 Luzern suddenly occupied the Habsburg-controlled areas of Rothenburg, Sempach, and the Entlebuch valley. Leopold replied by leading an army of some 4,000 feudal nobles to Sempach; there, on July 9, 1386, he was defeated and killed by a similar force from central Switzerland.

The Habsburgs still remained the lawful overlords of the small district of Glarus, where the inhabitants were anxious to imitate the successful moves toward independence of their immediate neighbours. They had supported Schwyz in 1323 and in 1351 had willingly allowed their land to be used as a base for confederate operations against the Austrian besiegers of Zürich. In June 1352 Glarus was admitted as a somewhat subordinate partner in the Swiss alliance, followed almost immediately by Zug. Both became subject to Austria in 1355; Zug was occupied by Schwyz in 1364 and remained under its protection after the Peace of Torberg in 1368. The men of Glarus occupied Windegg in July 1386; and in April 1388, unsupported by their neighbours, they met the Austrians at Näfels and won their freedom. Thereafter an independent Glarus was a member of the union. Bern characteristically took advantage of the Austrian embarrassment to secure Büren, Nidau, and Olten. After Näfels, the Swiss Confederation was a fact of history; and the eight states—Uri, Schwyz, Unterwalden, Zug, Luzern, Glarus, Bern, and Zürich—had to learn the lessons of cooperation.

The eight-state confederation

In 1370 all these except Glarus and Bern faced the demand from their ecclesiastics for exemption from taxation and military service. This, when war threatened, was unacceptable, and the states agreed by the Priests' Charter (Pfaffenbrief, October 1370) that clergy and laity alike were subject to the same laws; unauthorized commando expeditions were also prohibited, and, in certain cases, the contracting powers agreed to abide by a majority vote. Military success led to an agreement about laws of war in 1393 by eight signatories, including Bern and Solothurn—looting was to be controlled; women, children, and clerical property were protected; and deserters were repudiated by all.

Switzerland in the 15th and early 16th centuries. With the 15th century came an interval of peace, consolidation, and expansion. Zürich, stronger and wealthier, came to terms with its Habsburg neighbour while adding to its own territory, and Bern expanded to the east and west. The central states recognized that security meant expansion southward as the St. Gotthard route became increasingly used. Glarus opened talks with its southern neighbour, the Upper, or Grey, Confederation. There the bishop of Chur, the abbot of Disentis, and the local barons, Misox and Räzüns, accepted the existence of peasant leagues; thus the Grisons (valley area that included the city of Chur) became almost a Switzerland in miniature on the southern and eastern wings of the confederation.

Around the monastery of St. Gall a flourishing trading city had grown; and as the economic importance of the monastery declined in spite of its wide possessions, tension grew between city and abbot. The citizens found allies in the communities of Appenzell, over which the monastery claimed jurisdiction. The abbot sought help from the Austrians in the Rheintal, to which the Appenzellers replied by an alliance with Schwyz. In 1403 a monastic army was defeated, whereupon the abbot sought and obtained the support of Duke Frederick IV of Austria. Schwyz was bound by treaty to keep clear of such a conflict, but the citizen army of St. Gall beat off one attack and the Appenzellers another in June 1405. After this Appenzell was accepted as an ally by seven confederate states, excluding only Bern.

Alliance with Appenzell

First Italian conquests. In the south the men of Uri were becoming anxious about the security of their communications with northern Italy. The inhabitants of the Leventina (the narrow valley of the upper Ticino River) appealed for help and protection and so, in 1403, became subject to Uri and Obwalden (western Unterwalden); Bellinzona was purchased by Uri but was retaken by Milan in 1422. Uri and Unterwalden appealed for help from their partners. Zürich and Bern took no action, but Luzern and Zug cooperated and Schwyz sent a force toward Domodossola. All these forces joined at Arbedo, where on June 30, 1422, they were surprised and defeated.

The southern expeditions also made contact with Valais, part of which was controlled from Savoy and part ruled by the bishop of Sion. The latter in 1403 made an alliance with Uri, Unterwalden, and Luzern, which only increased internal dissensions.

Conquest of the Aargau and the Old Zürich War. A dispute in 1415 between Duke Frederick IV of Austria and the emperor Sigismund provided the confederates with a pretext to attack the Habsburg possessions south of the Rhine. A Bernese force occupied the Aargau, Zofingen falling in April 1415; a Luzern contingent occupied Sursee and St. Urban; and Zürich made similar gains. Sigismund was forced to pledge part of Aargau to Zürich and Bern—the former taking the portion of the Freiamt east of the Reuss, Bern securing the western half, with pickings left for Luzern. The remainder of the land became a "common lordship" (*gemeine Herrschaft*) of the confederation. This was to cause infinite trouble later, but it was also to prove part of the cement that held the confederation together.

In 1436 Frederick VII, count of Toggenburg and owner of Uznach, Sargans, Gaster, Rheineck, Altstätten, and Feldkirch, died childless. Schwyz and Zürich quarrelled over the partition of the inheritance, and war followed. Unsuccessful, in 1442 Zürich made an alliance with the Habsburg emperor Frederick III and in 1443 was at war with the whole confederation. The city was besieged; its *Bürgermeister* fell in an unsuccessful sortie at St. Jakob an der Sihl (1443) after negotiations for an armistice had broken down and the garrison of Greifensee had been liquidated. In 1444 Frederick III secured support from Charles VII of France, who sent a large force of irregulars to the neighbourhood of Basel. There, at St. Jakob an der Birs, this great army was halted by a Swiss detachment one-tenth its size, which fought until only a few wounded remained (August 26, 1444). The French mercenaries were unprepared for further such encounters, and they left for Alsace (thereafter France sought Swiss friendship rather than face hostility, and the already high reputation of Swiss fighters was enhanced). France made peace at Ensisheim (October 1444) with the confederation (minus Zürich, but with Basel and Solothurn added). This implied recognition, and it was followed in June 1446 by the Peace of Constance between Zürich and the confederates on the basis of a return to prewar frontiers, with Schwyz slightly advantaged and Austria excluded south of the Rhine.

Recognition by France

St. Gall and Thurgau. In August 1451 the abbot of St. Gall entered into a protective agreement with Zürich, Luzern, Schwyz, and Glarus; the city of St. Gall did likewise but added Zug and Bern. Appenzell and Schaffhausen obtained similar support in 1454. Fribourg secured complete independence from Austria in 1452 and assurance of support from Bern. The Swiss seized Thurgau from Sigismund of Tirol, cousin of the Habsburg emperor, in 1460–61. Like Aargau, it became a common lordship. This successful aggression was accompanied by economic advance and a growing degree of comfort and good living, to which the profits of mercenary military service contributed.

Bern gained the leadership that Zürich had sacrificed in its vain attempt to secure the Toggenburg inheritance, and Bernese hegemony was enhanced by the successful absorption of its feudal nobility into the government.

In 1466, with Bernese influence preponderant in the Aargau, Mülhausen (Alsace) secured its alliance. Support for Mülhausen involved hostility toward the Habsburgs and a general Swiss attack on the Sundgau and Waldshut. By the peace terms of 1468, Mülhausen remained independent and Waldshut was pledged as a guarantee of the payment of a war indemnity of 10,000 gulden by Sigismund of Austria. This was repaid when Charles the Bold of Burgundy lent Sigismund 50,000 gulden and took over Austrian rights in Alsace and the Black Forest as security.

The Burgundian War. Out of these events developed the Burgundian War. Bernese policy was largely shaped by the soldier Adrian von Bubenberg and by his rival, the capitalist politician Niklaus von Diesbach, who was also influential at the court of Louis XI of France. Charles of Burgundy used his rights under the Truce of Saint-Omer to overrun Alsace and threaten Mülhausen in 1470; as a result Louis XI secured a guarantee of Swiss neutrality in the event of a Burgundian attack on France. In 1474 the Swiss were persuaded to extend this neutrality to Sigismund of Austria by the Treaty of Constance, which was followed by Sigismund's denunciation of his concessions to Burgundy.

The execution at Breisach of Charles's representative made a Burgundian threat to the whole of Sigismund's possessions a certainty; the Swiss obtained a promise of financial support from Louis XI and in October 1474 opened hostilities against the Burgundian duke and his ally, Savoy. In March 1476 a Burgundian army was defeated by a Swiss force at Grandson, and rich booty was taken; the Burgundians answered by advancing against Morat. A large Swiss force from every state of the confederation accepted this challenge, relieved Morat, and defeated the enemy in the open field (June 22, 1476). This was the high-water mark of Swiss power; any army in Europe could now be met on at least equal terms. The final demonstration came at Nancy, where Charles the Bold was defeated and slain in January 1477. Had the confederates been able to agree on a common foreign policy, the whole of Franche-Comté could easily have been secured and much of Alsace as well.

High point of Swiss power

Divisions and reconciliation. Instead there was disunion: Zürich refused to support a Bernese "western" expansionist policy; the farmers of Bern, Zürich, and Luzern opposed their own governments; the inner Swiss states resisted any centralization or expansion of the federal union; and everywhere young men willingly sold themselves into service as mercenary soldiers. Civil war was averted by the hermit-saint Niklaus von Flüe (Bruder Klaus); and by the Agreement of Stans (December

1481), Fribourg and Solothurn were admitted to the confederation, now enlarged to ten states. All would help one another to repress any internal opposition.

Diesbach of Bern died in 1475, and his place as the leading Swiss notable was taken unworthily by Hans Waldmann (1436–89), a Zürich millionaire adventurer and dictator, with a policy of civic protection and domination over the agriculturalists, including the central states. Waldmann was deposed and executed in 1489, but the Swiss advance to great power status had been checked at a critical juncture, and the harmony of Bern and Zürich, on which so much depended, had been broken.

In 1499 the emperor Maximilian I, in pursuit of impractical ideals of an efficient and solvent empire, attempted to force imperial jurisdiction and taxation on his Swiss subjects. The result was resistance, leading to the Swabian War; the outcome was a double defeat for the Emperor—at Calven (May 1499) and at Dornach (July 1499). By the Peace of Basel that followed on September 22, the practical independence of the Swiss was assured and Basel (1501) and Schaffhausen (1501) were admitted to the confederation (further evidence that all south of the Rhine repudiated Habsburg overlordship).

The Italian campaigns. With the opening of the 16th century the "Old Confederation," completed by the admission of Appenzell in 1513, faced external conditions that transformed its international position. France had been united under an almost absolute hereditary monarch; the emperor after 1519 was ruler of Spain and much of Italy as well as of the German-Austrian Habsburg territories; the Italian states, which had given intellectual leadership to the West, were no longer able to keep out the "foreigner"; and the papacy, conscious of the danger from the infidel Muslims, could not even eliminate heresy within the Christian Church.

Changes in the Swiss international position

French invasions of Italy, and particularly claims of the French kings Louis XII and Francis I to the Duchy of Milan, affected the Swiss directly. Some 5,000 paid Swiss soldiers helped Louis enter Milan in 1499. Swiss armed men were found both with and against the French at Novara in 1500; their refusal to fight one another led to French control of Milan. Three years later, at Arona, the French reluctantly recognized the fact of Swiss occupation of Bellinzona; but already there was growing opposition to mercenary service and its implications.

The next important paymaster of Swiss troops was the warrior-pope Julius II. In 1510 he brought the confederation, together with Valais, into an agreement to support the Pope (and Maximilian) against Venice. The murder of two Swiss envoys at Locarno was the pretext for sending a Swiss force against the French in northern Italy in 1511, in a raid that reached Milan. In 1512, in conjunction with Venice, a large Swiss army occupied Verona, Pavia, and Milan; the French were again forced to leave, and the Swiss could have been masters of the duchy had political conditions made this feasible. Accepted as allies by Savoy and as "Protector of the freedom of the church" by the Pope, the Swiss had to face yet another French force, again at Novara (June 1513), of which they regained possession.

In 1515 Francis I purchased much Swiss goodwill, and on his invasion of Piedmont in 1515 many of the Swiss soldiers occupying northern Italy agreed to return home. The others, perhaps 20,000 strong, met the invaders at Marignano (September 13–14, 1515) and were driven back decisively after heavy fighting with serious losses. French artillery, and the arrival of Venetian reinforcements, may have been the effective instruments in this (but it meant that the day of Swiss invincible infantry was over, although this was not yet apparent). France also gained a treaty of Perpetual Peace in November 1516, whereby in return for money and economic advantages the Swiss renounced any claims on Milan but retained Bellinzona, Lugano, Locarno, and the Valtellina. Included in the expeditions to Pavia and to Marignano were men from Glarus accompanied by their chaplain, the Catholic priest Huldrych Zwingli (1484–1531).

The Reformation. The condition of the church in Switzerland was no better than elsewhere in western Europe. A poor population supported many privileged clergy, who were often inadequately educated and sometimes negligent in their duties. The many monasteries were wealthy but not popular, and the bishops saw no need for change in the parishes. Religion consisted largely of routine duties, attendance at mass, confession, rituals, and the performance of many external acts of piety. Clerical concubinage was widespread and tolerated by the authorities.

Condition of the church in Switzerland

The popes were paymasters of Swiss soldiers, who formed their bodyguard and served in the papal armies; but enthusiasm waned when payment was lacking or when the service demanded was too strenuous.

Huldrych Zwingli. The impact of the Reformation on Switzerland was felt more in the cities than in the countryside, and it was associated with the names of Erasmus, Zwingli, and Luther. Erasmus had been critical of worldly popes, ignorant friars, complacent monks, and petty abuses, while being careful not to cross the bounds of orthodoxy; he felt that, by the study of the Fathers and of the Bible, the Christian Church could return to the simplicity and excellence of its earliest days. Luther publicly attacked the sale of indulgences in 1517.

Zwingli likewise had turned to Bible study, including Hebrew, and had anticipated Luther in rejection of traditional doctrine where it seemed to conflict with Holy Writ. At the same time, Zwingli was actively concerned, as a patriotic confederate, with the ill effects of mercenary service and the consequential pensions paid to leading politicians by foreign powers. In 1518 he was elected by the canons of the Zürich Great Minster as their stipendiary priest (*Leutpriester*). From 1522 he developed his independent thought into a challenge to the church authorities, first on the question of compulsory abstention from meat eating during Lent, then about clerical marriage—his own marriage was not publicly admitted until 1524—and then to an attack upon the mass as a sacrifice. He defended his views in public debates in Zürich in January and October 1523, which led to making evangelical preaching compulsory and to the rejection of pilgrimages, relics, images, pictures, church organs, and the sale of indulgences.

Zwingli's reforms

The appeal to the Bible as the sole guide to doctrine and observance involved a clash with the Anabaptists, who in 1524 insisted that infant baptism was unbiblical and who called for an independent, locally based church instead of the all-embracing state church of the Zwinglians. They regarded tithes, interest, oaths, military service, and capital punishment as unacceptable and, in turn, were themselves unreasonably feared as antisocial revolutionaries. After a third public debate in Zürich in 1525, they were outlawed.

Other states followed the example of Zürich, the decisive action in every case being the substitution of a commemorative communion service for the Roman mass. Attendance at the Catholic mass was made illegal in Zürich in April 1525, an example followed later by the city of St. Gall and by Schaffhausen, Glarus, Appenzell, Basel, and Bern. Reform was accompanied by the dissolution, often by agreement, of the monasteries, their revenues being used for education and poor relief in some cases, for normal public expenditure in others. The acceptance of the Reformation in Basel was the result of a popular demonstration, itself a protest against the conservatism of a patrician oligarchy, and of the effective preaching, discussion, and writing of John Oecolampadius.

Zwingli's greatest triumph was to secure the adhesion of Bern to his teaching at a well-managed public discussion in January 1528. A Catholic attempt to demonstrate the errors of their opponents at the Baden disputation (1526), at which Zwingli was not present, was followed by efforts to eliminate "heresy" from the confederation. Bern refused to yield to this pressure; there was much sympathy for Zwingli's attack on pensions and mercenary service, and the moral and intellectual condition of the Bernese clergy was deplorable. In 1527 Bern's government accepted married clergy, freedom of evangelical preaching, and control of monastic property, and it finally agreed that the case for and against the older and

newer beliefs should be settled by public discussion. At this debate the Zwinglian triumph was both apparent and far-reaching; images and the mass were rejected, and Bern remained exclusively Protestant until the end of the 18th century. There was a minor revolt of the conservative peasants of the Bernese Oberland, which served only to stiffen the determination of the government to maintain religious uniformity.

Problem of jurisdiction over the common lordships

The spread of the Reformation in the common lordships of Aargau, Thurgau, and neighbouring areas provided a problem of jurisdiction that could only be settled by force. The inner Catholic states—Luzern, Uri, Schwyz, Unterwalden, and Zug—obtained an alliance with Ferdinand II of Austria, brother of the emperor Charles V, which was countered by a Protestant Civic Union that included Constance and Strassburg. When the Catholics made it clear that there would be no freedom for preaching the gospel in lands in which they shared authority, Zürich prepared for war. Zwingli tried unsuccessfully to form a Protestant union, of which Philip of Hesse would be the leading member. Although Philip brought Luther and Zwingli face to face at Marburg (September–October 1529), no full agreement was possible about the presence of Christ in the bread and wine of the Holy Communion.

An armed conflict between Zürich and the five inner Catholic states was soon terminated. The Peace of Kappel that followed in June 1529 suggested some toleration in the common lordships, but this was acceptable to neither side in practice. The alliance with Austria was torn up, but this, too, had little practical effect. The prince abbot of St. Gall was refused recognition, and his subjects were encouraged to revolt as well as to apostasy. A threat by a robber baron from the castle of Musso was represented as part of a renewed Catholic plot against the evangelicals; and the failure of Unterwalden to keep promises to Bern enabled Zürich to prevent indispensable supplies of grain and salt from reaching the inner Catholics and then to threaten coercion by force of arms. The second Kappel War brought the defeat and death of Zwingli (October 11, 1531) at Kappel and another defeat, also involving Bern, at Gubel (October 22, 1531).

By the second Peace of Kappel (November 1531), Zürich, Bern, Basel, Schaffhausen, and some other states remained Protestant but unable to advance their cause further; the abbot of St. Gall was restored and imposed his faith on his dominions; and the communities of the common lordships lost their right of future local religious option. Heinrich Bullinger (1504–75) replaced Zwingli as the chief minister of Zürich, but he had none of Zwingli's political influence. Bern turned to defend its southern borders from Savoy and Catholic Valais, which led to its occupation of Vaud (now a canton in southwestern Switzerland) and direct contact with Geneva.

Direct contact between Bern and Geneva

Geneva (Genève), which did not become part of the confederation until 1815, could escape domination by Savoy only by reliance upon Bern, which in turn needed for its security to control the territory, including Lausanne, as far as Lake Geneva. Guillaume Farel (1489–1565) after 1527 evangelized much of Vaud as far as Aigle but met with obstruction in Geneva, which, along with Lausanne, had secured an alliance with Bern and Fribourg. To protect their interests and the achievement of the Reformers, Bernese troops appeared outside Geneva in 1530, forcing the Duke of Savoy to pledge Vaud for security and to allow the gospel to be preached. In 1535 the mass was abolished in Geneva; and in 1536, to prevent a French occupation, a Bernese force easily overran Vaud. The territory on both sides of Lake Geneva was incorporated into the Bernese possessions, and Zwinglian worship was accepted everywhere.

John Calvin. John Calvin (1509–64; *q.v.*), already a distinguished French Humanist, had abandoned the Catholic faith and in 1536 issued from Basel his *Institutes of the Christian Religion*. As Calvin passed through Geneva in 1536, Farel, who was finding his pastoral duties there beyond his powers, called on him to stay. Calvin became, even more than Zwingli at Zürich, the dominant influence in Genevan affairs. His political opponents were driven underground; and the freethinker Jacques Gruet and the Unitarian Michael Servetus were put to death. Calvin's system and doctrine were similar, but not identical, to those of Zwingli; but in 1566 they were reconciled by the Second Helvetic Confession. A Presbyterian church with complete local autonomy for the congregations, with ministers, doctors, elders, and deacons, became a model for others to follow. Geneva's application for admission to the confederation was rejected; the danger from Savoy was continued, and as late as 1602 an attack (the "Escalade") was beaten off with difficulty. Thus Geneva was in many ways a besieged fortress, and it submitted to the requirements of a mixed lay and clerical consistory the more willingly for this reason. Its alliance with Bern and the determination of the French that Geneva should not be Savoyard enabled the city to become an intellectual centre and a haven for refugees until the French Revolution.

THE CONFEDERATION SINCE C. 1530

The Counter-Reformation and the Valtellina. While Calvin was preaching in Geneva, the Catholic Church belatedly set its house in order at the Council of Trent (1545–63). The reforms were welcomed by the Catholic cantons of Luzern, Uri, Schwyz, Unterwalden, Zug, Fribourg, and Solothurn, while Glarus and Appenzell remained with divided allegiance. The inner cantons insisted on the expulsion of the Protestant families from Locarno (1555); many of these found refuge in Zürich, where they contributed valuably to its industrial development, particularly in silk. The Jesuits established a school in Luzern in 1577, and a permanent resident papal nuncio was received there from 1596.

Reinforcement of the Catholic cause

Preachers from Geneva encouraged the French Huguenots to resist, and Catholic Swiss mercenaries fought against them. Numerous French Protestants found refuge in Switzerland after the massacre of St. Bartholomew (August 23–24, 1572). Ludwig Pfyffer of Luzern not only supported the Catholic "Holy League" against Henry of Navarre (later Henry IV) but also united the five inner states with Fribourg in a "Golden League" with Spain (1586), one result of which was the permanent division of Appenzell into two separate half cantons. The accession of Henry IV as king of France (1589) prevented civil war in Switzerland, where 12 cantons (Zürich not included) renewed the league with France in 1602, again allowing French recruitment of soldiers.

A Switzerland of about 1,250,000 inhabitants, divided by religion, laws, language, and economic interests, could no longer play an independent role in 17th-century Europe. Geneva, however, was saved from either Savoyard or French domination; and, even more significantly, the Grisons maintained their position as a valued ally of the confederation. There were three leagues—the League of God's House and the League of the Ten Jurisdictions (both Reformed) and the Grey League (Catholic)—which were threatened by Milan and Venice from the south and by the Habsburgs of Vorarlberg and the Tirol from the east. Internally, much power lay with the great local families, such as the Planta, traditionally pro-Spanish, and the Salis, supported by France and Venice.

An attempt by Venice in 1603 to gain economic advantage and control of the passes leading to the Austrian territories led to a Spanish–Milanese counterattack. The result was internal discord in the Grisons, which continued for a quarter of a century. The leader of the Protestant party in the Grisons, supported by Venice and France, was Georg Jenatsch (1596–1639), who was confronted in 1620 with a massacre of some 500 leading Protestants in the Valtellina. Bern and Zürich offered military aid to Jenatsch, but the inner cantons prevented it from arriving, and the Valtellina was left open to Spanish domination.

Jenatsch, after some preliminary successes, was forced into exile. He returned in 1624 with a French army sent by Cardinal de Richelieu to regain control of the invaded territory but not to restore the Reformed faith there. Jenatsch consequently changed sides and was murdered in January 1639 by conspirators.

Swiss neutrality

The Thirty Years' War. Switzerland's neutrality during the Thirty Years' War was the outcome of its religious and economic divisions rather than of conscious policy; although the value of a Swiss infantry army was diminished by 1618, it was still not negligible. At first the Habsburgs seemed likely to win, which might have had serious implications for eastern Switzerland; but by good management official neutrality was observed, although a number of individuals volunteered for military service with either side, and war needs brought profit to Swiss traders. The threat of invasion made agreement between the 13 Swiss cantons highly desirable, and all the more so because of the need to provide for the administration of the common lordships. The independence of each of the 13, with their allies—the cities of St. Gall, Mülhausen, and Biel (Bienne) and the abbot of St. Gall—was, however, fully recognized.

In 1631–32 Gustavus II Adolphus of Sweden narrowly failed to secure an alliance with the Swiss and insisted upon a stricter observance of neutrality; in September 1632 a Bernese force on its way to help allied Mülhausen was attacked in Solothurn, but further hostilities were avoided by mediation. In September 1633, perhaps because of deliberate negligence by Zürich, Swedish forces entered Stein am Rhein intending to attack the imperialists at Constance but retreated; and again, after much trouble, the situation was adjusted without bloodshed. A parallel episode involving Basel led in 1647 to an agreement for common Swiss defensive measures—the Defensionale of Wyl, which marked a further stage in common Swiss action.

The long negotiations that resulted in the Peace of Westphalia (1648), ending the Thirty Years' War, owed a good deal to the efforts of the representative of Basel—*Bürgermeister* Johann Rudolf Wettstein. In October 1647 he succeeded in obtaining a declaration from the Emperor that the city of Basel and the 13 cantons, with their allies and common lordships, were not subject to imperial jurisdiction. This was written into the final treaty and became part of the public law of Europe.

The Villmergen wars. Difference of religion after 1648 helped the relative stability that characterized 18th-century Switzerland. The Protestant cantons were wealthier and more thickly populated than their Catholic neighbours; but in the Diet they were in a minority, and no agreed alteration in the constitution of the confederation was possible. Internally, power rested in the hands of a relatively small number of patrician families; in Bern, Fribourg, Solothurn, Luzern, Basel, and even Zürich the aristocrats dominated the ruling councils and retained for their members power and the emoluments of office.

The gulf between nobles and peasants

The common people, in general, meekly accepted the religion and the legislation of their superiors. There was, however, a gulf between nobles and peasants; and after 1648 an economic recession helped to intensify the objections of the farmers to paying taxes and dues for the defense and support of the walled towns. Each canton had its own coinage, and in some of them tension was increased by attempts to replace a depreciated currency.

Open trouble started in 1653 with a demand from the Entlebuch farmers for better treatment by Luzern, closer consultation, more legal autonomy, a more satisfactory currency, and relief from a hated salt tax. The government obtained promises of help from neighbouring cantons and made a few concessions, and the trouble died down. But the example, once set, was more widely followed; and a general claim from the peasantry for greater attention led to a gathering at Huttwil (May 1653) and an uprising against Bern, which was easily suppressed, its leaders being punished.

In 1656, after the forcible expulsion of a harmless Protestant community from Arth, fighting took place with the five Catholic cantons against Zürich and Bern. In a battle at Villmergen (January 24, 1656) Bernese forces were defeated; meanwhile, forces from Zürich failed to capture Rapperswil. At the Third Land Peace of Baden, which followed, the right of each canton to enforce religious unity was reasserted. After incidents at Wigoltingen in 1664, Wartau in 1694, and St. Gall in 1697, peace was openly broken in 1712 because the aggressive abbot of St. Gall, Leodegar Bürgisser, had promoted the construction of a highway from Wattwil to Uznach that could be to the disadvantage of the Protestants in the Toggenburg. Bern and Zürich used this as a pretext to occupy most of Aargau, Thurgau, Rheintal, and Toggenburg. Attempts at a compromise failed; there was a serious fight at Villmergen (July 25, 1712), won by Bernese discipline, after which the Peace of Aargau (August 11, 1712) agreed that Protestants and Catholics should enjoy equal rights in the common lordships, repealed the clauses of the second Peace of Kappel (1531), and left the balance of power in the confederation in Protestant hands.

Louis XIV of France did not intervene directly. There had long been a standing agreement allowing Swiss soldiers to serve for pay with the French. This Franco-Swiss alliance had been renewed in September 1663, complete with pensions, arrangements for payments of recruits, and other advantages. But the French occupation of Franche-Comté (1668) and the revocation (1685) of the Edict of Nantes, which had granted religious liberty to the Huguenots, were resented. The Defensionale of Wyl was refurbished in 1668, and in 1674 the Swiss Diet publicly proclaimed its neutrality in continental disputes. French occupation of Strassburg was accepted as inevitable, and Basel itself was constantly watched by a French garrison in Hüningen. Following diplomatic moves by Bern and Zürich at the French court in 1687, French pressure on Geneva was removed and Swiss soldiers were permitted to serve in British and Dutch regiments if needed (a secret agreement by the Catholics in 1715 to serve France only—the "Trücklibund"—had no binding validity).

Relations with France

The death of the Duchess of Nemours, Princess of Neuchâtel (Neuenburg), in 1707 enabled Bern to arrange for the inheritance to pass to the Protestant King Frederick I of Prussia, but not without objections then and repercussions later.

The 18th century. From 1712 to 1798 Swiss neutrality was fully respected—the 18th century wars passed Switzerland by. The country remained predominantly pastoral and agricultural, poor, and little visited by foreigners for pleasure; it was around the cities of Basel, Zürich, and St. Gall that home industries flourished. Adequate capital and relatively cheap labour were available; weaving in linen, cotton, and silk occupied many hands; and watchmaking and clockmaking began to spread.

There were few exceptions to the general practice of obsequious deference to higher rank and obedience to authority. An attempt to promote a mutiny in the Bernese army in 1723 to secure the freedom of the inhabitants of the Vaud from Bernese oppression ended in failure. The small number of ruling families that controlled everything in Bern took care to stamp out any threat to this monopoly.

In Geneva the aristocratic ruling clique was less successful; fighting in the streets in 1738 ended with a compromise arranged by Bern and Zürich allowing the "citizens," themselves a minority among the inhabitants, a larger voice in affairs. But in 1768 and 1782 attempts to widen the franchise still further were forcibly smothered.

Cantonal separatism and religious exclusiveness were in some measure countered by the formation in 1761–62 of the "Helvetian Society," for all Swiss without distinction of birthplace or confession—and thus a better reflection of the ideas of the Enlightenment than its Catholic parallel, the Helvetische Konkordia Gesellschaft. This did not prevent trouble in Luzern, the most Catholic of Swiss cities, where a struggle between church and state grew out of an attempt to regulate or forbid public dances.

The French Revolution and Napoleon. Close to the surface there was a good deal of vague popular discontent: Fribourg, for example, in 1781 had to deal quite heavily with the peasants of Greyerz (Gruyères) before they submitted to dictation from the centre. The situation was altered by the American Declaration of Independence and by the French Revolution. Swiss residents in Paris formed themselves into a club of patriots in 1790

Popular discontent

and were in contact with radicals in Basel and Zürich and with well-wishers in Bern and Brugg. The chief exponents of revolutionary ideas, however, were Peter Ochs, a vain and ambitious artisan leader from Basel, and an idealist from Vaud, Frédéric-César de La Harpe, who acted as tutor to the future tsar Alexander at St. Petersburg. La Harpe returned, determined to secure the independence of Vaud from Bern. There was a rising of inhabitants of Lower Valais against their masters in Upper Valais; the last of the feudal servitudes were removed from the Basel peasantry in 1790; also in 1790 a Swiss battalion in the service of the French king mutinied in Nancy. Even Bern was prepared to offer some carefully guarded concessions. The inhabitants of Vaud, with a new-found watchword "Liberté et Patrie," wanted more.

The 13 cantons had renewed their military alliance with France in 1777 at Solothurn, but circumstances had altered greatly by the time the King's Swiss Royal Guard was annihilated in Paris by a mob in August 1792. Other Swiss regiments were unreliable and ill-equipped, and a Swiss foreign policy hardly existed. To prevent a Swiss revolution in which equality would end the traditional aristocratic regime, Schultheiss Niklaus Friedrich von Steiger of Bern took the lead; he became head of a party prepared for a possible war with France.

In the autumn of 1792 French military forces entered Savoy and threatened Geneva. Bern and Zürich sent 1,600 men to support the city, but they withdrew on receiving a French assurance that an attack would not take place. A revolution inside Geneva, protected by French arms, followed without incident.

The formation of the First Coalition Against France in 1793 (Great Britain, the Netherlands, Spain, Naples, Austria, and Prussia) was answered by French resistance. The French government demanded the expulsion from Switzerland of dangerous and hostile émigrés, and other opportunities for French intervention in Swiss affairs came easily. The French supported liberal movements in Stäfa and St. Gall; French and Austrian hostile forces crossed Swiss territory near Basel; French agents spread "democratic" propaganda; French generals coveted control of the Swiss passes; the French demanded the expulsion of the British ambassador and called for the annexation by France of part of Valais and the creation of an "independent" republic of Vaud. In 1797 French forces occupied Geneva and Biel; several cantons hurriedly liberalized their constitutions to give wider rights to hitherto disfranchised subjects.

French intervention in Swiss affairs

In January 1798 the French occupied Lausanne and proceeded to liberate Vaud from Bernese oppression; Bern itself was entered on March 5 after little more than token resistance. The remaining cantons, except Schwyz and Nidwalden, hurriedly surrendered, and the French proclaimed on March 28 that they had assumed governmental authority over the "Helvetian Republic."

The Helvetian Republic. Geneva, Neuchâtel, Biel, the territory of the bishop of Basel, Mülhausen, and the Valtellina were excluded from this new Swiss republic of 1798. The republic was to be "one and indivisible," with an elected legislative assembly and a directory. There were 23 cantons, a great council, a senate, and a cabinet, or directory of five, all indirectly elected. There was to be freedom of worship and conscience. Class distinctions were abolished, and all citizens were equal before the law. Justice was centralized; the directors chose the prefects, who, in turn, appointed the subordinate administrative officers, with the commune (*Gemeinde*) as the basic local unit. Large sums of money were paid to France by way of occupation costs, and attempts in central Switzerland to resist the new regime were crushed.

The renewal of war in Europe in 1799 was accompanied by local revolts, a breakaway movement in the Grisons, and an Austrian invasion there. Behind the Austrians came a Russian army, which occupied Zürich in June 1799 and was defeated at the second Battle of Zürich (September 25–26, 1799). For all practical purposes, at the end of 1799 Switzerland was a French-occupied country.

Within the new Swiss state the Republicans found the new democracy meaningless and called for a qualified return to earlier conditions, a suggestion emphatically rejected by the Patriots, defenders of the status quo. A little later the Unionists, who emphasized the coherence and indivisibility of the republic, were opposed by the Federalists, who insisted upon local self-determination and regional differentiation. The Directory was displaced by a committee of the Helvetic Council in January 1800 and this in turn by a controlling assembly of 50 supporting the Republicans. All parties appealed to Napoleon.

The Treaty of Lunéville (February 1801) enabled Napoleon to impose the Constitution of Malmaison in May 1801. This intensified the rivalries of Federalists and Unionists, and the latter produced in 1802 a second highly centralized Helvetic constitution, which was rejected by popular vote. Valais was accepted as an independent republic; there were serious opposition riots demanding a return to the old arrangements. French soldiers reappeared, and in February 1803 Napoleon produced the final text of his Mediation Constitution. A loose unitary state was formed, with 19 cantons, each with its own constitution, a legislature, a president (*Landammann*), and a chancery. The country now formed a free-trade area, with the peasants freed from feudal obligations, torture abolished, education encouraged, many monasteries dissolved, church and state separated, and marriage made a civil contract. Citizenship was widened, there was a federal army, foreign policy, and code of laws. France was permitted to recruit 16,000 Swiss soldiers, many of whom perished in the ill-fated Moscow campaign of 1812. The Napoleonic "Continental system" pressed hard upon a country that lived by exports and international services; there was a certain amount of smuggling and much unemployment and poverty. There was also, as elsewhere on the continent, a marked upsurge of nationalist feeling; cultural and scientific societies embraced the whole country, for which Johann Rudolf Wyss composed a national anthem, "Rufst Du, mein Vaterland." The Linth Canal (Linthkanal) was a federal enterprise, the first of its kind; Johannes von Müller wrote the first comprehensive history, *Geschichten schweizerischer Eidgenossenschaft* ("The History of the Swiss Confederation").

The loose unitary state of 1803

The restoration. There was no Swiss nationalist rising against Napoleonic domination after 1813 as there was in Prussia or Spain. Instead a renewed insistence upon Swiss neutrality, which might protect Napoleon's flank from an invasion, was accepted as public policy but ignored by the allies in their determination to occupy Paris and end the war. In December 1813 the Mediation Constitution was denounced and an attempt made to return to the pre-Revolutionary 13 sovereign cantons. Aargau and Vaud at once protested; the tsar Alexander I supported the protest, and Bern was forced to agree to an enlarged federation. The details were worked out in the "Long Diet" of 1814.

From the Congress of Vienna (1814–15) the Swiss hoped to obtain a recognized frontier, with the provinces annexed by France restored, compensation for damages inflicted by the war, and a recognition of neutrality and independence. The congress decided that the Valtellina, Chiasso, and Bormio should not return to the confederation and that the Pays de Gex should not come under the control of Geneva. Aargau and Vaud secured recognition, the former territories of the bishop of Basel were divided between Basel and Bern, Neuchâtel remained a Prussian principality within the Swiss confederation, the French annexation of Valais was denounced, and Geneva was admitted with narrowly defined frontiers, north Savoy and the Pays de Gex being accepted as custom-free zones. Swiss neutrality was guaranteed at Paris on November 20, 1815, by France, Austria, Great Britain, Portugal, Prussia, Sweden, and Russia.

Guarantee of Swiss neutrality

A new conservative Swiss constitution (*Der Bundesvertrag*) was signed on August 7, 1815. There were 22 cantons, each with its own constitution and each contributing to a federal army; those with external frontiers were allowed to levy customs duties on imports. Each canton had one vote in the Diet, which alone could (by a two-thirds majority) declare war, conclude peace, and enter

into alliances with foreign powers. On all other matters a simple majority was sufficient. Bern, Luzern, Fribourg, and Solothurn retained, with minor modifications, their patrician-ruled status. Zürich, Basel, and Schaffhausen widened their guild organizations. The remaining cantons adopted semidemocratic forms of government.

Switzerland to 1914. Between 1815 and 1830, despite economic difficulties and complaints that political refugees (including Louis Napoleon) were being given asylum, peace and stability reigned. Communications were greatly improved; commerce, including banking, advanced. New demands were heard for freedom of the press, religious toleration, rights of association, and greater free trade. After the July Revolution in Paris (1830), pressure for a more liberal Swiss constitution grew steadily; objections to the domination of the countryside by the towns were frequently heard, together with demands that popular sovereignty should become a reality. In Neuchâtel voices were raised against Prussian conservatism. In Schwyz the peasants threatened to form a breakaway state; and in Basel this actually took place, Basel-Landschaft separating from Basel-Stadt in 1833. Revisionists called for a representative parliament, a federal postal system, coinage, and a foreign office.

The Sonderbund War. The secularization in January 1841 of the monasteries of Aargau was condemned by the federal diet, which in turn led to numerous protests. When the Jesuits came to Luzern in 1844 there were demands for their exclusion from the confederation. Radical "volunteers" attempted to expel the Jesuits by force. The Catholic and conservative cantons refused to be intimidated and stood by their rights as guaranteed in 1815. In March 1845 volunteers from Bern marched against Luzern to expel the Jesuits and were easily repulsed. The result was that Luzern, Uri, Schwyz, Unterwalden, Zug, Fribourg, and Valais formed a protective union for mutual support—another breach of the Federal Pact. This soon became a *Sonderbund* (a separate federation), which was declared illegal in July 1847, when the diet resolved to inaugurate a new constitution and to drive out the Jesuits. The *Sonderbund* confidently hoped for support from the rulers of Austria, Prussia, and France. Civil war was imminent. In October a federal army under the command of Henri Dufour took the field against the rebels, whose expectation of outside assistance was disappointed. Dufour, with far superior forces, showed his strategic skill. Fribourg capitulated on November 14; Zug on November 21; and, after some fighting at Meierskappel, Hanau, and Gisikon, Luzern was entered on November 24. Schwyz, Uri, and Valais submitted in quick succession. The revolt was over within a month: the seven insurgent cantons had to meet the cost of the campaign; southern Appenzell and Neuchâtel were fined for failure to contribute to the army; Luzern and Fribourg were obliged to exclude Jesuits; and a revision of the constitution was worked out.

Formation of a separate federation

The new federal state, 1848–60. A government by two chambers was formed—a national council based on numerical representation and a senate, or council of states (Ständerat), consisting of two members from each canton. Together they formed a federal assembly (Bundesversammlung), with a federal council, or cabinet (Bundesrat), chancery (Bundeskanzlei), and supreme court of justice. The president, elected annually, was simply first among equals. Relations with foreign powers were thenceforth the exclusive affair of the federal government; mercenary service and the acceptance of pensions, gifts, tithes, or orders from foreign powers was forbidden. Equality before the law and freedom of the press, of movement, of association, and of religious worship were guaranteed to all. The Jesuits remained excluded, and clergymen could not hold elected offices. Bern was named as the capital, and the Swiss Federal Institute of Technology was opened in Zürich in 1855. Customs ceased to be levied between the cantons, and Switzerland became a unified economic area. The postal system became federal, as did currency, weights, and measures. In August 1847 the opening of the first Swiss railway, between Zürich and Baden, brought new problems—the country lacked coal; there were fierce disputes about capital, contracts, and ownership; and a struggle for control developed. Later the railway system was nationalized.

External affairs. Help to Charles Albert of Sardinia to eliminate the Habsburg regime was refused; even so, the troubles of 1848 in the Grand Duchy of Baden, in northern Italy, and in Neuchâtel nearly involved the confederation in war in defense of political refugees. In Neuchâtel —a canton of the confederation and a principality ruled by the king of Prussia—a republic was proclaimed; but in 1856 a "royalist" reaction gained temporary control and appealed to Frederick William IV of Prussia. The situation was soon reversed, and the royalist leaders were imprisoned, but it required the personal intervention of Napoleon III and the threat of a German-Russian-Austrian invasion to settle the matter. All Prussian rights in Neuchâtel were abandoned (for a consideration), although the monarch retained the empty title of prince.

Proclamation of a republic in Neuchâtel

Swiss neutrality had contributed to the Austrian defeats at Magenta and Solferino (1859). There were Swiss protests at the annexation of Savoy by France in 1860, but again a compromise had to be accepted not altogether to their advantage or satisfaction. Swiss neutrality narrowly escaped infringement during the Franco-Prussian War of 1870–71, when a French army entered Swiss territory, was disarmed and interned, but was allowed to return after peace was restored.

This was followed by renewed railway construction and continued controversy over private ownership, although it was not until 1882 that technical and financial difficulties accompanying the opening of the essential St. Gotthard route were overcome (an indirect consequence was the final abolition of separate cantonal currencies in 1874).

Religion and politics, 1860–1914. The final incorporation of the States of the Church into the kingdom of Italy and the Vatican Council of 1870, followed by the *Kulturkampf*—the conflict between state and church in Germany—had repercussions in Switzerland, where the "Old Catholics" were numerous. Obligatory civil marriages were introduced, in spite of opposition from the Catholic bishop of Basel and the papal representative at Geneva. In 1873 diplomatic relations with the Vatican were broken off (and not resumed until 1920). "Popular Initiative" had come in 1867, and the principle of the referendum was now accepted, complete internal free trade was assured, federal control over the army was extended, legal procedure was simplified, and greater economic and educational uniformity were furthered by constitutional revision in 1874.

As elsewhere, 19th-century Switzerland saw the rise of working class influences on the political scene. Home industry was being displaced by factories, where long hours were worked, often by small children. This trend brought about outbreaks of machine smashing by those who feared the loss of both livelihood and independence. Attempts at cooperative unions such as the Grütliverein, formed in 1838, were followed by the formation of trade unions proper. Successful demands for factory legislation were made by the Social Democrats, who emerged as a party of reform between 1870 and 1888.

Rise of working class influences

There were abiding difficulties over education, a sphere in which the cantons, determined to retain controlling influence, resisted federal coordination. In the Ticino local political rivalries almost led to a revolution in 1890 which was prevented by federal intervention. At the same time, the prosecution of German agents or spies sent by Bismarck caused some trouble with Germany, and the traditional Swiss acceptance of political refugees was resented by tsarist Russia. In each case the Swiss government successfully maintained its position.

Switzerland since 1914. Beginning with World War I, Switzerland faced a number of problems and changes during the 20th century.

The War of 1914–18. The advent of World War I in 1914 brought great problems: foreign visitors and workers left the country, which was obligated to defend its neutrality and independence. Tension between the French-speaking minority and the pro-Germans was in-

tensified when evidence was produced of secret information being sent by high-ranking Swiss officers to Germany. Difficulties were created by the considerable number of political refugees (including Lenin) living in Switzerland and by well-meant but ineffective attempts at peace mediation between the combatants. Receipts from Swiss customs dwindled, and an income tax became a necessity as defense costs mounted. Price fixing and rationing were also introduced. Discontent culminated in a general strike in November 1918, inflamed by Marxist elements and accompanied by an influenza epidemic that swept across Europe. Firm government action and the loyalty of the army quickly broke the strike, but political concessions, such as proportional representation, followed. The Soviet embassy was closed.

Peace in Europe brought its own special problems. France demanded, and obtained, full sovereignty over Savoy, reluctantly conceding a free zone. An attempt by the inhabitants of the Vorarlberg to become a 23rd canton of the confederation failed, but Liechtenstein was accepted as an ally and brought within the Swiss postal, customs, and monetary union.

The League of Nations. The League of Nations was formed in May 1920 with its headquarters at Geneva. The Declaration of London (February 1920) recognized the special nature of permanent Swiss neutrality and exempted the Swiss from participation in any future military "sanctions." Switzerland, however, could not be entirely indifferent to or unaffected by Italian Fascism and German National Socialism; there were deep divisions between the French- and German-speaking cantons and between the conservative "bourgeois" elements and the radical socialists. Something of this was reflected in the party disputes between the Catholic-Conservatives, Liberal-Democrats, and Social Democrats. Elections to the Federal Council were hotly disputed, while youthful adherents to a "National Front" rejected traditional democratic procedures in favour of obedience to a leader. Continuous demands for female suffrage from 1884 onward were rejected (until finally met in 1971).

Divisions within Switzerland

The world depression of the 1930s affected Switzerland less severely than it did the great industrial countries, but the same results on a reduced scale were apparent—bankruptcies, overproduction, and poverty. German claims to rule over all German speakers and German anti-Semitic legislation caused much alarm, as did Communist demonstrations—at one of these in Geneva (November 1932), 16 persons were killed and 60 wounded. Suggestions of a total revision of the constitution were decisively rejected, but agreements favouring industrial peace were readily entered into.

The admission of the Soviet Union to the League of Nations (1934); the Italian invasion of Ethiopia (1935), involving Switzerland in economic sanctions; and the Spanish Civil War (1936), with individual Swiss volunteers serving in the International Brigade, caused disillusionment with the League of Nations. Fascist and Nazi propaganda was countered and military service was made more acceptable. The German occupation of Czechoslovakia in March 1939 intensified defense measures so that the outbreak of war, following Hitler's invasion of Poland at the end of August, saw the Swiss fully prepared.

World War II and after. About 430,000 men were mobilized for the defense of the Swiss frontiers, rationing was introduced, and arrangements were made for adequate payment for soldiers on active service. Disapproval of the Soviet invasion of Finland was evidenced by the collection of 4,000,000 Swiss francs for war sufferers there. The German occupation of Denmark and Norway strengthened determination to resist if attacked, and more men were called to the colours. After the fall of France (when 42,000 men were interned), followed by intensified pro-German propaganda in Switzerland, the army command decided to defend, in case of invasion, only the "*réduit*," the heartland, including the St. Gotthard and Simplon tunnels.

Determination to resist if attacked

The expected invasion did not take place; instead, amid great economic difficulties and by supplying its neighbours with some equipment (chiefly precision instruments) and by assisting them indirectly in air warfare (and by suffering from mistaken air attacks, as when the Americans bombed Schaffhausen in April 1944), the Swiss rode out the war. At its end there were more than 100,000 refugees or internees within the country. The determination of the Allies that "war criminals" and high Nazi officials should not take refuge with their property in Switzerland caused difficulties, as did the reopening of diplomatic relations with the Soviet Union.

After 1945 Switzerland adopted by plebiscite many of the activities of the welfare state—old age pensions and social insurance of various kinds—and every effort was made to sell Swiss manufactured goods abroad, to attract visitors, and to forward "invisible exports" by banking, insurance, and other services. Without becoming a member of the United Nations, Switzerland participated fully in the Organization for European Economic Co-operation (OEEC) and in the General Agreement on Tariffs and Trade (GATT), and Basel became the centre for the World Bank.

By the 1970s more and more of the population had moved to or near the five great cities. Women were given the right to vote for the first time in 1971, and the country's general prosperity made the immediate future seem secure.

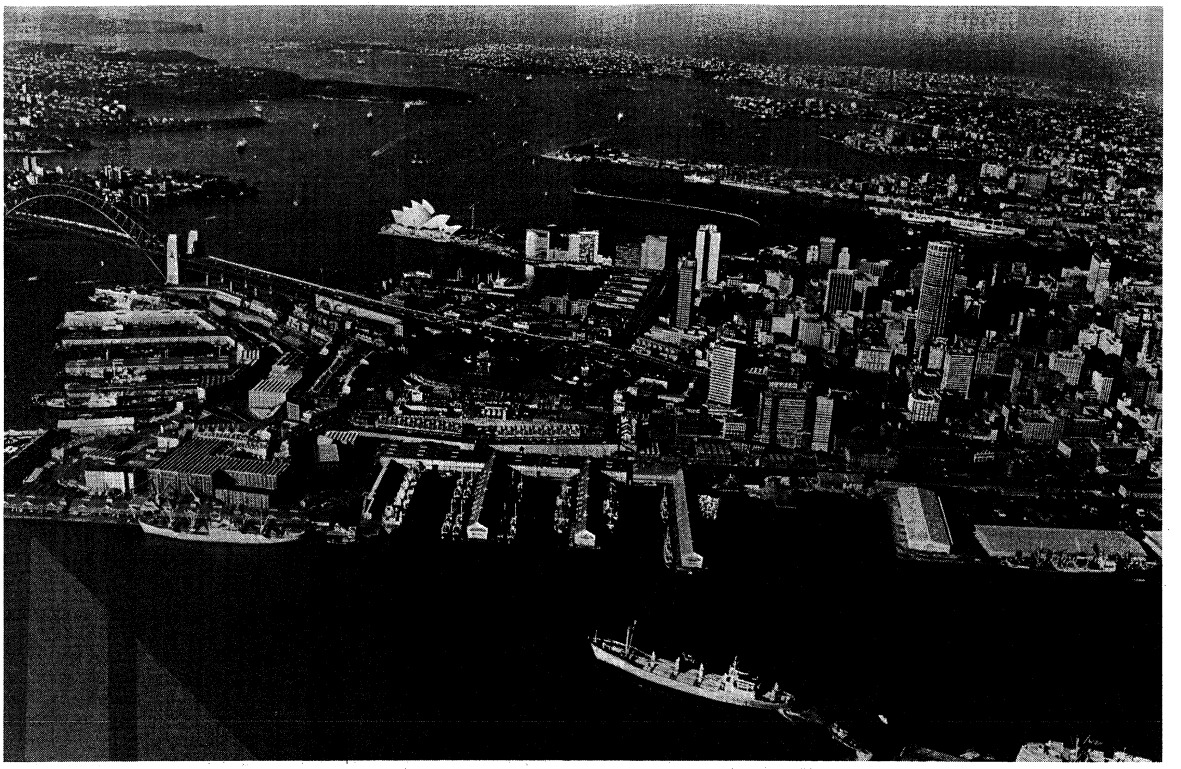
Sydney

The capital of New South Wales, Sydney is the oldest and, with a population of over 2,700,000 by the early 1970s, largest city in Australia. Because of its magnificent harbour and strategic position on the southeast coast of Australia, it is also one of the most important ports in the South Pacific. At the beginning of the 19th century, while it was still a small convict settlement and, indeed, even before the first settlers had penetrated 50 miles into the interior, it had already established trade with the Pacific Islands, India, China, South Africa, and the Americas.

The character of the city

The first sight of Sydney, whether from the sea or the air, is always impressive. Built on low hills surrounding a huge harbour with innumerable bays and inlets, the city is dominated by the bulk of the Sydney Harbour Bridge, one of the biggest single-span bridges in the world. The glittering confusion of water and buildings makes a striking impression either by day—under Sydney's brilliant light and blue skies—or by night.

Situated on latitude 34 degrees south and with an average mean temperature ranging from 72.1° F (22.3° C) in February to 54.1° F (12.3° C) in July, Sydney enjoys a warm, sunny, but temperate climate that has encouraged its citizens to develop a pleasure-loving and easy-going attitude to life and to make full use of the opportunities for sailing, swimming, and surfing at their doors. Although the average annual rainfall is 44.8 inches (1,138 millimetres), much of this falls in short tropical deluges in summer. The humid heat of summer, when



Sydney Harbour and commercial centre. At left is the Sydney Harbour Bridge; the sail-like structure on a point of land at left-centre is the city's new Opera House.

the prevailing wind is from the northeast, is tempered from time to time by the arrival of a cold front from the Tasman Sea heralded by a stiff wind from the south known locally as the "Southerly Buster." Sydney is unbearably hot only on a few days each year when a westerly wind brings the hot, dry air from the inland. In winter, however, the westerly wind is cool.

Because of its history as a great port and its more recent status as the site of the country's main international air terminal, Sydney is perhaps the only city in Australia with a genuinely international atmosphere. Most visitors to Australia begin and end their stay in Sydney. Yet it remains a very Australian city, hectic but casual, rough but good-natured, with a nice compromise between the Anglo-Saxon efficiency of its British heritage and the South Seas attractions of its climate and environment. (For related information see NEW SOUTH WALES.)

The history of Sydney. When the English explorer Capt. Arthur Phillip arrived off the coast of southeast Australia with the First Fleet in 1788, he sailed first to Botany Bay, which had been discovered by Capt. James Cook in 1770 and to which he had been directed by the British government. Finding the bay too exposed for safe anchorage and the surrounding country unsuitable for settlement, he looked further north and soon discovered the entrance to Port Jackson (now Sydney Harbour) only a few miles away. Phillip's first impressions of Port Jackson, which had been named but not explored by Cook, are recorded in a famous dispatch to Lord Thomas Townshend Sydney, then Home Secretary, dated May 15, 1788.

Discovery of the harbour

> We got into Port Jackson early in the afternoon, and had the satisfaction of finding the finest harbour in the world, in which a thousand sail of the line may ride in the most perfect security. . . .

Captain Phillip immediately decided to move the whole fleet to Port Jackson and to establish the first settlement on a cove, which had a good freshwater spring and in which his ships could anchor close to the shore in deep water. He called it Sydney Cove, after the Home Secretary. Today, Sydney Cove, where passenger liners tie up at the international terminal, is still the city's heart, though it is more commonly known as Circular Quay. The main commercial port, however, has been moved to Darling Harbour, another bay a little to the west.

The early history of Sydney was grimly dominated by its existence as a British penal colony. Convicts, dumped on this alien shore, found the environment a harsh one. The soil was poor, and the land was rough and had to be cleared by hand. The little settlement was often short of food until the settlers were able to cross the Blue Mountains and find the richer land to the west of the Eastern Highlands. There were also constant troubles between the governors, the free settlers, the convicts, and the marines and soldiers sent to guard them.

With the exploration and settlement of New South Wales, Sydney grew quickly; the British government provided free land, free convict labour, free capital works, and guaranteed markets for the produce of the new colony. Trading links with the rest of the world were quickly established. Under the enlightened governorship of Lachlan Macquarie (1810 to 1821), Sydney developed from a precarious penal settlement into a thriving, respectable town. Macquarie also began a program of public works, including the building of churches, hospitals, barracks, schools, and courthouses, and laid out several parks in and around the city. In this work he was aided by a convict-architect, Francis Greenway, who had been banished for forgery in England. Greenway built several fine buildings in the Regency style, notably the Hyde Park Barracks on Macquarie Street, and St. James's Church, which survive today.

Nineteenth century growth

The really rapid growth of Sydney—from 60,000 to 400,000 population—took place between 1850 and 1890, as suburbs of tightly packed terrace houses were built. These houses, with their balconies and cast iron railings in floral and geometrical patterns, are today Sydney's most attractive heritage from the past. The first railway, from Sydney to Parramatta, was opened as early as 1855.

The financial collapse of the 1890s acted as a slight check to Sydney's growth, but population doubled again by 1914 and reached the million mark soon after. Yet during this period Melbourne (*q.v.*), the capital of Victoria, was growing still faster, partly as a result of the gold rush in that colony. Temporarily overtaking Sydney both in size and importance, it became the financial centre of

Australia and the seat of the first Commonwealth Parliament from 1902 until the Federal Capital of Canberra was built halfway between the two cities. It was not until after World War II that Sydney again took the lead, partly as a result of a shift in Australia's trade toward North America and Asia and away from Britain. The Sydney of the early 1970s is slightly bigger than Melbourne and is equally important as a centre of finance, commerce, and manufacturing.

Other landmarks in the history of Sydney were the opening of the city underground railway in 1926, the Harbour Bridge in 1933, and the Opera House, a magnificent arts centre designed by a Danish architect, Jøern Utzon, in 1973.

The contemporary city. Greater, or metropolitan, Sydney is spread over an area of 670 square miles (1,735 square kilometres) and stretches from the Blue Mountains in the west to the Pacific Ocean in the east and from the Hawkesbury River in the north to south of Botany Bay. This suburban sprawl, caused partly by the cheapness of land in earlier days and by the ordinary Australian's determination to own his own house and garden, has caused great problems to the authorities responsible for sewerage and transport. (Several suburbs in Sydney were still unsewered by the early 1970s.) The sprawl is also in marked contrast to the comparatively small and compact central business district, which is crammed into a narrow rocky peninsula between two arms of the harbour.

Layout and boundaries

The same contrast can be seen in the style of buildings. Whereas most of the houses in the suburbs are one-story bungalows built of brick or wood, the high cost of land in the central business district has forced occupiers to build high. The rapid development initiated in the 1960s has transformed the city centre, which now looks like a smaller Manhattan rising from the shores of the Harbour, though in fact the buildings are not high by North American standards. A rival business centre is now rising in North Sydney, which is linked to the city by the Harbour Bridge.

The standard of architecture is generally mediocre, though there are a few handsome buildings surviving from the 19th century and a few contemporary buildings of distinction. Yet the general effect of Sydney is attractive, and the innumerable bays and arms of the harbour, stretching into the land and providing unexpected views from almost every street, make Sydney one of the most pleasing cities in the world.

Sydney is also fortunate in having two magnificent national parks within 25 miles of the city centre to the north and south. In these parks the natural Hawkesbury Sandstone bush can be seen at its best and forms a refuge for the wild life of the area. The mouth of the Hawkesbury River, with its many finger-like inlets, provides a superb expanse of sheltered water for yachtsmen, while both to the north and south of the city there stretches a string of magnificent sandy beaches, on which the Pacific surf breaks throughout the summer.

The people. By the early 1970s the population of greater Sydney was over 2,700,000. As in the rest of New South Wales, about 80 percent of these are of British stock and the remainder immigrants from Europe. These immigrants, however, have tended to crowd into the inner suburbs, some of which now have a distinctly Greek or Italian character.

Ethnic origins

The city is still growing rapidly, partly as a result of Australia's immigration policy and partly as a result of the decline of the rural population. In 1968 the State Planning Authority estimated that the city of Sydney would have grown to 5,500,000 by the year 2000. Some of this increase, however, would have to be housed in a wider Sydney region extending beyond the present boundaries of the metropolitan area. Some planners fear that this will lead to a vast conurbation stretching from Newcastle in the north to Wollongong in the south. These three cities already contain over two-thirds of the population of New South Wales.

Economic life. About 43 percent of the total Sydney population is in the work force, and of these about a third are employed in manufacturing (mostly in secondary industry) and the rest in tertiary industry or services. There is no major industry in the city itself, though oil refining is becoming increasingly important. Sydney has always been essentially a city of government; of local, national, and international commerce; and a shopping and entertainment centre for the State of New South Wales. More recently it has rivalled Melbourne as a financial centre, and the Sydney Stock Exchange is now the largest in Australia.

Sydney is still the largest port in Australia handling about 21,000,000 tons of cargo a year. A second port is being developed in Botany Bay, which is becoming the main industrial area of Sydney.

Political and governmental institutions. Sydney is the capital of New South Wales and the seat of its government and parliament. The state government has delegated matters of local interest to elected local councils, including the City Council, but has retained direct control of some important matters, such as police and transport. In addition, a number of functions normally exercised by local councils have been transferred to boards, commissions, trusts, and departments established by the state government. The most important of these responsibilities concern water, sewerage and storm drainage, electricity, major roads, fruit and vegetable markets, and many aspects of health and welfare. The result is a somewhat confused and complicated system of government. For historical and political reasons, moreover, the boundaries of the City Council have been changed several times. In 1968 the City Council was reduced to approximately its original boundaries so that today it is responsible only for the central business district and the inner suburbs. The outer suburbs elect their own councils.

Relations with the state government

Even within the area controlled by the City Council, large areas of land are controlled either by the state government or by the Commonwealth Government. This fact has greatly added to the difficulties of planning.

Services and transportation. Sydney has had a railway linking the city to some of its suburbs since 1855. Between World Wars I and II, this radial suburban rail system was electrified, and construction of the city underground railway was begun (the first section was opened in 1926). In 1933, after the completion of the Harbour Bridge, the north shore was linked directly by rail to the city. By the 1970s the underground railway was being extended to the eastern suburbs.

In spite of development and the existence of an extensive metropolitan bus service, public transport has failed to keep pace with demand. Since World War II, Sydney, like so many other cities, has fallen a victim to the motor car. The number of motor vehicles registered in New South Wales increased from almost 330,000 in 1939 to nearly 2,000,000 in 1970, and a high proportion are based in the Sydney metropolitan area. By the late 1960s over 580,000 vehicles entered or left the central business district on a typical day.

The resulting traffic problem is made worse by the geographical layout of Sydney. A high proportion of those who work in the central business district live in the outer suburbs and must find their way to and from the city by a limited number of routes. All those living on the North Shore, for instance, must cross the harbour by the Harbour Bridge, the only bridge crossing the harbour from north to south. (At the head of the harbour there is a second bridge, at Gladesville, which takes some of the traffic.) It is also difficult for traffic travelling from north to south through Sydney to bypass the city. The inevitable consequence is severe traffic congestion aggravated by the narrowness of the streets. Attempts to relieve this by building expressways and thruways have been only partially successful, and Sydney, like other cities, has begun to think of banning all traffic from certain sections of the inner city: to this end, a pedestrian plaza was created in Martin Place, in the centre of the city, in 1971.

Traffic congestion

A delightful alternative means of transport exists for those who live on the shores of the harbour in the public ferry system, but, for reasons that have always baffled the authorities, this has never been as popular or as profitable

as might be expected. The ferry boats crisscrossing the harbour nevertheless add a good deal to the attraction and amenity of the city.

The main airport, both for international and internal traffic, is at Mascot, on the shores of Botany Bay, to the south of the city, but this, too, is proving inadequate to the growing demand, and a second airport is planned for the late 1970s. Access to and from the present airport is poor. On the other hand, travellers by sea are fortunate in that passenger liners generally tie up at Circular Quay in the very heart of the city, from which they can stroll to the city centre.

Sydney has only recently become a centre for international tourists. The number of first-class hotels is still inadequate, and they are not of the highest standard, but Sydney has many excellent motels offering accommodations at a moderate price. There are a great many restaurants, particularly in the eastern suburbs, many of them quite good and a few excellent. It is possible to find restaurants offering almost every kind of international cooking, though all of them serve good Australian wine and Sydney's famous oysters. The entertainment quarter of Sydney and the centre of its night life is King's Cross. This is a small, crowded, and somewhat sleazy area that has nevertheless had a certain irresistible gaiety and vitality for the two generations of American soldiers stationed in Australia during World War II or sent there from Vietnam on rest and recreation leave.

The role of tourism

Cultural life and recreation. Sydney is, above all, a city for physical enjoyment. Few great cities in the world offer such unrivalled opportunities for swimming, surfing, sailing, and other outdoor sports. It is still possible to swim from several beaches in the harbour itself—though pollution is slowly reducing the number of these—and the surf beaches to the north and south of the city are world famous. One of these, Bondi, is a 15-minute drive from the city centre. Some of the beaches to the north of the city, especially those on the Palm Beach peninsula, are very beautiful. The surf is good, though variable, and made comparatively safe by the voluntary lifesaving association, which provides guards and rescue equipment on all beaches throughout the summer months. Sydney is also a city of yachtsmen. On any weekend Sydney Harbour is covered with sails of every shape and size, while the Pittwater, 25 miles to the north, is almost equally popular. There are also many golf courses and excellent facilities for football, cricket, and tennis, and the racecourse at Randwick is first class.

Sporting traditions

Australians have been accused of being sports-mad, and Sydney-siders, as they call themselves, are certainly no less devoted to sport than their compatriots in other cities. Yet Sydney also has a vigorous cultural and intellectual life. There are three universities in the metropolitan area; the University of Sydney, the University of New South Wales, and Macquarie University. A fine public library, two museums, and an art gallery (to which an extension was added in 1971), and a large number of private galleries devoted to contemporary Australian art add to the cultural attractions. A serious shortage of theatres and concert halls existed in the city, but this was remedied when the controversial Opera House—in fact a major arts centre—was opened in 1973. This beautiful and costly building was designed by a Danish architect, Jøern Utzon, who won an international competition held for the purpose in 1955. Built on a magnificent site on the harbour, surrounded by water on three sides, its white shells have already become almost as much a symbol of Sydney as the Harbour Bridge. It contains a concert hall for the Sydney Symphony Orchestra, a large theatre for opera and ballet, a smaller theatre for plays, a cinema, and rehearsal and recording studios. Until the centre's completion, the Sydney Symphony Orchestra had to play in the Town Hall, which was acoustically inadequate, but the Orchestra has long maintained a high standard. For opera and ballet Sydney depends on the Australian national companies, which visit the city for a season each year. Sydney has several small theatre groups, but none has yet reached the highest standard.

Four morning papers, two evening papers, and four Sunday papers are published in the city. Television and radio are competitive. In addition to the Australian Broadcasting Company, which has its headquarters and main studios in Sydney, there are three commercial television stations and six commercial radio stations.

Thus, though Sydney today is a large, sophisticated, international city offering services and cultural amenities comparable with those offered by any great city in the world, there is still no doubt that its most lasting impression and greatest attraction is its physical setting, in which a very high proportion of Sydney's residents can glimpse at least a strip of blue water from their windows and nearly all can live within half an hour or an hour of a beach.

BIBLIOGRAPHY. The best sources for facts and figures about Sydney are *The Sydney Region Outline Plan*, published by the State Planning Authority of New South Wales (1968); and the *City of Sydney Strategic Plan*, published by the Council of the City of Sydney (1971). A charming portrait of contemporary Sydney, unencumbered by statistics, is GAVIN SOUTER, *Sydney* (1965), with photographs by QUINTON DAVIS. The early history of the convict settlement is graphically told from contemporary documents in JAMES JOHNSTON AUCHMUTY, *The Voyage of Governor Phillip to Botany Bay* (1970); and JOHN COBLEY, *Sydney Cove, 1788* (1962). All early histories of Australia necessarily deal with Sydney in part. There are good biographies of *Lachlan Macquarie* (1942) and *Francis Greenway* (1949), both by M.H. ELLIS.

(J.D.Pr.)

Syllogistic

Syllogistic is the study of the logical structures that make it possible to infer a proposition (a conclusion) from other given propositions (the premises). Its foundations were laid by Aristotle in his book *Analytica priora*. Though Aristotle defined the syllogism broadly as "an argument, in which, certain facts having been laid down, something different follows with necessity simply from their being so," he himself investigated almost exclusively the so-called categorical syllogism; *i.e.*, a type confined to simple declarative statements and its variations involving expressions of necessity and possibility, known as modalities. Later, other forms of syllogistic reasoning and especially those of what is called propositional logic (*i.e.*, a logic using unanalyzed whole propositions as its units) were dealt with by Stoic logicians. Though the European tradition usually followed Aristotle in trying to transpose all other forms of syllogistic reasoning into categorical syllogistics, important differences developed between the true Aristotelian syllogism and the mainstream of later traditional logic. In this article, the main emphasis will be placed upon the accepted results of modern research in this field.

NATURE AND ELEMENTS OF SYLLOGISTIC

Since the propositions that compose all syllogisms are built up from terms and operators (signs expressing logical connections), traditional logic begins with an analysis of terms. Terms may be singular (such as "Plato" or "the author of *Hamlet*") or general (such as "man," "triangle," or "healthy"). General terms may be taken either in extension (also called denotation), which indicates the set of individuals to which a term applies, or in intension (also called connotation), which describes the set of attributes that something must have to qualify for the predication of the term. The extension, for example, of "bachelor" is the set including all men that are bachelors, and its connotation is the set of such attributes as being human, being male, being above the legal age of marriage, and being single. If the connotation of a term *a* includes that of *b*, the extension of *b* will include that of *a*. Whereas the class of bachelors is included in the class of men, the attributes of "man" are included in the class of attributes of "bachelor." The definition of a term is an analysis of its connotation.

Basic definitions

To form a proposition of the most primitive sort, a singular term (the subject) may be joined to a general term (the predicate) by "____ is (a) ____" or "____ is not (a) ____," signs called copulae. "Plato is a philosopher" is called an affirmative proposition, and "Plato is not

stupid" is called a negative proposition. General terms cannot form propositions merely by being joined by copulae; in order to construct a complete proposition, a sign of quantification must be added—traditionally "every" or "some," as in "Every philosopher is a man." Instead of writing "Every man is not perfect," it is customary to write "No man is perfect," the "no" doing double duty as a sign of negation *and* quantification. A proposition of the type "Every ____ is (a) ____" is called universal affirmative; "No ____ is (a) ____" is called universal negative; "Some ____ is (a) ____" is called particular affirmative; and "Some ____ is not (a) ____" is called particular negative. These forms of propositions are also referred to, in that order, as *A*-, *E*-, *I*-, and *O*-propositions, the vowels being taken from the Latin words *affirmo* ("I affirm") and *nego* ("I deny"). Negative and affirmative propositions are said to differ in *quality;* universal, particular (and singular) propositions are said to differ in *quantity*.

Truth and validity of inference

A proposition is said to be *inferred* from other propositions if it is validly drawn as a conclusion from them. A conclusion is validly drawn if it is a logical consequence of the premises, and this is the case whenever it is impossible that the premises be true and the conclusion false. The following cases are therefore possible:

1. A true conclusion invalidly drawn from true (or false) premises,
2. A false conclusion invalidly drawn from true (or false) premises,
3. A true conclusion validly inferred from true (or false) premises, and
4. A false conclusion validly inferred from false premises.

The only case that cannot arise is:

5. A false conclusion validly inferred from true premises.

Therefore, to know the truth or falsity of the premises and the conclusion does not enable one to determine the validity of an inference. To judge the validity of an argument, one must examine its logical form, which is what syllogistic teaches him to do in the proper way.

PROCEDURES OF IMMEDIATE INFERENCE

In expressing syllogistic propositions, logicians find it convenient to employ a notation introduced by Jan Łukasiewicz, an important early-20th-century logician: lowercase Latin letters *a*, *b*, *c*, . . . are employed to stand for general terms (*i.e.*, for term variables); capital letters *A*, *E*, *I*, and *O*, are then used as symbols for the syllogistic operators, which, together with the terms, make up the four kinds of propositions. Accordingly, "Every *b* is an *a*" is written "*Aba*"; "Some *b* is an *a*" is written "*Iba*"; "No *b* is an *a*" is written "*Eba*"; and, finally, "Some *b* is not an *a*" is written "*Oba*."

Square of opposition

Relations among propositions. In order to display the logical relations obtaining between different pairs of propositions of these four forms, they are customarily arranged in a so-called square of opposition (Figure 1). It is important to note that, in considering these different forms of opposition between propositions, the logical tradition conventionally distinguishes empty terms (such as "round square," "centaur," or "*perpetuum mobile*"), which cannot be truly applied to any individual, and excludes them from being introduced in the place of term-variables in syllogistic propositions. It is also necessary to be aware that the operators *I* and *O* ("Some ____ is (a) ____" and "Some ____ is not (a) ____") are taken in the sense of "At least one and possibly all ____ is (or is not) (a) ____." With these specifications made, it may be seen that "*Aba*" and "*Eba*" are contraries—*i.e.*, they cannot be jointly true; that "*Iba*" and "*Oba*" are subcontraries—*i.e.*, they cannot be jointly false; that "*Aba*" and "*Oba*" and also "*Eba*" and "*Iba*," taken pairwise, are contradictories—*i.e.*, if "*Aba*" is true, "*Oba*" must be false and vice versa; and, finally, that if "*Aba*" is true, "*Iba*" must also be true, and if "*Eba*" is true, so is "*Oba*." In the last cases, however, since the implication does not hold analogously in the opposite direction, it is said that "*Aba*" "subalternates" "*Iba*," and "*Eba*" subalternates "*Oba*," "*Aba*" being the subalternant and "*Iba*" the subalternate (and, similarly, for "*Eba*" and "*Oba*"). For any given pair of terms *a* and *b*, exactly two of these four forms of proposition are true: for every pair of terms "*a*" and "*b*," either "*Aba*" and "*Iba*" will be true or "*Eba*" and "*Oba*" or, finally, "*Iba*" and "*Oba*."

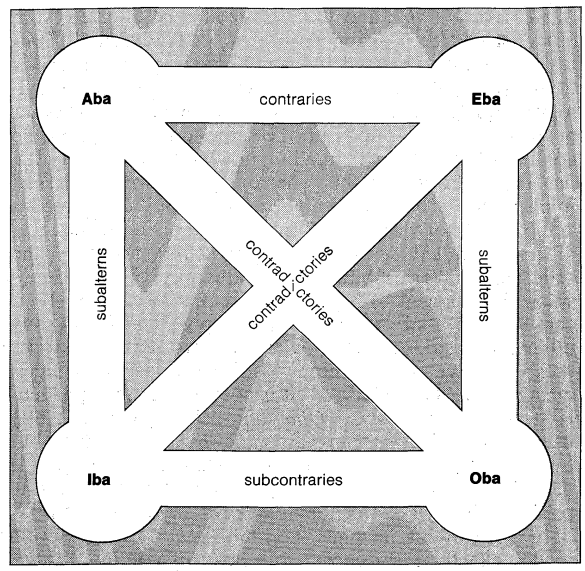

Figure 1: The square of opposition (see text).

If the extensions of general terms are symbolized by circles, it is possible to develop a series of so-called Euler diagrams (Figure 2)—named after the Swiss mathematician Leonhard Euler, who promulgated the method (though he had not invented it). The diagrams show how the five possible relations of terms may be visualized: α: exactly matching; β: *b* included in *a*; γ: *a* included in *b*; δ: partially overlapping; ε: entirely distinct. As long as negated term variables—*e.g.*, "not-man" or "non-smoker"—are not considered, the five diagrams exhaust the possibilities. These figures will make clear the logical relations between pairs of propositions that are alike in quality but have the order of the terms *a* and *b* inverted: ("*Aba*," "*Aab*"), ("*Aba*," "*Iab*"), ("*Iba*," "*Aab*"), ("*Iba*," "*Iab*"), ("*Eba*," "*Eab*"), ("*Eba*," "*Oab*"), ("*Oba*," "*Eab*"), ("*Oba*," "*Oab*"). As the former logical relations were traditionally called those of opposition, the ensuing relations are those of conversion.

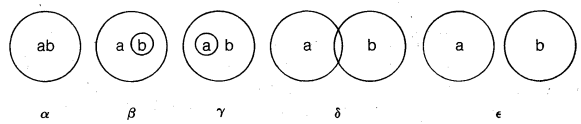

Figure 2: The Euler diagrams (see text).

Conversion

The identification of logically valid conversions is facilitated by the use of so-called truth tables (Table 1).

Table 1: Truth Table Correlating Propositional Forms with Euler Diagrams

Euler diagram	propositional form				converse propositional form			
	Aba	Eba	Iba	Oba	Aab	Eab	Iab	Oab
(α)	t	f	t	f	t	f	t	f
(β)	t	f	t	f	f	f	t	t
(γ)	f	f	t	t	t	f	t	f
(δ)	f	f	t	t	f	f	t	t
(ϵ)	f	t	f	t	f	t	f	t

A "t" in a given line and column signifies that the propositional form given at the top of the column will be true for the Euler diagram indicated at the left by Greek letters (referring to the different diagrams of term relations in Figure 2); an "f," on the other hand, signifies that the propositional form will be false. The columns for "*Eba*" and "*Eab*" are identical, as are those for "*Iba*" and "*Iab*." "*Eab*," therefore, may safely be inferred from "*Eba*," and

"*Eba*" from "*Eab*"; and "*Iab*" may also be inferred from "*Iba*," and "*Iba*," again, from "*Iab*." Traditionally, this logical fact is expressed by saying that *E*- and *I*-propositions are capable of simple conversion. Generally, a syllogistic proposition *Y* may be inferred from another proposition *X* built up from the same terms whenever the column of *X* has no "t" in a line in which the column of *Y* has an "f." Following this criterion it is shown that "*Aba*" implies "*Iab*" (but not vice versa) and that "*Eba*" implies "*Oab*" (but not vice versa). In this kind of inference (traditionally called *conversio per accidens*) not only the order of the terms but also the quantity of the proposition is changed. From the columns of Table 1, it can be seen that "*Oba*" cannot imply "*Oab*," nor any other propositional form with inverted terms, because these all have one or more "f's" in the last three lines, where "*Oba*" has only "t's." It is possible that, for particular terms *a* and *b*, both "*Oba*" and "*Oab*" may be jointly true (*e.g.*, if *a* = "German" and *b* = "blond"); but this joint truth depends on the accidental content of the particular terms, not on the logical structure of the propositions. Thus, "*Oba*" is not eligible for any conversion.

Equipollence, obversion, and contraposition

Since, in all of its lines, column "*Aba*" exhibits truth values exactly the opposite of those in column "*Oba*," another logical connection—traditionally called equipollence (near in sense to the modern term "equivalence")—can be identified, asserting that "*Aba*" is logically equipollent to "*Not-Oba*" (or "*NOba*") and vice versa. The same relation holds between "*Eba*" and "*Iba*" (or "*Iab*"). Using "≡" as a sign for equivalence, the logician can write "*Eba* ≡ *NIba*" and "*Eba* ≡ *NIab*." Furthermore, negated term variables can be introduced for terms like not-man or nonsmoker by employing a superposed bar, $\bar{a}$, $\bar{b}$, . . ., provided only that, just as terms defining the null (empty) class were earlier excluded, all terms defining the universal class shall be disqualified—in short, that, for every *a*, $\bar{a}$ is not empty. Thus every syllogistic proposition is equivalent to the proposition that results by changing its quality (affirmative to negative or vice versa) and at the same time negating the second (predicate) term: thus, "*Aba*" is equivalent to "*Eb*$\bar{a}$," and "*Iba*" to "*Ob*$\bar{a}$," a change traditionally called obversion. Another type of immediate inference, called contraposition, rests on the fact that some syllogistic propositions imply the proposition that results from the original proposition when both of its term variables are negated and their order is reversed. Only in the case of "*Aba*" and "*Oba*" is the resulting proposition logically equivalent to the original one. It is evident, for example, that "If every member is a smoker, then every nonsmoker is a nonmember"; and that "If some member is not a smoker, then some nonsmoker is not a nonmember"; *i.e.*, "Some nonsmoker is a member," or "There are members besides smokers."

After the foregoing definitions of equipollence and obversion, it is possible to define each of the operators *A*, *E*, *I*, and *O* by negation plus any one of the other three operators. "*Aba*" may be taken as basic, for example, and "*Eba*" defined as "*Ab*$\bar{a}$," "*Iba*" as "*NAb*$\bar{a}$," and "*Oba*" as "*NAba*." Corresponding definitions can be framed with other operators as basic. Instead of employing *A*, *E*, *I*, and *O*, for instance, modern logic uses for the same task only two operators, $(\forall x)$ and $(\exists x)$, the universal and existential quantifiers, which express only quantity ("all" and "some," respectively), leaving the quality, in the case of negative syllogistic propositions, to be expressed by obversion.

Summary of inference relations. Summing up (and using "⊃" for "implies" and "≡" for "is equivalent to"), the logical laws of Table 2 can be stated, each of which provides the basis for an immediate inference (from one syllogistic proposition to another).

Table 2: Summary of the Laws of Immediate Inference

law no.	law	law no.	law
From the square of opposition		**By conversion**	
2.1	Aba ⊃ NEba	2.11	Eba ≡ Eab
2.2	Eba ⊃ NAba	2.12	Iba ≡ Iab
2.3	NIba ⊃ Oba	2.13	Aba ⊃ Iab
2.4	NOba ⊃ Iba	2.14	Eba ⊃ Oab
2.5	Aba ⊃ Iba	**By obversion**	
2.6	Eba ⊃ Oba	2.15	Aba ≡ Eb$\bar{a}$
2.7	NIba ⊃ NAba	2.16	Iba ≡ Ob$\bar{a}$
2.8	NOba ⊃ NEba	**By contraposition**	
2.9	Aba ≡ NOba	2.17	Aba ≡ A$\bar{a}\bar{b}$
2.10	Eba ≡ NIba	2.18	Oba ≡ O$\bar{a}\bar{b}$

RULES AND LAWS OF THE SYLLOGISM

Categorical syllogistic inferences. A categorical proposition contains just one subject term, one predicate term, and one syllogistic operator to join them. A categorical syllogism is an inference of one such proposition from two others. Each premise must have one term, called the middle term, in common with the other premise and one term in common with the conclusion. The term functioning as predicate of the conclusion is called the major term, and the one functioning as subject of the conclusion is called the minor term of the syllogism. The premise containing the major term, conventionally stated first, is called the major premise, and the other is called the minor premise. In the syllogistic example:

Terms, moods, and figures

syllogism	proposition type
No man is perfect	*E*
Every logician is a man	*A*
Therefore, no logician is perfect	*E*

"perfect" is the major, "man" the middle, and "logician" the minor term.

The quantity and quality of the three propositions—expressed, as before, in terms of the proposition types *A*, *E*, *I*, and *O*—determine what are called the moods of the syllogism. The example just given thus belongs, as shown in the right-hand column, to the mood *EAE* (reading down). Since the three propositions may take four different forms each, there are $4^3 = 64$ different moods. Another way in which the forms of syllogisms differ is in their figure, which is the pattern in which its terms *S*, *M*, and *P* (subject, middle, and predicate) are arranged in the premises (see Table 3). This pattern is effectively determined by the function of the middle term, which may be subject in the major and predicate in the minor premise, as in the foregoing example (first figure); predicate in both premises (second figure); subject in both premises (third figure); and, finally, predicate in the major and subject in the minor premise (fourth figure).

Table 3: The Four Figures of the Syllogism

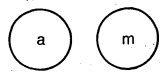
(1)	(2)	(3)	(4)
M-P	*P-M*	*M-P*	*P-M*
S-M	*S-M*	*M-S*	*M-S*
S-P	*S-P*	*S-P*	*S-P*

Analysis of the valid moods. Since there are 64 moods in four figures, there can be 256 forms of the categorical syllogism. It is one of the tasks of syllogistic to discover which of these forms are valid and to show that all others are invalid. Aristotle accepted 14 valid moods officially and five unoffically (those of the fourth figure). In the Middle Ages, these 19 moods were given Latin names, such as *Barbara*, *Camestres*, or *Datisi*, which indicated the moods through their vowels, names that were listed in mnemonic verses. Since five of these 19 syllogisms have universal conclusions, from which corresponding particular propositions can be inferred (by passing from "all" to "some" by laws 2.5 and 2.6), there will be five additional valid syllogisms—traditionally called *Barbari*, *Celaront* (first figure); *Cesaro*, *Camestrop* (second figure); and *Camenop* (fourth figure). Upon examination, it would seem that a syllogism in *Barbara* is self-evident; and Aristotle, in fact, accepted all first-figure syllogisms as self-evident and deduced all other syllogisms from them (see below *Reduction to the first figure*). But Euler diagrams (see Figure 2) can also be employed. Taking as an example *EIO*, in the second figure (*Festino*), written

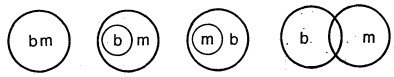
Identification of valid moods

Eam · *Ibm* ⊃ *Oba*,

(using · for "and"), the relation of *a* and *m* can be shown by the Euler diagram (ε):



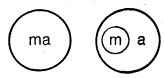
The second premise, "Some *b* is *m*," is satisfied by each of the diagrams (α) through (δ):



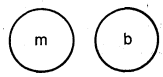
since, in each case, at least some of the "*b*'s" must be inside the extension of "*m*." Because, by the first premise, *a* is wholly excluded from *m*, however, at least some members of *b* will be outside of *a*; and this is just what "*Oba*," the conclusion, asserts. Similarly, it can be shown that *AEE*, in the third figure, is not valid; *i.e.*,

Ama · *Emb* ⊃ *Eba* (invalid).

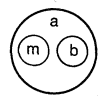
"*Ama*" is satisfied by the Euler diagrams (α) and (β),



and "*Emb*" by diagram (ε),



Clearly, the arrangement



is possible, in which case "*Aba*" would be true. Because *b* might equally well fall extensionally wholly outside of *a*, however, or *a* and *b* might merely overlap, all four propositional forms concerning *a* and *b* are compatible, and thus no conclusion follows.

Rules for testing validity

To shorten the task of testing the 256 possible syllogistic forms, three sets of general rules for the validity of categorical syllogisms have been formulated.

There are, first, the rules of distribution. A term is said to be distributed in a given proposition if that proposition implies all other propositions that differ from it only in having, in place of the original term, any other term whose extension is a part of that of the original term. Thus the term "student" is distributed in the propositions

Every student is a member;
No general is a student;
No student is a general;
Some boy is not a student;

inasmuch as each proposition remains true if one inserts, say, "law student" or "girl student" instead of "student." "Student" is not distributed, however, in the propositions

Every member is a student;
Some student is a boy;
Some boy is a student;
Some student is not a girl;

which may become false under a corresponding insertion for "student." In general, negative propositions distribute their predicate term, and universal propositions distribute their subject term. Therefore, in "*Eba*," both *b* and *a* are distributed, in "*Aba*" only *b*, and in "*Oba*" only *a*; "*Iba*," however, distributes neither of its terms.

There are two rules of distribution:

1. The middle term must be distributed at least once in the premises, and
2. No term may occur distributed in a valid conclusion unless distributed in the premises.

Thus "*Aam* · *Ibm*" has an undistributed middle term. In the syllogism

Ama · *Obm* ⊃ *Oba* (invalid),

however, the middle term is distributed; but *a*, distributed in the conclusion, is distributed in neither premise, a fault called illicit process.

The rules of quality are the following:

3. One premise, at least, must be affirmative, and
4. If one premise is negative, the conclusion must be negative; and a negative conclusion requires one negative premise.

Though rules 1–4 are sufficient to test any syllogism, three more rules facilitate the testing: one more rule of quality, viz.,

5. If both premises are affirmative, the conclusion must be affirmative,

and two rules of quantity:

6. At least one premise must be universal, and
7. If either premise is particular, the conclusion must be particular.

All syllogisms satisfying all of these rules are valid; and a syllogism violating at least one of them is invalid.

Analysis by law, case, and application

Underlying logical structures. Though inferences framed in the first figure have usually seemed particularly natural or evident and have thus been given prominence, the logical structures lying at the roots of all syllogistic figures are the same; the different figures only bring into focus their different aspects. The logical forms can be approached from various angles:

1. Given a general law that some class has (or lacks) a certain property, one may then establish that something has (or lacks) this property by showing that it is a member of that class (first figure);
2. Given the same general law, if one wishes to establish that something is not a member of that class, he may do so by showing that it lacks (or has) that property (second figure);
3. If it has been shown that something has (or lacks) a certain property and that it is a member of a certain class, one can then infer that no general law asserting that all members of this class lack (or have) that property can be valid (third figure).

If the different functions of the syllogistic propositions are described as "the statement of a law," "the establishment of a case," and "the application of the law to the case," the special nature of the figures may then be schematically summed up as in Table 4. In all three figures, the proposition of the application step is the only one capable of assuming all four propositional forms, *A*, *E*, *I*, and *O*.

Table 4: Functional Summary of the First Three Figures of the Syllogism

figure	law	case	application	case	law
first	affirmed	affirmed	affirmed		
second	affirmed		denied	denied	
third			denied	affirmed	denied

As for the fourth figure, although, like the first, it conforms to the law-case-application model, it does so with special emphasis not on the class to which the property is applied but on the property itself, of which the argument shows that it has (or lacks) application to something, viz., to all or some of the members of a certain class.

Reduction to the first figure. Aristotle, in *Analytica priora A* 5–7, reduced all other syllogisms (called by him "imperfect") to those of the first figure, the "perfect" (*i.e.*, self-evident) syllogism. He proved their validity, as would be said today, by deriving them as theorems from the axioms of his system—thus qualifying as the first scholar known to have developed an axiomatic system.

Direct reduction

Aristotle used two main methods of proof: direct and indirect reduction. The first has its logical basis in an *a fortiori* argument: if a syllogism *X* is valid, he argued, the logician may also infer the validity of every syllogism *Y* such that the premises of *Y* imply those of *X*, and the conclusion of *X* implies that of *Y*. The reduction, for example, of *Cesare* (second figure),

Eam · *Abm* ⊃ *Eba*

to *Celarent* (first figure), *Ema · Abm ⊃ Eba*, proceeds thus: "*Eam*" implies "*Ema*" (by 2.11); the second premises of *Cesare* and of *Celarent* are the same; therefore, the premises of *Cesare* imply those of *Celarent*. But *Celarent*'s conclusion, being identical, implies that of *Cesare*; therefore, *Celarent*'s validity implies that of *Cesare*. More complicated is the reduction of *Camestres* (second figure),

$$Aam \cdot Ebm \supset Eba$$

to *Celarent* (first figure). "*Aam · Ebm*" implies (by 2.11) "*Aam · Emb*." After changing the order of premises, one obtains "*Emb · Aam*," from which, by *Celarent*, "*Eab*" can be inferred. But this implies (again by 2.11) the conclusion of the original *Camestres*. Thus, *Camestres* has been reduced to *Celarent*, the one having been logically derived from the other.

Indirect reduction

Baroco (second figure) and *Bocardo* (third figure) cannot be reduced by conversion because *AO* premises (or *OA* premises) imply only *IO* (or *OI*) premises by conversion, which do not even form a valid syllogism, still less a perfect one. Therefore, Aristotle fell back on another proof, indirect reduction (or *reductio ad impossibile*), based on another logical law: that if a syllogism is valid, the negation of its conclusion (posited for the sake of argument) together with either of its premises will imply, as a conclusion, the negation of the remaining premise; *i.e.*,

1. $(p \cdot q \supset r) \supset (p \cdot \bar{r} \supset \bar{q})$

and

2. $(p \cdot q \supset r) \supset (\bar{r} \cdot q \supset \bar{p})$.

To show that *Baroco* (second figure),

$$Aam \cdot Obm \supset Oba$$

is valid, its conclusion "*Oba*" is hypothetically negated (by 2.9) to "*Aba.*" But "*Aam · Aba*" implies by *Barbara* (first figure) "*Abm,*" which is the contradictory of the original second premise. The hypothesis that *Baroco*'s premises may be true and its conclusion false for the same terms leads to a contradiction ("*Abm · Obm*"); therefore, this hypothesis must be false; *i.e.*, *Baroco* is valid. The reduction of *Bocardo* (third figure) is strictly analogous.

Aristotle had already stated (*Analytica priora B* 11–13) that indirect reduction can be used not only for *Baroco* and *Bocardo* but for all moods of the second and third figures and that, even within the first figure, *Darii* and *Ferio* may be reduced via *Camestres* and *Festino* (second figure) to the first-figure mood *Celarent*, using one step of direct and one of indirect reduction in each case—which reduces the number of axioms, or forms commended only by their self-evidence, to just two: *Barbara* and *Celarent*. In fact, all of the 24 valid syllogisms may be arranged into groups of three, with each member derivable from the other two by indirect reduction.

Development from antilogisms

Inasmuch as the validity of a syllogism means that the truth of the premises is incompatible with the falsity of the conclusion, then the fact that, for example, *Ama · Abm ⊃ Aba* is a valid syllogism may be expressed in another way by saying that "*Ama,*" "*Abm,*" and "*Oba*" (the negation of the conclusion) cannot be jointly true, or, equivalently (using "∼" to symbolize "not"), that *∼(Ama · Abm · Oba)*. Thus, *AAO* is defined as a (basic) antilogism. Other antilogisms are *AAE, EAI, AIE,* and *EIA* and, for the fourth figure, *AAE* and *AEI*. Since in any conjunction the order of terms is logically indifferent, the number of antilogisms from which all 24 categorical syllogisms may be developed can be reduced to just three: *AAO, AAE,* and *AIE*.

Several other types of categorical syllogism have been described (see also RELATED ENTRIES under SYLLOGISTIC in the *Ready Reference and Index*); a sorites, for example, is a polysyllogism in the form of a chain (with intermediate conclusions suppressed), with the conclusion uniting the subject of the last link with the predicate of the first, thus: *Aba · Acb · Adc . . . Eyx ⊃ Eya.* An enthymeme, as used in post-Aristotelian times, is a syllogism in which one of the premises (or even the conclusion) is suppressed, being thought too obvious to need expression. And, finally, in *Analytica priora B* 23, Aristotle introduced the inductive syllogism, which establishes a general rule by making an assuredly complete examination of all cases (one by one) and showing it to be true for every one.

Noncategorical syllogistic inferences. Besides categorical syllogisms, there are also noncategorical syllogisms of several types—hypothetical, disjunctive, and (in some treatments) copulative syllogisms. Since the fundamental difference between propositional logic, which treats unanalyzed entire propositions as its units, and predicate logic, which deals with terms in combination, was not appreciated by logicians before the rise of modern mathematical logic, there has been widespread confusion on this topic. The famous and influential *La Logique; ou l'art de penser* (1662; Eng. trans., *The Port-Royal Logic*, 1851), for example, failed to recognize the difference between implication between terms and implication between propositions and threw together arguments containing propositions such as "If the Chinese are Muslims, then they are infidels" and "If one of the elect perishes, then God is mistaken," the first being of the type expressed in modern logic by $\forall x[Fx \supset (Gx \supset Hx)]$, in which such expressions as Fx signify that "x has the property F," and the second being of the form "$p \supset q$" (in which p is called the antecedent and q the consequent). In 1887 the logician John Neville Keynes, long the registrar at the University of Cambridge, insisting on these important formal differences, suggested the name conditional for the first kind of proposition and hypothetical for the second. Noncategorical syllogistic has mainly and wisely been restricted to the important argument forms of propositional logic.

Hypothetical and disjunctive syllogisms

Hypothetical syllogisms are called pure if they consist of propositions all of which are of the form "$p \supset q$"; *e.g.*, (1) "If p then q, and if q then r; therefore if p then r." Mixed hypothetical syllogisms, however, which have one hypothetical and one categorical premise and a categorical conclusion, have two valid moods: (2) "If p then q, and p; therefore q" (called *modus ponens* from the Latin *ponere,* "to affirm"), and (3) "If p then q, but not-q; therefore not-p" (called *modus tollens,* from *tollere,* "to deny"). (For relevant fallacies, see LOGIC, APPLIED: *The critique of forms of reasoning: Formal fallacies.*)

Disjunctive syllogisms, which contain propositions built up with the "either . . . or" operator (symbolized $\vee$), have two important moods: (4) "Either p or q, but not-p; therefore q"—or: " . . . but not-q; therefore p" (called *modus tollendo ponens*); (5) "Either p or q, and p; therefore not-q"—or: ". . . and q; therefore not-p (called *modus ponendo tollens*). Mood (5) is valid, however, only if "either p or q" is taken in the sense of "at least one of p or q is true, but not both"; it is invalid, on the other hand, if "p or q" is taken in the nonexclusive sense, which does not rule out the joint truth of p and q.

A more complex form of noncategorical syllogism is the dilemma. It has two moods, one constructive, the other destructive: (6) "If q then p, and if r then p, and either q or r; therefore p"; (7) "If p then q, and if p then r, and either not-q or not-r; therefore, not-p." By an operation known as conditionalization, it is also possible—in what is essentially a reversal of the case in the dilemma—to draw hypothetical conclusions from categorical premises.

Complex and compound syllogisms

Syllogisms can also have as their terms not simple concepts like a, b, or c but terms built up from such simples by conjunction ("$a \cdot b$") or disjunction ("$a \vee b$"). Such terms, which are called complex, combine into complex propositions (example: "Every student or professor is eligible"). Compound propositions, on the other hand, are those constructed by combinations of other propositions by operators such as "If p then q," "Either p or q," or "Both p and q." Compound propositions may contain simple or complex propositions or both. "Either every student is efficient or popular, or all professors and schoolteachers are frustrated," for example, is a compound proposition formed from complex propositions.

The logical analysis of inferences from complex and compound propositions has been brought to a satisfactory level only in the 20th century by the recent development of the necessary formal methods and powerful calculi by modern mathematical logicians.

INTERPRETATION OF SYLLOGISTIC AS AN AXIOMATIC DEDUCTIVE SYSTEM

Aristotle's methods of reduction achieved something approaching an informal axiomatic system of syllogistic. At the turn of the 18th century, Gottfried Leibniz, a German Rationalist philosopher and mathematician, improved upon this method by showing how the laws of conversion and subalternation may be proved syllogistically using syllogisms of the second and third figures, and how these syllogisms, in turn, may be derived indirectly from the perfect moods. But neither of them stated rigorously the logical laws according to which these reductions and proofs were made. A formalized axiomatic system of syllogistic has, in fact, been made possible only by the methods of modern logic.

Auxiliary theory and base. For such an axiomatic representation of the syllogistic system, the following main elements are needed: As an auxiliary theory, the laws of the logic of propositions are employed (some of which were mentioned earlier). The logician may either accept as axioms (*i.e.*, without proof) the three to six axioms of the propositional calculus as variously presented by the German mathematician Gottlob Frege, by Bertrand Russell, or by Jan Łukasiewicz, three pioneers in fields of modern logic, and deduce from them all of the propositional laws that he may need; or, alternatively, he may specify certain laws (usually a dozen or more) after discovering which he will actually use.

The system must, moreover, have a base from which to derive its theorems, a list that should specify (1) primitive expressions (letters or other symbols); (2) rules of formation, according to which the logician may build up other expressions from the primitive ones; (3) axioms of the system; *i.e.*, propositions that are accepted without proof; (4) definitions, which enable the logician to substitute one form of expression for another (optional); and (5) rules of inference, which state all of the steps he may take in deriving further expressions from axioms or from other expressions already derived.

Elements of the base

For the axiomatization of syllogistic, the following list (from Łukasiewicz) contains a sufficient base:

A. Primitive expressions:
1. Three term variables, *a*, *b*, and *m*.
2. Primitive syllogistic operators *A* and *I*, each of which may be joined to any two of the term variables.

B. Rules of formation (for well-formed formulas):
1. An expression consisting of *A* or *I* followed by any two term-variables *a*, *b*, or *m* is a well-formed formula or a syllogistic expression, designated by alpha (α), beta (β), and so on.
2. If α is a syllogistic expression, $N\alpha$ (read "Not-α") is also a syllogistic expression.
3. If α and β are syllogistic expressions, $\alpha \cdot \beta$ and $\alpha \supset \beta$ are also syllogistic expressions.

C. Axioms of the system:
1. *Aaa*
2. *Iaa*
3. *Ama · Abm ⊃ Aba (Barbara)*
4. *Ama · Imb ⊃ Iba (Datisi)*

D. Definitions:
1. $Eba =_{df} NIba$
2. $Oba =_{df} NAba$

E. Rules of inference (for deriving expressions from others):
1. If α is an axiom or a derived expression (theorem) of the system, so is any expression that is the result of replacing one term-variable of α by another term-variable in all places of its occurrence in α (rule of substitution for term variables).
2. If α is a law of propositional logic, the result of replacing any propositional variable *p*, *q*, *r* . . . in α by a syllogistic expression may be asserted as a theorem provided that the same expression is inserted in all places of its occurrence (rule of substitution for propositional variables).
3. In any derived expression, the expressions that are defined by rules D1 and D2 may be substituted for any occurrence of the expressions that define them (rule of substitution for definitions). This rule does not require, however, that the replacement cover all occurrences.
4. If α and $\alpha \supset \beta$ are derived expressions, β is a theorem (rule of detachment). This rule is an application of *modus ponendo ponens* (see above *Noncategorical syllogistic inferences*).

The rules of formation generate all of the syllogistic expressions, without regard to their validity or invalidity. To select from these expressions those that are valid (theorems of the system), the foregoing axioms and rules of inference are sufficient. To show that all 24 valid syllogisms may be derived formally, it is sufficient to show how *Barbara*, *Celarent*, the rules of contradictory opposition, and the rules of conversion can be derived in the system, since this is the basis used by Aristotle.

Properties of syllogistic as a system. It is interesting to note what deductive power is possessed by each of the axioms in the system; *i.e.*, which theorems would be lost by dispensing with a given axiom and what other expression might serve as a substitute for it. Axiom C1 ("*Aaa*") is needed to derive the theorem "*Iba ⊃ Iab*" and the other rules of conversion. Since the derivations of exactly half of the 24 moods depend on conversion, only the rules of opposition and 12 of the syllogisms would remain as theorems. In the place of C1, one might add C5, "*Iba ⊃ Iab*," as an axiom to restore the full deductive power of the set of axioms. Without axiom C2 ("*Iaa*"), which guarantees that all of the terms are nonempty (*i.e.*, have application to something), the logician is left without the rules of subalternation and the other rules of opposition (except contradiction). Therefore, with axiom C2 would go all of the nine moods of the syllogism that depend on subalternation for their proof. Addition of the theorem C6 *Aba ⊃ Iba* instead of C2, however, would restore full deductive power to the system. Leaving out axiom C3 (*Barbara*) would cost only two syllogisms besides *Barbara*, viz., *Baroco* and *Bocardo*, each of which could thus serve as a substitute for C3. Since axiom C4 (*Datisi*) is needed in the proofs of C5 and C6, the result of leaving it out would be very damaging; it would equal the results of dropping C1 and C2 together, so that $9 + 12 = 21$ syllogisms would be blocked, leaving only *Barbara, Baroco*, and *Bocardo*. Any one of the syllogisms *Ferio, Cesare, Dimaris, Fresison*, or *Camenes*, however, could, taken as an axiom, repair the damage. If all four syllogistic operators *A*, *E*, *I*, and *O* were admitted instead of just two (*A* and *I*), the logician could also take *Barbara* and *Celarent*, as Aristotle did, as axioms together with C1 and C2. If, instead of C1 and C2, he would take C5 and C6 as axioms, the resulting set of axioms would be the base corresponding best to Aristotle's approach.

Deductive power of axioms

Since derivations in the system of axiomatic syllogistic depend entirely on rules for the manipulation of concatenations of signs, and not on any intuitive insights or knowledge of the meaning of these signs, it may be regarded as a formal deductive system in the modern technical sense. Thus, the formal properties of such a system can be investigated without giving the symbols any particular interpretation. One such formal property, internal consistency, is attributed to a system if it is impossible to derive a contradiction in it. Another formal question, the independence of its axioms, is at issue when the logician asks whether one of the axioms is redundant because it can be proved from the other axioms. Finally, the logician may ask whether the system is complete, in the sense that it is always possible, for any well-formed formula α, to devise a proof either that it is a theorem or that its negation is a theorem.

Consistency of a system

If a system is inconsistent, it is, for all purposes of deduction, without value, since any proposition whatsoever must then be derivable in it. That this is so is easily shown: A contradiction must be of the form "$p \cdot \bar{p}$." If "$p \cdot \bar{p}$" is a theorem, then according to the propositional law "$p \cdot \bar{p} \supset p$," one infers, by the rule of detachment, *p*. With *p*, it follows also that "$p \vee q$"—because "$p \supset (p \vee q)$" is again a law of propositional logic. If "$p \vee q$" is a theorem, however, it is possible to derive $\bar{p}$ again from "$p \cdot \bar{p}$" and to have, by an application of *modus tollendo ponens*, also *q*. This means that in an inconsistent system any proposition that one likes is derivable as a theorem, and the system is therefore deductively useless.

A system is sufficiently shown to be consistent if its axioms are consistent; for the rules of inference guarantee that no false proposition will be derivable from true ones. Therefore, in case of inconsistency anywhere, the

axioms themselves already must have been inconsistent. Hence, a proof of the consistency of a formal system must cite an interpretation for the axioms that makes them all true propositions. For the system of syllogistic, various such interpretations, mostly from arithmetic or propositional logic, have been given.

Independence and completeness

In a similar way—and in a manner resembling Aristotle's method of invalidating moods by counterexamples—it may be shown that each of the axioms is independent of the others (*i.e.*, is not derivable from them) by producing an interpretation that makes the axiom in question false and the other axioms true. It is then obvious that this axiom cannot logically follow from the others, since its falsity would be incompatible with their joint truth. Simple proofs of independence have been devised—with interpretations taken from the propositional calculus and arithmetic—for all of the axioms except *Barbara*, for which the proof is complicated. These proofs have shown that none of the axioms can be regarded as being the one and only principle of syllogistic.

The preceding system is strong enough to derive all valid theorems of syllogistic from the stated axioms. For completeness, however, it is further required that a formal proof be provided for the negation of any invalid syllogistic expression. But, since this cannot be done, the system is not complete. The system may be strengthened by adding two axioms, viz., the negations of "*AAI*" and "*EEI*" in the second figure, and certain rules of rejection, corresponding to the rules of substitution and the rule of detachment for inference. Though with these additions to the base, it is possible to reject all invalid syllogistic moods, it is still not possible to reject such invalid syllogistic expressions as those having more than three terms and some of those having two terms. By an ingenious method, devised by the Polish logician L. Słupecki, a stronger rule of rejection has been formulated that makes the system complete in the sense defined.

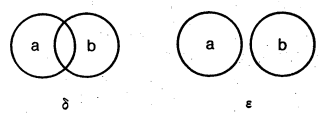
EXTENSIONS OF SYLLOGISTIC

Singular and negative terms. Expressions like "Socrates" or "the founder of psychoanalysis," called singular terms because they refer to but one unique particular, yield propositions that are formally different from general ones. All syllogistic laws, however, are formulated for general propositions only. Though Aristotle seems to have thought that singular propositions were a special kind of universal proposition, the rules of opposition fail for them and they cannot be converted or changed by contraposition, because proper names can only take the subject place in a proposition. "Socrates is mortal" can be replaced, of course, by "Everything identical with Socrates is mortal," which defines a class of only one member; but this solution does not really introduce singular terms into syllogistic but keeps them out while taking care of all statements that contain them. Moreover, if proper names can only replace subject terms, the only allowable syllogisms incorporating singular premises are those in which singular terms occur twice in the subject place. One may therefore substitute singular terms instead of b in the first and second figures and in place of m in the third figure. These requirements limit the syllogisms that can have singular terms to *Barbara, Celarent, Cesare, Camestres, Darapti,* and *Felapton.*

Confinement to subject position

Aristotelian syllogistic avoids negative terms like $\bar{a}$, $\bar{b}$, and $\bar{m}$. The modern way of expressing syllogistic propositions, however, is to treat *E*- and *O*-propositions as *A*- and *I*-propositions with a negated predicate term. Because the modern functional calculus allows the negation of subject terms as well, the foregoing syllogistic can only cover a fragment of the class of possible expressions of predicate logic. The question arises, therefore, whether the axiom system for syllogistic might be extended to cover propositions with negated term-variables—which would make the so-called exclusive propositions, such as "Only students are members," and exceptive propositions, such as "All but (except) heroes are frightened," also amenable to syllogistic treatment. The exclusive proposition can be translated into "Every nonstudent is a nonmember" and represented as "$A\bar{b}\bar{a}$," which is equivalent to "Aab" by contraposition. Moreover, the exceptive proposition, being translatable into the conjunctive proposition "Every nonhero is frightened and no hero is frightened," is of the form "$A\bar{b}a \cdot Ab\bar{a}$," which amounts to saying that a and b are disjunctive terms in the mutually exclusive sense. Because the terms may be combined in four ways, ba, $b\bar{a}$, $\bar{b}a$ and $\bar{b}\bar{a}$, each of which can take the four operators *A*, *E*, *I*, and *O*, there are 16 logically different forms of syllogistic propositions and 16 further converse forms; *i.e.*, 32 forms of propositions in this system. If one now disqualifies empty terms, he must also exclude universal terms, which apply to everything (like "self-identical" or "mentionable") since, if a is a universal term, $\bar{a}$ must be empty. A problem now arises in the interpretation of the Euler diagrams (δ) and (ε):

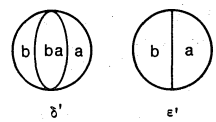
Exclusion of universal terms



δ ε

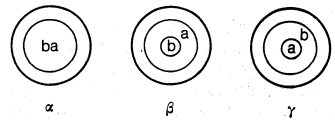
There can be objects that are $\bar{b}$ and objects that are $\bar{a}$; but it is possible that there are no objects that are both $\bar{b}$ and $\bar{a}$, because b and a might be complementary classes that between them exhaust the universe. There may then be cases of "$Ib\bar{a}$" and "$I\bar{b}a$," but not of "$I\bar{b}\bar{a}$," or there may be cases in which no $\bar{b}$ is an $\bar{a}$ (*i.e.*, "$E\bar{b}\bar{a}$," which is equivalent to "$A\bar{b}a$"; *i.e.*, to "Everything that is not b is a," there being nothing else in the universe but things that are a or b).

Two more diagrams must therefore be introduced, presenting the special subcases of (δ) and (ε):



δ' ε'

in which the circle represents the total universe of discourse. To bring the rest of the diagrams up to this level of abstraction, such a circle should then be added also to the diagrams (α)–(γ):



α β γ

By introducing negative terms, the rules for the validity of syllogisms are somewhat altered. Since "Aba" is equivalent to "$Eb\bar{a}$," the valid syllogism "$Em\bar{a} \cdot Eb\bar{m} \supset Eb\bar{a}$" arises—merely another way of expressing *Barbara.* Moreover, "$Em\bar{a} \cdot Eb\bar{m} \supset Aba$." Since these syllogistic forms seem to violate the rules of quality, it should be stipulated that those rules should apply only to a syllogistic without negative terms. An axiom system called $CS(n)$ has been devised, which differs from the system described above by admitting negative terms, by dropping *Barbara* from the axioms, by using as definitions "$Eba =_{df} Ab\bar{a}$" and "$Iba =_{df} NAb\bar{a}$," and by having a special rule of inference for double negation.

Empty terms and existential import. The fact that no empty terms may replace any of the term-variables is a deficiency of traditional syllogistic that calls for certain precautions. In the early 1970s, for example, no one knew whether gravitation waves existed; but, from "Every gravitation wave is a physical phenomenon," there is a danger that, without this ban on empty terms, the proposition "Some gravitation wave is a physical phenomenon" might be inferred. This statement, however, implies by conversion that "Some physical phenomenon is a gravitation wave," which in turn would most naturally be interpreted as asserting the existence of gravitation waves.

Modifications owing to emptiness

In order to admit terms regardless of their emptiness or nonemptiness, certain revisions of the earlier laws are required. It is important to specify, for example, which syllogistic expressions are to be false if containing empty terms. Three different specifications have been discussed by logicians: (1) that *A*-, *I*-, and *O*-propositions, but not

E-propositions, presuppose the existence of both terms for their truth; (2) that *A*- and *I*-propositions, but not *E*- and *O*-propositions, presuppose nonemptiness of their terms; (3) that *I*- and *O*-propositions presuppose nonemptiness, whereas *A*- and *E*-propositions do not.

In cases (1) and (2), all of the laws $CS(n)$, with the exception of inversion and contraposition ("$Aba \supset I\bar{b}\bar{a}$" and "$Aba \supset A\bar{a}\bar{b}$") would remain valid. Since these theorems are not used by $CS(n)$ for the derivation of syllogisms, however, all syllogistic moods remain. Specification (3) has much more to commend it. *A*- and *E*-propositions may be defined as negations of the corresponding *O*- and *I*-propositions. But "*Iba*" is most naturally interpreted as asserting the existence of objects that are both *b* and *a* and must therefore be false if *a* or *b* is empty. The same applies, correspondingly, to "*Oba*" in relation to *b* and $\bar{a}$. Since "*Aba*" and "*Eba*" are negations of "*Oba*" and "*Iba*," respectively, they must be true if "*Iba*" and "*Oba*" happen to be false through lack of reference of their terms. In this way, the laws of contradictory opposition remain valid. But subalternation is invalid: "*Aba*" may be true merely because "*Oba*" fails for lack of existential reference of *b*; but in this case "*Iba*" is also false. Contrary opposition and subcontrary opposition now vanish from the logical square: "*Aba*" and "*Eba*" may both be true and "*Oba*" and "*Iba*" may both be false in case there is a lack of reference for *b*. The most important law that is sacrificed, however, is "$Aba \supset Iba$," since the derivation of all moods having universal premises and particular conclusions depend on this law. The effect is the same as that of dropping the axiom "*Iaa*" from the system described earlier: *Barbari, Camestrop, Felapton, Celaront, Cesaro, Darapti, Bramantip, Fesapo,* and *Camenop* are then lost and only 15 moods remain. Since specification (3) for the existential import of *A*-, *E*-, *I*-, and *O*-propositions is equivalent to those adopted for general and particular propositions in the modern predicate calculus, the 15 remaining moods are the theorems of the syllogistic when interpreted in the predicate calculus. This is not to say, however, that Aristotle's syllogistic is incorrect, but only that he and his followers never formulated the existence postulates for their syllogistic terms. If these were made explicit and added to the premises of all syllogistic laws, they would all again become laws of predicate logic also.

Boolean algebra and Venn diagrams

When negative and empty terms are admitted, syllogistic becomes a special case of Boolean algebra, which can be defined as any system incorporating the concepts of a universal class, of a null class, and of the complement of a class, and those of class union and class intersection. The null class is denoted by 0, the universal class by 1; and if *a* is a class, $\bar{a}$ is its complement class. Emptiness is expressed by saying that the class is identical with the null class or that "$a = 0$"; universality, expressing the fact that the term *a* applies to everything, is represented by "$a = 1$." Clearly, if a term is empty, its complement class is identical with the universal class. The class that contains the common members of the terms *a* and *b* is denoted by $a \cap b$ and is called the intersection of *a* and *b*. The union of classes *a* and *b*, expressed by $a \cup b$, is the class of all of those things that belong either to *a* or to *b*. If two classes have the same objects as members—that is, if *a* and *b* are extensionally identical—then this fact is expressed by "$a = b$." Nonidentity of classes is expressed by "$a \neq b$."

In this language, the syllogistic propositions may now be expressed in the following way:

$$\begin{aligned} Aba &= _{df}\ b \cap \bar{a} = 0 \\ Eba &= _{df}\ b \cap a = 0 \\ Iba &= _{df}\ b \cap a \neq 0 \\ Oba &= _{df}\ b \cap \bar{a} \neq 0. \end{aligned}$$

Barbara, in this notation, is then:

$$(m \cap \bar{a} = 0 \cdot b \cap \bar{m} = 0) \supset b \cap \bar{a} = 0$$

and *Datisi* becomes:

$$(m \cap \bar{a} = 0 \cdot m \cap b \neq 0) \supset b \cap a \neq 0.$$

To test such Boolean syllogisms for validity, the Venn diagrams, so-called after the British logician John Venn, who devised them in 1880, provide an ingenious method. He represents the extension of the three terms by three interlocking circles as shown in Figure 3. A region that is said to be empty in a premise is shaded out; and a region said to be not empty is marked by a cross inside the region. The Venn diagram for *Barbara* is shown in Figure 4. Its first premise states that the intersection of *m* and $\bar{a}$ is empty; therefore, one shades out all of *m* that is outside of *a*. The second premise states that the intersection of *b* and $\bar{m}$ is empty; therefore, one shades out all of *b* that is outside of *m*. The conclusion, finally, states that the intersection of *b* and $\bar{a}$ is empty. If, accordingly, the logician wants to shade out the region of *b* that is outside of *a*, he finds that this has been done already by the stipulations of the premises: the conclusion states nothing that has not been stated by the premises taken together; therefore, *Barbara* is valid.

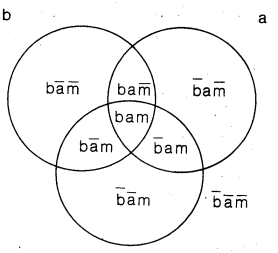


Figure 3: Basis of the Venn diagrams.

Venn proofs of *Barbara* and *Datisi*

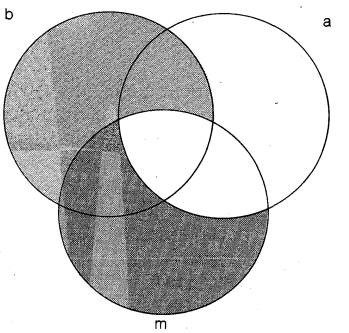

Figure 4: Venn diagram for *Barbara*.

The proof of *Datisi* proceeds as follows (see Figure 5). The first premise is illustrated by shading out the region of *m* that is outside of *a*. The second premise requires that a cross be placed in the region where *m* and *b* overlap. Since part of this region has been shaded out already, the cross can be put only into the part still left white; *i.e.*, the part where *m* and *a* and *b* overlap. The conclusion calls for a cross to be put into the overlapping region of *a* and *b*. The logician finds, however, that there is a cross already in this part; therefore *Datisi* is valid.

Problem of a syllogistic of possibility and necessity

Modal and other special operators. Aristotle devoted the greater part of his *Analytica priora* to the analysis of modal syllogisms; *i.e.*, syllogisms complicated by the addition of such modal operators as "possible" and "necessary," as in the statements "It is possible that some of the soldiers who retreated are not cowards" and "Every cat is necessarily a mammal." Aristotle's treatment of modal syllogistic, however, was unsatisfactory: among other de-

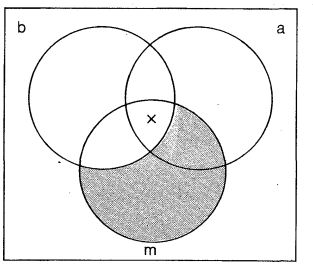

Figure 5: Venn diagram for *Datisi*.

fects, it was confused by his failure to decide whether a modal operator should determine the whole proposition (first example above) or only its predicate (second example). This problem reflects the dilemma that, if modal operators modify predicates only, then no special *modal* syllogistic is required, because the propositions have a normal structure (but with peculiar predicates); but if they modify whole propositions, then again no modal *syllogistic* is needed, because the special rules for the modal operators are independent of the intrinsic character of the statements. Thus modal syllogistic would best be developed in the propositional logic and not in the predicate logic of ordinary syllogistic, and it would then be merely a special case of general modal logic. Aristotle's treatment of it under syllogistic must then be attributed to his overrating of this new method rather than to the intrinsic aptness of the allocation.

Over the past decades new fields of logic have been drawn up under such names as the logic of assertion, the logic of epistemic propositions, deontic logic, and tense logic, to mention only a few. One may thus ask whether there is also a syllogistic that employs the special operators of these branches instead of the copula and the operators *A*, *E*, *I*, and *O*. In a role parallel to that of the modal functors, deontic operators might now be introduced such as "it is obligatory that," "it is forbidden that," or "it is allowed that"; the copulae might be varied according to tenses like past, present, and future; or epistemic functors like "____ is known to be a ____" might be employed. Here again, however, it is likely that in due time these new fields will be found subject to the same criticisms just raised against a modal syllogistic and that they might best be discussed in the field of propositional logic.

PRESENT STATUS OF TRADITIONAL LOGIC

Since the rise of modern mathematical logic alongside traditional logic, the relation between these two branches has sometimes been strained. Admirers of mathematical logic have asserted (1) that traditional logic is without useful application in the sciences, (2) that it covers only a very small fragment of logic, and (3) that it contains fundamental errors; *e.g.*, the acceptance of inferences from general to particular propositions.

The admirers of traditional logic have sometimes replied (4) that mathematical logic is merely a branch of mathematics, not of philosophy, and (5) that the results of mathematical logic cannot be compared in philosophical significance with the classical syllogistic theory.

Rejoinders to critical points

Point (4) is merely a matter of definition and can be neglected; point (5), however, seems to be confuted by the profound influence that modern logic has already exerted on the course of philosophy. Point (1) must be conceded: syllogistic theory was important for science at a time when science was endeavouring to bring particulars under general concepts and to establish a system of classification. In modern science, however, there is not much scope for such activities. Syllogistic arguments are used, however (in enthymeme form), when scientific results are applied, as in the application of law or in medical therapy. Point (2) is true: syllogistic is, indeed, a very small part of logic; but it is a very fundamental and important one. Almost all new ideas in the history of logic have been developed in connection with some special aspects of syllogistic theory. Point (3) is simply false: traditional logic is as correct as modern formal logic. But it is not formalized and, thus, not all of its presuppositions have been made explicit.

To sum up, syllogistic is a special part of logical theory. Its systematic importance has been overrated, however, by those who have tried to bring all of logic into the compass of Aristotelian logic. Because syllogistic is the first deductive system ever devised and was constructed by Aristotle with so high a level of rigour and logical purity, it has proved to be very fruitful as a starting point for generations of later logicians. Modern logic is not in opposition to traditional logic; it is a continuation of it—with better instruments and methods and in a much larger field.

BIBLIOGRAPHY. The standard edition of Aristotle's texts on syllogistic is: *Aristotle's Prior and Posterior Analytics*, with introduction and commentary by W.D. ROSS (1949). For the interpretation of Aristotle's syllogistic, see the chapter "La Syllogistique," in L. COUTURAT, *La Logique de Leibniz* (1901, reprinted 1961); J. LUKASIEWICZ, *Aristotle's Syllogistic from the Standpoint of Modern Formal Logic* (1951; 2nd ed., with a chapter on modal syllogistic, 1957); G. PATZIG, *Die Aristotelische Syllogistik* (1959; 3rd ed. 1969; Eng. trans., *Aristotle's Theory of the Syllogism*, 1968); and STORRS MCCALL, *Aristotle's Modal Syllogisms* (1963).

Traditional logic: The best textbook is J.N. KEYNES, *Studies and Exercises in Formal Logic* (1884; 4th ed., 1906). Remarkable for discussion of traditional theories in the conceptual framework of mathematical logic is A.N. PRIOR, *Formal Logic*, 2nd ed. (1962), with bibliography. The best history of logic is W. and M. KNEALE, *The Development of Logic* (1962), with bibliography.

Modern developments, axiomatization, and extensions of syllogistic: I.M. BOCHENSKI, "On the Categorical Syllogism," *Dominican Studies*, 1:35–57 (1948); a development of an axiomatic system for syllogistic with negative terms is given in I. THOMAS, "*CS*(*n*): An Extension of *CS*," *Dominican Studies*, 2:145–160 (1949); C.A. MEREDITH, "The Figures and Moods of the *n*-term Aristotelian Syllogism," *Dominican Studies*, 6:42–47 (1953); A. MENNE, *Logik und Existenz* (1954); P. LORENZEN, "Über Syllogismen als Relationenmultiplikationen," *Arch. math. Logik GrundlForsch.*, 3:112–116 (1957); OTTO BIRD, *Syllogistic and its Extensions* (1964), the best introduction to the subject, with bibliography.

Sylvester II, Pope

Sylvester II, pope from 999 to 1003, was renowned, as Gerbert, for his scholarly achievements, his advances in educational methods, his shrewd political judgments, and the exceptional ability that lifted him from his peasant origin to two archbishoprics—Reims and Ravenna—and supreme headship of the church.

Early life and career

Gerbert was born of humble parentage about 945 near Aurillac in the ancient French province of Auvergne. He was trained at Saint-Gerald in grammar, arithmetic, and music under the tutelage of Raymond Lavaur, who later became abbot of Aurillac, where Gerbert probably became a monk.

Gerbert was taken to Spain in 967 by Count Borrell of Barcelona and remained there three years. At the monastery of Santa María de Ripoll, which was noted for its fine library, he studied the quadrivium (the higher division of the liberal arts, which includes music, arithmetic, geometry, and astronomy) under Bishop Atto of Vich.

In 970 Gerbert accompanied Borrell to Rome, where his mathematical knowledge delighted Pope John XIII, who presented him to the Holy Roman emperor Otto I. Gerbert was then entrusted with his first royal pupil, Otto II. Lively Socratic discussions, however, convinced Gerbert that he lacked training in logic, and, when a skilled logician, Archdeacon Gerann of Reims, visited Rome, Gerbert gained permission to study in Reims under Gerann's tutelage.

Logic and dialectic so captivated Gerbert that, after being invited by Adalbero (who later ordained him) to teach at the cathedral school, he became famous for reorganizing logical and dialectical studies. Gradually, he eliminated simpler logical works and added monographs on logic by Boethius, an early-6th-century Roman philosopher.

Gerbert's fame aroused the jealousy of Otric, master of the cathedral school at Magdeburg in Saxony (presently in the German Democratic Republic), who denounced Gerbert to Emperor Otto II. In December 980 Otto provoked a debate in Ravenna between Gerbert and Otric on the subject of classifying knowledge. The vehement argument that resulted was terminated only when the Emperor intervened.

Otto subsequently gave Gerbert the headship of the wealthy monastery of St. Columban of Bobbio (southwest of Piacenza, Italy), and Benedict VII consecrated him abbot of the monastery. Gerbert, however, was inexperienced in administration and unfamiliar with the land law in the region of Lombardy. As a result he encountered violent hostility from monks, clerics, and nobles,

Opposition to Gerbert's monastic rule

who possessed much of Bobbio's extensive property through long-term civil-law land leases and refused to make contractual payments or supply troops demanded by Otto. Some even stole the abbey's agricultural products. Within Otto's palace in Pavia (west of Piacenza), nobles plotted against Gerbert and even against Otto himself.

Rebellion followed Otto's death (December 983), forcing Gerbert to flee from Bobbio and hasten to Reims. He travelled and wrote urgent letters to arouse Germans, Belgians, and Lorrainers against Duke Henry of Bavaria, who was plotting to become king by seizing the three-year-old King Otto III. Gerbert resumed teaching at Reims but he really longed to be summoned to the imperial court.

After the deaths of the last Carolingian kings (Lothair in 986 and Louis V in 987), Adalbero and Gerbert influenced the nobles to elect Duke Hugh Capet king against the claims of the remaining Carolingian, Duke Charles of Lorraine. As Hugh's secretary and adviser, Gerbert became involved in Hugh's resistance to Charles's attempt to dethrone him. Before Adalbero died, in January 989, he indicated Gerbert as his successor, but Hugh unwisely chose Arnulf, an illegitimate son of King Lothair. In September Arnulf betrayed Reims to Charles, his uncle, who forced Gerbert to remain in the city. After eight months Gerbert managed to escape to Hugh's court, where he was falsely accused of having been the leader in "enormous crimes" of collaboration with Duke Charles.

In June 990 the bishops and Hugh appealed to Pope John XV to condemn and depose Arnulf and approve their consecration of a new archbishop. After Hugh captured Charles and Arnulf in March 991, a council at Saint-Basle de Verzy, near Reims, degraded Arnulf. Gerbert was elected archbishop and soon became embroiled in controversies with the papacy. He administered his ecclesiastical duties capably, but the clergy's confidence in the legality of his election decreased. When a newly appointed bishop refused to be consecrated by him and travelled to distant Rome for consecration by the Pope, Gerbert hastened to Rome to defend the legitimacy of his election. In the meantime, however, Pope John had died and Gerbert was heard by his successor, Gregory V, who rejected Gerbert's plea.

Returning north through Pavia, he met Otto III, then 16 and recently crowned emperor. Gerbert's witty intelligence charmed Otto, who immediately made use of his talents for writing letters. They parted reluctantly after August 5, 996. In January 997 a council declared that all bishops involved in Arnulf's deposition were removed from office. By April Gerbert, no longer tolerating the clergy's acceptance of these decrees, left Reims for Otto's court in Aachen (in modern West Germany), never to return to France.

He became a teacher again and a musician in Otto's chapel; he also travelled with Otto to Magdeburg, where he displayed his inventiveness by constructing a timepiece (*horologium*). In October he followed Otto to Italy, where Otto had him appointed (*c.* April 998) archbishop of Ravenna, an important city for Otto's control over Italy. Gerbert instigated a new agricultural policy in Italy by having Bobbio's frustrating long-term leases quashed and restricting future leases to the lifetime of the grantor abbot or bishop; this was, perhaps, the most important legislation enacted for Italy during the reign of Otto.

Elected pope

Within a year after Gerbert took over the see of Ravenna, Gregory V died, and Otto was able to choose Gerbert as Gregory's successor. He was consecrated—the first Frenchman to be elevated to the throne of Peter—on April 9, 999, and took the name Sylvester II, declaring his cooperation with Otto's ideal of a renewed Christian Roman Empire.

Their unanimity is shown by numerous documents issued by papal and imperial chanceries that use similar terms. Each appeared as intercessor for a petitioner in documents of the other and also participated in councils of the other. The two men disagreed on only one important political decision, the crowning of Duke Bolesław as king of Poland. Sylvester permitted establishment of Gniezno as an archbishopric independent of the German hierarchy but refused Otto III's desire to elevate Bolesław to kingship. Sylvester did agree, however, to create Stephen king of Hungary and to erect an independent archbishopric there. Otto's sudden death, on January 23, 1002, terminated their close cooperation.

Sylvester II, detail from the ivory vessel used at the consecration of Otto III, 996. In the Domschatzkammer des Aachener Domes, Aachen, West Germany.

To extend papal influence, Sylvester communicated with Vladimir I, the grand prince and first Christian ruler of Russia; demanded that King Olaf I Tryggvason of Norway, who made Christianity the official religion of the country, abandon the use of runic writing; sent ambassadors to Dalmatia (a coastal district of modern Yugoslavia); reprimanded the Doge of Venice and the Patriarch of Grado (on the northeastern coast of Italy) for the Venetian clergy's loose morals; held semi-annual general councils; and restored Arnulf to the Reims archbishopric, ending the divisive Reims controversy. He granted Poland its first archbishop (in 1000); and he denounced simony (the buying and selling of ecclesiastical offices) and nepotism and demanded celibacy. Bishops and nobles often exerted authority over wealthy abbeys; the abbeys thus petitioned Sylvester to free them from all exterior control except that of the papacy. Included in their request was the important right to elect their own abbots. Sylvester's acquiescence reduced the power of the bishops and increased that of the pope. To strengthen the papacy still further, Sylvester began its feudalization by enfeoffing Count Daiferio of Terracina in return for military service.

Sylvester died on May 12, 1003, and immediately legends about his great learning surfaced, revealing the impression he made on contemporaries. Some attributed his learning to magical arts learned in Spain, some to the devil's coaching, some to an artificial head that answered his questions.

Assessment

Gerbert was a great scholar, and he was also a good teacher and devised several practical means for learning: a chart for learning rhetoric; his writing about the abacus, which became the basic work on the subject and included

the use of Hindu-Arabic numerals, which he had learned in Spain; celestial globes; a hemisphere for learning the imaginary celestial circles; and auxiliary spheres, one for identifying constellations and another with planetary orbits. He acquired an astrolabe and wrote about its uses. He prepared a work on geometry that attempted to fill the gap caused by the existence of a fragmentary Euclid and that included writings by the Roman surveyors. He had an extraordinary knowledge of music and seems to have constructed several organs and also a monochord for studying music theory. His philosophical tract *De rationali et de ratione uti* ("Concerning the Rational and the Use of Reason") emphasized problems of definition and classification of knowledge.

Gerbert was an avid collector of manuscripts, which he kept locked in four or five chests; only three of these manuscripts have been identified. He also kept copies of his letters, which were written in good Latin; his original collection has disappeared, but two copies have survived. Only one contemporary biography exists: a work written by Richer of Saint-Rémy, who believed that Gerbert was sent to Reims "by the Divinity Itself." (This account was discovered only in modern times, in the cathedral library in Bamberg, Germany.) Thus for a long time even learned men relied on legends for knowledge of Gerbert.

Eventually, however, scholars discovered and published critical editions of his writings that dispelled many of the fables that had accumulated around him.

Gerbert remains the dominating figure of the late 10th century for modern scholars, who are concerned especially with more precise dating of his letters and a more detailed understanding of his political roles, his teaching (especially in logic, dialectic, mathematics, and astronomy), his transmission of Arabic learning, his relations with Otto III, his papacy, and his influence on later ages.

BIBLIOGRAPHY. RICHER, *Histoire de France (888–995)*, ed. and trans. into French by ROBERT LATOUCHE (1937), by Gerbert's pupil, is basic and accurate but with omissions; it ends in 998. Editions of Sylvester's works include ALEXANDRE OLLERIS, *Oeuvres de Gerbert* (1867), with an extensive biography; JULIEN HAVET, *Lettres de Gerbert* (1889), critical edition, superseding previous editions; and HARRIET LATTIN, *The Letters of Gerbert, with His Papal Privileges As Sylvester II* (Eng. trans. 1961), based on manuscripts and the Havet edition of letters—dates letters and privileges, lists Sylvester II's non-extant and spurious documents, and contains an extensive bibliography. LA SALLE DE ROCHEMAURE, *Gerbert Silvestre II* (1914), is the best biography to date (illustrated); see also OSCAR G. DARLINGTON, "Gerbert, the Teacher," *Am. Hist. Rev.*, 52:456–467 (1947), which emphasizes practical aspects but misunderstands Gerbert's astronomical instruments; HARRIET LATTIN, *The Peasant Boy Who Became Pope* (1951), thoroughly researched and illustrated but slightly fictionalized; and E.R. CHAMBERLIN, "Pope Silvester II, 999–1003," *History Today*, 19:115–121 (1969), based on old scholarship.

Symbolism and Iconography, Religious

Symbolism, the basic and often complex artistic forms and gestures used as a kind of key to convey religious concepts, and iconography, the visual, auditory, and kinetic representations of religious ideas and events, have been utilized by all the religions of the world since time immemorial.

NATURE AND SIGNIFICANCE

Religion, according to the traditional interpretation of 18th-century Rationalism, was understood as a system of experiences, ideas, teachings, and practices the central focus of which is a belief in supernatural beings. Because of an emphasis on dogmatic or rationalistic interpretations during that period, the symbolic aspects were de-emphasized. During the age of Romanticism (roughly 1760–1870) the importance of the symbolical and pictorial for religion was rediscovered and revived, as noted in the works of the English poet and artist William Blake and three Germans: the theologian Friedrich Schleiermacher, the philologist and archaeologist George Friedrich Creuzer, and the Roman Catholic writer Joseph von Görres. In the 20th century the symbolical character of religion has often been stressed and upheld in contrast to all attempts to present it rationally. To some extent, the symbolic aspect of religion is even considered by some scholars—because of psychological and mythological studies—as the main characteristic of religious expression. Scholars of the study of comparative religions and of ethnology and psychology have gathered and interpreted an abundance of material on the symbolical aspects of religion, especially in relation to Eastern and primitive religions. In recent Christian theology and liturgical practices a revaluation of their symbolical elements has occurred.

The importance of symbolical expression and of the pictorial presentation of religious facts and ideas has been confirmed, widened, and deepened both by the study of primitive cultures and religions and by the comparative study of world religions. Systems of symbols and pictures that are constituted in a certain ordered and determined relationship to the form, content, and intention of presentation are believed to be among the most important means of knowing and expressing religious facts. Such systems also contribute to the maintenance and strengthening of the relationships between man and the realm of the sacred or holy (the transcendent, spiritual dimension). The symbol is, in effect, the mediator, presence, and real (or intelligible) representation of the holy in certain conventional and standardized forms.

RELIGIOUS SYMBOLS AND SYMBOLIZATION

The word symbol comes from the Greek *symbolon*, which means contract, token, insignia, and a means of identification. Parties to a contract, allies, guests, and their host could identify each other with the help of the parts of the *symbolon*. In its original meaning the symbol represented and communicated a coherent greater whole by means of a part. The part, as a sort of certificate, guaranteed the presence of the whole and, as a concise meaningful formula, indicated the larger context. The symbol is based, therefore, on the principle of complementation. The symbol object, the picture, the sign, the word, and the gesture require the association of certain conscious ideas in order to fully express what is meant by them. To this extent it has an esoteric and at the same time an exoteric, or a veiling and a revealing, function. The discovery of its meaning presupposes a certain amount of active cooperation. As a rule, it is based on the convention of a group that agrees upon its meaning. Symbols, however, may also be individually and subjectively constructed.

Concepts of symbolization. In the historical development and present use of the concepts of symbolization, a variety of categories and relationships must necessarily be differentiated. Religious symbols are used to convey concepts concerned with man's relationship to the sacred or holy (*e.g.*, the cross in Christianity) and also to his social and material world (*e.g.*, the *dharma-cakra*, or wheel of the law, of Buddhism). Other nonreligious types of symbols have achieved increasing significance in the 19th and 20th centuries, especially those dealing with man's relationship to and conceptualization of the material world. Rational, scientific–technical symbols have assumed an ever increasing importance in modern science and technology. They serve partly to codify and partly to indicate, abbreviate, and make intelligible the various mathematical (*e.g.*, $=$, equality; $\equiv$, identity; $\sim$, similarity; $\parallel$, parallel; or $<$, less than), physical (*e.g.*, $\sim$, alternating current), chemical (*e.g.*, , benzene ring), biological (*e.g.*, ♂, male; ♀, female), and other scientific and technical relationships and functions. This type of "secularized" symbol is rooted, to a degree, in the realm of religious symbolism. It functions in a manner similar to that of the religious symbol by associating a particular meaning with a particular sign. The rationalization of symbols and symbolical complexes as well as the rationalization of myth have been in evidence at least since the Renaissance.

The concept of the religious symbol in its literal sense and in the symbolical expression of religious realities, however, also embraces an abundantly wide variety of

types and meanings. Allegory, personifications, figures, analogies, metaphors, parables, pictures (or, more exactly, pictorial representations of ideas), signs, emblems as individually conceived, artificial symbols with an added verbal meaning, and attributes as a mark used to distinguish certain persons all are formal, historical, literary, and artificial categories of the symbolical. If one looks for a definable common denominator for the various types of symbols, one could perhaps choose the term "meaning picture" or "meaning sign" to best describe the revealing and at the same time the concealing aspects of religious experience. The symbol (religious and other) is intended primarily for the circle of the initiated and involves the acknowledgment of the experience that it expresses. The symbol is not, however, kept hidden in meaning; to some extent, it even has a revelatory character (*i.e.*, it goes beyond the obvious meaning for those who contemplate its depths). It indicates the need for communication and yet conceals the details and innermost aspects of its contents.

Varieties and meanings associated with the term symbol. Different forms and levels of the experience of and relationship to reality (both sacred and profane) are linked together with the concepts of symbol, sign, and picture. The function of the symbol is to represent a reality or a truth and to reveal them either instantaneously or gradually. The relationship of the symbol to a reality (whatever it may be) is conceived of as somewhat direct and intimate and also as somewhat indirect and distant. The symbol is sometimes identified with the reality that it represents and sometimes regarded as a pure transparency of it. As a "sign" or "picture" the representation of the experience of and relationship to reality has either a denotative or a truly representative meaning. The doctrine of the eucharistic (sacramental) presence of Christ in the teachings of Eastern Orthodoxy, Roman Catholicism, and the Protestant Reformers (Luther, Zwingli, Calvin, and Kaspar Schwenckfeld) concretely demonstrate the various and extensive levels of symbolical understandings. These levels extend all the way from the concept of physical identity in the transubstantiation theory of Roman Catholicism (in which the substance of breadness and wineness is believed to be changed into the body and blood of Christ, though the properties of the elements remain the same) through Luther's Real Presence theory (in which Christ is viewed as present, though the question of how is not answered because the question of why he is present is considered more important), and Zwingli's sign (symbolic or memorial) theory, to the concept of mere allusion. The concept of the symbol, however, includes all these interpretations.

Denotative and cognitive aspects

Furthermore, a symbol in its intermediary function has aspects of epistemology (theory of knowing) and ontology (theory of being). As a means of knowledge, it operates in a characteristically dialectical process of veiling and revealing truths. It fulfills an interpretative function in the process of effectively apprehending and comprehending religious experience. In doing so, the word, or symbol—with its meaning, contextual use, relationship to other types of religious expression, and interpretative connection with the various forms of sign, picture, gesture, and sound—plays an important part in the process of symbolical perception and reflection. Although the symbol is an abbreviation, as a means of communication it brings about—through its connection with the object of religion and with the world of the transcendent—not only an interpretative knowledge of the world and a conferral or comparison of meaning to life but also a means of access to the sacred reality. It may possibly even lead to a fusion, or union of some sort, with the divine. To this extent, the sacrament of the Lord's Supper, the liturgical and ritualistic mystery in Christianity—with its many symbolical signs, pictorial representations, significative actions, interpretative words, and various levels of approach to the divine reality—is an example of a highly developed form of a complex symbolic action. Here, the concept of analogy is important; the symbol functions in these ways because it has an analogous cognitional as well as existential relationship to that which it signifies.

The symbolic process. To trace the origin, development, and differentiation of a symbol is a complicated process. Almost every symbol and picture in religion is at first either directly or indirectly connected with the sense impressions and objects of man's environment. Many are derived from the objects of nature, and others are artificially constructed in a process of intuitive perception, emotional experience, or rational reflection. In most cases, the constructions are again related to objects in the world of sense perception. A tendency toward simplification, abbreviation into signs, and abstraction from sense objects is quite evident, as well as a tendency to concentrate several processes into a single symbol. A good example of this last tendency may be seen in ancient Christian portrayals of the triumphant cross before a background of a star-filled heaven that appear in the apses of many basilican churches. In these representations the Crucifixion, Resurrection, Ascension, exaltation, and Transfiguration of Christ are joined to apocalyptic concepts (centring on sudden interventions by God into history) inherent in the doctrine of the Last Judgment. An excellent example of such an apse mosaic is to be found in the S. Apollinare in Classe, near Ravenna (in Italy). On the other hand, there is a tendency to accumulate, combine, multiply, and differentiate symbolical statements for the same thought or circumstance, as seen, for example, on the sarcophagi (stone coffins) of late Christian antiquity—especially in Ravenna. Here, the same idea is symbolically expressed in various manners; *e.g.*, by means of persons, objects, animals, and signs, all appearing side by side.

Development and differentiation of a symbol

The forms and figures of symbolical thought can change into exaggerations and rank growths, however, and lead to transformations and hybrids—figures with several heads, faces, or hands—as exemplified in the statues and pictorial representations of the deities of India (*e.g.*, the multi-armed goddess Kālī) and of Slavic tribes (*e.g.*, the four-headed Suantevitus). The meaning of individual symbols can change and even be perverted. The lamb that in ancient Christian art symbolizes Christ may also symbolize the Apostles or mankind in general. The dove may symbolize the Holy Spirit or the human soul. The wheel or circle can symbolize the universe, the sun, or even the underworld. The encyclopaedic Christian allegorism (symbolism) of the Middle Ages offers many interesting examples, as noted in the writings of Isidore of Seville, a 6th- to 7th-century Spanish theologian, and Rabanus Maurus, a 9th-century German abbot and encyclopaedist.

The foundations of the symbolization process lie in the areas of the conscious and the unconscious, of experience and thought, and of sense perception, intuition, and imagination. From these arises the structure of religious symbolism. Sensation and physiological and psychological processes participate in the formation of the symbol structure. Extraordinary religious experiences and conditions, visions, ecstasy, and religious delirium brought about by intoxication, hallucinogenics, or drugs that produce euphoria and changes in consciousness must also be taken into consideration. The symbol itself, however, is intended as an objective concentration of experiences of the transcendent world and not as a subjective construction of a personally creative process. In cultic and mystical visions and trances, the forms and processes of the external world and of the religious tradition are condensed and combined with mythical images and historical events and take on a life of their own. The process of rational conceptualization and structuralization, however, also plays a part in the origin and development of many symbols. There is a correlation between sense perception, imagination, and the work of the intellect.

The foundations of the symbolization process

Symbols in the religious consciousness. The formation of religious symbols that occur when unconscious ideas are aroused or when a process of consciousness occurs is principally a matter of religious experience. Such symbols usually become intellectual acquisitions, and, as religious concepts are further elaborated upon, the symbols may even finally become subjects of major theological questions. In Christian theology, for example, summaries of dogmatic statements of faith are called symbols (*e.g.*,

the Apostles', Nicene, and Athanasian creeds and the confessional books of Protestantism, such as the Augsburg Confession of Lutheranism). This particular use of the term symbol is exceptional, however.

In the development of the symbol, religious experience, understanding, and logic are all connected, but each places different accents on the individual categories and species of symbol. Occasionally, religion is regarded as the origin and the product of certain established (or fundamental) symbols. In such cases the outcome of the process of the structuralization of religious consciousness would then be the establishment of a symbol that is generally applicable to a particular historical species of religion. Conversely, one could ask whether the experience and establishment of an individual or collective symbol by a creative personality or a community is not itself the establishment of a religion. If so, the classical symbol that was developed at the time of the foundation of any one particular religion would then be constitutive for its origin and further development (*e.g.*, the T'ai Chi or the combination of Yin and Yang for the Chinese, the cross for the Christian religion). In any event, the symbol belongs to the essence of man's coming of religious consciousness and to the formation of history's institutional religions. It plays a fundamental and continual part in the further growing of such religions and in the mental horizons of their followers.

Religion as both origin and product of symbols

THE RELATION OF THE SYMBOL AND THE SACRED

Symbols as the incarnate presence of the sacred or holy. Whatever the experience of reality that lies behind the religious symbol may be, it is above all the experience of the sacred or holy, which belongs essentially to any concept of religion. The historical study of religions has shown that it is fundamentally the symbol that mediates and forms for man's religious consciousness the reality and the claim of the holy. Religion is a system of relationships, a system of reciprocal challenges and responses the principal correspondents of which are the sacred or holy and man. Though there are many forms of experience in which the sacred or holy is distinctly known and felt, the experience is often acquired in worship, in which this system of relationships is realized and continually renewed and in which the sacred or holy supposedly makes itself present. The details of worship serve to objectify and regulate in a perceptual and material manner the presupposed presence of the sacred or holy, of which the symbol and the picture are intended to be its materialization. In its material manifestation the sacred or holy is adapted to man's perceptual and conceptual faculties. Viewed from the aspect of its holiness, the symbol originates in a process of mediation and revelation, and every encounter with it is supposed to bring about a renewed actualization and a continual remembrance of this revelation.

The actualization of the presence of the holy by means of symbolic representation can, in extreme cases, lead to an identification of the physical manifestations with the spiritual power symbolized in them. The symbol, or at least an aspect of it, is then viewed as the incarnated presence of the holy. The sacred stone, animal, plant, and drum and the totem symbol or the picture of ancestors all represent the sacred or holy and guarantee its presence and efficacy. The origin of many such symbols clearly indicates the identity that was presumed to have existed between the symbol and the sacred or holy. The Greek god Dionysus as a bull, the Greek goddess Demeter as an ear of corn, the Roman god Jupiter as a stone, the Syrian god Tammuz-Adonis as a plant, and the Egyptian god Horus as a falcon all are viewed as manifestations of the deities that were originally identified with these respective objects of nature.

The symbol as the incarnated presence of the holy

Symbols as indicators of the sacred or holy. The symbol is understood to have a referential character. It refers to the reality of the sacred or holy that is somewhat and somehow present. When the symbol is an indicator of the sacred or holy, a certain distance exists between them, and there is no claim that the two are identical. Short of actual identification, various degrees of intensity exist between the symbol and the spiritual reality of the sacred or holy. The symbol is a transparency, a signal, and a sign leading to the sacred or holy. The objects, gestures, formulas, and words used in meditation—for example, the Buddhist *mudrās* (gestures), *pratimās* (images), *mantras* (magic formulas)—and in mysticism—for example, the crystal or the shoemaker's ball in the contemplative experience of Jacob Böhme, a 16th- to 17th-century German cobbler and mystic; the navel in Omphalicism (a method [called Hesychasm] of contemplating the navel in order to experience the divine light and glory in medieval Greek Christian mysticism of the monks of Mt. Athos); and the pictures of the deity in the language of Hindu, Islāmic, and medieval Christian mysticism—all of these are truly symbols, but nonetheless they have at most only an indirect mediating relationship to the divine, a purely noetic (intellectually abstract) significance with regard to the reality and presence of the sacred or holy.

Symbols of sacred time and space. The symbolical forms of representation of the sacred or holy are to be understood as references to or transparencies of the sacred or holy. The sacred manifests itself in time and space, so that time and space themselves become diaphanous indications of the holy. The holy place—a shrine, forest grove, temple, church, or other area of worship—is symbolically marked off as a sacred area. The signs, such as a stake, post, or pillar, that delimit the area themselves are endowed with sacred symbolic meanings, which often can be noted by their particular designs. The ground plan of the sacred building and its orientation, walls, roof, and arches are all utilized to symbolize the sacred or holy. Prehistoric places of worship—*e.g.*, Stonehenge (in England) and other megaliths of Europe and the shrines and holy places of ancient Egypt, Babylon, China, and Mexico—were invested with symbolical meanings.

Sacred places are often pictorial reflections of the universe and its design and partake of its holiness. The domes of Christian churches are symbols of heaven, the altar a symbol of Christ, the Holy of Holies of the Temple in Jerusalem a symbol of Yahweh, the Holy of Holies in Shintō shrines (*honden*) a symbol of the divinity, and the prayer niches in mosques a symbol of the presence of Allāh. In many instances shoes may not be worn on holy ground (*e.g.*, Shintō temples), and hands and feet are to be washed before entering into a holy place. The woodwork of demolished Shintō shrines, when taken to private homes, makes the sacred or holy present in the homes of pious Japanese families.

Time as a transparent symbol of the sacred may be represented by means of the cycle of the sacred year and its high points—*e.g.*, New Year's (as in ancient Near Eastern religions), the times of sowing and reaping, and the solstices and equinoxes. Or the lapse of time may be represented in signs and pictures. Cosmic, mythical, and liturgical time and destiny are portrayed, for example, in the Buddhist symbol of the wheel of life, *bhava-cakra*, with its causal chain of human deeds and succession of existences, entwined by the claws of a devouring monster; the figures of Aion (Time) in late Greco-Roman and Persian antiquity show a figure with a winged lion's head standing on a globe and encircled by a snake. Time itself, its course, division, and fixed points, is both an allusion and the bearer and mediator of the sacred or holy (see also FEAST AND FESTIVAL; CHURCH YEAR; JEWISH RELIGIOUS YEAR).

The cycle of the sacred year

Ceremonial and ritualistic objects as indicators or bearers of the sacred or holy. Liturgical and ceremonial objects can also indicate or lead to the sacred or holy. Not only holy pictures and symbols (*e.g.*, the cross in Christianity or the mirror in Japanese Shintō) but also lights, candles, lamps, vessels for holy materials, liturgical books, holy writings, vestments, and sacred ornaments are indicators of the sacred or holy. Liturgical vestments and masks are intended to transform the wearer, to remove him from the realm of the this-worldly, and to adapt him to the sphere of the sacred or holy; they help him to come into contact with the divine—for example, by obscuring his sexual characteristics. The vestments

may be covered with symbols, such as those worn by Arctic shamans (medicine men with psychic transformation abilities). They are signs of the function of the wearer and his relationships to the sacred or holy and to the profane world. Such vestments are frequently derived from those of rulers or from ceremonial court dress; *e.g.*, Japanese Shintō and Roman Catholic and Eastern Orthodox Christianity. They are supposed to create a fitting atmosphere of solemnity and dignity. In Western Christianity, the liturgical vestments have a very specific symbolism: the alb (a tunic) symbolizes purity of heart; the stole, the raiment of immortality; and the chasuble (an outer eucharistic, or holy communion, vestment), the yoke of Christ. The liturgical vestments of the Eastern Christian churches have a similar symbolism. The ritual headdress and the crown express the sacred dignity of the wearer. The vestments of the various religious orders (Oriental and Occidental) express the holiness of the members of the community, their nearness to the sacred or holy, and the significance of religious life for them. In the reception ritual of Jainism and Buddhism, the monastic vestments are put on as a sign of an entrance in a new state of life. This ritual in Jainism resembles that of a wedding ceremony. The taking over of the monastic garb is an essential part of becoming a *sādhu*. The monks of the Jainistic Śvetāmbara sect wear five objects (*e.g.*, shells) as symbols of the five monastic virtues. In early Christianity the white baptismal vestment was a symbol of rebirth, new life, and innocence (see also RELIGIOUS DRESS AND VESTMENTS; CEREMONIAL AND RITUALISTIC OBJECTS).

Other relations between the symbol and the sacred. The sacred or holy as represented or manifested in the symbol has, generally speaking, a sanctifying function (elevating one to a closer relationship to the sacred or holy) and an exorcising function (decreasing or eliminating those aspects that hinder one's relationship to the sacred or holy). Remembrance (*anamnēsis*) and imitation (*mimēsis*) are the analogous and associative means of representing the reality and indestructibility of the sacred or holy and its power, which defends, protects from injury, bans evil, and guarantees salvation. Symbolic signs and pictures (*e.g.*, masks; sex, animal, or plant symbols, such as the skulls or horns of animals) are placed on houses and sacred places to make present the saving and sanctifying power of the sacred or holy.

RELATION OF RELIGIOUS SYMBOLISM AND ICONOGRAPHY TO OTHER ASPECTS OF RELIGION AND CULTURE

Relation to myth and ritual. The symbol has a long-established relationship with myth (sacred stories that define the human condition and man's relation to the sacred or holy). Often containing a collection of symbolic forms, actions, expressions, and objects, myths describe gods, demons, men, animals, plants, and material objects that are themselves bearers of symbolical meanings and intentions. Thus, it is sometimes difficult to distinguish between a myth and a coherent complex of symbols brought together in story form. Examples are myths of cosmogony (origin of the world), theogony (origin of the gods), and anthropogony (origin of man). The details and contexts of religious teaching, dogma, and theology also produce or form symbolic values or refer to traditional symbolic representations. Symbol structures and pictorial representations are brought into connection with dogma and theological statements—*e.g.*, the Buddhistic *karma-saṃsāra* (law of cause and effect and reincarnation) theory and the *bodhisattva* (buddha-to-be) theory or the Christian teaching of the Last Judgment, punishment of sin, hell and purgatory, and eternal reward (Paradise). In worship, individual actions and objects used in the ritual are given a symbolic meaning that transcends their immediate practical purpose. Magic, in its ritual, also uses various formations of symbols, pictures, and symbolical actions that may be seen as parallels to the distinctively religious use of symbols (see also MYTH AND MYTHOLOGY; RITUAL).

Relationship of symbolism and doctrine

Relation to meditation and mysticism. The spiritualization of religious experience in forms of meditation and mysticism assimilate and rework the existing symbols and pictures of an older historical period of religion, giving to some symbols a higher value and placing others in the centre of focus. At the same time it develops new forms the appearances of which stem especially from the visionary experiences of the mystic and from his need for a suitable means of expression and from the objects of meditation training; *e.g.*, holy sounds and words (*om*), the lotus flower, the *vajra* (ritual object shaped like a thunderbolt), and the wheel in Buddhist meditations or the ladder, the heart, and the letters IHS (the first three letters of the Greek word for Jesus) in Christian mysticism. In contemplation, colours, forms, sounds, signs, and pictures become ways and means of penetrating to the centre of the mystical union. Jacob Böhme's work is characteristic of the development of an especially rich mystical language of symbols. Mysticism supplies conventional and customary religiosity with new pictures and symbols (see also MYSTICISM).

Relation to the social realm. The field of symbolism and iconography shows a strong interdependence that existed between religion and other areas of culture that were later to become autonomous and profane (or secularistic). The social domain under the influence of religion develops its own symbolism for expressing its values and objectives. Conversely, religion often draws its symbols and pictorial forms from the social, political, and economic domains. Persons (*e.g.*, king, father, mother, child, slave, brother) and conditions and structures in society and the state (*e.g.*, government, a people, family, marriage, occupation) all receive meaning as symbolical and pictorial motifs in myth and cult. Examples of such motifs are throne, crown, sceptre, standard, arms, instruments, the figures of the father, mother, and child, and symbols of familial relationships. The morals, law, administration of justice, and the customs and habits of a society contain religious symbols and symbolical actions, as in the anointing of a king and in the administering of the oath or ordeal or in the observance of traditions and customs associated with birth, marriage, and death.

Reciprocal influences of culture and religion

Relation to the literary and visual arts. Religious symbols and pictures may be identical with, related to, or similar to those of language (metaphors) and to pictorial expressions in prose and poetry. They are related in allegory, parable, fairy tales, fables, and legends in which they can appear in a form that is closely related to that of religious symbolism. Religious symbols are used in the plastic arts, in architecture, and in music. Symbols also have been developed in those arts and then introduced into religion. A few examples of such symbols are house, room, door, column, sound, harmony, and melody (as when Christ was viewed as the "new melody" in the words of Clement of Alexandria, a 2nd-century philosophical theologian). Here, also, the interdependence and the continual reciprocal influence of religion and culture may be observed.

Relation to other areas of culture. The formation of religious symbols and pictures has been stimulated by numerous other areas of human culture—such as the philosophy of nature, the natural sciences (especially botany and zoology), alchemy, and medicine (including anatomy, physiology, pathology, and psychiatry). In the works of Jacob Böhme, alchemy (*e.g.*, the elements, fire, salt, sulfur, mercury, tincture, gold, essence, the philosopher's stone, and the transmutation) found an all-inclusive symbolical use; and in the works of Robert Fludd, an English physician and mystical philosopher of the 16th and 17th centuries, medical, cosmological, alchemical, and theosophical (esoteric religious) symbols were fused together (*e.g.*, the contrast of light and darkness and the idea of man as a microcosm). Symbols, also religious and mythological (such as signs of astral gods for the planets in astronomy), have achieved new importance in the conceptual presentations of distinctively scientific systems; *e.g.*, in physics, cosmology, psychiatry, and psychology. Even spaceships bear symbolic or mythical names. Psychoanalysis and depth psychology have re-evaluated the role of the religious symbols and have used them in interpreting psychological processes, such as in the works of the Swiss psychiatrist Carl Jung. Jung

Relationship of religious symbols to scientific symbols

interprets religious processes as symbolic ones and emphasizes the growing of individual and social symbols in the unconscious. According to his interpretations, many of the symbols, transforming the archaic libido into other functions, come out of dream experiences in a kind of intuition or revelation. Important symbols are duality (male–female, animus–anima), trinity, and quaternity.

Changes in symbolical relations and meanings. Symbols emerge and disappear and change in their value and function. Although symbols have a tendency to be normative, stable, and to have a fixed meaning value, the demise of old symbols and the genesis of new ones or changes in the meaning of existing symbols nevertheless occur. Many ancient Christian symbols (*e.g.*, the fish) had long lost their recognition value or had been pushed into the background. With the renewal of ancient Christian symbolism in modern times, they have had a re-evaluation. The triangle and the eye as recently used in Christianity are relatively new symbols for God. The old and formerly very meaningful religious symbolism of the axe and hammer has almost disappeared. The symbolism of kingship and sovereign authority has, on the other hand, been maintained in religious language and in the religious conceptual framework, although the political structures from which it originated have disappeared or lost their relevance. The disintegration of individual symbols and the change in the emphasis on the role of symbolism in general are partly consequences of cultural, intellectual, social, and economic transformations.

MODES OF SYMBOLIC EXPRESSION

In the long history of the forms of symbolical expression a narrower (exclusive) and broader (inclusive) idea of what a symbol is has gradually evolved. This evolution is reflected in the various manners of symbolical expression that may influence and combine with one another. Many scholars question whether a picture or a verbal expression, for example, strictly corresponds to the idea of a symbol. Just as the ideology and terminology of the ancient Greek mystery (salvatory) religions distinguished between that which is shown and seen (*deiknymenon*), that which is done (*drōmenon*), and that which is said (*legomenon*), so also can one make distinctions among three types of symbols: the visual symbol, the symbolical action that is dramatically enacted in worship, and the linguistic symbol, which includes music and other sounds. Viewed in these various aspects, the complex character of the symbol becomes apparent.

Diagrammatic and emblematic. Symbolic representations are usually depicted in diagrammatic or ideographic modes as signs, abbreviations, images, and objects of all kinds that indicate a larger context. In this category belong the simplified or abstract forms of objects of nature or other objects and geometrical forms, as well as colours, letters, and numbers. The circle, the disk, the rosette, or the swastika, for example, may symbolize the sun, universe, or a star. The square and the cross may symbolize the Earth or the four cardinal points; the wreath, the labyrinth, the spiral, the plait, and the knot may indicate eternity, the flow of time, or a magical spell.

Geometric, numerical, chromatic, and alphabetical symbolism

Ornamental designs in primitive artwork, those of the American Indians, for example, frequently have a symbolical meaning and embody fundamental figures, such as the straight line, circle, rectangle, rhombus, or ellipse. The cross in its varying forms: the Latin (†), Tau (T), ankh (☥), Saint Andrew's (X), and the forked (Y) may symbolize man and his extremities. Among various peoples and in different religions a number of basic colours have at times different and sometimes even opposite meanings. White, for example, may signify joy and festivity or death and sadness. Red has the most pronounced symbolical value: it refers to the liturgical, priestly sphere and also to life and death. In Christianity, colour symbolism is associated with the sacred year; in Buddhism with the picture of the universe, the regions of which are classified according to particular colours; and in the religion of the Maya of Mexico and Central America with the four world directions—east (red), north (white), west (black), and south (yellow). The symbolism of metals and precious stones also is related to their colours (*e.g.*, emerald with green).

The symbolism of the letters of the alphabet varies according to the alphabet (*e.g.*, A and Ω in Greek or *A* to *Z* in English) and is often connected with magic and prophecy—which is also true of the symbolism of numbers. In the picture writing of hieroglyphic systems and in the ideographic (idea-sign) writing of earlier times there is a direct relation between the word-sign and the object to which it refers. In alphabetic writing, numbers and letters are interchangeable if the letter has a number value, as, for example, in Greek and Hebrew alphabets. In some religions, the world of the gods is arranged according to a number system; *e.g.*, into enneads (nines), triads (threes), or dyads (pairs). The idea of oneness was then extended to a numerically arranged pantheon. Gnosticism (a Hellenistic esoteric dualistic system) and Kabbala (a Jewish esoteric mystical system) developed number symbolisms. The letters received a symbolic character in two ways: first, as components of a word for which they stood—*e.g.*, the Hebrew tetragram (four-letter) YHWH (Yahweh) for God, the Latin IOM for Jupiter Optimus Maximus (Jupiter the Best and Greatest), and the Greek IHS for Jesus—or, second through their numerical value, as in A and Ω, the beginning and end of the Greek alphabet, signifying Christ. They then became means of abbreviation—signs possessing a specific content and meaning.

Pictorial. Pictorial symbolism in its many forms is a further development of nonrepresentational, ideographic symbolism and also, to some extent, its origin. In depicting the world of nature, pictorial symbolism captures and mediates the religious experience of reality. The picture shows plainly and clearly the rich and intricate connections of its symbolic content. It may present a part for a whole (a head, a hand, a foot, or an eye for a complete figure) or the whole itself. Symbolic expression of religious experience by means of painting has had a long history.

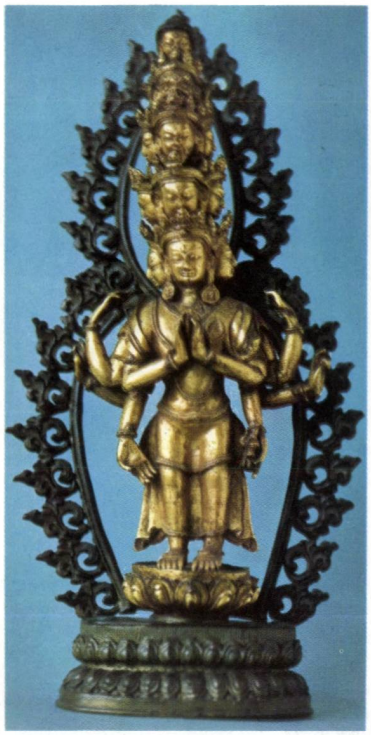
Sculptural representations of the sacred or holy have their origin in cult. They range from Stone Age idols to the sacred sculpture of early Mesopotamian and Egyptian cultures, from the statues and reliefs of Greco-Roman gods, divinized heroes, and their deeds to the symbolic sculpture of India with its Hindu gods and demons, from the sacred sculpture of China and Japan with their respective pantheons to that of Mahāyāna (Greater Vehicle) Buddhism with its *bodhisattvas* (buddhas-to-be), saints, and spirits. These sacred figures, which may appear in statue or relief form, are sculptured out of various materials. The reliefs on the interiors and exteriors of temples have a decorative function similar to that of wall painting. They narrate a myth or tell a sacred history. Particular parts of the body and symbolical objects may also be sculpturally represented. They may be the male and female sexual organs (*e.g.*, the *liṅga-yoni* in Hinduism); the hand of Sabazius, a Greek god sometimes identified with Dionysus (the god of wine), whose hand is portrayed as raised in blessing and encircled by a number of rather bizarre appendages; and human limbs used as votive offerings for the cure of the part of the body represented. Representative symbolic sculpture tends either to simplify the figure in an abstract, geometrical, or expressionistic style or to imitate nature realistically.

Sacred figures in sculptured or relief forms

Gestural and physical movements. Gestures and bodily movements play an important part in religious ritual and in the religious conduct of man. Such behaviour derives its meaning from its relationship to the holy.

In proceeding to and from a holy place, a worshipper generally proceeds according to certain symbolic patterns: rectilineal, circular, and vertical. Rectilineal movement to and from a holy place is intended to gradually prepare the worshipper for the spatial encounter with the holy and after the encounter to remove him from the sacred sphere. Special streets for processions often are marked off or built to a temple or holy place, such as in ancient Egypt, Mesopotamia, and China. The great procession from Athens to Eleusis for participants in the mysteries possessed a symbolic meaning. Worshippers not only enter a holy place but may also walk around it.

Triumphant cross, symbolizing Christ, before a star-filled heaven, the eternal, surrounded by the symbolic words or letters ΙΧΘΤΣ (ICHTYS; fish), SALUS MUNDI (salvation of the world), and Α and ω (Alpha and Omega; beginning and end); one set of symbols bringing together several Christian ideas of the relationship between man and God, the temporal and eternal, earth and heaven, the transfiguration and ascension of Christ, the Last Judgment. Apse mosaic in the church of S. Apollinare in Classe, near Ravenna.



Avalokitesvara, the compassionate *bodhisattva,* shown as a composite figure with eleven heads and eight arms, symbolic of his ability to sense man's needs everywhere in the universe. In the Rijksmuseum voor Volkenkunde, Leiden, The Netherlands. Height 35 cm.

The symbol: unity and multiplicity

Two-headed Janus, who sees forward and backward, personification of the month of January; romanesque high-relief sculpture of stone In the Museo del Duomo, Ferrara, Italy.

Buddha s footprint, the "sign of a grand man," containing the symbols of the swastika, the wheel of the law, the *tri-ratna* (the "three jewels" of the Buddhist creed), and the lotus. Stone relief from Gandhara, 2nd century AD. In the Prince of Wales Museum of Western India, Bombay.

The Trinity represented by Christ as man, the Holy Spirit as a dove, and God as a hand; Armenian miniature of the baptism of Jesus, 1273. In the Topkapı Museum, Istanbul. 16 × 11 cm.

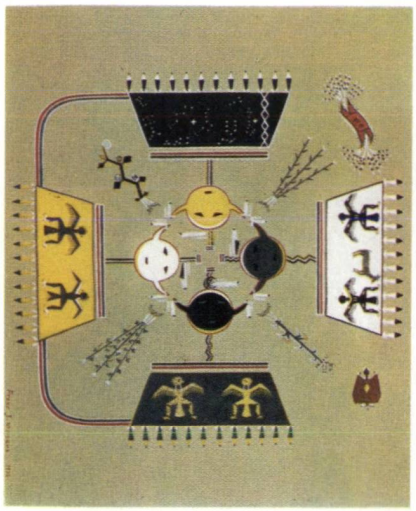
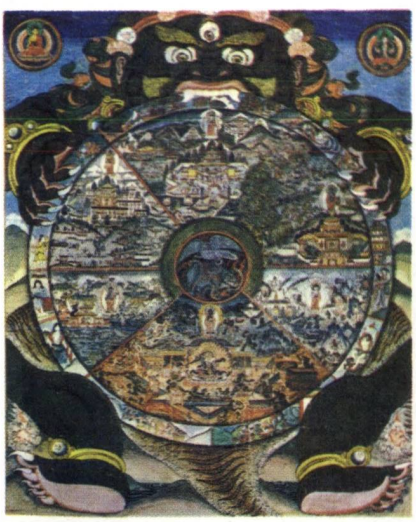
Symbols of space and time



"The Skies," watercolour copy of a Navajo sand painting. Four holy plants radiate from the central four storm figures. The dawn, midday, evening, and night skies are shown in the east, south, west, and north. Paired guardians in the east are a medicine pouch and a bat. In the Museum of Navaho Ceremonial Art, Santa Fe, New Mexico.

Cathedral of Notre Dame, Chartrès, France, completed mid-13th century. The nave and apse form a cross; the steeple and bell tower may be interpreted symbolically as the "fingers of God."

Borobudur *stupa*, Buddhist monument in central Java, built in the form of a *mandala*, late 8th century. The surrounding galleries are decorated with reliefs representing scenes of the life and religious development of the Buddha.



Bhava-cakra ("wheel of life," circle of existences), Tibetan *tanka*, probably 19th century. In the Newark Museum, New Jersey. 109.2 × 86.3 cm.

Stonehenge, circular earthwork and stone religious site, Wiltshire, England; late Neolithic to Early Bronze Age (1800–1400 BC).

Plate 2: By courtesy of (top left) the Museum of Navaho Ceremonial Art, Inc., Santa Fe, New Mexico, Newcomb Collection, (centre left) the Newark Museum, New Jersey; photographs, (top right) Alain Perceval, Paris, (centre right) Brian Brake—Rapho Guillumette, (bottom) Aerofilms Ltd.

Poseidon, Apollo, and Artemis, detail from the marble east frieze of the Parthenon, Athens, *c.* 440 BC. In the Acropolis Museum, Athens. Height 109.2 cm.

"Tree of Jesse," symbolizing Jesus' descent from the house of David, illuminated page from Rabanus Maurus's *De laudibus sanctae crucis,* from Anchin, mid-12th century. In the Bibliothèque Municipale de Douai, France. 29 × 20 cm.

The sacred or holy in the image of man, animals, and plants

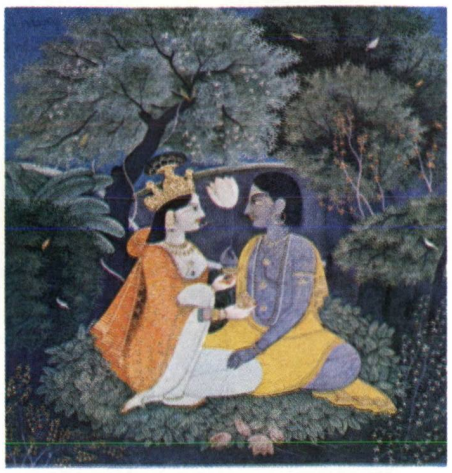
Horus as a falcon, Egyptian bronze, 26th dynasty to Ptolemaic dynasty (7th–3rd centuries BC). In the Brooklyn Museum, New York. Height 28.8 cm.

Buddha Amitabha and two Bodhisattvas on lotus blossoms, the "Amida-Trias." Japanese bronze known as the Tachibana Shrine, 7th–8th century. In the Horyu-ji, Nara Prefecture, Japan.

The four Evangelists represented by their symbols—Matthew by a man, Mark by a lion, Luke by an ox, and John by an eagle—illuminated page (f.27v) from the Book of Kells, Hiberno-Irish, 8th century. In Trinity College Library, Dublin.

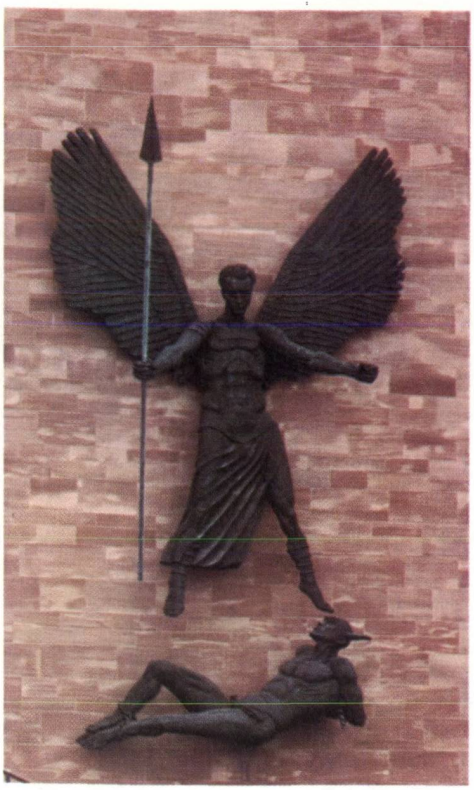
Nineatallali, (top right) Giraudon, (bottom left) Benri-do, Kyoto

Symbols from the realm of family and society



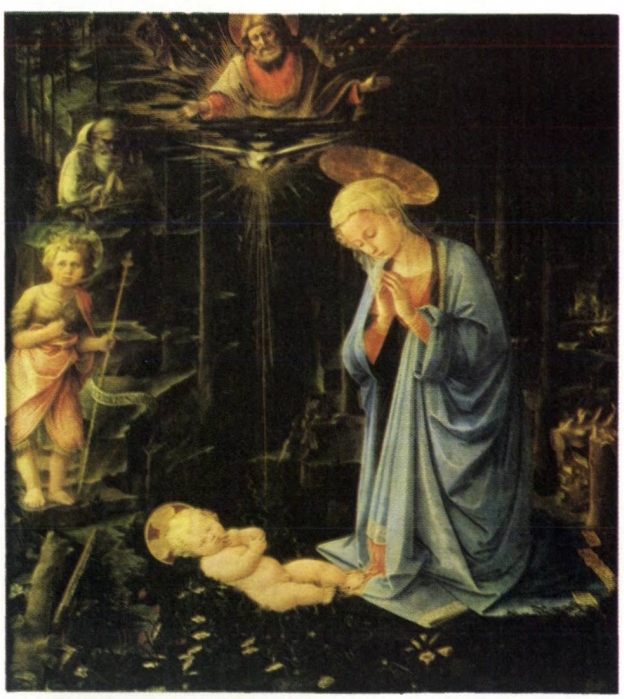
Krsna (right) with his beloved, Rādhā, painting in the Kangra style from India, 18th century. In the Prince of Wales Museum of Western India, Bombay.

The child Krsna, bronze from India, 16th–17th century. In the Detroit Institute of Arts. Height 11.4 cm.



The warring archangel, shown in "St. Michael Triumphing Over the Devil," bronze by Sir Jacob Epstein, 1959. Coventry Cathedral, England. Height 7.6 m.

Christ enthroned as Lord of All (Pantocrator), with the explaining letters IC XC, symbolic abbreviation of "Iesus Christus." Mosaic in the cathedral of Monreale, Palermo.



"The Virgin Adoring the Child," painting by Fra Filippo Lippi, *c.* 1460. In the Staatliche Museen Preussischer Kulturbesitz, West Berlin. 127 × 116.8 cm.

Plate 4: By courtesy of (centre) the Detroit Institute of Arts, (bottom right) the Staatliche Museen Preussischer Kulturbesitz, Berlin; photographs, (top left) Pramod Chandra, (top right) A.C. Cooper Ltd., (bottom left) Farrell Grehan—Photo Researchers

Rectilineal and circular movement thus complement each other. Movement to and from a holy place may also be vertical as well as horizontal, as to and from a holy place on top of a mountain or pyramid. All these various types of movement give expression to the symbolism of the holy way or path.

The sacred dance combines rectilineal and circular movements and may also include hopping, jumping, and hand movements. Hand and finger movements in temple dances in Indian and other Asian cultures are strictly regulated and have a precise symbolic meaning. The liturgical dance in a rudimentary form was maintained for a long time in Christianity, as has been the procession. Dancing has not only a significative but also a magical function. It seeks to enchant the holy power.

Symbolism of hand movements

Hand movements are widely used in ritual and liturgical actions; the touching of holy objects, materials, or men is performed according to a canon (rule) that precisely regulates these gestures and their accompanying prayers and blessings. The gesture of blessing may imitate a symbolic form, such as that of the cross in Christianity. Here the position of the fingers is regulated and has a special meaning, as is also true in the Hindu and Buddhist practice of meditation (*mudrās*). Stroking, thrusting, striking, pushing, waving, and hand clapping also can be symbolical gestures. By raising his hands in prayer, the worshipper approaches the realm of the heavenly gods; by kneeling, the realm of the underworld. This apparently was the original meaning of kneeling before it became an expression of humility. The bow as an intimated genuflection generally indicates respect. The kiss and the embrace—and sometimes also the actions of breathing or spitting upon someone or anointing a person with spittle—were originally magical manipulations; in later usage, they indicated union with or a strengthening of the community or the transferral or communication of power. The holy kiss, whether practiced or only verbally depicted, plays an important part in many religions. Standing is a posture of respect; sitting expresses the reception and acceptance of the sacred word or teaching. It is also the position for meditation as it is practiced in Buddhist monasteries. Symbolic gestures may be either individually or collectively performed.

Verbal symbolism. Gestures are usually accompanied by words. The spoken and written word in religion generally is not thought of primarily as symbolic but rather as a form of rational communication, of communication of thought. Despite its predominantly rational character in modern times, however, language does develop expressions that extend into the area of the symbolical. In its origin, language most likely was richly symbolical. Linguistic symbolism, however, has always had a certain tendency toward rational transparency and logical coherence, and thus words, objects, and pictures—in their origin as symbols—are very closely related. The visual value of the object and picture is later translated into language and enhanced by it.

Linguistic symbolism generally is metaphorical; the allegory, a particular development of the metaphor, symbolically represents an idea by means of a coherent complex of metaphors. Specific genres of narration and literature, such as myth, belong in this category. In a figurative, interpretative, and cryptic sense, names and metaphors denote the person or thing in question. God sometimes is metaphorically called a "spring" or a "rock"; Christ, "the Beloved"; Mary (the mother of Jesus), "the Rose"; and Vardhamāna Malāvīra (the founder of Jainism) and the Buddha (Siddhārtha Gautama, the founder of Buddhism) are called "the Conqueror."

Symbolic syllables and names

Individual syllables or sounds may also have a symbolic quality. The *om*, which is used to introduce the holy texts of Hinduism and is a meditation syllable used in Buddhism, provides one example. Understood magically as an emanation of the divine, the word or a name or a part of a word can become an independent hypostatized (substantial) object, a representation, or even the incarnation of the divine, such as the Logos (Word) in the Gospel According to John or *hū* ("he") and *al-ḥaqq* ("the truth") in Islāmic mysticism or the name Metatron in Kabbala. A holy writing or book in its entirety may represent the divine in the same way, as the Bible in Christianity, the Qur'ān in Islām, and the *Ādi Granth* in Sikhism.

Musical symbolism. Music, like the word, also may have symbolic meaning. The basic elements out of which musical symbolism is built are sounds, tones, melodies, harmonies, and the various musical instruments, among which is the human voice. Sound effects can have a numinous (spiritual) character and may be used to bring about contact with the realm of the holy. A specific tone may call one to an awareness of the holy, make the holy present, and produce an experience of the holy. This may be done by means of drums, gongs, bells, or other instruments. The ritual instruments can, through their shape or the materials from which they are made, have symbolic meaning. The Uitoto in Colombia, for example, believe that all the souls of their ancestors are contained in the ritual drums.

The relationship between religious ideas and music is of special importance when the sacred word is set to music or when the music supports or interprets the sacred word by orchestral accompaniment. Medieval and modern Christianity in the West has made important contributions in this area. The symbolic word may be enriched, intensified, and increased in meaning when it is given a musical form. In the medieval technique of motet composition, different but parallel texts from the Bible or the liturgy would be simultaneously sung in various voices to appropriate but different melodies. This is an example of the structuralization of symbols into a coherent whole, a process that may sometimes also be encountered in the visual arts.

Conjunction and combination of various modes. In ritual, liturgy, liturgical and devotional art, and in religious literature and experience, many different types of symbolical expression are frequently combined. Pictorial art may be symbolically interpreted or its present meaning may be reinforced by the addition of a verbal explanation or possibly even by music. In ritual, symbolical words, tones, noises, gestures, signs, odours (*e.g.*, the odour of the sacrifice or the fragrance of incense as an expression of prayer and offering), colours, and pictures are combined. Pictorial art often depicts religious texts and ideas; in so doing it not only uses the human form but also objects of nature, scenery, sacred architecture, and particular symbols. A picture or sign on an emblem often receives its interpretation by the inscription of a verbal explanation. Conversely, in an illustration of religious texts, the picture or sign interprets the text. Over against verbal and musical symbols stands the sacred value of silence. It may indicate devotion, contemplation, or the presence of God.

ICONS AND SYSTEMS OF ICONOGRAPHY

Throughout the history of their development, religious iconography and symbolism have been closely interrelated. Many religious symbols can be understood as conceptual abbreviations, simplifications, abstractions, and stylizations of pictures or of pictorial impressions of the world of sense objects that are manifested in iconographic representations. In conceiving, describing, and communicating the experience of reality, the realistic picture and the nonrepresentational sign both have as their primary function the expression of this experience in religious terms. In religious pictures that are of a compound or complex nature, particular symbols occasionally reappear. These pictures may also include other types of symbolic representation, such as words, tones, gestures, rituals, and architecture.

Relationship of symbolism to experience

Iconographic forms. *Temples and other sacred places.* The architectural iconography of sacred buildings and places of worship is a field of its own. The place of worship, insofar as it is understood as the image of the universe and its centre, must be architecturally patterned according to a specific design of the universe. The place of worship may be considered to be the navel of the world; *e.g.*, the *omphalos*, a round stone in the temple at Delphi (in Greece), the holy stone in the Church of the

Holy Sepulchre, in Jerusalem, or the rock in the temple area of the Dome of the Rock (Mosque of Omar), in Jerusalem. A holy place usually is built around these holy points.

The cross-shaped ground plan of the Christian transept church is sometimes interpreted as an architectural portrayal of the crucified Christ, the apse with its altar representing Christ's head. The holy place as a structural creation together with its natural setting may create an idyllic or overwhelming effect, evoking in the beholder an experience of religious awe or devotion. The Shintō and Buddhist temples of Japan and the beauty of the landscape in which they are set, the mountain temples of ancient Greece, and Christian churches and chapels built in such dramatic settings as Mont-Saint-Michel in France all inspire a sense of wonderment. The Buddhist temple in all the splendour and richness of its form, trappings, and surroundings or the *stūpa* (a building containing relics of the Buddha) represents the presence of the Buddha.

Great importance, therefore, is often attached to the exterior form of the holy place, and its construction is governed by a canon of symbolical and iconological principles. The individual parts of the building—the walls, columns, ceilings, vaults, and towers—usually have pictorial and symbolic functions. Generally, the ceiling or vault presents a picture of heaven. Special accent is placed on the portals and the paths leading to them, on the position of the tables of offering, altars, sacred pictures, and relics. The bell tower, or campanile, is characteristic of Christian churches and is popularly interpreted as the finger of God. Ancient Christian basilicas (large, roofed buildings, generally with aisles) were viewed as images of the heavenly Jerusalem. The pictorial aspect of the place of worship extends not only to the building in the entirety of its architectural form but also to the painted, sculptured, and mosaic artwork that decorates it. The exteriors of Hindu and Buddhist holy places, such as the famous terrace temple of Borobudur on Java, and the pediments and friezes of Greek temples utilize an abundance of figures and reliefs representing scenes from myth and sacred history. The facades of Egyptian temples are covered with tableaus of the gods and depictions of ritual ceremonies. The facades and portal walls and sometimes the outside walls of Christian churches portray the main figures and events in the history of salvation, legends of the saints, and the Last Judgment. Inside the holy place, this pictorial and interpretative function is continued in the figures and scenes on its walls, capitals, and vaults. The adytum (sanctuary), the apses, and the altar may be decorated with symbols or pictures of the divinity or of other gods and saints.

Icons and images. Pictures are the main subject matter of iconography, which also includes free-standing sculptured forms and reliefs. Free-standing figures or statues are important in ritual as well as in partly serving magical purposes, which cannot always be separated from religious ritual. Such figures, which later became objects of personal devotion and meditation, include representations of the gods and demons in various prehistoric religions and of Buddha, Christ, and the various Buddhist and Christian saints. Generally, Judaism, Islām, and ancient Shintō have rejected any representation of the divine.

Pictorial representations of myths and historical events

Painted or sculptured tableaus of historical or mythical events originally belonged in a ritual setting. The function of a wall painting, wall or floor mosaic, or relief was or is to establish the ritual actions as authentic re-enactments of their mythical or historical prototype and to make these mythical or historical events continually present. These tableaus also may be found on the interiors and sometimes the exteriors of houses and on cemetery monuments. They are made to serve private devotion and a personal confession of faith. In the form of a framed picture, Oriental roll picture, print, or book illustration, such an iconographic tableau contains religious information, mediates, and stimulates contemplation and devotion.

Iconographic themes. In the religions of highly developed cultures and in the universal religions, complicated systems of iconography have been developed. In the course of time, however, these systems have been subject to change. Icons (images) may depict the divine in its oneness and in the plurality of its differentiations, emanations, and incarnations, as well as man in his various relationships to the sphere of the holy. They may also depict the world as the stage of divine action, as the realm of the diabolical, or as the battleground of these two warring forces. They may portray evil, the diabolical, and the Satanic (the negatively sacred); or, more positively, they may depict the offer of salvation, redemption, and damnation. Furthermore, icons may portray the ritual means of attaining salvation or moral relationships and duties. Icons may borrow from myths and other religious narrative material to depict the historical past and the present, as well as the future and the afterlife. Icons, finally, may represent religious doctrine and the theological treatment of dogmatic themes, as well as other religious beliefs, religious experiences, and conceptions of a more individualistic nature.

Iconographic types. There are many fundamentally different points of departure in the ways of conceiving the contents of religious pictures and of forming them. These differences, which go back to very early times, continue to exist side by side throughout the history of religions, some dominating at one time while others recede in importance.

Anthropomorphic motifs. The object that generally is depicted in religious pictures or sculpture is an anthropomorphic (human-form) representation. Man is shown as the image and likeness of the holy and as engaging in typically religious behaviour; conversely, the divine appears with anthropomorphic characteristics. This tendency is found quite early in the history of religions. Examples include the religious pictures used in ancestor worship; the spirit and soul idols of various primitive cultures in animism; the fetish, or charm, figures of West African fetishism; and the magical objects of hunter and agrarian cultures. This type of anthropomorphism reaches its high point in the ritual and mythical pictures of the great polytheistic religions and is especially characteristic of ancient Greek religion and also of Jainism in its pictures of the Tīrthaṅkaras (saviours).

Importance of human forms in representations of the holy

In universal religions, such as Buddhism and Christianity, anthropomorphic pictures of the divine were maintained despite criticism. They were not intended to be interpreted realistically but rather as symbolically representing the divine. Buddhism adapted the gods and anthropomorphic myths of the then popular Asian religions and developed the figure of the *bodhisattva* (buddha-to-be) to represent the attainment of Nirvāṇa (the state of extinction or bliss). In Christianity, the picture of Christ usually serves as a representation of the divine. God the Father also is anthropomorphically depicted, usually as an old man wearing papal or imperial insignia. Individual parts of the body may be depicted and serve as symbols of the divine: *e.g.*, the hand of God may stand for Christ, the creative power of God, God's covenant with man, or for God's fidelity and truth; the phallus or foot may symbolize Śiva (a Hindu god). Man may be portrayed as a miniature copy of the universe or as the recipient of salvation and also the bearer of the divine, as in the Christian iconography of Mary and the saints.

Theriomorphic, or zoomorphic, motifs. Besides animal demons in primitive religions and totemism (a belief system and social system based on animal symbolism), animal images frequently occur in other more sophisticated religions. The animal form as a representation of the divine (theriomorphism, or zoomorphism) is characteristic of polytheism. It has been maintained in Hinduism, to some extent in Buddhism, and occasionally in Christianity. Besides the theriomorphic (animal-form) representations of the holy (*e.g.*, the ancient Egyptian gods and animals that are symbols of the divine or the lamb symbolizing Christ in Christianity), there are also theriomorphic (animal-form) pictures of the universe and its powers and of the world of the demons. In many religions the animal kingdom is depicted as a part of creation, as in the portrayals of creation in ancient Greek myths and in

the Bible. Animals also play important roles in allegories. Various forms of the shepherd–flock motif have been developed to describe God's relationship to man.

Besides being represented in human form, the Christian Evangelists Mark, Luke, and John are symbolically depicted in animal form (lion, ox, and eagle, respectively). Byzantine iconography sometimes depicts St. Christopher (patron of travellers) with a dog's head. Parts of animals (skulls, horns, wings, and feet) also serve as symbols of the power of the divine or diabolical.

Plants as representations of the holy

Phytomorphic motifs. Phytomorphic, or plant-form, representations of the divine also are rich in diverse examples and often enigmatic. Holy plants and plants considered to be divine are represented in connection with gods in human form. The god sometimes is the plant itself, as the Egyptian god Nefertum is the lotus, or begets the plant, as the Egyptian Osiris or the Greek Demeter as deities of corn, or the deity comes forth from the plant, as the Egyptian goddess Hathor from the sycamore or the *bodhisattva* from the lotus, or the god unites with or is transformed into the plant, as the Greek heroine Daphne changed into the laurel tree, which thus became sacred to Apollo. The genealogy of Christ from "the root of Jesse," the father of the Israelite king David, is represented as a tree the last blossom of which is Christ. The biblical story of creation describes the vegetative surroundings of man and his dependence on plants (*e.g.*, the tree of knowledge). The tree of life, the world tree, and the primeval cosmic plant all have characteristics related to the nature and origin of the cosmos.

The grapevine is a prominent ritual motif. It is found, for example, in representations of Dionysus and Christ. Painted and sculptured leaf, flower, and plant motifs decorate Christian churches and many religious and funeral monuments. Plants bound into a wreath symbolically promise victory over death and the joys of heaven. In such instances, the simple forms of nature may sometimes be depicted in a nonrepresentational and ultimately abstract and stylized manner.

Hybrid motifs. In religious iconography, anthropomorphic, theriomorphic, and phytomorphic motifs may be combined. The result of this fusion of forms may be seen in the numerous hybrid figures of primitive culture (*e.g.*, totem poles, Uli figures of New Ireland, and ancestral tablets). Such combined motifs occur also in ancient Near Eastern figures of winged demons with human heads and animal bodies or in winged beings with animal heads and human bodies and in the winged Greek goddesses, as well as in the winged protectresses of the dead in ancient Egypt and the angels and demons in Christian art. In Christianity, the snake in the Garden of Eden is sometimes portrayed with a human head (the face of Satan). In the Middle Ages, representations of the living cross with its arms depicted as hands appear. The cross also has been combined with various other anthropomorphic and phytomorphic elements.

A composite picture of plants, animals, and men together with other natural objects and architectural structures often becomes a sacred scenic background against which the mythical and ritual action takes place. Such scenic depictions were developed in Hellenism and adopted by early Christianity. Paradise scenes including plants, animals, men, Christ, and the saints are later enriched by symbolic and diagrammatic elements. Renaissance painting and East Asian Buddhist and Taoist art also use such combinations when depicting sacred, mythological, and allegorical scenes.

Chrematomorphic motifs. Objects that are used, or chrematomorphic objects, provide another form of pictorial representation. Holy objects, especially those used in worship, fall in this category. The holy book, the cross, the throne and other insignia of power and majesty, lights, lamps, and canopies become representatives of the holy. Garments also may have a symbolic meaning of their own apart from their wearer, as, for example, the veil or the blue mantle of Mary as symbols for the tent of heaven.

Absence of representational forms. The absence of an expected object, person, plant, or animal in a picture or the absence of all pictorial representation may also represent the holy or divine. In the Holy of Holies of the Jewish Temple in Jerusalem there was no picture of Yahweh in or on the ark of the Covenant, although it was supposed to be a sort of portable throne for God. Ancient Christian art often depicted an empty throne on which perhaps lay a folded purple robe or a book (*hetoimasia*) as a symbol of the invisible presence of God. In mosques the empty prayer niche (*miḥrāb*), which is oriented toward Mecca, represents the presence of Allāh. Buddha apparently was not iconically represented in early Buddhist art in accordance with the theory of "emptiness" (*śūnya*) and the radically negative transcendence of the aim of salvation, Nirvāṇa. The rejection of a picture as a means of representing the holy also is a symbolical way of positively asserting the presence of God.

Depiction of the presence of the holy by nonrepresentation

Hostility toward and prohibition of pictures are found in ancient Shintō, Judaism, Islām, the various radical movements (*i.e.*, the iconoclasts, or image destroyers) of 8th-century Christianity that were influenced by Islām, and, centuries later, in some elements of Reformed Protestantism.

INFLUENCE OF MAN'S ENVIRONMENT ON RELIGIOUS SYMBOLISM AND ICONOGRAPHY

Influences from nature. The main streams of the influence from nature are derived from man's experience of nature itself, his position in the universe, and his attempt to master his world in religious terms. Man's sense of the holy influences the way he perceives and understands nature. The space that surrounds man provides him with the dimensional coordinates of his religious experience. Height, depth, breadth, direction, proximity, and distance are the spatial forms in which the holy manifests itself. The holy may reside on a mountaintop, in heaven, in a chasm, in the underworld, in watery depths, or in a desert. The holy way or path provides man with his direction to the divine and a means of approaching it. The spatial position of the holy and the direction to it may also be abstractly expressed—*e.g.*, by means of symbolical numbers or coordinates. The infinity of space may be represented by geometrical and linear figures.

Emptiness or fullness may characterize the utilization of spaces and surfaces that are usually intended for the reception of symbols and signs. Works of art may be totally absent in certain architectural structures; or all available space may be filled with a dense profusion of all kinds of figures and objects, all of which may sometimes be encircled by an ornamental network or web of branches, vines, leaves, and blossoms; an example of such embellishment is Islāmic art. The ebb and flow of time and things, the flow of water, and the cyclic recurrence of time are pictorially expressed—in symbols such as the wheel, spiral, wave, and circle. Time appears as the god of destiny—*kāla* in ancient Indian and Zurvān in ancient Persian religions. In late antiquity time takes the form of a demon entwined with snakes (Aion). The snake biting its own tail, the ring, and the spiral are frequently recurring symbols of fate and eternity; in Christianity, eternity is represented by the A and Ω, and the wreath.

Other physical, chemical, and physiological facts of nature also serve as sources of symbolic and iconographic concepts. Examples include the experiences of seeing, hearing, tasting, smelling, and touching; the myriad forms of plant and animal life; heaven and its astral and meteorological phenomena, which may be represented realistically or abstractly through symbols or personifications; and the colours and various colourful natural occurrences such as the rainbow (often symbolizing God or Christ) or the sunrise and sunset or minerals and precious stones. In the depiction of natural happenings, plant, animal, and human forms may blend into one another, as in the symbolic circle of the Mesopotamian god Tammuz in which the tree of life is combined with figures of fertile wild and domestic animals and the figure of a shepherd. All these symbols represent the preservation and regeneration of life. They also represent nature as a holy power.

Another area of nature symbolism is that of the micro-

cosm and macrocosm of heaven and Earth. Heaven and Earth are depicted as a dually or polarly related pair, which generally are theistically personified as a man and a woman. These roles may sometimes be reversed, as in ancient Egypt: the heavenly divinity a goddess, Nut, and the Earth divinity a god, Geb. In Greek myths on the origin of the gods (theogony), the world of the gods and man results from such pairing. Mother Earth is a central figure of many myths: she is the mistress of fertility and death.

The importance of social relationships in concepts of the holy

Influence of human relationships. Another group of pictures and symbols that are especially significant in depicting the relationship of God and man are those drawn from the area of family and social relationships, especially the roles of the father and mother. These relationships to some extent are determined by the structure of the society and its economy. The mother image is closely bound up with Earth symbolism, vegetation, agriculture, fertility, the reappearance of life, and the lunar cycle. The father image usually is associated with the sphere of heaven, authority, dominion, age, wisdom, and struggle. Love, betrothal, marriage, sexual union, family, and friendship also are significant in symbolization. The relationship between brothers and sisters is of importance, especially in the structure of religious communities, as in the totemistic organization of primitive societies and in the various fraternal groups and secret organizations of modern societies.

The image of the child, the subject, or slave again indicate man's relationship to God; the image of the ruler, king, or master expresses the power and authority of the deity. Even the structure of the world of the gods is explained in terms of family (*e.g.*, father, mother, and child as a trinity or divine twins).

Symbolism of sex and the life cycle. The symbols of sexuality and the life cycle perform a function similar to those of time and eternity in the higher religions. They indicate the permanence of the cycle of sexual functions and the return and renewal of individual and collective physical life that those functions bring about. The endless renewal of life is variously represented. It may be as realistic depictions or diagrammatic and stylized abbreviations of man and woman, god and goddess, masculine and feminine animals in the act of love and sexual union, as in reliefs on Hindu temples, or as depictions of sex characteristics (*e.g.*, in Indian *liṅga-yoni* symbolism). The theme of renewal also may be depicted in representations of woman with emphasis on her function as mother, as in the nursing-mother figures of ancient Greece. The life cycle also is represented by figures portraying the different ages of man or by depictions of pain and suffering, as in pictures of Buddha's death, which also indicate his breaking out of the endless chain of existence.

Cultural influences. Other cultural, political, social, and economic institutions and conventions also influence religious symbolism and iconography. Work and leisure, war and peace, and the myriad things associated with them—occupations, positions in society, classes and their functions, the tools of domestic and professional life, technical equipment, forms of international relations and strife—all play an important part in man's interpretation and understanding of religious reality and hence in his symbolization of this experience. Hunters, farmers, shepherds, artisans, and merchants and their activities are represented in religious pictures and appear in the verbal symbolism of religion. Tools and weapons become expressions of religious activity. In the universal and missionary religions, such as Buddhism, Christianity, and Islām, the believer is summoned to take up spiritual arms and fight for salvation. In Judaism, Christianity, and the religion of ancient Rome, the relationship between God and man is regulated according to the model of a peace treaty. In ancient German and Indian religions the military virtues of loyalty, duty, and comradeship are stressed. Man's religious activities may also be expressed in terms of play and sport, training, competition, and victory.

Conceptual influences. Ideas, theories, and structured systems of thought also are incorporated into religious symbolism. Abstract ideas—such as wholeness, unity, and the absolute—and the power of the spirit are concretely expressed in religious terms. The idea of unity plays an important part in expressing the oneness of the divinity. Mathematical principles expressed in number symbolisms are used to organize the world of the gods, spirits, and demons, to describe the inner structure of man, and to systematize mythology and theology. The concepts of duality or polarity find expression as the body and soul of man: the divine pair; the syzygy (paired emanations) in Gnosticism; the dualism of God and the devil, of the good and evil principles, of the ethically good and evil; and, finally, as the two natures of Christ. The number three, or triplicity, is represented in divine triads, the trinity, and the body–soul–spirit structure of man; as is number four, or quaternity, in the four cardinal points, the picture of the cosmic whole, the divine quaternity. Other higher number groups play similar roles. Time and eternity may be expressed in abstract symbolical terms as well as concretely in picture form.

Symbolism of numerical concepts

INFLUENCE OF RELIGION ON SYMBOLISM AND ICONOGRAPHY

Symbolism of religious figures and spiritual authorities. Religious figures and spiritual authorities themselves form a vast complex of symbols: gods, saviours, redeemers, heroes, the avatars (incarnations) and the Īśvaras (manifestations) of Hinduism, the heroes and gods of epics, the great founders, lawgivers, saints, and reformers of the great religions. The Christian saints are characterized by a very complicated system of symbols. Theologians, mystics, and contemplatives may also be symbolically and pictorially represented; the doctors (teachers) of Roman Catholicism and Eastern Orthodoxy and fathers of the early church have standard iconic forms, attributes, and symbols (*e.g.*, St. Augustine is represented by the heart; St. Jerome by the lion). Persons connected with ritual and representatives of the religious institution (*e.g.*, hierarchs, priests, assistants in the liturgy, male and female dancers, and musicians) may also be symbolically and iconographically depicted. Such functionaries—together with the major figures of a religion, such as a prophet or founder—represent the idea of mediation and thus have an important iconographic function in the artistic decoration of a place of worship.

The offering. The offering, the place of offering, the altar and its trappings, the instruments that prepare and destroy the offering, the fire that consumes it, the liquids and drinks used in the rite, the sacred meal, and the rites of communion all are objects of iconography and symbolism. The offering symbolizes the idea of submission to the ideals of a religion, the giving up of valuables and possessions for religious purposes and for the service of human brotherhood, and the giving up of one's life for religion.

Organized religions. A religious community recognizes itself and its ideas by symbols. Examples are the *yin-yang* (union of opposites) symbol bound by the circle of stability (*t'ai-chi*) in Chinese universalism; the swastika in Hinduism and Jainism; the wheel of the law in Buddhism; the *khaṇḍā* (two swords, dagger, and disk) in Sikhism; the star of David or *menora* (candelabrum) in Judaism; and the cross in its various forms in Christianity.

CONCLUSION

The further development of symbolism and iconography in the higher religions of the modern world that maintain complicated theoretical and doctrinal systems is an open question. In the years between 1920 and 1960 in the Christian communities, revivals of the liturgical traditions and of ritual symbolism were in progress, though criticized vigorously by many theologians. The value of symbols and pictures, mainly in worship, however, found wide recognition. Liturgical symbolism became valued anew and stabilized. Theological systems, like that developed by Paul Tillich, have been based on the concept of the symbol. On the other hand, during the 1960s some indifference toward symbols and pictures developed be-

cause of an emphasis on the moral and social tasks of religion. Symbols, myths, pictures, and anthropomorphic ideas of God in the terms of space and time were rejected by many theologians and philosophical structures of thinking (*e.g.*, the theory of the demythologization of the Bible; or, the "God-is-dead" theology) became substitutes for them. In the great non-Christian religions, this process seems to be less acute. In the view of a more rationalistic and technological thinking within the horizons of a secularized, sceptic, and agnostic society, however, religious symbols seem to be dispensable. In spite of these developments and attitudes, a new and increasing interest in symbols is appearing, especially among the younger generations of the latter part of the 20th century who have come into contact with both Eastern and Western religious and cultural traditions with their rich sources of symbolic images and modes of thinking. Even in the field of politics and social organization, new symbols have been arising. Thus, a resurgence of an understanding for the specific values of symbolism and iconography has been recognized in the latter part of the 20th century, in spite of all apparently opposite trends.

Symphony

The term symphony (literally, "sounding together"), though it has many meanings in musical literature, is commonly understood to refer to a lengthy composition for orchestra, often employing a sonata form (see below) in one or more large sections called "movements." Symphonies of this sort began to be composed during the so-called Classical era in European music history, *c.* 1740–1820 (the early part of this period and the decade immediately preceding it are sometimes called pre-Classical, as are the symphonies written before about 1750). During the 19th century, which included the Romantic era, symphonies grew longer, and composers concerned themselves with ways of unifying the movements; extramusical programs and new approaches toward tonality (the major–minor system of chord progressions) were among the solutions to the problems of large-scale symphonic form. Late in the century, symphonies—and orchestras—had grown to such an extent that reaction set in, culminating in the Neoclassic movement of the early 20th century, in which composers turned again toward principles of balance and formal discipline, using new techniques to achieve dynamic coherence. Economic considerations forced a reduction in the size of orchestras and amount of rehearsal time available to mid-20th-century composers, further justifying a return to less extravagant symphonic thinking. But throughout the 19th century a number of outstanding symphonists were able to reconcile the demands of fashion with strict musical logic; these composers represent the mainstream of symphonic activity, and their works remain models for much 20th-century activity in the genre. Throughout the following article two concerns predominate: a survey of the chief symphonic works and composers and consideration of the evolution of symphonic thought.

THE CONCEPT OF SYMPHONY BEFORE C. 1750

Early works entitled symphony. The word *symphōnia* was used by the Greeks in reference to notes sounding together in harmony and by extension meant an "ensemble" or "band" rather than a musical form. The word implies a pleasant concord of different notes and has been used in fields other than music to denote a pleasing combination of various elements. In the New Testament Gospel According to Luke (King James Version), *symphōnia* is translated as "musick," as distinct from *choroi*, "dancing." In the Middle Ages the name was given to several musical instruments, among them a double-headed drum, bowed stringed instruments, a large hurdy-gurdy, and bagpipes. Mention is made in 1582 of *eine Symphonei*, evidently a stringed keyboard instrument.

Vocal and instrumental works

From the mid-16th century, symphonia (and related spellings) is a term often found in titles in which it simply indicated ensemble music, whether for instruments with voices or either alone. A collection of madrigals published in Antwerp in 1585 is entitled *Symphonia angelica . . . raccolta per Huberto Waelrant*. Later notable examples are the *Sacrae symphoniae* of the Venetian composer Giovanni Gabrieli (Book I, 1597; Book II, 1615), collections of elaborate vocal and instrumental music, often for multiple choirs; and the *Symphoniae sacrae* of his celebrated German pupil, Heinrich Schütz (1629, 1647, 1650). Schütz's collection reveals his debt to the colourful and brilliantly orchestrated Italian style in works ranging from several voices to large polychoral compositions with solo parts and instruments. His countryman Samuel Scheidt's 70 *Symphonien auff Concerten-Manir*

(1644) likewise combine instrumental and vocal ensembles to enrich the texture and heighten the drama of his music.

Symphonies for instruments alone during the early Baroque era (*c.* 1600–30) occur as independent pieces and as introductions or interludes in theatrical productions. The Italian Biagio Marini's Sinfonia *"La Orlandia"* (1617) is a duet for violin or cornetto (a wind instrument with finger holes and cup-shaped mouthpiece) and continuo in five brief contiguous sections, distinguished by contrasting metres and new melodic material in each section. (The continuo is a harmonic accompaniment improvised over the written bass line, usually played on a keyboard instrument and a bass viol or other bass melody instrument.) Early operas often include instrumental symphonies. Jacopo Peri's *Euridice* (first performed 1600) includes a sinfonia for three flutes; Claudio Monteverdi's lavish musical drama *Orfeo* (1607) is punctuated with five richly scored sinfonias, while a *sinfonia da guerra* ("sinfonia of war") accompanies a staged battle in his *Il ritorno d'Ulisse in patria* (*The Return of Ulysses to his Country;* 1641). Each act of Stefano Landi's opera *Il Sant' Alessio* (1632) opens with a sectional sinfonia. Many other opera and oratorio composers used short descriptive or introductory sinfonias, often of sectional form with contrasting metres and tempos.

Formal precursors of the Classical symphony. *The Italian overture.* It remained for a Neapolitan, Alessandro Scarlatti (1660–1725), to formalize the overture to his operas as a fast–slow–fast *sinfonia avanti l'opera,* as in his opera *Dal male il bene* (*Good from Evil;* 1681). The so-called Italian overture of this and later works, scored for strings and continuo, has been widely considered to contain the germ of the later three-movement symphony. In contrast with the more contrapuntal French overture, which begins with a pompous slow movement and continues in a fugal section (involving imitation of a melody among several voices), the Italian style is immediately tuneful and predominantly homophonic (chordal) in texture. The first fast movement may be trivial; its symmetrical phrasing is unexpressive. The contrasting second movement may be more lyrical, perhaps anticipating tunes heard later in the opera. The last movement, sometimes a minuet, is an exuberant curtain raiser. This format spread quickly outside Italy, even to France. Jean-Philippe Rameau's *Zoroastre* (1749), for example, includes such a fast–slow–fast overture. Rameau, indeed, was considered an exponent of the Italian style, particularly in his lucid harmonic treatment. This late-Baroque concern with tonal clarity prefigured the attitudes of early Classical symphonists. Among the devices used to assure clarity are melodies constructed of arpeggiated ("harplike," or broken) chords and passages in unison or in parallel thirds or sixths (sequences of harmonies formed by thirds, such as C–E or D–F, or sixths, such as C–A or D–B). These features are not common in Baroque music that is strictly contrapuntal (based on interwoven melodic lines) in texture.

Characteristics of Italian and French overtures

Evolving approaches to other forms. While the opera overture settled into a form that eventually inspired early symphonists, the term sinfonia, or symphony, as yet had no formal definition. As late as 1771 *Encyclopædia Britannica,* reflecting ancient Greek usage, defined symphony merely as " . . . a consonance or concert of several sounds agreeable to the ear, whether vocal or instrumental, called also harmony." Sinfonia was used interchangeably with concerto, consort, overture, suite, and so on. Commonly a brief instrumental interlude, as in a song, was called a symphony, even into the 19th century. In the late Baroque era (*c.* 1700–50) the term was applied to such dissimilar pieces as J.S. Bach's didactic *Three-Part Inventions* for keyboard, called *Sinfonien* in the 1723 copy, and the orchestral "Pastoral Symphony," a quasi-descriptive interlude in Handel's *Messiah* (composed 1741), said to have been based on an Italian shepherd bagpipe tune and very much in the tradition of earlier descriptive symphonies in opera.

Bach's *Sinfonia VII* in E minor and *Sinfonia XI* in G minor are interesting in that in each piece the opening material recurs at the end. In *VII* this repetition is merely suggested, but in *XI* the last eight measures of the piece virtually duplicate the first eight. The whole intermediate body of these pieces develops the motivic material presented at the beginning, and the initial material is transformed contrapuntally and harmonically. In the closing bars the tension thus aroused resolves and the rhythmic drive reins in. This suggestion of an expository unit moving from the home key to a different key, followed by an extended development that explores still more remote keys and the motivic and contrapuntal implications of the beginning, concluding with a recapitulation in which the energy of the development is somewhat dissipated by a return to the opening material, prefigures the sonata form of the Classical symphonists (see below). Bach uses this technique in some of his instrumental concerto movements; the concertos have other elements in common with early symphonies, especially in the mood of their lyric slow movements and fast duple-metre finales.

Exploitation of key relationships

The word sinfonia was applied to a trio sonata for flute, oboe, and continuo in Johann Joseph Fux's *Concentus Musico-instrumentalis* (1701), a collection of suites each comprising a number (as many as 15) of bipartite (two-section) dances and descriptive pieces. An intellectual and influential Viennese court composer, Fux departed in this sinfonia from the typical 17th-century suite, which is merely a collection of contrasting dances in the same key. The work falls into two major divisions, both comprising three short movements; the key scheme is F major, D minor, F major—F major, D minor, F major, and the last three movements have programmatic titles. Here is not merely a collection of various dances but a conscious attempt to relate movements tonally and thereby create larger hierarchic units. F major and D minor are closely related keys, and it would not be possible to omit a single movement without destroying the symmetry of the whole (not that either group of three, or even each dance, does not sound good by itself). By means of this simple, balanced harmonic structuring Fux advanced beyond the looser architecture of the typical suite; and by framing a minor-key movement between two movements in the same related major key he anticipated the overall form of many early symphonies.

Importance of tonal harmony

Both Fux and Bach were products of the evolution of tonal harmony, a system of key relations which brought with it the possibility of basing large-scale forms not only on melodic variation or counterpoint, as earlier, but on harmonic tension and modulation. (Modulation, unlike simple change of key, implies the establishment of a new tonic, or tonal centre, by means of progression through a number of related keys.) The wide-ranging modulations and affective harmonic progressions of German Baroque composers depended on well-tempered tuning, a system that permits exploration of keys distant from the tonic without the necessity of retuning to accommodate the remote harmonies. Bach exploited this system to the utmost, as did many of his North German contemporaries; but their rich harmonic palette was foreign to the south, where many important symphonists arose. Concerned less with powerful emotions (*Affekten*) and more with clarity, the southerners avoided intricate counterpoint and convoluted harmonic progressions, preferring a restricted chord vocabulary and clear-cut symmetrical phrasing dominated by tuneful melody.

The Neapolitan intermezzo. Besides the suite and opera overture, the short humorous intermezzo, which originated in Naples and flourished *c.* 1685–1750, strongly influenced pre-Classical symphonists. Neapolitan composers, headed by Alessandro Scarlatti, concerned themselves in the intermezzo with dramatic, comic interplay between two singers in two or three short acts made up of arias, recitatives, and duets. Because the texts demanded clear articulation and careful declamation, they influenced the melodic phrase structure, giving rise to repeated-note figures and brief rhythmic or melodic motives. These phrases normally fall into two-measure units. Counterpoint was abandoned, for it tended to obscure the text; and harmonies became simple and slow-moving. Intermezzo melodies abound in ornaments, sudden ac-

cents, syncopation (displaced accents), and playful leaps reflecting the text declamation and lack the broad, spun-out arch and driving rhythm of typical Baroque melodies. Rather, they are made up of short motives joined one to another and give rise to frequently articulated phrase groups. This word-derived idiom furnished the melodic impulse of the early symphonies.

THE SYMPHONY PROPER

Early Classical period. *Italy.* Chord-generated melodies (those arising from arpeggiated triads) abound in 18th-century symphonies, among which a number of stereotyped "theme families" can be distinguished. These furnished raw material for further development. In fact, a composer's originality found expression not so much in his original theme as in his realization of the implications of the theme later in the composition. Certain tunes are by nature not highly implicative; they are perfect closed units that cannot be easily developed and so are superficially inappropriate for symphonic use. Such, for example, are many folk tunes; and this explains why great symphonists rarely use folk tunes without at least distorting them so as to open them to development. On the other hand, motivic melodies, such as those in the intermezzi, coupled with slow harmonic motion, lend themselves well to fragmentation, recombination, extension, elision, reharmonization, and other developmental techniques. By the 1740s, Italian symphonists had learned to sustain interest by these means and to obtain contrast by dramatically apposing tunes of different character in different keys (usually the tonic, or home key, and the dominant, located five tones above the tonic, or related major or minor keys).

Early uses of sonata form

Among Italians influenced by these factors was Tomaso Albinoni (significantly, a composer of 48 operas). The third movement of his *Sinfonia in D Major*, fifth of the *Sei sinfonie a quattro* (1735), displays a simple sonata form (also known as "first movement form," though not so limited). Sonata form, crucial in the symphony's evolution, is based on the dramatic apposition and eventual reconciliation of contrasting keys. In essence it consists of an exposition in which one or more themes are presented, the first (often forceful in character) in the tonic key and the second (often lyric) in the dominant. Sometimes a third, closing theme follows in the dominant. The two key areas contrast not only harmonically and melodically but often in instrumentation, loudness, and texture. So-called monothematic sonata movements lack a contrasting second melody; indeed, it is not so much the character of the tunes but the dynamism of the opposed key areas that is essential to the dramatic structure. The transition between tonic and dominant areas was to become a focus of interest to later composers, but in early symphonies the transitions were brief and simple.

The exposition, often marked to be repeated, comes to a close on a key other than the tonic (usually the dominant) and is followed by a development section, beginning on the dominant, in which themes previously heard are reharmonized, fragmented, or otherwise reshaped. Again it is not melodies so much as harmonies that arouse tension in the development. The composer confronts the problem of returning to the tonic via more distant chords, and this is sometimes accomplished by modulations that bear no thematic relation to the exposition. In early symphonies this process is only tentatively exploited, and developments are brief, sometimes involving merely transposition of the original first theme to a new key. Later the development assumed the character of the meat in the sandwich, as it were.

Following the development comes a recapitulation of the exposition, this time all in the tonic key (before *c.* 1770 the recapitulation sometimes retained the key scheme of the exposition, except for the closing bars), resolving the harmonic tension of the development. The recapitulation may be simply a virtual repetition of the exposition, with appropriate key changes, or may be truncated, expanded, or otherwise varied so as to continue developmental processes. Many early symphonies take advantage of the implications of a varied recapitulation, literal repetition being abhorrent to imaginative composers. It will be observed that when both themes appear recapitulated in the tonic, the function of the transition between themes differs from that in the exposition, in which it leads from one key to another. After the 1750s, however, the first theme was often omitted in the recapitulation. Obviously, the recapitulation's tonal scheme allows extended treatment of the tonic, but sometimes a coda (tail) is added after the recapitulation to consolidate further the focal nature of the tonic.

It is important to understand that sonata form was subject to great variation and deviation from "textbook" norms throughout the symphony's history. Ideas of a "typical" sonata form did not evolve until *c.* 1830. Nevertheless, the vocabulary of exposition, development, recapitulation, transition, and so on is capable of wide application and will simplify the remainder of the present article.

Albinoni's *Sinfonia in D Major* as a whole is forward-looking. The orchestra lacks a continuo, harmonic orientation replaces counterpoint, and the movements are of larger scale than typical Baroque dance movements. The central minuet-and-trio movement, surprisingly modern-sounding, contrasts lightheartedly with the sonata form. Minuets and song-form movements relieve the dramatic tension of sonata movements; and from this time on minuets appeared frequently in symphonies. Gradually losing dance character, they moved from the last or middle position to penultimate place when, later, a fast fourth movement appeared as finale.

The symphonies of Sammartini

A leading early symphonist, the Italian Giovanni Battista Sammartini, is known from some 77 extant symphonies, some of them available in modern editions. A prolific composer of instrumental chamber music, his use of incipient sonata form, restricted harmonic vocabulary, and motivic, not highly ornamented melodies pointed to the future. Though dependent on Baroque models for inspiration during his first period of activity (to *c.* 1740), he had abandoned the continuo by about 1760, filling the harmony instead with horns or trumpets—which, however, were restricted in their ability to play in certain keys and therefore operated to constrict the available harmonic vocabulary. More than many contemporaries, Sammartini infused inner parts with contrapuntal life, especially in earlier works, although he rarely used extended imitation. His rhythmic energy was appreciated by opera-writing contemporaries, from whom (especially the Italians Niccolò Jommelli and Rinaldo di Capua) he perhaps drew inspiration for the long, expressive cantabile (singing) phrases that, along with a firm grasp of modulation, characterize his later works. His slow movements are especially rich. Another late characteristic is the extended role of wind instruments, which are given independent, idiomatic parts. Sammartini wrote for oboes, flutes, and bassoons among the woodwinds (bassoons doubling the bass line); clarinets were also in use at this time, usually interchangeably with oboes. Significantly, Mozart heard Sammartini's music during a visit to Milan.

A third Italian, Padre Giovanni Battista Martini, renowned as a teacher and music historian, left 24 symphonies dating roughly between 1736 and 1777. There is remarkable consistency among this corpus. All but one are in the then-normal three movements (Sammartini wrote a number in four), and all have outer movements in a major key, whereas the middle slow movements are nearly always minor. Music of the Classical period greatly favours major keys; according to one investigator all but about 2 percent of 18th-century symphonies are major (excepting their expressive slow movements). Martini, although trained in counterpoint, avoided it in these works, favouring instead a treble-dominated texture over a simple, slow-moving bass. His chord vocabulary was restricted, his orchestration elementary. His melodies reflect a number of banal formulas in current use, but his manipulation and development of these formulas was skillful. Mozart visited Martini several times in Bologna in 1770.

In the hands of these and other Italian composers, symphonic style evolved considerably by 1740, and there was

continued fruitful experimentation through the 1750s. That Italians influenced contemporary and later German and, especially, Austrian symphonists cannot be doubted; but the extent of indebtedness and mutual influence cannot now be fully determined because of the scarcity of available scores. Relatively few of the surviving early symphonies have appeared in reliable modern editions, and those known to survive in manuscript represent but a fraction of the thousands composed. The early history of the symphony remains, therefore, a matter of speculation and debate, despite the enormous progress in research and publication in the mid-20th century.

German and Austrian composers. Germany and Austria were important centres of symphonic composition after about 1740. In Mannheim, Germany, the Bohemian Johann Wenzel Stamitz developed a remarkably well-trained orchestra that by 1756 comprised (in addition to 30 strings) four horns, pairs of flutes, oboes, clarinets, bassoons, trumpets, and timpani. With this ensemble, independent wind writing and creative orchestration flourished. Stamitz—himself a violinist and composer of more than 70 symphonies, chiefly mature works—and his contemporary Ignaz Holzbauer evolved a bold style born of the confluence of Italian melody and German seriousness. Counterpoint is abandoned; expression arises from orchestral crescendos and diminuendos (anticipated by Jommelli), characteristic melodic effects such as sighing appoggiaturas (falling figures) and rocketing arpeggiated (broken) chords, and strong dynamic, thematic, and textural contrasts. This style degenerated into mannerism with Stamitz's son Karl (composer of about 80 symphonies) and Johann Christian Cannabich, who enlarged the Mannheim orchestra.

The Mannheim composers

Mannheimers paid special attention to their development sections, which have been described as a "mosaic of fragments." They tended toward incomplete recapitulations, wrote tender slow movements, extended the number of movements to four: allegro (lively), andante (slow), minuet, and presto (rapid). Insisting on disciplined and precise performance, they wrote all parts out in full instead of leaving some to be realized by the players. With the rise of independent wind parts after *c.* 1770, the continuo became redundant and was abandoned; in outdoor music and in huge orchestras it had become inaudible anyway. Musical textures, which in early works were equally appropriate for string quartet or orchestra, became truly symphonic. Holzbauer occasionally features bassoon solos (as in the *Symphony in E Flat Major*, Opus 4, No. 3), liberating that instrument from simply doubling the bass. The elder Stamitz and Holzbauer were particularly highly regarded in Paris and strongly influenced symphonic activity there.

In Berlin and northern Germany another school arose, dominated by Carl Philipp Emanuel Bach, Johann Gottlieb Graun, and other musicians reared in a tradition of rigorous counterpoint and formal conservatism. Retaining three-movement format and avoiding strongly contrasting themes, they maintained contrapuntal interplay in the prevailingly homophonic texture. Even more than the Mannheimers, they concerned themselves with melodic development and ornamentation and with emotional expressiveness—an aesthetic approach they termed *Empfindsamkeit* (sensitivity). C.P.E. Bach's set of six symphonies commissioned by Baron Gottfried Bernhard van Swieten (completed 1773) aroused enthusiasm for their humour, technical challenge, and novelty of harmonic invention. Even more intensely passionate are the late *Orchestral Symphonies for Twelve Obbligato Parts* (1780), with their clever instrumentation and affective harmonies punctuated by unison passages. Reflecting the literary *Sturm und Drang* (storm and stress) movement, the Berliners powerfully influenced Haydn and Mozart and even Beethoven.

Another son of J.S. Bach, Johann Christian, the so-called London Bach, was perhaps yet more important for the future, influencing Mozart, who met him in London (1764) and again in Paris (1778). His 50 or so symphonies lack the passionate gestures of the Berliners' but are finely wrought and sophisticated in melody and orchestration. The *Sinfonias for Double Orchestra*, Opus 18, reflect in their *style galant* tunes the influence of his study with Martini in Italy, as well as French and Mannheim characteristics (*galant* was the 18th-century term for modern, light, elegant style). Numbers two and three of the set served as opera overtures. Simple in form, complex in texture, J.C. Bach's works are now considered to epitomize elegant, fashionable chamber music.

The style most influential on Haydn, Mozart, and Beethoven was that of the Viennese school, headed by Georg Matthias Monn and Fux's pupil Georg Christoph Wagenseil. The Viennese experimented further with orchestration and tone colour, emphasized the violin's melodic role, and displayed popular influence in their playful minuets. Monn, though perfectly at ease with counterpoint, ignored it in his symphonies. His four-movement *Symphony in E Flat Major* for pairs of oboes and horns, strings, and continuo is noteworthy for its wide dynamic range and gracious melody so characteristic of Viennese music. The first movement's first theme recurs in the recapitulation transformed into a virtuoso horn duet, reflecting the skill of the players at his disposal and the liberation of horns from a mere harmony-filling role. Elsewhere in the movement are found the slow, repeated-note bass and inconsequential viola part common in early symphonies. As yet the development is quite short and thematically limited, and the movement's scale is small—only a little more than three minutes. But as is often the case, the first movement is the most extended of the four, first movements having gained importance beyond the first movements of opera overtures. In later works Monn dropped the continuo and extended the role of the winds. Together with Johann Stamitz he has been considered highly influential in establishing modern symphonic style, although perhaps Wagenseil, an experienced keyboard player and opera composer, was a more successful composer, especially notable for skillful thematic construction and manipulation, working ornamentation into structure. Also active in Vienna was Haydn's friend Karl Ditters von Dittersdorf, who contributed no fewer than 115 symphonies.

The Viennese school

The Viennese style became widely disseminated in Europe. As many as 25 Viennese composers migrated to Paris; others moved to Dresden, Mannheim, and Munich and even as far as Dublin, St. Petersburg, and North America. Their style thus became truly international, and the innovations of these minor masters paved the way for the fully developed symphonic style of Haydn and Mozart. The music of the Viennese composers, mainly intended for elite entertainment, reflects the virtuosic attainments of many private orchestras and the cultured taste of aristocrats who commissioned a constant stream of symphonies and lighter chamber music.

The mature Classical period. *Haydn.* Joseph Haydn, despite his isolation from urban musical centres for much of his life, was revered throughout Europe, beloved by Mozart and Beethoven, and widely published and copied—so much so that the authenticity of many works attributed to him remains in question. One hundred and eight symphonies are thought to have been written by him; one of these is lost. Few composers show such remarkable growth as Haydn; from his insignificant youthful pieces, entirely dominated by the style of his pre-Classical elders, to the towering achievement of his last works, his symphonies display an evolution in form and content that had tremendous effect on his followers.

Viennese in style, some of his early symphonies display originality in the use of nonstandard phrase lengths and in their monothematic tendencies. *Symphonies Nos. 1* and *2* are in three movements, lacking a minuet. These works require a continuo (the slow movement in *No. 2* consists only of a bass and treble part), and horns and oboes are as yet not independent. *Symphony No. 3* and others incorporate contrapuntal movements. The sonata recapitulations are subtly altered; but unlike Stamitz', they are generally complete. Melodically, Haydn drew on folk music for inspiration, especially in minuets but also on *galant* and operatic styles. His work reveals a gradual growth in appreciation of the idiomatic qualities of wind

instruments, especially in trios of minuets (*e.g., Symphony No. 22, Symphony No. 40*); in *Symphony No. 5* he included winds in the slow movement, unusual at this time, and in *Nos. 6–8* he wrote independent wind solos, recalling the instrumental dialogue found in the Baroque concerto grosso. *Symphonies Nos. 6* and *11* begin with slow introductions, a characteristic which became common in Haydn's symphonies after *No. 84*.

With his appointment to the service of Prince Esterházy in 1761, Haydn's individuality began to emerge, partly because of his opportunity to experiment with the Esterházy orchestra. The bulk of his symphonic production dates from these years before 1771. Although humour and good nature pervade these works, stronger emotions and tension also begin to appear, as in the minor-key *Symphonies Nos. 26, 39,* and *49*. The *Farewell Symphony* (*No. 45*), with its adagio (slow) coda, displays Haydn's wit and is one of the best of his symphonies from the decade before 1780. This transitional period shows him striking out into more remote keys, introducing new themes in development sections, and growing more confident in formal craftsmanship and orchestration. Powerful and concentrated, the symphonies of the so-called *Sturm und Drang* period recall the *Empfindsamkeit* of C.P.E. Bach. By turns rigorously contrapuntal and lucidly witty, the vitality evident in the forms reflects Haydn's overflowing adventurousness. Contredanse (country dance) melodies may have inspired some of his themes, for example in the finale of *Symphony No. 88*.

Haydn's later works

The late *London* and *Paris Symphonies* reflect the influence of Mozart and show Haydn at the height of his power. No two movements are alike; the "mosaic" of theme elements pervades even transition sections and codas; each instrument shares in the melodic development; minuets grow in fire or dignity while finales exploit varieties of rondo form (see below). His slow movements, often straightforward sets of variations, engage in artful modulations prefiguring the romantic aspect of Beethoven. *Symphony No. 103* is especially thematically economical, and its movements are related by thematic resemblances, foreshadowing the cyclic nature of many 19th-century symphonies.

Haydn, though by no means the "father of the symphony," contributed enormously to a definition of the harmonic basis of Classical form, the dramatic role of key relationships, and the expressive capabilities of the winds. Major–minor contrasts, wide-ranging modulations, and reconciliation between counterpoint and homophony underlie his unambiguous moods, so different from those of Mozart. An eclectic architect, he amalgamated all the styles of his time in uniquely free and expressive shapes.

Use of rondo-form movements

Rondo form (in which a recurrent theme alternates with other material, as A B A C A) had been found especially in Italian opera and French instrumental music before *c.* 1770; in the 1770s and '80s it became second only to sonata form in symphonic importance. Exploited already by C.P.E. Bach, Stamitz, and others, rondos became a favourite last-movement form with Haydn and Mozart after about 1773. Haydn wrote a number of slow movements as rondos (*Symphonies Nos. 73, 74, 76*) and employed rondos 12 times in his last 17 symphonies. Mozart avoided the rondo in his last symphonies, perhaps because of the light nature of the form. Its vogue seems to have been brought about by the public's demand for structural simplicity and repetitive tunefulness. In the hands of Haydn and Mozart, however, the rondo increased in complexity, demonstrating in the so-called sonato-rondo the characteristics of sonata form, such as developments of earlier-stated material by means of fragmentation and modulation.

The symphonies of Mozart. Wolfgang Amadeus Mozart raised the symphony to heights never surpassed. Of his 50-odd symphonies, produced between 1764 and 1788, the earliest ones are conventional but precocious, reflecting influences of J.C. Bach, Sammartini, and Haydn. An invigorating first movement predominates, followed by a light cantabile movement and a fast finale or minuet (minuets in his symphonies date mostly after 1767). The *Symphony in B Flat Major,* K. 22 (1765; Köchel numbers are the standard way of identifying Mozart's works) contains a lovely chromatic (containing notes foreign to the key) slow movement in the key of G minor.

Mozart's synthesis of Italian and German structures

Mozart's exposure to Europe's main musical currents led him to synthesize the playful Italian homophonic and operatic style with serious German polyphony. This is evident in the agitated *Symphony in G Minor,* K. 183 (1773)—a *Sturm und Drang* work and his first minor-key symphony—and in the cheerful *Symphony in A Major,* K. 201 (1774). In these works the balance of interest shifts to the last movement. The addition of codas ("tails," extended closing sections reaffirming the tonic), the increased length and scope of slow movements and minuets, and a growing orchestral sensitivity all point toward maturity. In contrast with those of Haydn, Mozart's slow movements lean toward the sonata form with its inherent drama.

Mozart, unlike Haydn, was not a formal experimenter; he re-used successful structural formulations in later works. It was his treatment of melody that set him apart. He preferred to ignore monothematic structure; and his first and second themes, neither folklike nor mosaic-like, contrast strongly. His harmonic range is narrow compared with Haydn's, but within his range he constantly transformed thematic material. Development sections expand with the introduction of new thematic material and modulations over a wider tonal field. His recapitulations tend to be straightforward. In this mature period, Mozart's symphonies became unified thematically and expressively, using fuller imitation, more singing figuration, freer instrumentation (the *Paris Symphony,* K. 297, in D major, introduces clarinets). Mozart rejected Mannheim gesture in favour of better integrated dynamics.

Mozart's last 10 years saw him further exposed to Haydn's influence and very aware of J.S. Bach's music. The monumental last six symphonies reflect his experience as an opera and chamber music composer. The *Symphony in C Major,* K. 425, has a rare, slow chromatic introduction, while K. 504 in D major (*Prague Symphony*) dispenses with the minuet, has all three movements in sonata form, and uses canonic development (development by means of exact imitation). The last three symphonies (K. 543, in E flat major; K. 550, in G minor; K. 551, in C major, or the *Jupiter Symphony*), summits of the Classical genre, are bold in their harmonies and counterpoint; the serious minuet of K. 550 foreshadows the scherzo of Beethoven's *Fifth Symphony*. (The scherzo is a rapid, rhythmic, minuet-derived form.)

Mozart was no revolutionary. Receptive to the influence of others, he rejected more than he assimilated, transforming all into a uniquely personal idiom. Several of his symphonies were used as opera overtures, but the best ones are so complete in themselves as to make their use as incidental music unthinkable to modern taste. Mozart's and Haydn's mature symphonies are comprehensive in mood and design. The various movements balance one another so well that those who are accustomed to hearing them would find it difficult to accept the substitution of other movements. This tendency toward intimate relation among the standard four movements reflects the urge of these composers to seek unity on the highest hierarchic level—a trend foreign to most of their lesser contemporaries but a basic factor in the symphony's evolution throughout the next two centuries.

Beethoven. With Ludwig van Beethoven the symphony became no longer entertainment music but an expression of monumental intellect and innermost feeling, as in Haydn's and Mozart's late works. The *Symphony No. 1 in C Major* (completed 1800) is Haydnesque, particularly in the opening theme of the finale (comparable to the finale of Haydn's *Symphony No. 88*), but full of originality. Its four classically structured movements reflect Beethoven's concern with expressive woodwind writing and dynamics. The third movement (Menuetto) is prophetic of Beethoven's later whirling scherzos. The slow introduction to the first movement is remarkable for its avoidance of the tonic, a technique used often in later works to arouse tension.

The *Symphony No. 2 in D Major* (1802) is transitional and, like the *Symphony No. 1*, somewhat diffuse. A long introduction announces a work of grand dimensions. The lyric slow movement is rich in themes that are organically unified. A dynamic scherzo, only slightly dancelike, and an expanded sonata finale (with an enormous coda introducing a new theme) point toward the revolutionary length and structure of the *Symphony No. 3 in E Flat Major* (*Eroica;* completed 1804), a work that many consider to herald the dawn of musical Romanticism. The *Eroica* (Beethoven's title) no longer aims at an elite audience. Its first movement employs a multitude of themes, again drawn together into a cohesive organism and developed in a context of great harmonic tension. The tonic, E♭, is avoided near the beginning for 14 measures. A pathetic funeral march, replacing the ordinary slow movement, is followed by a vigorous scherzo; this leads to a variation finale, based on a theme from his *Creatures of Prometheus* ballet and full of contrapuntal development. The symphony marked a new fusion of old formal structures with Beethoven's dynamic outlook.

The *Eroica* symphony

The cheerful *Symphony No. 4 in B Flat Major* (1806) and fateful *Symphony No. 5 in C Minor* (1808), so unalike in character, were composed side by side. The *Fifth*, like the *Third*, a visionary work, is unified by the famous four-note motif that permeates all four movements in one form or another. The scherzo and finale are joined, and an explosion of C major in the last movement is celebrated with three trombones (possibly their first use in a symphony), piccolo, and contrabassoon. This grandiose edifice is constructed with relentless logic and rhythmic drive, hallmarks of Beethoven's mature style.

The *Symphony No. 6 in F Major* (1808), called the *Pastoral*, is in five movements, the first two and last in sonata form, each, according to Beethoven, expressing an aspect of rustic life. The whole has a unity of character that reflects a deeper rhythmic unity. A descriptive "Storm" movement links the scherzo ("Merrymaking of the Peasants") with a calm "Thanksgiving after the Storm" finale, which, incidentally, incorporates a Swiss yodel tune. The relaxed human and poetic qualities of the *Sixth* set it apart from the *Fifth* and from the demoniac *Symphony No. 7 in A Major* (1812), with its expanded scherzo and trio, blazing finale, and spirited first movement preceded by a long modulatory introduction.

The small scale of the first three movements of the *Symphony No. 8 in F Major* (1812) leaves one unprepared for its breathtaking finale. Its minuet is a subtle parody of the classical minuet of Mozart and Haydn.

The *Symphony No. 9 in D Minor* (*Choral*) found Beethoven deaf at its first performance in 1824. It marked a turning point in music history, not only for its novel inclusion of chorus and vocal soloists in the last movement and the extraordinarily variegated sonata form of that movement—incorporating a Turkish march, double exposition, double fugues, strophic (stanzaic) variations—but for the scope of the whole, a summary of Beethoven's ethical and symphonic achievements.

In his development of motifs and variation of entire themes Beethoven went unchallenged. He expanded the limits of Classical form, particularly in his finales, and increased the length of the symphonic process to more than four times the 15 or so minutes required for a pre-Classical symphony. Further, his orchestral sensitivity allowed all instruments a structural role while simultaneously making new demands on player and listener alike. Besides widening the scope of the orchestra with extra winds and percussion, he made it more than ever a cohesive single instrument, bequeathing to the 19th century a standard against which composers measured the effectiveness of their own orchestrations. Finally, through the immense concentration of his symphonies he made it impossible for his followers to equal the sheer quantity of production of the Classical composers; far too much effort went into creating a symphony to allow pouring them out by dozens.

Other composers. So overwhelming was the impact of Beethoven's symphonies, along with that of Mozart's and Haydn's mature ones, on later generations that they utterly obscure the productions of many other worthy symphonists. François Joseph Gossec, an early French symphonist, and Pierre van Maldere came to grips successfully with the dominating German–Italian idiom and were important among the Parisians influenced by Stamitz and his school. Van Maldere was eulogized for his imaginative thematic structures as well as for the unusually serious nature of his compositions, which strongly contrasted with the more lighthearted style characteristic of the Mannheimers.

An English composer, William Boyce, eclipsed by the London Bach, wrote eight sinfonias that betray in design the strong influence of theatre music. Basically merely overtures in French or Italian styles, they show none of the modern characteristics being formulated at the time in Germany; England, in general, was not quick to adopt the new symphonic style.

Eastern Europe produced revolutionary composers of whom until recently little has been known. Stamitz, Bohemian by birth, overshadowed such competent composers as Jiří Benda. Benda's symphonies, dating mostly between 1750 and 1765, are generally brief, in three movements, and close to the Italian overture in form and feeling. The sonata form is not exploited, although characteristics such as contrasting themes and contrast within a single theme (a technique used also by Mozart) suggest a Mannheim influence or at least a revolt against Baroque conventions.

Revolutionary composers of Eastern Europe

Luigi Boccherini, Giovanni Giuseppi Cambini, Michael Haydn (Joseph's brother), Leopold Mozart (father of Wolfgang), and many other important chamber music composers contributed numerous symphonies well worth performance. Later composers included the conservative Swede Franz Berwald and a brilliant but short-lived Spaniard, Juan Crisóstomo Arriaga, influential mostly in their own countries; and Muzio Clementi, Luigi Cherubini, Louis Spohr, and Carl Maria von Weber, who, although better known for work in other genres, were nevertheless popular symphonists. Spohr wrote a number of highly pictorial programmatic symphonies, going well beyond Beethoven's *Sixth*.

The Romantic era. *The period between Schubert and Liszt.* Among 19th-century symphonists several trends can be distinguished. Concerned to some extent with self-conscious emotional expression, they often tended to use looser forms and slower paces than the Classical composers. Sometimes this led to lax discipline but not in the case of the finest composers, among them Schumann, Brahms, and Dvořák, who were all very conscious of their debt to Beethoven, Mozart, and Haydn. With later composers, such as Anton Bruckner, Peter Ilich Tchaikovsky, and Gustav Mahler, the normal balance of form was sometimes upset in favour of romantic license, but they too derived their basic goals from the Classical composers, with a more or less heavy admixture of the influence of Richard Wagner.

Franz Schubert is known primarily as a songwriter. His nine symphonies stand in the shadow of Beethoven's but are revolutionary and Romantic in a way utterly different from Beethoven's. Whereas Beethoven wrestled with melodic problems, Schubert was a born melodist and consequently concerned himself more with the harmonic basis of form. He was likewise the more sensitive orchestrator, and in the last three symphonies he greatly expanded the role of the brasses.

His Symphony No. 1 in D Major (1813) and *Symphony No. 2 in B Flat Major* (1815) illustrate Schubert's departure from Classical models. Although the first movements are in sonata form, their pace is slower than the ordinary Classical allegro and is supported by long nonthematic passages that expand the harmonic arch. In the youthful sonata-form movements the second theme group is often set in an unexpected key before the music turns to the dominant at the end of the exposition. In recapitulations, too, Schubert shies away from harmonic simplicity and Classical expectation; his phrasing also is often irregular. Schubert's slow movements, scherzos, and minuets are not as strikingly original. Clear references to move-

ments and themes of Beethoven occur in these early works, and in key scheme and major–minor contrast Schubert often betrayed his indebtedness to Beethoven. He was unembarrassed to borrow melodic material, which he transformed in an utterly personal way. This is particularly the case in the *Symphony No. 4 in C Minor* (the *Tragic;* 1816). The *Symphony No. 5 in B Flat Major* (1816), scored for a smaller orchestra, more strongly recalls Mozart and Haydn. The highly emotional *No. 6 in C Major* (1818) is of larger scale, based as usual more on rhythmic and harmonic impetus than melodic development. The incomplete draft of the *Symphony in E Minor-Major* (1821) has inspired attempts at completion. But it is the last two (the *Symphony in B Minor* or *Unfinished*, 1822, and *Symphony in C Major*, or *Great*, 1828) that raise Schubert to high rank among symphonists. Composed for large orchestras, they nevertheless reflect Schubert's experience in writing for voice and piano.

Schubert's *Unfinished* and *Great* symphonies

The *Unfinished* consists of two complete movements in $\frac{3}{4}$ and $\frac{3}{8}$ time and a sketch for a scherzo. The complete movements form a convincing unity; masterful in harmonic organization and orchestration, they are expressive without being diffuse, a criticism often levelled against passages in Schubert's earlier works. The *Great* is of Beethovenian scale, partly because of extensive repetition. The scherzo and related slow movement, no longer simply rustic pieces, are both sonatas. Irregular phrases, modulatory schemes, and rhythmic force give evidence of Schubert's concern with form based on slowed-down and far-reaching harmonic motion. His rhythmic manipulation was un-Classical, his themes personal and of more than Classical significance.

Berlioz and Liszt

With the first group of symphonists born in the 19th century the Romantic style was fully fledged. The French composer Hector Berlioz and the Hungarian Franz Liszt contributed large symphonic works that to some extent departed in form from the Classical sonata-centred model. The literary program to Berlioz' *Symphonie fantastique: Épisode de la vie d'un artiste* (1830) was not written until the music was well along toward completion. The symphony was thoroughly planned out thematically and formally and stands as a musical unity without regard to the program, which Berlioz himself eventually withdrew. A very personal expression nevertheless, the *Fantastique* introduces a structural *idée fixe*, a theme (representing his mistress?) recurring throughout the five movements in various rhythmic forms, serving to unite the "scenes" musically as well as dramatically.

Harold en Italie (1834; after Byron's poem), like the *Fantastique*, makes use of pre-existent material and is unified not only by a program but by a recurrent theme, a viola solo representing Harold. This theme is not subject to the kind of variation given the *idée fixe* in the *Fantastique;* yet from it springs much of the melodic inspiration of the whole work. Berlioz' third symphonic work, *Roméo et Juliette* (1839), rarely heard in its entirety, incorporates chorus and vocal soloists into its five large sections, which are programmatically derived from episodes of Shakespeare's drama. Not coincidentally, Berlioz was a great admirer of Beethoven. Beethoven's unity of moods, thematic development, and dramatic orchestration were models for Berlioz to extend, although he did so outside the formal confines of the sonata and with even more explicit passion.

Liszt owed much to Berlioz, both in his handling of enlarged orchestral forces and in thematic transformation (as opposed to development). The three movements of his *Faust Symphony* (1854) bear the names of Goethe's characters: Faust, Gretchen, and Mephistopheles; and the final movement parodies themes of the first two in a satisfyingly diabolical manner. Characters aside, the music is highly effective and balanced; Liszt revised the score over several decades. The score is dedicated to Berlioz.

Liszt's other symphonic work, the *Symphony to Dante's Divina Commedia* (1856), depicts the Inferno, Purgatory, and Paradise. Liszt, at times a devout Catholic, portrayed Dante's scenes with great imagination and passion, cleverly suiting his melody—sometimes simple and tranquil, sometimes chromatic and writhing—and harmony to the special characters of the three levels. The symphony is dedicated to Wagner, who suggested the third-movement setting of the Magnificat for female chorus and orchestra. As do many operas of Wagner, Liszt's work uses the leitmotiv, an extension of Berlioz' *idée fixe.*

If Berlioz and Liszt represented a trend toward freedom and extramusical content in symphonic writing, Schumann and Mendelssohn were more conservative though not strictly comparable. All four were deeply concerned with formal discipline, but Schumann and Mendelssohn departed less widely from Classical norms and made less point of extramusical associations.

Mendelssohn's symphonic works

Felix Mendelssohn wrote 16 symphonies and a symphony-cantata. Twelve of the symphonies are immature works; but the remainder fairly exemplify his style: facile, full of light melody and brilliant orchestration, occasionally oversentimental, according to some critics. He is best known for his *Symphonies No. 3* (*Scottish*) and *No. 4* (*Italian*), both in A major–minor. The *Scottish* (also called *Scotch*), completed in 1842, although not programmatic, is expressive of Mendelssohn's poetic nature. Its beginning was sketched during a visit to Scotland in 1829. In structure the work consists of four movements played without pause, with a slow introduction. Its fairy-like scherzo, which incorporates part of a Scottish folk song, exemplifies the delicate moods that Mendelssohn excelled in creating. The other movements are well developed, the many contrasting themes integrated contrapuntally and extended with interesting modulations. But although it is full of good music, the symphony is less powerful than its companion, the *Italian* (finished 1833). This happy work, inspired by visits to Rome and Naples, is particularly colourfully orchestrated. It ends with a dance movement incorporating three themes; the minor tonality does not detract from its vivacity. The first movement, too, has three themes, the third introduced in the development section. The second movement, recalling a religious procession, and the third, a quasi-minuet and trio, are picturesque without being descriptive and represent Mendelssohn at his finest—uncomplicated, lush, and vigorous.

Schumann's miniaturist style

Robert Schumann, like Mendelssohn and Mozart, wrote his symphonies at an age when most longer-lived composers are just beginning to mature and wrote only a few truly great ones. Like many first-generation Romantic composers Schumann was essentially a miniaturist, most at home in songs and short piano works. His orchestral style reflects these qualities; rhythmically restless, often repetitive, not sensitively scored, they have been praised more for their harmonic subtleties and wonderful lyric melodies than for development of these ideas.

The *Symphony No. 1 in B Flat Major* (*Spring;* 1841), based on a poem by Adolph Böttger, originally had titles given each movement; these were soon rejected by Schumann and indeed are irrelevant to the music. The first movement, opening with a slow introduction (a tradition since the days of Haydn), incorporates three contrasting themes (the third introduced toward the conclusion of the movement) as well as the opening dramatic figure of the introduction. The slow movement and unusual scherzo (it has two different trios, rather than one) are linked thematically and played without a pause between them. The impulsive progress of the finale is interrupted before the recapitulation by slower passages for flute and hunting horns, perhaps intended by Schumann to be descriptive.

The *Symphony No. 2 in C Major* (1846) is tightly organized and owes something in design to Beethoven. It has been overshadowed by more frequent performances of the last two symphonies, *No. 3 in E Flat Major* (*Rhenish;* 1850) and *No. 4 in D Minor* (1841, rev. 1851). The five-movement *Rhenish* is less "classical" than the *Symphony No. 2.* Inspired by a ceremony at Cologne Cathedral as well as by the appearance of the cathedral itself, the polyphonic grandeur and harmonic richness, especially of the fourth movement, are tempered by the relaxed pace and rustic character of the scherzo and

following short, quiet slow movement. The outer movements are related both thematically and in mood, and the last two movements also share material, forming a large cohesive structure.

Even more cohesive is the plan of the *Fourth Symphony* in which all four movements are played, as in Mendelssohn's *Scottish Symphony*, without pause. A single theme recurs in various guises in all four movements; this thematic transformation is a hallmark of Schumann's style, as of Berlioz' and Liszt's. The last movement introduces new material but without destroying the cyclic nature of the whole work. Cyclic structure, which relates separate movements by means of re-use of thematic material, is a feature of much symphonic writing after Beethoven. As composers gradually departed from repetitive forms, cyclic construction became a chief mode of achieving unity over a large time span and greatly enlarged harmonic vocabulary. An advanced form of cyclic construction may be seen in the Belgian composer César Franck's influential single *Symphony in D Minor* (1888).

Brahms and his contemporaries. Although Johannes Brahms's four symphonies are popularly considered to be no less important than the greatest earlier symphonies, the contribution of his contemporary Anton Bruckner is controversial. Bruckner, a devout Catholic whose church music is among the finest of his generation, is noteworthy not only for the excessive length and heavy orchestration of many late movements but for his Wagnerian harmonies, large-scale repetitions, and (at its best) monumental conceptions of form. Bruckner gathered much from studying late Beethoven and Schubert. Yet his style evolved little in the course of nine symphonies (he was over 40 when he wrote his first symphonies; two other unnumbered early ones are never heard, and his last was incomplete at his death). Entirely personal in expression, his symphonies underwent frequent revision. They are in four movements and are basically unprogrammatic, even conservative. Despite his devotion to Wagner and Beethoven, Bruckner remained provincial; his technique was grounded on traditional studies, and his movement types seem to follow a set of typical formulas that derived from Classical patterns, especially the sonata. Within these formal types he develops themes powerful in their simplicity and monolithic in harmonic expanse. Chords reminiscent of German chorale (hymn melody harmonizations) and tremolo or pizzicato (plucked) accompaniments occur along with organ-like counterpoint and pedal tones (sustained notes against changing harmonies). Hardly imbued with youthful vigour, some scherzos still have roots in the fertile Austrian popular music that nourished Haydn and Beethoven. These movements, however, are not sufficient to lighten the overall impression of density. Unlike those of Brahms, Bruckner's symphonies are not immediately rewarding; yet connoisseurs, including Mahler, respect Bruckner's heroic finales, in which themes from earlier movements are sometimes combined. *Symphony No. 4 in E Flat Major* (1874, first performance of revision, 1881), with a Beethovenian andante and scherzo recalling the hunt, is noteworthy for the use of four themes in the first movement. *No. 7 in E Major* (1881–83, rev. 1885), well received at first hearing, is Wagnerian in orchestration (Wagner tubas play in the adagio) and makes use of contrapuntal techniques developed in the Renaissance. In the last two symphonies the adagio movements occur after the scherzos rather than before.

Traits of Bruckner's symphonic style

The symphonies of Brahms, each highly individual, appealing on first hearing, and rewarding to rehear, could hardly be more different from Bruckner's. Yet Brahms, his technique grounded on thorough study of Classical and Baroque works, was no less essentially conservative. He retained the four-movement format and familiar methods of thematic development and rigorous contrapuntal craftsmanship, avoided programmatic content, and was always concerned with aural effect. These concerns are reflected in his orchestration, which is never merely flashy, never astonishing. His entire remarkable skill and attention to detail served the lyrical, spontaneous flow of his melody. His tunes, Romantic as Schubert's, are developed with consistency, refinement, and a harmonic interest foreign to many lesser contemporaries (especially those seduced by Berlioz and Liszt but without understanding their talent). Brahms is a master of understatement. Finished in 1876, 20 years after it was begun, his *Symphony No. 1 in C Minor* was the fruit of a mature man's experience. It carried on where Beethoven left off, drawing inspiration especially from Beethoven's *Fifth*. The triumph of major over minor, epitomized in the finale, underlies the whole. The key scheme of the movements is cyclic, based on a succession of rising major thirds: C minor, E major, A♭ (= G♯) major, C minor–major. The third movement, formally a scherzo with trio, slackens tension as though to prepare for the marvellously developed finale, which is preceded by a broad introduction (as is the first movement) that sets harmonic and thematic goals for the remainder.

Individuality of Brahms's symphonies

Clear goal orientation also characterizes the *Symphony No. 2 in D Major* (1877). Unlike the *First* in mood, it is pervaded in all movements by optimistic calm. First and last share a three-note motif that is joined by other serene themes in the first movement, which includes a long horn solo near the end. The second movement begins in B major, a third lower than the first, and the fast third movement begins a lower third still, in G major; the finale returns to D. This third-based tonal scheme, like that of the *First*, marks Brahms as a true Romantic, as do the tempo changes within movements, the sensuous modulations that circumscribe harmonic goals, and the intense major–minor conflicts.

Modal tension—major versus minor—characterizes the cyclic *Symphony No. 3 in F Major* (1883), the movements of which are related by material derived from Brahms's "motto" motif, FAF, *frei aber froh* ("free but joyful"). Winds are prominently featured, particularly clarinet and horn, as elsewhere in these symphonies. Brahms retained Classical outlines as usual; but, as in the *First*, the scherzo with trio serves to throw the vigorous, stormy finale into relief. The first movement plunges to the heart of things from the opening chords, harmonizing the motto; there is no introduction, no coyness in exposing the main themes. Chromatic harmony and contrapuntal development are fully exploited.

Brahms's architectural skill is nowhere more in evidence than in the finale of the *Symphony No. 4 in E Minor* (1884–85), an extended chaconne, or set of variations over an (eight-bar) repeated bass melody. This movement is almost Baroque; and elsewhere in the work Brahms employs Baroque contrapuntal techniques, chromatic labyrinths, and modal melody that hovers between major and minor but is neither. In this work particularly, but throughout the symphonies, Brahms epitomized the tendency of the later Romantics to seek a balance between the expressive forms of the early 19th century and older traditional technique, to apply to the wealth of available harmonic and orchestral colour constructive methods consciously founded upon study of Beethoven (particularly *Symphonies No. 4*, *No. 7*, and *No. 8*), Handel, and other models. These disciplined composers (including Schumann and Mendelssohn) reacted partly against what they felt to be the extramusical emphasis and compositional excesses of Berlioz, Liszt, and lesser figures, who took as their point of departure the less conventional Beethoven of *Symphonies No. 5*, *No. 6*, and *No. 9*.

Dvořák and Tchaikovsky

Both trends found reflection in the symphonies of Dvořák and Tchaikovsky, composers who were products of growing nationalistic tendencies in music. Antonin Dvořák continued a distinguished line of Bohemian symphonists stretching back to Stamitz. Conscious of his musical heritage, Dvořák infused his music with folk-derived elements, particularly dances; his last symphony, *No. 9 in E Minor (From the New World*, 1893), even incorporates American tunes; but these are almost incidental to the strong Slavonic character of the work. An early devotee of Wagnerian sonorities, Dvořák in his later symphonies returned to the more conservative models and orchestrations of Beethoven and Brahms. It is these later works, through which Dvořák is known today, that have led detractors to call him a "second-rate Brahms." In fact, Dvořák's melodic invention, often based on irregular

folklike scale forms, and his captivating irregularity of phrase length, surprising variety of orchestration, and impetuous rhythms are entirely personal.

Peter Ilich Tchaikovsky, on the other hand, was not comfortable working with pre-established formal models but was at his best in ballets and tone poems in which his somewhat extravagant nature found fuller scope for expression. Of his eight symphonies, only *No. 4 in F Minor* (1877), *No. 5 in E Minor* (1888), and *No. 6 in B minor* (*Pathétique*, 1893), actually fourth, sixth, and eighth in order of composition, are well-known. These are controversial works, partly because their novel structures are not easily analyzed (or heard) in standard formal ways. Some feel that Tchaikovsky's freedom and tendency to musical autobiography were inimical to purely abstract musical expression and that understanding of his music depends on knowledge of his state of mind at various times or upon some extramusical imagery or program. This attitude conflicts with an essential determinant of symphonic idiom, which is that the establishment and working-out of tensions in the piece are primarily occasioned by purely musical, formal means; and that extramusical data, interesting though they may be, are not directly relevant to apprehension and appreciation of the symphonic process. If Tchaikovsky's symphonies are to be considered successful as symphonies, they must make purely musical sense—and the three mentioned fulfill this condition.

Tchaikovsky's kind of musical logic, however, is quite different from that exemplified by the main-line German symphonists. Isolated in his formative years from the influence of Brahms and Wagner, he learned instead by hearing Mozart and Italian opera, characteristics of which he fused with elements of non-European melody, harmony, rhythm, and colour; in this he followed Aleksandr Borodin and other Russians. He strongly favoured the minor mode, no doubt partly because of its inherent instability. This unique confluence of stylistic sources produced a new model for later symphonists, particularly in regard to orchestration and a re-evaluation of sonata form based on a fresh conception of tonal harmony.

Mahler as the culmination of the Viennese tradition

Mahler. With Gustav Mahler, the central path, if not the culmination, of Viennese symphony was regained. In importance Mahler's nine completed symphonies (a 10th was left unfinished at his death) stand equal to any corpus since Beethoven's. That this has been so recently recognized may have something to do with historical perspective but is more probably a matter of relevance of his music to the mood of the mid-20th century. Nowhere else in music is found such explicit cynicism, such deliberate distortion of the familiar; by the same token no symphonist exceeds him in desire for reconciliation. Mahler's melodies and harmonies are strongly goal oriented; that his goals are so frequently frustrated or beset with obstacles reflects a truly contemporary outlook.

Mahler's symphonies, like those of Tchaikovsky and Berlioz, suffer from being too often considered solely in the light of extramusical associations. Mahler himself suppressed the programs of his early symphonies and subjected their music to frequent revision. Structurally, the symphonies are entirely logical, even simple, beneath the multitude of themes and wealth of colouristic detail. Mahler was a fastidious and brilliant orchestrator. The seeming superfluity of orchestral resource he called for, especially in the later symphonies, is handled with restraint and sensitivity—Mahler was a conductor as well as a composer and knew well the capabilities of the instruments.

Enormous in time scale, Mahler's symphonies contain sufficient variety and contrast to maintain interest. Underlying this stylistic multiplicity—including parodies of folk song, waltzes, fanfares, marches, text painting (four symphonies include voices), chorales, borrowings from other composers as well as his own songs—was a leaning toward cyclic structure, with themes or motives shared among movements, as in his song cycles and those of Schubert and Schumann. Mahler also experimented with tonal structure to the extent of combining movements in unrelated keys, so that the ear never tires of a single tonal area. *Symphonies No. 5, No. 6,* and *No. 7,* themselves a huge cycle, show him coming to grips with Classical sonata form, greatly expanded though it is. Unity on a lower level is achieved through extensive counterpoint. These later works show an economy of structure that is foreign to Bruckner, from whom Mahler nevertheless learned much.

Nielsen and Sibelius

The 20th century. Important symphonists of the early 20th century include many non-Germans. Carl Nielsen and Jean Sibelius, the former Danish, the latter Finnish, both owe much to the Viennese symphonists but acquired individual styles that resulted in new conceptions of symphonic form. Nielsen's six symphonies display a kind of unity based on "progressive" or "emergent" harmony, one key moving on to the next in such fashion that the gamut of harmonies in a single symphony (or movement) does not totally relate to a single tonic. His harmonies sometimes fluctuate between two or more goals and incorporate chromatic and modal features. This untraditional harmonic tension is an aspect of the breakdown of normal Classical ways of establishing tonality, for which the 19th century (and Wagner in particular) is largely responsible. (Nielsen, however, was an anti-Wagnerian.) This "destructive" impulse, elements of which may already be heard in Haydn, led to constant re-evaluation of the basis of sonata form and hence of the symphony as a whole. As the traditional harmonic foundation weakened—partly because the enlarged time scale makes long-term harmonic relationships hard to hear—symphonists sought new unifying techniques, among them cyclic forms, extramusical plots, progressive harmony, etc. None of these is incompatible with dramatic sonata form, taken in its broadest sense. Nielsen retained and emphasized key conflict as a dynamic force and experimented with counterpoint and conflicting rhythms (*e.g., Symphony No. 4, The Inextinguishable,* 1916; and *Symphony No. 5,* 1922), joined movements, and the rest.

Sibelius wrote his seven symphonies between 1899 and 1925. Like Nielsen's, they departed from Classical models (notably Beethoven's *Fifth*) and reflected especially the advances of Brahms and Bruckner. Sibelius was a restrained orchestrator, a non-Wagnerian. Although nationalistic, he used no folk songs and incorporated no programs. He had little immediate influence, isolated as he was after World War I, but is highly regarded presently in his native country, England, and the United States. Sibelius, like Nielsen, is not tied to Classical tonic–dominant opposition. He sometimes introduces modal scales and polar harmonic goals between which the music oscillates. A chief unifying device is a repeated bass line or sustained pedal tone. His themes are often groups of melodic fragments, meaningless when out of context, that are capable of being combined in various ways. The gradual integration of these motifs is an important means of development. In this Sibelius resembles Borodin; the effect is quite unlike that of Mahler's long melodies. Structurally Sibelius is terse and simple. He eliminated transitions and introductions, avoided simple recapitulation, and kept harmonies static or ambiguous over long stretches. Rarely was he merely playful. He was fond of low, dark sounds. Sibelius is hardly unemotional but certainly is not effusively romantic. His symphonies represent a great contrast with Mahler's, and he strikes a new path away from the sonata.

Elsewhere in the early 20th century important symphonic contributions were being made by the Frenchman Albert Roussel, whose four symphonies are elegant and classical in form; the American Charles Ives, who quotes well-known tunes in his highly dissonant four symphonies; and the Englishmen Sir Edward Elgar and Ralph Vaughan Williams. Their works are not often heard outside their native countries, and the extent of their influence on the growth of symphonic thinking remains to be determined. A more important innovator, the Viennese Arnold Schoenberg, considered his *Chamber Symphony,* Opus 9 (1906), "the climax of my first period." Basically still sonata-oriented and tonal, this work departed from the gargantuan orchestrations of Mahler and Richard Strauss and is scored for 15 soloists, 10 of whom play

winds. The idiom is highly dissonant and motivic, straining at the limits of traditional tonality and pointing to Schoenberg's formulation of dodecaphony, or 12-tone serialism (deriving melody and harmony from the composer's ordering of the 12 tones of the chromatic scale).

Stravinsky's imaginative force

Igor Stravinsky likewise inherited a living tradition and transformed it with great imaginative force. Like Schoenberg, he was not primarily a symphonist; his early *Symphony in E Flat Major* (1905–07) is no more original than anything of other Russians such as Borodin or Aleksandr Glazunov. But the *Symphony in C* (1940) and *Symphony in Three Movements* (1942–45) are unique. The former, a Neoclassical work, reinterprets in Stravinsky's language the thematic construction and sonata form of the Classical era. The result, far from a simple parody of Classical style (such as in Sergey Prokofiev's *Symphony No. 1 in D Major* or *Classical Symphony* of 1917), was an altogether fresh and revealing insight into the implications of Haydn's work. The *Symphony in Three Movements*, inspired by wartime impressions, is independent of models, yet in outward form the movements appear traditional. Two other of Stravinsky's works deserve mention here: the *Symphonies of Wind Instruments* (1920, rev. 1947) and the *Symphony of Psalms* (1930), which includes chorus. These works are symphonies only in the 17th-century sense of ensemble pieces; in both form and structure they are dissimilar from the other symphonies.

Chief among other Russians are, besides Prokofiev (seven symphonies), Nicolay Myaskovsky (also seven) and Dmitry Shostakovich (14 by 1972). Shostakovich's large corpus marks him as one of the most important and prolific living symphonists. His works are uneven in quality. A number are programmatic, dealing with Russian political and social upheavals. Shostakovich at times concerns himself with incorporating popular and folk tunes, giving expression to national feelings, and, more basically, with problems of achieving cyclic unity by such means as leitmotivs and thematic recurrences and joining movements without pause.

The mainstream of American symphonic production resides with Roy Harris, Walter Piston, William Schuman, and Roger Sessions. Important as teachers, these men have influenced younger symphonists such as Easley Blackwood and helped create a distinctive style of composition that resulted in the first important symphonic output in the Western Hemisphere. Although many younger composers on both sides of the Atlantic are turning to avant-garde techniques, including experiments in formlessness, and to small instrumental and vocal ensembles as well as to electronic sources, the future of the symphony seems secure. Extremely large orchestrations are not widely favoured, partly because of the difficulty and expense of mounting a performance; yet Blackwood has written one symphony for an orchestra larger than Mahler's as well as one for chamber orchestra. Audiences tend to favour works in familiar forms. Prizes and commissions assure a steady output of symphonies and many have been written for college and university orchestras. Flourishing amateur orchestras also furnish outlets for the young composer. As regards the masters of the 18th and 19th centuries, there seems no possibility that their symphonies will become museum pieces in the foreseeable future. On the contrary, the recording and broadcasting industry has brought about renewed interest in even the lesser known symphonists. Scholars and public alike have now almost unlimited access to the treasures of three centuries of symphonic production.

(La.L.)

Syracuse

Syracuse (Italian Siracusa) is a city on the east coast of Sicily; it was the island's chief Greek city in ancient times. Its nucleus is the southward-projecting island of Ortygia, half-enclosing a bay (the Great Harbour), defined on the south by the eastward-curving coastline at Plemmyrium.

History. Settled *c.* 734 BC by colonists from Corinth led by the aristocrat Archias, Syracuse soon dominated the coastal plain and hill country beyond. The original Greek settlers formed an elite (*gamoroi*); the Sicel natives (Siculi) worked the land as an oppressed class. Colonies at Acrae and Casmenae (about 12 miles [20 kilometres] to the west) and Camarina (about 43 miles [70 kilometres] to the south) illustrate the extent of Syracusan influence and prosperity.

In the early 5th century BC, the Syracusans were defeated by Hippocrates of Gela, a city to the west. The power of the *gamoroi* was subsequently ended by a democratic revolution, and in exile they turned to Hippocrates' successor, Gelon, who captured Syracuse and transferred his government there. His defeat of a great Carthaginian invasion in 480 at Himera confirmed his supremacy; and under him and his brother Hieron, Syracuse reached a high point of power and cultural brilliance. A revolution in 466 overthrew the third tyrant, Thrasybulus, and under a democratic constitution the Syracusans, though abandoning the territorial empire Gelon had acquired, survived wars against the city of Acragas and the Siculi. Most importantly, they also survived a long siege by the Athenians (415–413) during the Peloponnesian War, ultimately destroying the Athenian forces and weakening Athenian power in Greece itself. A few years later Sicily faced a Carthaginian resurgence. Syracuse was saved from the fate that overtook Acragas and other cities by its general, Dionysius, who obtained autocratic power in 405 and reigned as "tyrant" until 367. He fought three wars against the Carthaginians, confining their territorial dominions to the western part of Sicily, and he extended Syracusan control to most of the "foot" of Italy. His son

Dionysius II enjoyed a decade of peace before his autocracy was challenged. The brief rule of Dion preceded a period of anarchy ended by the Corinthian Timoleon, who defeated Carthage and reordered Sicilian affairs (345–336), introducing a moderate oligarchy in Syracuse. In 317 this was overthrown by the adventurer Agathocles, who became "tyrant" and later king. He again established a Syracusan empire, which broke up at his death in 289.

In the ensuing chaotic conditions Sicily was rescued by Pyrrhus of Epirus from further Carthaginian encroachments, but his mercenaries later seized Messana. Their defeat by Syracuse under a new leader, Hieron II, caused the intervention of Rome, with whom Hieron came to terms. After Hieron's death in 215, the Syracusans became allies of Carthage and were besieged by the Romans in 213. After its fall in 211, Syracuse became the seat of the Roman governor, sharing in the general prosperity that Roman rule brought, despite the depredations of the infamous governor, Verres, slave revolts in the hinterland (135 and 104), and the impact of the civil wars at the end of the republican period.

Roman rule

In AD 280 Syracuse was ravaged by Frankish invaders but soon recovered a prosperity that lasted until its capture by the Arabs in 878. During the late Roman and Byzantine periods and under Norman, Swabian, and Spanish rule, it shared the vicissitudes of the rest of the island, surviving as a not unimportant appanage of the Sicilian realm, especially in the Aragonese period (14th–16th centuries), when it formed a special enclave. Shattered by an earthquake in 1693, it owes some of its finest architecture to the reconstruction period. The Allied invasion of 1943 in World War II caused it some damage, swiftly repaired in a new and greater postwar prosperity. The present city, capital of Siracusa Province (*provincia*), is a centre for processing local agricultural produce and has several other light industries. The harbour, with its commerce and fishery, and tourism are further sources of prosperity.

Archaeological remains. Only in modern times has Syracuse begun to cover as wide an area as its ancient predecessor. Remains of antiquity on the continuously inhabited Ortygia are less striking than those in Neapolis, long a country district. Here the Greek theatre, Roman amphitheatre, and altar of Hieron II, pillaged in 1526 to build defensive walls, were archaeologically studied in 1839 by the Duca di Serradifalco but owe most to the systematic investigations of Paolo Orsi between 1890 and 1935. The theatre now visible is that of Hieron II. It had a capacity of 15,000 and was built on the site of two earlier theatres. Above it is a nymphaeum (fountain) that was one of the ancient city's sources of water. Hieron II's great altar, over 200 yards long on which 450 oxen could be sacrificed simultaneously, flanked a shady piazza developed in the Roman period. The amphitheatre was built late in the 2nd century AD as an arena for gladiatorial shows. The quarries in the same district, the source of the city's building stone, have been turned into luxuriant gardens; here the Athenian prisoners were quartered in 413. The most imposing evidence of Syracusan power consists in the fortifications of the Epipolae Plateau, culminating in the Euryalus fort at their western end. Begun by Dionysius I, they were probably strengthened by Agathocles but in their final form are the work of the scientist and engineer Archimedes.

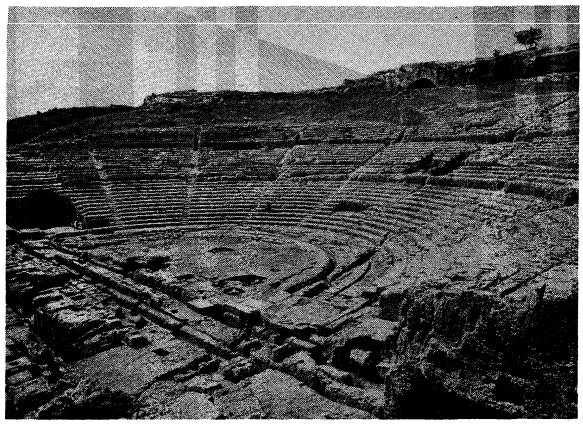
Ancient Syracuse.



Ruins of the Greek theatre of Hieron II (3rd century BC) at Syracuse, Sicily.
Leonard von Matt—EB Inc.

The cathedral on Ortygia, with a fine Baroque facade, incorporates the Doric columns of the temple of Athena built as a thank offering for the victory of Himera. Architectural reliefs in painted terra-cotta from earlier buildings in this area are preserved in the museum. The remains of the temple of Apollo (*c.* 565 BC) stand near the bridge to the mainland (another temple of the same period, that of Olympian Zeus, lies on the west side of the Great Harbour).

Ortygia

The streets of Ortygia give frequent witness of the medieval and Renaissance contribution to the charm of Syracuse. The best 14th-century facade is that of the Palazzo Montalto. The Palazzi Bellomo and Parisio span the 13th- to 15th-century Gothic styles. Giovanni Vermexio's Palazzo del Municipio (1628) and Luciano Alì's Palazzo Beneventano del Bosco (1775) represent the best among many notable survivals of the 17th- and 18th-century city.

BIBLIOGRAPHY. The history of Syracuse is chiefly dealt with in general histories of Sicily. D. MACK SMITH, *History of Sicily*, 2 vol. (1968), is the standard history of postclassical Sicily. A good, well-informed, pocket guide is M. GUIDO, *Syracuse: A Handbook to its History and Principal Monuments* (1958). See also M.P. LOICQ-BERGER, *Syracuse, historie culturelle d'une cité grecque* (1967). The archaeological remains are most accessibly treated in general works on Greek and Roman architecture. For the most recent excavations, see the successive volumes of *Fasti Archaeologici*. On the Euryalus fort see F.E. WINTER, "The Chronology of the Euryalus Fortress at Syracuse," *American Journal of Archaeology*, 67:363–387 (1963).

(A.G.W.)

Syria

Syria, officially al-Jumhūrīyah al-ʿArabīyah as-Sūrīyah (the Syrian Arab Republic), is a country situated on the east coast of the Mediterranean Sea on the southwestern fringe of the Asian continent. It has an area of 71,498 square miles (185,180 square kilometres), and, in the early 1970s, a population estimated at about 6,300,000. It is bounded by Turkey to the north, by Iraq to the east and southeast, by Jordan and Israel to the south, and by Lebanon to the southwest. The capital is Damascus (Dimashq) on the Baradā River in an oasis at the foot of Jabal (mount) Qāsiyūn. The present territory does not coincide with ancient Syria, which was the fertile strip between the eastern Mediterranean coast and the desert of northern Arabia.

The persistent Middle East crisis between the Arab states and Israel has resulted in political instability in Syria. Since the Arab-Israeli War of 1967, Israel has occupied the 444 square miles (1,150 square kilometres)

of the Golan Heights region in southwestern Syria. Severe strains are placed on the Syrian economy by the demands of national security and defense, which exhaust more than 40 percent of the national budget, leaving little for development. Syria is linked with Libya and Egypt in the Confederation of Arab Republics. (For an associated physical feature, see TIGRIS-EUPHRATES RIVER SYSTEM; see also the city article DAMASCUS; for historical background, see BABYLON; CALIPHATE, EMPIRE OF THE; NEAR EAST, ANCIENT; OTTOMAN EMPIRE AND TURKEY, HISTORY OF THE; and SYRIA AND PALESTINE, HISTORY OF.)

THE LANDSCAPE

Relief features. *The coast.* The relatively short coast stretches for about 110 miles along the Mediterranean between Turkey and Lebanon. Its sandy bays alternate with rocky headlands and low cliffs. North of Ṭarṭūs, the narrow coastal strip is interrupted by spurs of Jabal Alawite (an-Nuṣayrīyah mountains) immediately to the east. It then widens into the Plain of ʿAkkār, which continues south across the Lebanon border.

The mountains. The Jabal Alawite range borders the coastal plain and runs through the country from north to south. The mountains have an average width of 20 miles, and their average height declines from 3,000 feet in the north to 2,000 feet in the south. Their highest point, 5,125 feet (1,562 metres), occurs east of Latakia. Directly to the east of the mountains is the Ghāb Depression, a 40-mile longitudinal trench that contains the valley of the Orontes River.

The Anti-Lebanon Range, or Qalamun Sinnir, marks Syria's border with Lebanon. The main ridge rises to a maximum height of 8,625 feet (2,629 metres) near al-Nabk while the mean height is between 6,000 and 7,000 feet. Mr. Hermon, a single ridge, is connected farther west to the main range by the Zabdānī Saddle. Syria's highest point, it rises to 9,232 feet (2,814 metres).

Smaller mountains are scattered about the country. Among these are Jabal ad-Durūz that rises to 5,905 feet (1,800 metres) in the extreme south; the Palmyra Range that includes the Jabal ash-Sharqī and stretches northeastward across the central part of the country; Jabal az-Zāwīyah that rises to 3,067 feet (935 metres) east of the Ghāb Depression; and Jabal ʿAbd al-ʿAzīz that attains 3,018 feet (920 metres) in the east.

The Syrian Desert. The undulating plains occupying the rest of the country are known as the Syrian Desert. In general their elevation lies between 984 and 1,640 feet; they are seldom less than 820 feet above sea level. The area is not a sand desert but comprises rock and gravel steppe; a mountainous region in the south central area is known as al-Ḥamād.

Drainage. *Underground water.* Most of the country's drainage flows underground. On the surface, impervious rocks consisting of clay, marl (clay, sand, or silt), and green sands, cover a relatively small area. Porous rocks cover about half of the country and are mainly sandstone or chalk. Highly porous rocks consist of basalt and limestone. Water penetrates the porous rocks, forming underground springs, rivers, or subterranean water sheets close to the surface. Although the springs are profuse, the water sheets are quickly exhausted and may turn saline in areas of low precipitation.

Principal rivers

Surface water. The Euphrates River is the most important water source and the only navigable river in Syria. It flows southeastward across the eastern part of the country; the Khābūr, Jaghjaghah, Balīkh, and Sājūr rivers are its tributaries. The coastal rivers are generally short; they include the Qindīl, the northern Kabīr, the Sinn, the Bāniyās, and the southern Kabīr.

The Orontes is the principal river of the mountainous region. It rises in Lebanon, flows northward through the mountains and the Ghāb Depression, and enters the Mediterranean near Antioch, Turkey. The Yarmūk River, a tributary of the Jordan River, drains the Jabal ad-Durūz and Ḥawrān region and forms part of the border with Jordan in the southwest.

Several scattered lakes are to be found. The largest is Mamlaḥat (Sabkhat) al-Jabbūl southeast of Aleppo; a seasonal saline lake, it permanently covers a minimum area of about 60 square miles. Other major salt lakes are Jayrūd to the northeast of Damascus and Khātūnīyah to the northeast of al-Ḥasakah. Lake Muzayrīb is a small body of fresh water to the northwest of Darʿā; the larger Baḥrat Ḥimṣ is a reservoir to the west of Homs.

Soils. Because of aridity, vegetation plays only a secondary role in soil composition. With the exception of the black soil in the northeastern region of al-Jazīrah, soils are deficient in phosphorous and organic matter.

The most common soils are various clays and loams (mixtures of clay, sand, and silt). Some are calcareous (chalky); others, especially in the area of the Euphrates Valley, contain gypsum. Alluvial soils occur mainly in the valleys of the Euphrates and its tributaries and in the Ghāb Depression. (A.-R.H.)

Climate. *Temperature and precipitation.* The coast and the western mountains have a Mediterranean climate with a long dry season from May to October. In the extreme northwest there is some light summer rain. On the coast, summers are hot, with mean daily maxima of 84° F (29° C), while the mild winters have mean daily minima of 50° F (10° C). Only above 5,000 feet are the summers relatively cool. Inland the climate becomes arid, with colder winters and hotter summers. Damascus and Aleppo have average daily maxima of 91 to 99° F (33 to 37° C) in summer and average daily minima of 34 to 40° F (1 to 4° C) in winter. In the desert, at Palmyra (Arabic, Tudmur) and Dayr az-Zawr, average daily maxima in summer reach 99 to 104° F (37 to 40° C), with extremes of up to 114° F (46° C). Snow may occur in winter away from the coast, and frosts are common.

The coast and western mountains receive 30 to 50 inches of rainfall annually. Rainfall decreases rapidly eastward; the steppe receives ten to 20 inches a year. Jabal ad-Durūz receives more than eight inches. In the desert, or al-Ḥamād, rainfall decreases to less than five inches a year. Rainfall is variable from year to year, particularly in the spring and autumn months. (C.G.S.)

The winds. In winter the prevailing winds blow from the east, the north, and the west. In summer, the prevailing winds are either northerly or westerly. During the summer, the coastal region is subject to westerly winds during the day and easterly at night. Once or twice a year sand-bearing winds, or khamsin, raise a wall of dust almost 5,000 feet high, which darkens the sky.

Vegetation and animal life. *Plants.* Yew, lime, and fir trees grow on the mountain slopes. The date palm is found in the Euphrates Valley. In both coastal and inland regions, plants include grains, olives, vines, apricot trees, oaks, and poplars. Lemon and orange trees grow along the coast. Garigue, a degenerate Mediterranean scrub, and maquis, a thick scrubby underbrush, cover many slopes.

Forests

Forests are found in the mountains, especially in the Jabal Alawite. Glossy-leaved and thorny drought-resistant shrubs such as the myrtle, the boxwood, the turpentine, the broom, the arbutus, and the wild olive, abound to the south. Excessive exploitation of the forests for their wood has largely turned them into scrub. Some forests are, however, protected by the government. The steppe is characterized by the absence of natural tree cover, except for some sparsely-distributed hawthorns. All other trees—such as those in the orchards of Damascus and Aleppo and along the banks of the Orontes and Euphrates rivers—are cultivated. For a brief period before June the land is covered with a great variety of flowering and grassy plants such as the asphodel, lily, tulip, hyacinth, daffodil, and cyclamen. Under the implacable sun of June, however, the plants soon wither, casting off their seeds onto the dry ground.

Animals. Wild animal life is sparse. Wolves, hyenas, foxes, badgers, wild boar, and jackals can still be found in remote areas. Deer, bears, squirrels and such small carnivores as the marten and the polecat are also found, while desert animals include the gazelle and the jerboa (a nocturnal jumping rodent). Vipers, lizards, and chameleons are common in the desert. Eagles, buzzards, kites, and falcons frequent the mountains. Among the insects, mos-

quitoes, sandflies, grasshoppers, and occasionally locusts are harmful.

The mule is the beast of burden in the mountains and the camel on the steppe. Other domesticated animals include horses, donkeys, cattle, sheep, goats, and chickens. Bees are also kept.

Traditional regions. There are four traditional regions —the coastal strip, the mountains, the cultivated steppe, and the desert steppe.

The coast. On the coast, the fertile alluvial plains are intensively cultivated in both summer and winter. The region is the site of Syria's two principal ports of Latakia (al-Lādhiqīyah) and Ṭarṭūs.

The mountains. Jabal Alawite is the only densely forested region. It is the ancient stronghold of the Nuṣayrīs, or ʿAlawites, who form a sect of Shīʿite Islām. The economic resources of the mountains are too meagre to meet the needs of the evergrowing population, and there is a migration to the Ghāb Depression and coastal towns.

The cultivated steppe. This region constitutes the principal wheat zone; agriculture is fairly intensively pursued along the banks of the rivers. The villages are characterized by domelike huts which are built of mud because of the scarcity of wood and stone; the few stone and cement houses are owned by the wealthy. Some of Syria's most important cities—Damascus, Aleppo, Homs, Ḥamāh, and al-Qāmishlī—are situated here.

The desert steppe. The arid country is the natural domain of the nomads and seminomads. Sheep graze until the beginning of summer when water becomes scarce, after which the shepherds lead their flocks either westward into the cultivated steppe or to the hills. The area once contained oases which served as caravan towns on the trade route joining Mesopotamia and the Indian Ocean with the countries of the Mediterranean. The most famous of these towns is Palmyra at the northern edge of the Syrian Desert. The most important feature of the region is the Euphrates River.

The nomadic domain

Patterns of settlement. *Rural settlement.* The choice of a Syrian village site is usually determined by the availability of water. Some of the Alawite Mountain villages, however, have given priority to the requirements of defense and fortification. Village dwellings are built close together, and village streets are extremely narrow. Usually, there is a small central common overlooked by a minaret (a tall tower attached to a mosque from which the populace is called to prayer). There are usually a few small shops, containing articles manufactured in the cities or towns. Travellers are accommodated by the village headman according to local custom.

Work takes place according to the seasonal rhythm of agriculture. Women generally share in all agricultural labour except plowing. Agricultural machinery, introduced on a large scale after World War II, caused unemployment and drove numbers of the villagers to the cities.

Urban settlement. Ten centuries of Greek and Roman rule left an urban mark still to be seen in the towns of Latakia, Palmyra, and Buṣrā. The urban tradition of Islām is represented by such cities as Damascus and Aleppo. The continuation of old commercial and religious interests has enabled the cities to maintain their economic and cultural supremacy under the four centuries of Ottoman rule. The great abyss between the rural and urban areas seems to preclude any economic or social balance. Today, however, the cities are inundated by rural immigrants, and unemployment is rife.

The cities

The national capital of Damascus, situated in the southeast on the banks of the Baradā River, is the largest city in Syria with an estimated population in the early 1970s of more than 835,000. It is the national headquarters of government and the diplomatic community, and is the main centre of education, culture, and industry. It also serves as the marketing centre for mid-Syria and produces traditional handicraft products such as brocades, engraved wood, gold and silver ornaments, and carpets. It is well served by transport facilities and public utilities. The old houses in Damascus are built of soft unbaked bricks, wood, and stone. Contemporary buildings are built of concrete, while hewn stone is reserved for official buildings, mosques, and churches.

Located between the Orontes and Euphrates rivers, Aleppo is a trade and light industry centre of almost 639,000 inhabitants. Its limestone buildings have given the city its name of Halab ash-Shahbā' ("Aleppo the White"). The city is well served by roads and railroads and is surrounded by an area that specializes in the production of sheep for market in Damascus and other countries. The Mediterranean port of Latakia has a population of about 126,000. It is surrounded by a rich agricultural region and contains some industry. Because of its seaside location, the city is a major tourist centre.

Homs is located in the midst of a fertile plain east of the Orontes River. With a population of almost 216,000, it is a hub of the country's road and railway systems. Ḥamāh, to the northeast of Homs, is bisected by the Orontes River and has a population of about 137,000. It contains irrigated orchards and is an agricultural trade centre. There is also some light industry.

PEOPLE AND POPULATION

The Syrian people evolved from several origins over a long period of time. The Greek and Roman ethnic influence was negligible in comparison with that of the Semitic peoples of Arabia and Mesopotamia—Aramaeans, Assyrians, Chaldeans, and Canaanites. Later the Turks, like the Greeks and Romans before them, influenced political and economic structures, but failed to produce any noticeable change in the dominant Arab character of the Syrian people.

Population groups. *Linguistic groups.* The mother tongue of about 80 percent of the population is Arabic. According to their numerical importance the other languages are: Kurdish, spoken in the extreme northeast and northwest; Turkish, spoken in villages east of the Euphrates and along the border with Turkey; Armenian, spoken in Aleppo and other major cities; Circassian, spoken in a number of Golan district villages, east of Homs and Aleppo, and in the town of Manbij; Syriac, spoken in two villages near Damascus and in the northeastern town of al-Qāmishlī; and Hebrew, used as the liturgical language of the small Jewish community. English is taught as a foreign language to more than 70 percent of the school children; others are taught French, German, or Russian.

Ethnic groups. There is a rough correspondence between ethnic and linguistic groupings, although some ethnic groups have been partially assimilated by the Arab majority that includes the Bedouin. Second in number to the Arabs, the Kurds have partially lost their mother tongue. The Turkmen intermingle freely with the Kurds and Arabs, but have lost none of their ethnic identity in some northern villages. The Armenians may be divided into two groups—the early settlers, who have been more or less Arabized; and the later immigrants, who came after World War I and retained their identity and language. The Assyrians are quickly disappearing as a group because of intermarriage and migration to the cities. Most of the Jews have emigrated to Israel; the remaining few thousand live in Damascus or Aleppo.

Religious groups. Islām, the predominant religion, is practiced by about 88 percent of the population. The Muslims are divided into several sects. The Sunnites number about 72 percent of the Muslim population and are in the majority everywhere except in as-Suwaydā' *muḥāfaẓah* (governorate) in the south and the Latakia *muḥāfaẓah* in the north. The ʿAlawites number about 600,000, three-fourths of whom live in the Latakia *muḥāfaẓah*, the rest residing mainly in the *muḥāfaẓāt* of Homs and Ḥamāh. The Druzes (*q.v.*) number about 190,000, of whom some 8 percent live in as-Suwaydā' *muḥāfaẓah* and the rest in Damascus, Aleppo, and al-Qunayṭirah.

The Muslim sects

The Ismāʿīlites number about 60,000; over 80 percent live in as-Salamīyah and around Ḥamāh, and the rest in the Alawite mountains. The Shīʿites number about 25,000 and are found mainly in Damascus, Aleppo, and Idlib. The Yezidis are a small group, and many of them have adopted the Sunnite rite.

Christians constitute about 12 percent of the Syrian people. They are divided into 11 churches, listed here according to their numerical importance: Greek Orthodox, Armenian Orthodox, Greek Catholic, Syrian Orthodox, Armenian Catholic, Syrian Catholic, Maronite, Protestant, Nestorian, Latin, and Chaldean. Jews numbered about 20,000 in the early 1970s.

Demography. *Population growth.* The population was estimated at about 6,500,000 in 1971. The figure included some 400,000 Syrians who live abroad but retain their citizenship. The average annual rate of growth in population was 32 per 1,000 in the period 1965–70. At this rate the population will double in 22 years.

More males are born than females. About 10 percent of the infants in rural areas die in their first year; this rate drops considerably in the towns. Individual life expectancy varies on the average between 50 and 55 years.

Immigration and emigration. The last wave of immigration consisted of 80,000 Palestinian Arabs who fled to Syria in 1948. Increasing numbers of workers and profes-

sionals have been leaving the country since the 1950s for other Arab nations, the United States, and western Europe. This movement has caused an alarming drain of Syrian manpower, and has reduced the number of doctors and engineers to one-third of the original total.

Distribution of the population. The overall population density is 90 per square mile. Only about half the country's land can support population, however, and in addition about 44 percent of the population lives in the cities; the density in the arable areas is consequently about 98 per square mile. The desert steppe contains 150,000 Bedouins and 25,000 oasis inhabitants; the area's population density is less than five persons per square mile. In the rest of the country the density, which varies considerably, is highest in the west and northeast, and is fairly high along the banks of the major rivers.

Syria's rate of population increase is out of all proportion to the rate of economic expansion. Family planning and birth control are becoming popular among the educated, despite an official policy of awarding bonuses and allowances to expanding families.

THE NATIONAL ECONOMY

Syria is favourably located on the regional trade routes running between the Mediterranean and the countries of Mesopotamia and the Persian Gulf, and between Asia Minor and the Arabian Peninsula. Commercial aviation routes and oil pipelines cross Syrian territory.

Oil and natural gas reserves

The extent and distribution of resources. *Mineral resources.* Petroleum in commercial quantities was first discovered in the northeast in 1956. Workable reserves are estimated at 260,000,000 tons and potential reserves at 1,200,000,000 tons. The most important oil field is that of Suwaydīyah, followed by those of Qarah Shūk and Rumaylān. The fields are a natural extension of the Iraqi fields of Mosul and Kirkūk. Natural gas was discovered at the field of Jbessa in 1940. Its reserves are estimated at 115,284,000,000 cubic feet.

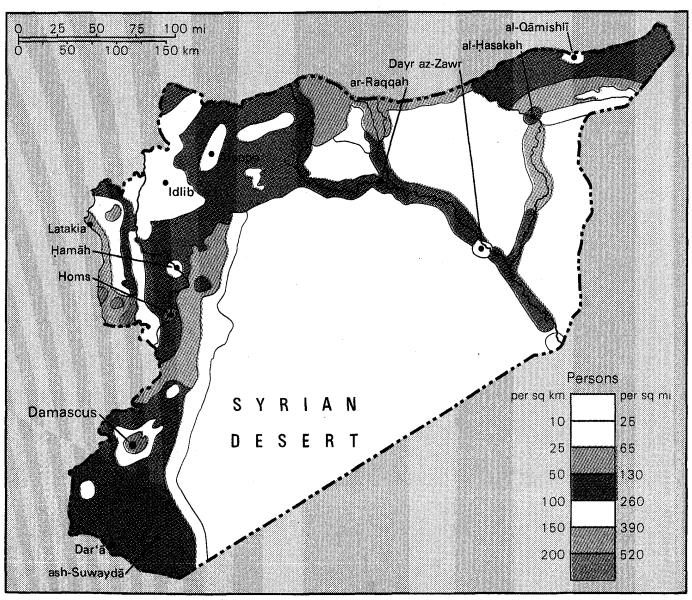
Raw phosphates were discovered in 1962; reserves are estimated at 240,000,000 tons in the four richest beds at Khunayfis, Ghadīr al-Jamal, Ṣawwānah, and Wādī ar-Rakhim. About 500,000,000 tons of rock salt lie to the west of Dayr az-Zawr at depths ranging from about 300 to 600 feet.

Iron ore at Kurd Dāgh in the northeast is estimated at 62,000,000 tons. Asphalt has been found northeast of Latakia, and west of Dayr az-Zawr, and table salt is provided by the salt lakes of al-Jabbūl, Palmyra, and al-Buwarah. Syria is rich in limestone, basalt, and marl, and has scattered reserves of chrome and manganese.

Biological resources. Forests occupy about 5 percent of the country's total area. Systematic economic exploitation is hampered by the wide variety of trees and the fact that no one kind is widespread enough to be utilized on an industrial scale. The commercially important forest plants include sumac, which is used as a spice; the wild pistachio, which is important for its oil-rich fruit; laurel, which is used in the production of cosmetics; and the mulberry, whose leaves are fed to silkworms. Pine tree branches are used for smoking tobacco leaves. Other useful plants are such winter vegetables as *khubbayzah*, a kind of spinach; *ʿakkūb*, a flowering plant; and the truffle. Licorice is widely exploited for its root, which is used in the pharmaceutical industry.

Game animals are scarce except for the wild boar and the hare. Game fowl are available in fairly large numbers, and include wild ducks and pigeons.

Power resources. Local oil supplies constitute a major power resource. With the exception of the Euphrates River, which has a considerable hydroelectric potential, other rivers flowing through Syria are capable of producing only small amounts of hydroelectric power.



Population density of Syria.

Sources of national income. *Agriculture, forestry, and fishing.* Agriculture constitutes the major source of income. It provides work for nearly half the population, including a large proportion of townspeople. In 1969, there were about 3,000 fishermen using small and medium-sized boats. The fish catch was over 1,200 metric tons in 1969. Forestry workers did not exceed a few hundred in the early 1970s.

The dominance of agriculture

Wheat is the most important food crop, although its production is constantly subject to great fluctuations in rainfall. Barley, maize (corn), and millet are the other important grains. Cotton is the largest and most reliable export crop. Lentils are a major domestic food, but are also exported. Other vegetables include onions, potatoes, and sugar beets. Olives, grapes, and apples are grown at high altitudes, while citrus fruits are cultivated along the coast. High-grade tobacco is grown in the area around Latakia.

Numbers of livestock are raised, including sheep, cattle, camels, and poultry. The mountains north of Latakia are being reforested. Elsewhere, poplar trees are grown along irrigation ditches and are used for building construction, although most of the nation's timber has to be imported. The annual fish catch ranging from 600 to 1,200 metric tons includes sardines, tuna, groupers, tunny, and both red and grey mullet, but the lack of refrigerated transport and storage facilities have prevented possible development of inland markets.

Mining and quarrying. The principal limestone quarries are located north and west of Damascus, especially near the city of Aleppo, which itself is built of limestone. Basalt, used for road pavement, is quarried in Jabal ad-Durūz and near Homs and Aleppo. Marl is used in the cement industry; the main quarries are in the vicinity of Damascus and Aleppo, and at ar-Rastān. Sandstone suitable for glass manufacture is mined in the Palmyra mountains. Phosphate ore is mined in Jabal ash-Sharqī and rock salt is extracted from the mid-Euphrates region. Asphalt and gypsum are also mined, and table salt is produced from the salt lakes.

Manufacturing. Most of the traditional handmade manufactures—damask steel, swords and blades, brass and copper work, wood engravings, gold and silver ornaments, mother-of-pearl inlays, silk brocades—have disappeared since the introduction of industrial processing.

Wool, cotton, and nylon textiles are the most important manufactures. The mills are mainly in Aleppo, Damascus, Homs, and Ḥamāh. Next in importance are the technical engineering industries, most of which are in Damascus. The chemical and industrial engineering products include cement; glass panes, bottles, and utensils; pharmaceuticals; plywood; and batteries. The food processing industry produces salt, vegetable oils, cotton cake, canned fruit and vegetables, tobacco, and dairy products. There is also an oil refinery at Homs that supplies local needs. Other industries include a fertilizer plant, and distilleries.

Energy. Muscular energy—both animal and human—is still used in operating oil-extracting mills and in the

production of pottery. Modern factories, however, are run by electricity, supplied either by state-owned generating plants or by factory generators. Gas is used on a minor scale in small industries such as goldsmithing, but its supply is limited. Coal is imported and is also used on a limited scale, mainly by blacksmiths.

Electric power

Electricity, largely generated by thermal stations, is used mainly for lighting. Thermoelectric generation depends upon the fuel oil produced by the oil refinery at Homs. There are small hydroelectric stations such as those on the Orontes and Baradā rivers. A large increase in production is anticipated when the Euphrates River project is completed in 1974. The dam will have a generating power of 800,000 kilowatts, and a potential capacity of 1,100,000 kilowatts.

Financial services. The Central Bank of Syria issues the national currency and exercises control over all other banks that operate in the country. The Commercial Bank of Syria finances trade, markets agricultural products, and carries out foreign exchange operations. The Real Estate Bank finances the building industry and carries out all ordinary banking operations. An Industrial Bank finances the private industrial sector, while an Agricultural Bank extends loans to farmers and agricultural cooperatives. A Popular Discount Bank makes loans to small manufacturers, artisans, and production cooperatives. There is one semi-official insurance company and a stock exchange connected with the central banks.

Foreign trade. Syria has an unfavourable balance of trade. The deficit is made good from tourism, transit trade returns, oil pipeline royalties, and overseas earnings.

Imports include industrial and agricultural machinery, motor vehicles and accessories, drugs, food, and fabric. Exports consist of ginned cotton, petroleum, cotton seeds, barley, lentils, cotton and woolen fabrics, dried fruit, olive oil, vegetables, skins, and raw wool. Foreign trade is controlled through a special state central agency, Syrian Import-Export (Simex).

Management of the economy. Socialism became the official economic policy in 1958. Since then, the trend has been toward Socialist transformation and industrialization. In commerce, state control is mainly restricted to foreign exchange operations.

The private sector. Small private businesses and cooperatives are still in operation, and the retail trade is still part of the private sector, despite competition from consumer cooperatives in the large cities.

The public sector. The government controls the most vital sections of the country's economy, and largely regulates private business. The state operates the oil refinery, the large electricity plants, the railways, and various manufacturing plants.

Taxation. Indirect taxes, which produce the most tax revenue, are levied on industrial products, customs, exports, and state domains. Direct taxes are levied on wages, circulating capital, livestock, and the transfer of property.

The General Federation of Workers

Trade unions and employer associations. The General Federation of Workers, with which almost 200 unions are affiliated, was founded in 1938, and in the early 1960s grew tremendously in power and scope. Composed only of industrial employees, it is represented on all industrial boards and is responsible for a wide range of social services and benefits for its members and all workers in general. There is also a federation for artisans and vocational workers, and there are also associations for the professions and a General Federation of Farmers.

Employers are not permitted to run businesses employing more than ten workers. An employers' association is virtually nonexistent.

Contemporary economic policies. The government encourages private savings by paying higher rates of interest on deposits, and by guaranteeing investment by citizens of other Arab countries. There are severe restrictions on all luxury imports, including automobiles. At the same time strenuous efforts are made to mobilize economic potential, combat unemployment, and discourage emigration. Financial and technical assistance, which is offered free or at minimum interest rates, is usually sought from Socialist countries such as China, Bulgaria, and the Soviet Union. Aid, at higher interest rates, is also sought from France and other capitalist countries.

Problems and prospects. The most serious national problem is the financial drain caused by the demands of national security and defense arising from the Arab-Israeli conflict. There is also a severe loss of professional, technical, and manual labour to Lebanon, to the oil-rich Arab countries, to the United States, and to western Europe. Purchasing power, generally low, discourages prospective investors. It is anticipated that the formation of an Arab common market will provide buyers for Syria's produce and stimulate economic expansion. The Euphrates River Project is expected to promote both industrial and agricultural growth.

TRANSPORTATION

Railways. Three major railways were built before World War I under the Ottoman Empire. A northern line runs northeastward from Aleppo into Turkey and then east along the border to al-Qāmishlī, where it crosses the northeastern extremity of Syria en route to Baghdad (Iraq). The second (the Hejaz Railway) runs from Damascus to Maʿān (Jordan), and a third from Aleppo to Tripoli (Lebanon) and to other towns on the Lebanese coast. Smaller lines run between Homs and Rīyāq (Lebanon), and between Beirut (Lebanon) and Damascus. In 1967, the Syrian government began the construction of a railway from Latakia to Idlib, Aleppo, ar-Raqqah, Dayr az-Zawr, and al-Ḥasakah, passing by the Euphrates River Dam.

Roads. Paved roads were first constructed for military use before World War I. The road network has continued to expand and improve everywhere except in the arid region in the east. By 1971 there were over 7,100 miles of roads, of which about 5,100 miles were paved or gravel. The best road is a 225-mile highway between Damascus and Aleppo. A paved road is under construction between Damascus and Baghdad, Iraq.

Ports. The two ports, Latakia and Ṭarṭūs, were built after independence. Construction at Latakia was begun in 1952; it has two main jetties, wharves, and warehouses. The port of Ṭarṭūs is also equipped with two jetties and wharves. Its basin is larger than those of Latakia and Beirut, Lebanon, combined. Baniyas is used to ship oil from Iraq.

Air transport. Syria has international airports at Damascus and Aleppo and domestic airports at al-Qāmishlī, Latakia, Dayr az-Zawr, and Palmyra (Tudmur). Only the facilities at Damascus and Aleppo can handle jet aircraft. International services connect Syria with the Arab and east European countries, France, Italy, Pakistan, India, and the United Kingdom. Domestic services are provided by Syrian Arab Airways.

ADMINISTRATION AND SOCIAL CONDITIONS

The structure of government. *Constitutional framework.* The constitution declares that Syria constitutes an integral part of the Arab homeland, that all legislative power lies with the people, and that freedom of expression and equality before the law is guaranteed. The enforcement of these principles has not been thorough, however, because of constant political and military tensions.

The regional (Syrian) leadership of the Baʿth Arab Socialist Party (see *The political process* below) elects the head of state and appoints the cabinet, which exercises legislative as well as executive powers. Suffrage is not universal, and elections take place within each of the various popular and labour unions.

Local government. Syria is divided into 13 *muḥafażāt* (governorates), one province-level city, 47 *manāṭiq* (districts), and 120 *nawāḥī* (subdistricts). The governors, or *muḥāfiẓīn*, enjoy some power within their administrative divisions, but local government is centralized and is dependent upon the minister of the interior.

The Baʿth Party

The political process. Most authority is wielded by the ruling Baʿth ("Renaissance") Arab Socialist Party, the only legally recognized political party in the country.

Syria, Area and Population

	area		population

Since its foundation in 1941, the party has undergone radical internal changes as a result of successive coups d'état and internal power struggles. The party has branch organizations in all Arab countries, each headed by its own regional leadership. The organs of administration are the National Command, the Regional Command, and the People's Council; the latter operates as a legislature. The supreme national leadership is composed of representatives from each regional branch, who are elected by their own party congresses. The regional leadership for Syria is the highest authority in the country, but is subordinate to the national leadership.

Though all other political parties are officially banned, several manage to operate under varying measures of toleration. These include the Communists, the Arab Nationalists, the Arab Socialists, the Muslim Brotherhood, and the Syrian Nationalists.

All participation in the political life of the country is channelled through the particular popular organization to which a citizen may belong. In addition to the unions mentioned earlier, there is a General Union of Students, a Revolutionary Youth Union, and a General Federation of Women.

Justice. The principles of Syrian law and equity derive basically from Islāmic jurisprudence, and secondarily from the French civil code. The headquarters of each administrative district has a First Instance Court for criminal cases and another for private disputes. The capital city of each governorate also has a criminal court, a court of labour relations, a court of common pleas, a juvenile court, and a court of summary jurisdiction. Damascus houses a state tribunal with jurisdiction over claims raised against governmental agencies, as well as a military tribunal, and the *muftī*'s court for the maintenance of Islāmic law. The principal provincial towns also have courts of agrarian relations to settle litigation arising between landowners and labourers.

The armed forces. Military service is compulsory for all adult males over 18 years of age; only sons are exempted, and college students receive deferments. Military service lasts for 30 months, during which time general and technical—as well as military—education and training are given. The army is responsible for defense, public works, road construction, public health, and controlling the mass media. The air force, equipped with Soviet assistance, has a substantial number of jet combat aircraft. A small navy consists of a few minesweepers, patrol vessels, and torpedo boats, and surface to surface missile patrol boats. Arab guerrilla organizations operate from Syria and receive training facilities, but do not come under the control of the Syrian government.

Social conditions and services. *Educational services.* The literacy rate is about 50 percent. Schooling is compulsory for all children above six years of age, and all school books are free. In the early 1970s there were over 5,000 elementary schools; elementary education lasts for six years. In 1970 it was announced that all preparatory and secondary schools would be open to all elementary students who wished to continue their education. Within this framework, increased attention is being given to technical education, which is given to about 15 percent of those who finish the three years of preparatory school. There are about 38,000 university students, most of whom attend the universities of Damascus and Aleppo. A university was founded in Latakia in 1971, and about 10,000 students attend universities abroad. There is a shortage of facilities for scientific training; about three-fourths of Syrian university students study the arts, the humanities, law, and similar disciplines. The majority of those who go abroad specialize in medicine, engineering, and various branches of technology.

Higher education

Health and welfare services. Except for typhoid, malaria, and dysentery, there are no serious endemic diseases in Syria. Excluding the hospitals and out-patient clinics of the armed forces, some 32 state and 49 private hospitals and sanatariums provide a combined ratio of about one bed for every 1,000 citizens. There are also a number of public and private out-patient clinics, maternal and child-care centres, antituberculosis centres, malaria eradication centres, and rural health centres.

Child mortality, relatively high, is mostly caused by measles and diseases of the digestive and respiratory systems. Tuberculosis is widespread, particularly among the Bedouin, the peasants, and residents of city slums.

The Ministry of Social Welfare and Labour is empowered to find work for, and distribute cash allowances to, the unemployed. The ministry also encourages such youth activities as sports, athletics, scouting, literacy campaigns, and the organization of cooperatives. The government gives substantial grants to private welfare societies.

Housing. The shortage of housing is acute because of the pace of change from an agricultural to an industrial economy, and the accompanying migration to the cities. To further aggravate the shortage, young adult males are breaking with tradition and leaving their parental homes for their own houses.

The Ministry of Municipal and Rural Affairs undertakes the construction of blocks of low-income flats in the cities.

Wages and the cost of living. Labour legislation establishes minimum wage limits, prohibits child labour, and organizes relations between workers and employers. But economic and social conditions as well as the extent of unemployment make rigorous enforcement impractical. Employees in heavy industry receive the highest industrial wages, textile workers the lowest. State employees have more job security. Up to 75 percent of the average salary is generally spent on housing and food, leaving little for clothing, medicine, and recreation.

Health conditions. Health conditions and sanitation in the cities, towns, and larger villages are generally satisfactory. Running water is supplied to almost all houses, buildings, and public places. Each municipality maintains its streets and collects refuse regularly.

Medical services are badly distributed; three-quarters of the doctors are concentrated in the large cities. In the rural districts, health conditions are unsatisfactory because of polluted water and the lack of drainage and sewage systems.

Social and economic divisions. The upper-income group is composed of the owners of small industrial businesses, important merchants, and senior officials. The middle-income group comprises the great majority of shopkeepers, professionals, and farmers. Workers, peasants (farmers who do not necessarily own the land they cultivate) and most employees—the remaining 75 percent of the population—belong to the lower-income group.

The process of Socialist transformation has caused much social, political, and economic confusion, and has led to emigration among the rich. The rising birth rate has caused family lands to be broken up into ever smaller

lots, and has reduced the standard of living of the poor, forcing some of them also to emigrate.

CULTURAL LIFE AND INSTITUTIONS

The cultural milieu. The long periods of foreign, and particularly Ottoman, rule contributed little to the development of a national culture. Education was confined to a few, who maintained the country's ancient libraries and manuscripts. After independence in 1946, a new cultural life began to stir on a humble scale, mostly through the medium of a small number of clubs that received some financial assistance from the state.

In 1958 the Ministry of Culture and National Guidance was created, and has since been active in directing and promoting the nation's cultural life. An important objective has been the affirmation of the Arab national character in the face of foreign cultural influences.

The state of the various arts. Until World War I, the artistic representation of animal or human life was proscribed by Islām. Figurative art was restricted to geometric designs as manifest in the arts of arabesque and calligraphy, which decorates most palaces and mosques.

The fine arts

Following World War I drawing was taught in the schools and talented artists began to emerge. A faculty of fine arts was instituted at the University of Damascus in 1963. Some of the teachers, such as Fateh Moudarres, are well-known artists. Syrian artists are concerned more with content than with form or style.

Sculpture is mainly confined to decorations hewn in white marble. Damascus is particularly famous for this type of sculpture, and beautiful examples of it can be seen in its mosques, palaces, and public buildings.

National folk traditions have been emphasized by the state, which has established a wax-work museum for national folk traditions in Damascus. One of the oldest forms of folklore—the epic—continued in the form of recitations about the exploits of legendary characters. The National Theatre and other theatrical and folk-dance companies give regular performances.

Cultural institutions. The Ministry of Culture has established an Arab institute of music and opened numerous courses in the figurative and applied arts, as well as centres for teaching the domestic arts. The Arabic Language Academy, founded in 1919 and the oldest such academy in the Arab world, runs the Ẓāhirīyah Library, well-known for its rare manuscripts and old book editions. The University of Damascus, however, is the most important of Syria's cultural centres.

Press and broadcasting. The history of Syria's newspapers has been one marked by suppression. There are now four daily papers, two of which are published in Damascus. In addition, there are two weeklies run by the federations of workers and of peasants. All newspapers are under direct government control, and the magazines and journals are run mostly by official or semi-official bodies.

Syrian broadcasting began in 1947 and has since become the most powerful rival of the local press. Arabic transmission by the Syrian Broadcasting Service extends over 17 hours a day. Short programs are also transmitted in English, French, Turkish, and German. Broadcasts—many of which are devoted to instruction—reach almost every Syrian home.

The Syrian Television Service, started in 1960, reaches a large audience throughout the country. Programs are transmitted for seven hours a day, with additional hours at weekends and during holidays. Broadcasting includes educational and cultural programs, drama, music, news, and sports.

PROSPECTS FOR THE FUTURE

Syria's mild Mediterranean climate and its favourable position on regional trade routes should enable its people to prosper. Complex political circumstances, however, and impoverishment have retarded its progress. In recent years the state of war, declared or undeclared, with Israel has had profound repercussions. Political and military tensions have checked the development of the democratic process, and have diverted resources into channels that have little relationship to its economic and social problems. The most pressing of these problems is the rapid increase in the population, which is out of proportion to the rate of economic growth. In consequence it is estimated that one-third of men of working age and almost all women have no paid employment and are driven to emigrate in ever increasing numbers. Syria is nevertheless making determined efforts to plan and carry out a number of industrial, agricultural, and social projects, some of which are vital to its future growth.

Syria and Palestine, History of

The geographical area covered by this article extends from the foothills of the Anatolian Plateau in the north to the Sinai Desert in the south and from the Mediterranean coast on the west to the Euphrates River on the east (including the present states of Israel, Jordan, Syria, and Lebanon). The greater part of this large area, however, consists of the Syrian Desert and plays little part in history except as a reservoir of nomads who, at intervals, erupted into the surrounding settled lands. The settlements that provide the units for a historical picture of ancient times form a semicircle called the Fertile Crescent, sweeping around from the southeastern Mediterranean coast to the river valleys of Mesopotamia. This area and its fringes are of crucial importance, for it is here that the first steps were taken that led to the development of civilization.

The Fertile Crescent

This article is divided into the following sections:

I. Early history, to *c.* 1600
- Stone Age cultures
  - Paleolithic and Mesolithic
  - Pre-pottery Neolithic
  - Pottery Neolithic
- The end of the Neolithic and the dawn of civilization
  - The Chalcolithic
  - The beginnings of towns and city-states
- The Early and Middle Bronze Ages
  - Early Bronze Age cities
  - The Amorite invasion
  - Middle Bronze Age

II. Syria and Palestine, *c.* 1550 BC–AD 634
- The era of the Egyptian and Hittite empires, *c.* 1550–1200 BC
  - The struggle of the Great Powers for Syria and Palestine
  - Organization and culture
  - The coming of the Hebrews
  - The Sea Peoples and the advent of the Philistines
- Syria and Palestine, *c.* 1200–*c.* 330 BC
  - The Philistines
  - The Syro-Hittite states and the Aramaeans
  - The Phoenicians
  - The Hebrews
  - The era of the Assyrian, Neo-Babylonian, and Achaemenian empires
- Syria and Palestine in the Hellenistic and Roman periods, *c.* 330 BC–AD 634
  - The Macedonian conquest
  - The Hasmonean state in Palestine
  - The Romans in Syria and Palestine
  - Syria and Palestine in the late Roman and Byzantine periods, *c.* 300–634

I. Early history, to c. 1600

STONE AGE CULTURES

Paleolithic and Mesolithic. For hundreds of thousands of years, during the Paleolithic Period, or Old Stone Age, primitive men lived on natural resources, both animal and vegetable. Paleolithic man was differentiated from other animals by little more than the fact that his lesser physical strength and natural weapons were compensated for by the tools and weapons that his greater mental development enabled him to provide. During this long Paleolithic Period, men in Syro-Palestine were culturally linked with men in the Eurasian landmass. Good records of their occupation have been found, especially in the caves of Mt. Carmel, where a long succession of levels has been excavated.

The contribution of Syro-Palestine to history does not lie here but begins at a time when the northward recession of the ice cap at the end of the last glaciation brought a different climate to the region at approximately 10,000 BC. The challenge of this change in environment resulted in an enormous step forward, in that man began to seek to control his environment—that is, he began to cultivate plants and domesticate animals. Having taken this step, he was no longer forced to follow the seasonal migration of animals or growth of grains but could produce his own food supply within reach of his home. Settlement is dependent on a food supply controlled by means of agriculture and stock herding, and from the first village settlements developed the first towns and, ultimately, civilization.

Development of agriculture

Archaeologists have proved that it was in Syria and Palestine, along with adjacent areas in northern Iraq and Anatolia, that agriculture and the domestication of animals began, and experts in the environmental sciences have shown why this is so. Clearly, the earliest steps in the domestication of plants or animals must have taken place in those areas in which these plants and animals are found wild. The habitat of the wild species has been extensively studied, and archaeological excavations have provided paleobotanists and paleozoologists with specimens from early sites that have enabled them to begin the study of the process of domestication.

The two grains important to early man in the western part of the Old World were barley and wheat. Wild barley grew throughout the whole of Anatolia and from there spread in a belt past the south end of the Caspian Sea toward India as well as down the Mediterranean coast to southern Palestine. Cultivated barley is found in early sites but never without wheat, and it was the presence of wild wheat that was the controlling factor in incipient cultivation. Two kinds of wild wheat prove to have been especially important: *Triticum boeticum*, which was the ancestor of *Triticum monococcum*, or einkorn; and *Triticum dicoccoides*, the ancestor of *Triticum dicoccum*, or emmer. The habitat of the ancestor of einkorn covers the whole of Asia Minor across to northern Iraq and also down the Mediterranean coast into Syria. That of emmer was much more restricted, covering an area from northeastern Iraq westward to the Mediterranean coast as far south as the hills of Galilee. Emmer also proved to be more important than einkorn, as it was more adaptable to different environments. The habitat area of wheat, and especially that of emmer, provided the environment in which all the known earliest transitions took place from man as a hunter and gatherer of wild foods to man as a settled agriculturalist. The natural habitat of the earliest domesticated animals—goats, sheep, cattle, and pigs—lay in the same general area.

This transformation was gradual. At the end of the Ice Age and of the equivalent cool and wet period in the Mediterranean area, man had to adapt himself to a new environment and to new sources of food. This stage, beginning *c.* 10,000 BC, is usually known as the Mesolithic Period. Man was still basically a food gatherer, but in western Asia the changing natural resources turned his attention more to vegetable foods. There is archaeological evidence of this Mesolithic stage in most of the area in which the subsequent Neolithic was to develop. Within the geographical limits of this article, sites providing evidence of the Mesolithic are confined to the southern part of Syria (and here and below the modern political division of Syria and Lebanon is ignored) and to Palestine (again ignoring modern political divisions). No Mesolithic sites are known in the northern part of Syria, and the development in Palestine of the flourishing Mesolithic culture known as the Natufian provided the basis for the genesis of the earliest known Neolithic stage.

Natufian culture

The classic site for the Palestine Mesolithic is found in the caves on the western side of Mt. Carmel, facing the Mediterranean, where a very long period of Paleolithic occupation was followed by occupation by Mesolithic man. These Natufians lived in the caves much as their predecessors had lived, burying their dead, with elaborate equipment, on the terraces in front. They still depended on hunting for their livelihood, mainly on gazelle. They certainly also harvested grain, for many sickle blades and finely carved bone handles in which they were set have been found, as well as implements for grinding grain—a grain, however, that was probably of the wild variety. Evidence has been found at 'Ayn al-Mālihah, near Lake Hula in the Jordan Valley, of another Natufian group with similar equipment and burial customs, but this group lived very differently. Here there was an incipient village with the inhabitants living in a group of round huts. Tall Murāba'āt in inland Syria is a similar site. A considerable number of Natufian sites are known, stretching as far south as Bayḍā' (Beidha) near Petra, indicating a vigorous and thriving population at this time.

The present evidence is that the Mesolithic Natufians used wild grains, and their sites are found in the habitat of the wild ancestors of einkorn and emmer wheat and of barley. This practice was in itself conducive to the development of fixed settlements. The ripening period of the grain lasted only two to three weeks, and during this time the year's supply of perhaps a ton per family had to be harvested. If grain was to be eaten the year round, a central base is implied. As far as is known the Natufians had not begun the practice of cultivating the plants, involving both preparing the land and the storing

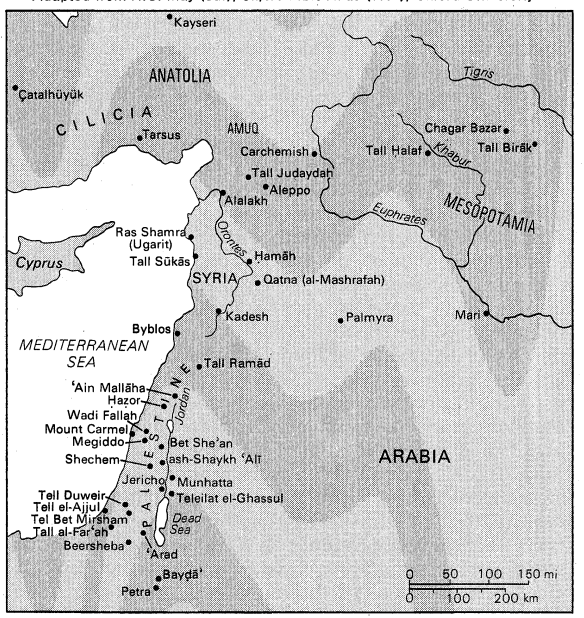
of seed grain. Wild grain is differentiated from cultivated grain by well-defined characteristics that can be identified in the impressions found in the course of excavations. Wild grain is dependent for survival on its ability to scatter freely as it ripens. When man started to reap grain, he would have preferred specimens with a tougher spike axis, which would not scatter as he cut it. Inevitably, a greater proportion of the tougher spike-axis grains was successfully harvested and was included in the next year's seed corn. Thus, man developed a type of grain that had lost the characteristics required for survival in a wild state but was much more useful when deliberately sown. When grain impressions are found showing the characteristics of the tough spike axis, it can be taken as certain that it was cultivated by man.

The physical characteristics of wild animals were also affected by domestication, usually in the direction of reduction in size. This process is rather more difficult to chronicle, partly because the bones recovered in excavations are usually fragmentary, partly because the criteria of domestication are not yet fully established, and partly because it requires many generations to bring about changes that are reflected in the skeletal remains.

The vigorous Natufian stock of Palestine and southern Syria was ancestral to the people who evolved the earliest Neolithic culture, fully settled and practicing a developed agriculture. The site of Jericho in the Jordan Valley beside the spring ʿAyn as-Sultān (ʿAin es-Sultan) has provided evidence of the full sequence. The earliest evidence of occupation there consists of a structure that is probably a sanctuary. The flint and bone equipment of the people who constructed this sanctuary is Mesolithic Natufian, closely similar to that of the lowest Mesolithic level of the Mt. Carmel caves. It may be deduced that Mesolithic hunters established their sanctuary beside the perennial spring that today still waters the wide-stretching Jericho Oasis in evidence of its life-giving importance. The date of this first appearance of man at Jericho is given as *c.* 9000 BC by carbon-14 (a radioactive carbon isotope, the rate of disintegration of which is used to calculate ancient dates).

Jericho

Adapted from H.G. May (ed.), *Oxford Bible Atlas* (1962); Oxford University Press



Principal sites in Syria-Palestine from the Mesolithic Period to the 18th century BC.

Pre-Pottery Neolithic. *Pre-Pottery Neolithic A.* The site proved so attractive to the Mesolithic hunters that eventually they settled there permanently. For a long time they lived in flimsy huts of a type suitable to a nomadic way of life, but they were clearly no longer nomads, for the accumulation of successive huts built up a deposit of 13 feet (4 metres). Eventually the huts were succeeded by one-room round houses, solidly built of brick, in plan clearly derived from the preceding huts. At this stage, occupation spread to the full ten acres of the subsequent town, and the first Neolithic stage of Jericho, now designated Pre-Pottery Neolithic A, was established. The qualification pre-pottery has been included in the title, since until about 1950, when it was accepted that a true Neolithic site was marked by the appearance of pottery. Jericho was the first major site with Neolithic levels earlier than the appearance of pottery, though now this stage in the Neolithic of western Asia is well-known from similar evidence elsewhere.

Soon after the spread of these early houses over the site, there was the significant development of the construction of a town wall of imposing dimensions, associated with at least one massive stone tower 30 feet (9 metres) in diameter, and enclosing the whole ten acres. Such an enterprise implies a fully developed communal organization. The carbon-14 dates show that this stage was reached *c.* 8000 BC.

Jericho was now a town housing perhaps 2,000 to 3,000 persons; this in itself implies an agriculture sufficiently developed to support a large population in one place, though hunting still formed part of the economy, with foxes apparently the favoured meat diet. Evidence has been found, however, of cultivated emmer wheat and cultivated barley. Grains of the wild ancestors have not been found, and they would not have been native to the Jordan Valley with its Sindo-Saharan climate, so it is plausible to suggest that the emergence of the cultivated types took place in the hills, perhaps in the neighbourhood of the Mt. Carmel caves, where the settlement at Wadi Fallah provides evidence of early agriculture. It is also plausible to suggest that to secure a sufficient area for agriculture it was necessary to use irrigation. The communal organization required for such a project could be the origin of the organization implied by the construction of the defenses.

Irrigation

Jericho Pre-Pottery Neolithic A lasted about a millennium. Knowledge of similar settlements, though none on this scale, is growing. It shows that groups with a similar equipment, which at Jericho had developed without a break from the Mesolithic Natufian, and with similar houses are to be found all over Palestine—*e.g.*, at Wadi Fallah on the Mediterranean coast, at Shaykh ʿAli (Sheikh Ali) and Munhatta in the Jordan Valley, and at Bayḍā' to the south, where the earliest Neolithic levels are dated to *c.* 7000 BC.

Palestine thus provides evidence of the development of a fully settled Neolithic culture based on agriculture. It was not the only region in which this took place. The process also certainly took place in the uplands of north-eastern Iraq, of which the type site is Jarmo, dated to *c.* 6750, and in southern Anatolia at Hacilar, *c.* 7000. Both sites were Pre-Pottery, but their equipment and their architecture were different, both from each other and from Jericho. Each area was probably the centre of independent development of agriculture. On the present evidence, however, the first development took place in Palestine, as suggested by the date of 8000 BC for the fully grown walled town of Jericho.

In the northern part of Syro-Palestine, there is evidence of Pre-Pottery stages at Ras Shamra (Level VC) in the north and at Ramād (Level III) in the south, dated at Ras Shamra to *c.* 6600 BC. The equipment and architecture are different from those of Jericho Pre-Pottery Neolithic A, especially in the houses with rectilinear walls and floors of lime plaster. It seems at present that occupation was sparse in this northern area, perhaps because of the absence of a preceding Mesolithic population, though observations may be modified by fuller exploration. It seems probable, too, that this first Neolithic occupation in northern Syria had its roots in Anatolia, where from 6500 BC there flourished a Neolithic culture that is brilliantly exemplified at Çatalhüyük, where rectangular houses with beautifully polished plastered floors have been uncovered (see ANATOLIA, ANCIENT).

Pre-Pottery Neolithic B. It is very probable that the next stage in Palestine is derived from the north Syrian

Neolithic. At Jericho and a number of other sites in Palestine, such as Wadi Fallah and Shaykh ʿAlī, there is an abrupt break. The round houses of Pre-Pottery Neolithic A are succeeded by rectangular houses with floors and walls covered with polished plaster. At Jericho there is clear evidence of the break, with erosion and with erosion and torrent channels cutting into the earlier levels. Above these erosion levels, the new style of houses appears fully developed. In addition to the change from curved to rectilinear walls, the buildings are very different in character, being large and with multiple rooms grouped around courtyards. The flint industry is new, as are most of the types of stone utensils, such as querns for grinding grain. There is still no pottery. The carbon-14 dates at Jericho indicate that the new stage began late in the 8th millennium and may have lasted through the greater part of the 7th.

Architecture of Pre-Pottery Neolithic B

It is clear that newcomers, designated Pre-Pottery Neolithic B, had arrived and had displaced the earlier inhabitants. A Pre-Pottery Neolithic culture that had developed elsewhere had displaced the Pre-Pottery Neolithic culture indigenous to Palestine. The style of architecture indicates that the newcomers came from north Syria; reference has already been made to the rectilinear architecture and plastered floors of Ras Shamra and Tall Ramād (Tell Ramad). The link is made clearer by the fact that at Tall Ramād there were plastered portrait skulls resembling those of Pre-Pottery Neolithic B of Jericho.

Skull decoration

The Jericho skulls constitute one of the most remarkable achievements of Neolithic art. The skulls, usually the cranium only, were removed from bodies buried beneath the floors of the houses after decay had begun but was not complete, and the lower part of each was covered with plaster modelled into the features of the face with extraordinary fidelity and artistic skill. The surface was often painted to represent the complexion; and, in one case, a moustache was depicted. These plastered skulls can, with some assurance, be related to a cult of ancestor worship.

Further evidence of the northern origin of these newcomers is provided by the appearance of einkorn wheat. The wild ancestor of this wheat is not indigenous to Palestine but is found in Syria and Anatolia, and it seems likely that it was brought south by the newcomers.

The new culture spread widely in Palestine, but other sites there do not always present the clear-cut division that exists at Jericho. At some sites, especially those in more arid surroundings, there appears to have been a divergent development from the preceding Mesolithic, which only at this stage became fully Neolithic. In others, it can probably be inferred that the Pre-Pottery Neolithic A people retreated before the advance of the Pre-Pottery B people. This may account for the fact that the earliest Neolithic levels at Bayḍā', about 100 miles (160 kilometres) south of Jericho, predominately Pre-Pottery Neolithic A in character, date only from about the time of the arrival of the Pre-Pottery Neolithic B people at Jericho. The subsequent levels at Bayḍā' in the first half of the 7th millennium show the arrival of the later culture but with more mingling of characteristics than at Jericho; additional groups in contact with the newcomers had probably arrived.

There is thus now fairly adequate documentation for the development of the Neolithic in the Syro-Palestinian area. By *c.* 8000 Palestine saw the full flowering of settlement derived from the indigenous Mesolithic and based on an economy in which agriculture played an appreciable part. This is the first known development of a full Neolithic economy. By *c.* 7000 BC a separate culture had developed in Anatolia and, shortly afterward, another in northeastern Iraq; but the earliest date so far established for northern Syria is mid-7th millennium. It is probable, however, that in due course the north-Syrian culture became preponderant over the whole area of Syria and Palestine, which formed a relatively unitary cultural province by the second half of the 7th millennium.

Pottery Neolithic. The next stage of cultural development certainly came from the north, with the addition of pottery to domestic technology. Pottery was long thought to have come into use with the earliest villages, but it is now clear that the earliest vessels of molded clay came more than 1,000 years later, and the earliest true fired pottery in north Syria came nearly 1,000 years after that.

The earliest known vessels that may be considered as ancestral to pottery have been found at Çatalhüyük in Anatolia, first in Level VIII, about 6750 BC and fully developed, in Level VII, about 6200 BC. It is reasonable to accept that inventions in this area would in due course spread to the south, for in it is an important source of obsidian, which was widely used at an early date. Even as early as Pre-Pottery Neolithic A at Jericho, tools were made of obsidian imported from near Kayseri in central Anatolia; how obsidian was transmitted is still an unsolved problem. The early ware at Çatalhüyük may have been the progenitor of the earliest molded vessels in Syria. In Syria it is known as white ware, or pozzolanic ware, and is not true pottery, for it is not fired clay but rather molded plaster. Pozzolanic ware appears in Ras Shamra (VB) at Tall Sūkās (Tell Soukas) on the coast south of Ras Shamra, in the classification known as Amuq A, based on soundings in tells in Amuq Plain, and Tall Ramād II, dating to *c.* 6000 BC. It clearly represents first experiments in making molded vessels, as opposed to stone or wood-carved vessels. At Tall Ramād II only these vessels are found. In Ras Shamra and the Amuq A classification, with less closely defined stratification and possibly covering a longer period, it is accompanied by the first true ceramic vessels fired in some form of kiln. This constituted a considerable technological advance; man had now begun to alter the natural properties of materials by applying to them extraneous influences such as fire.

Pozzolanic ware

The first pottery to appear in north Syria is found over such a wide area that it can be used both to establish chronology and to define cultural areas. It is known by the clumsy but descriptive phrase dark-faced burnished ware. Its ancestry is certainly northern and can be suggested in finds at Çatalhüyük VIII dated before 6200 BC. It appears at Ras Shamra *c.* 6000 BC and at Amuq A. The ultimate spread of this pottery was enormous, covering Cilicia and Syria as far south as Byblos, where it is found in the early Neolithic levels in which the plastered floors reflect the continuation of the Syrian Pre-Pottery province, and at Tell Ramad, where it appears in Level III.

Dark-faced burnished ware

The finds of pottery of this type indicate a wide range of a technological development and also a great impetus toward settlement, for in many sites the pottery appears in the earliest levels. The widespread occurrence of fired pottery most likely resulted from the transmission of techniques rather than the movement of peoples.

Most of the excavations that have penetrated the levels where pottery first appears have at that depth become soundings of relatively limited extent. Not a great deal is known, therefore, about the characteristics of the settlements. At Ras Shamra the houses seem to have been single-roomed with rectilinear stone walls and plastered floors. The houses were scattered haphazardly and widely spaced over the whole mound. In the soundings at Tall Judaydah (Tell Judeideh), the houses of the Amuq A level had walls covered with finely polished wall plaster. Tall Ramād II had rectilinear walls of stone foundations and a superstructure of mud bricks forming rooms of somewhat irregular shape. There is evidence for the cultivation of emmer wheat in the Amuq A stage. At Ras Shamra there is an increase in the remains of domesticated animals—the bones of pigs, oxen, and sheep being found.

It is possible that this evidence of an increase in stock breeding is associated with a significant opening up of the countryside. The early postglacial vegetation of coastal Syria consisted of coniferous forest on the Lebanon Mountains and of oak forest in the al-Buqayʿah (Bekaʿa) Plain to the east, both dense and inhibiting to early occupation. The open oak forest–savanna area east of the Anti-Lebanon and in Palestine was more suitable country for early settlement; this is probably the reason for the Mesolithic or early Neolithic development in Palestine. In the 6th millennium BC, the forest cover of Syria was

Opening of the countryside

gradually much reduced, very possibly in connection with stock breeding. As a result, the culture or cultures of northern Syria spread steadily, though probably slowly to the south, using both the coastal and the inland routes.

The spread of the culture associated with the dark-faced burnished pottery probably spanned most of the 6th millennium, for it appears at Ras Shamra and in the Amuq area about 6000 BC, but, if the carbon-14 dating is correct, it did not reach Byblos until *c.* 5000 BC. It later penetrated into Palestine, where it is found mainly in the coastal area in the first half of the 5th millennium.

THE END OF THE NEOLITHIC AND THE DAWN OF CIVILIZATION

The Chalcolithic. The ultimate extension into Palestine of pottery-using Neolithic people was preceded by a development of great significance in northern Syria. About 5300 the Chalcolithic Ḥalafian culture appears in Mesopotamia, with its centre in the region of the Khabur (modern Nahr al-Khābūr) River. It was probably brought by newcomers of nomadic origin, perhaps from the foothills of the southern Taurus Mountains. Pottery of the Ḥalaf type, extremely sophisticated and elaborately decorated, appears at Ras Shamra, in Amuq C, and at Ḥamāh on the Orontes River. The spread of true Ḥalaf pottery was very wide and that of derived types even wider. This is significant evidence of a new cultural pattern, with trade links over the wide plains area of the Fertile Crescent from east of the Tigris to the Mediterranean coast, in the east extending into southern Mesopotamia, in the west as far south as Ḥamāh and Tell Tabbut el-Hamman, and in the north into the Anatolian Plateau. The stage is important as indicating the breakup of the tradition of largely (though never completely) self-sufficient village economy. It is also important for the introduction of the use of metal, which was in itself a stimulus to the development of trade, for the sources of copper are limited. Moreover, the introduction of metal tools and weapons led to the growth of a class of specialized craftsmen who had to be supported by food surpluses produced by the rest of the population.

While this technological and economic revolution was taking place in north Syria, the preceding stage of the widespread pottery-using Neolithic of that area was spreading south into Palestine. The highly developed Pre-Pottery Neolithic B culture of Palestine came to an abrupt end, and a number of sites show a gap in occupation and a clear change in culture. The most striking evidence comes from Jericho. The latest carbon-14 dating for Pre-Pottery Neolithic B at Jericho is *c.* 6600 BC; this is not from the latest level, and the settlement may have lasted until the end of the 7th millennium. It must then have been empty and abandoned for a millennium or more, as must have been the other contemporary sites. For this strange gap there is at present no explanation. The next occupation was of an utterly different character. Into the ruins of the preceding settlement at Jericho were dug large numbers of pits, some of them very deep, in which were the huts of the newcomers. Their flint techniques were completely new, and they used pottery, the finer examples of which were characterized by a decoration of burnished red chevrons. This pottery has not been found in Syria, though it is fairly widespread in Palestine; it may be a relatively local development, technologically inspired by the pottery-using province to the north. Its chronological position is suggested by the occurrence of this Pottery Neolithic A ware of Jericho at Tel Batash (Tell Batashi) on the coastal area, down to which the dark-faced burnished ware had spread. At Tel Batash, again in pit dwellings, Pottery Neolithic A ware was found in association with dark-faced burnished ware of the type with "scratched" decoration found at Byblos. It probably belongs to the stage of Ras Shamra IV C, Amuq C, and Itamāh L, at those sites to be dated toward the end of the 6th millennium, though chronologically it may well be somewhat later in Palestine. The way of life of these newcomers was probably that of pastoralists, perhaps migrating seasonally with their flocks.

The cultural hiatus at Jericho

In the next stage in the north, the long-lived dark-faced burnished ware gradually disappeared, and its place was taken by a red-washed ware whose origins are obscure. The pottery forms in this ware, first appearing in the mid-5th millennium, are readily recognizable, especially the type of jar with what is known as a bow rim, and decoration in bands of incised chevrons. It can be readily recognized in the next arrivals at Jericho, designated Pottery Neolithic B, and at a large number of other sites in Palestine. At Jericho, the new arrivals continued to live in pit dwellings, and their way of life in Palestine was still Neolithic, though contemporary with the Chalcolithic Tall Ḥalaf (Tell Halaf) culture in the north.

By *c.* 4500 BC, Mesopotamian influence had died out in the north, and Ḥalaf ware is no longer found. It is, in fact, a period of cultural recession and at some sites is followed by a gap.

The beginnings of towns and city-states. The last centuries of the 5th millennium saw the beginnings of the development of town life in Mesopotamia that were to lead to the city-states in that area of the 3rd millennium. This culture in Mesopotamia is called the Ubaid. Ubaidi pottery penetrated into Syria. It was found on the Mediterranean coast—for instance, in Ras Shamra III B, which was dated by carbon-14 to *c.* 4180 BC, and in the Amuq E stage, which probably had a long and ill-defined duration. Syria did not at this stage reflect the urbanizing tendencies of Mesopotamia in the Ubaid period. At sites such as Ras Shamra and Tall Judaydah, where the pottery associated with this phase is found, buildings are irregularly arranged, though rectangular in plan. At Tall Birāk (Brak), in the Khabur Plain, the earliest levels belong to the final stage of Ubaid, but the successive temples—clear evidence of an urban civilization with strong Mesopotamian contacts—belong only to the second half of the 4th millennium, to the Uruk–Jemdat Nasr stages. It would in fact appear that the spread of urbanization from Mesopotamia into Syria was patchy and sporadic. At some sites, the Chalcolithic Ḥalafian culture may have continued alongside the newer developments. At some sites (*e.g.*, Chagar Bazar in the Khabur) there is no trace after the final Ḥalaf stage, mixed with some Ubaid, of the Uruk and Jemdat Nasr stages; there may, therefore, have been a gap in occupation from *c.* 4000 to *c.* 2800 BC. At Mari, on the Middle Euphrates, a site that was to become very important in the 3rd and 2nd millennia, there is scant evidence for the Ubaid–Uruk period. In the Orontes Valley and Amuq Plain, there was also a very considerable decrease in settlements of appreciable size during the course of the 4th millennium. On present evidence Syria was a backward area for much of the 4th millennium, and the nascent city-states of Mesopotamia were not yet much interested in the area.

The Ubaid period

In Palestine there is growing archaeological evidence for the 4th millennium BC. The second Pottery Neolithic stage, the Pottery Neolithic B already referred to, overlaps chronologically with a stage that is certainly Chalcolithic, for there is a linking of distinctive pottery forms. The new stage is known as Ghassulian, from Teleilat el-Ghassul (Tululeit Ghassul) in the Jordan Valley where it was first identified. Though the Ghassulian has links with Pottery Neolithic B, it certainly represents the arrival of newcomers, probably from the northeast. Closely linked with the Ghassulian is the Beersheba culture of southern Palestine, and here its full character emerges. The settlements were villages with primitive often semi-subterranean dwelling places, such as those of the Pottery Neolithic B. But the inhabitants were artisans and skilled workers in copper and other materials. The carbon-14 method at first gave dates for these settlements in the second half of the 4th millennium, but more refined dating techniques suggest dates in the first half of the millennium. Palestine at this stage was therefore absorbing the technological advances that had reached Mesopotamia and Syria in the Ḥalaf period.

The next stage in Palestine is marked by the arrival of fresh and successive waves of newcomers in what can best be called the Proto-Urban phase, as a prelude to the Early Bronze Age. This terminology is not universally accepted. Some experts prefer to classify some elements

Proto-Urban phase

as Late Chalcolithic and some as Early Bronze Age. The main group, Proto-Urban A, originated to the north, probably in the Amuq Valley. A small group of the same people even penetrated to the north, to Tarsus in Cilicia. The newcomers, when they arrived in Palestine, were still villagers. They introduced new pottery, new burial methods, with the first rock-cut tombs containing multiple burials, and they were certainly sedentary. Their settlements constituted the genesis of the Early Bronze Age towns of Palestine. At Tell Gath in southern Palestine, five levels preceded the intervention of the Egyptians at the beginning of the 1st dynasty (*c.* 3100 BC), and at Jericho the period is represented by at least five and possibly seven occupation stages. Not all sites show this same development toward urbanization, but it was clearly taking place. During this period other groups, Proto-Urban B and Proto-Urban C, were arriving, again from a northern direction, and combining with the Proto-Urban A group.

In the last centuries of the 4th millennium, therefore, Syria and Palestine were occupied by village populations, with connecting links from east to west in Syria and from Syria in the north to Palestine in the south. The succeeding millennium shows the development of these villages into towns and probably city-states and also the influence upon them of the Euphrates Valley empires to the east and of Egypt to the southwest.

THE EARLY AND MIDDLE BRONZE AGES

At this stage, written records become available in addition to archaeological evidence. For Syria, historians tend to regard periods or sites for which there is no written evidence as *terra incognita*. Archaeologists work out their sequence and gratefully accept evidence that texts supply to fix points of chronology. Textual evidence from the direction of Mesopotamia is greater for Syria, but negligible for Palestine. For the coastal area, Egyptian contacts provide valuable fixed points for the archaeological evidence.

The reign of Sargon I

The epigraphical evidence concerning Syria is explicit only in the second half of the 3rd millennium. Sargon I of Akkad (2334–2279) marched across to the Mediterranean, and his records deal with the Syrian states with which he had relations, warlike or diplomatic. He needed the wood, stone, and metal that the west could provide. Records, however, carry the history of Syrian states to a pre-Sargonid stage. At Mari there were rulers of importance before the middle of the 3rd millennium. Mari was certainly one of the most important Syrian towns of the period. In culture, it was strongly influenced by Mesopotamia, but its kings had Semitic names. Epigraphical evidence is scrappy, but the general picture is similar for most of northern Syria: a growth of towns with strong Mesopotamian influence, the rulers mainly Semitic, but a large proportion of the population non-Semitic, representing the indigenous population prior to incursions of a ruling stratum from the Syrian Desert.

The towns of the Mediterranean coast at this stage assume a new importance based on the growth of Egypt. It is possible that down to the 4th millennium, Egypt was the recipient of progress rather than its instigator. The Neolithic stage was late in Egypt, and the Ghassul–Beersheba people of Palestine may have instigated the development of copper working there. From the beginning of the 1st dynasty (*c.* 3100 BC) Egypt became an expanding power. The Early Bronze Age towns of Palestine and coastal Syria show Egypt's impact, sometimes that of trade but sometimes implying political control.

'Arad

Early Bronze Age cities. The places in Syria and Palestine with which Egypt had contact grew rapidly to have the status of towns. One of the most remarkable of the new towns is 'Arad in southern Palestine. 'Arad sprang up in an area with few agricultural advantages but nevertheless had become a large walled city by Early Bronze I (*c.* 3000 BC). Its importance was certainly connected with Egyptian trade, possibly in bitumen (or asphalt) from the Dead Sea. Other walled cities dating from the beginning of the Early Bronze Age include Megiddo, Tall al-Fārī'ah (Tell el-Far'ah), and Jericho. A similar walled city appeared at Byblos, and urban development is suggested at Ras Shamra, though the evidence from excavations there is limited. It is clear that the culture of the Mediterranean coast is closely related to the southernmost part of Palestine. The pottery evidence shows that on the combined cultures of the Proto-Urban stage in Palestine a new influence supervened, to which perhaps is to be ascribed the full development of urbanization. This is linked by pottery with northern Syria, whence the preceding people had also come.

The more ample archaeological evidence in Palestine enables the various stages of the Early Bronze Age to be more closely linked with Egyptian chronology than that of the corresponding period in Syria, the Egyptian chronology being more exact than that of Mesopotamia. In Palestine, Early Bronze I overlaps with the 1st dynasty of Egypt, whose first king, Narmer, destroyed the Proto-Urban town of Tell Gath. Early Bronze II extends to the beginning of the 3rd dynasty (*c.* 2686 BC), and Early Bronze III in Palestine covers the 3rd, 4th, and 5th dynasties. The correlations are based on Egyptian imports into Palestine, sometimes bearing the names of pharaohs, or at least fairly closely dated.

Egyptian imports into Palestine imply close contacts, at least in the area of trade, and Egyptian records suggest that Egypt may have exerted some political control over the cities of Palestine. But it is difficult to assess how much this was real or how much traditional bombast; certainly the basic culture remained Palestinian–Syrian.

Byblos

Probably the relations between Egypt and Byblos typify Egyptian contact with the Syrian coast. Egypt lacked stone, metal, and, above all, wood. As Egypt of the 1st dynasty developed an urban civilization and an empire, its need for these materials grew. They were to be found in Syria, where the Early Bronze Age culture just described covered the length of the coast. Byblos was the most important port, with its hinterland the best source of lumber and other materials Egypt needed. The Byblos of the Early Bronze Age was a very different place than that in the early period. It was a walled city, with houses closely built up, regularly orientated, and with a degree of uniformity of plan. Contacts between Egypt and Byblos probably began at the beginning of the Early Bronze Age, but they are epigraphically confirmed by gifts to the temples of Byblos bearing the name of Khasekhemui, the last king of the 2nd dynasty (*c.* 2890–*c.* 2686 BC), associated with finds belonging to the beginning of Early Bronze III.

Early Bronze III marks the full urban development of Palestine, and it is probable that further archaeological exploration in Syria will show that period, *c.* 2700–*c.* 2300, to be the most prosperous for the 3rd-millennium towns of the entire Syro-Palestine area. During the period, a new people certainly arrived, as evidenced by a new type of pottery known as Khirbet Kerak ware. Its origins are northeastern, possibly Caucasian. It is much more in evidence in northern than in southern sites. It must have been brought by newcomers, but the evidence in Palestine is clear, and is probable in Syria, that there was no disruption but rather an infiltration of newcomers. It can be suggested—but very tentatively—that the recrudescence of copper working, which is a certain fact in Palestine, where for the earlier part of the Early Bronze Age metal weapons are scarce, was due to newcomers from the metal-bearing area to the northeast.

Inland Syria

Early Bronze Age Palestine and coastal Syria culminate in a flourishing urban civilization in the third quarter of the 2nd millennium. In inland Syria, the picture is probably similar. Mesopotamian textual references for this period can seldom be related to the states that emerge in the 2nd millennium. Nevertheless, the references show that embryo cities existed. The economies of the inland states were linked with Mesopotamia, and during the 2nd millennium the desire of the Mesopotamian states for the products of the Syrian coast and the Mediterranean increased. The coastal states were reached by tendrils from Mesopotamia, but their main development came from coastal trade with Egypt. The interlocking trade between Mesopotamia, the Mediterranean, and Egypt was to

reach a fuller development in the 2nd millennium, but its Early Bronze Age development was clear.

It is certain from the survival of certain personal names that the population of Syro-Palestine in this period was Semitic. It can be suggested that these people were Canaanites, but the name Canaan appears only in the 2nd millennium, when coastal Syria and Palestine again shared a common material culture. This culture was not directly derived from the Early Bronze Age culture but emerged as an amalgam after the nomadic incursions described below. It seems preferable, therefore, to reserve the term Canaanite for the 2nd millennium stage, but it is not a distinction where dogmatism is necessary.

The Amorite invasion. In the last centuries of the 3rd millennium the urban civilization of Syria and Palestine suffered a series of setbacks. The inhabitants of the fringes of the Syrian Desert, nomadic or seminomadic pastoralists, warlike in character, succeeded in breaking into the town-centred states of northern Syria and the coastal areas from the Euphrates to the Mediterranean. In the Sumerian language, the invaders were known as Martu and in Akkadian as Amurru—the Amorites of the Old Testament. Their language was West Semitic. By about 2050 they seriously menaced much of Mesopotamia of the 3rd dynasty of Ur (*q.v.*), but their penetration into the settled states of Syria and northern Mesopotamia may have begun as early as the end of the 4th millennium. During the 3rd millennium Amurru kings, recognizable by their West Semitic names, appear in Mesopotamian records, and it is clear that some of the newcomers had settled down and formed small principalities. There remained, nevertheless, a great wandering population not interested in town life; it was these Amurru elements that broke into the settled lands of Syro-Palestine in the last centuries of the 3rd millennium.

Dating the invasion of the Amorites

The precise date of their invasion is difficult to fix and may, indeed, have varied appreciably according to the strength of the different towns and principalities. Pressure on the empire ruled from Ur was serious by the middle of the 21st century. At the other extremity of the Fertile Crescent there was a break at Byblos when trade with Egypt ceased at the beginning of the First Intermediate Period (*c.* 2160), a break probably due both to disruptions at Byblos and to incursions of nomadic Asiatics into Egypt, probably connected with the same population movements. The fact that Asiatic incursions into Egypt had reached this scale by this date supports the Palestinian evidence that the break came about the 24th century. It is reasonable to suppose that the new invaders from the desert fringes penetrated more easily into the weaker states of Palestine and perhaps some of those of north Syria before they affected major Syrian sites, such as Byblos, or endangered the great empires of Ur and Egypt.

The archaeological evidence of the nomad incursions is dramatic. In Syria, great centres such as Ugarit (Ras Shamra) and Qatna (al-Mashrafah [Meshrife']) cease to yield evidence of any built-up town. The evidence of the arrival of the newcomers is provided by graves dug into the slopes of the mounds that had built up over the centuries-long growth of the pre-existing towns. At Byblos, however, the evidence is somewhat different; houses still stood on the town site, but these were different in architecture and scattered irregularly over the earlier built-up area. The most striking point at Byblos is the sudden appearance of a flourishing metallurgic industry that manufactured tools, weapons, vessels, as well as an enormous quantity of presumably votive figurines in copper or bronze. The greater part of these objects were found in votive deposits in sacred areas that may have existed earlier and that certainly continued in existence afterward; the votive deposits, however, belong to this period. The most famous deposit, the Montet jar, after its discoverer, Pierre Montet, is probably to be dated between 2130 and 2040 BC.

Nomadic "tinkers"

Deposits of tin in the neighbourhood of Byblos may have attracted there bands of "tinkers," nomadic groups with no ethnic roots who, through the millennia, have wandered over Asia and Europe. Nevertheless, the archaeological links, in the form of weapons and ornaments, make it clear that this stage at Byblos can be related to the break brought about by the newcomers at such sites as Ugarit and Qatna. Tinkers may have taken advantage of the disruption caused by other populations on the move.

In Palestine, the evidence of the break is even clearer, for the archaeological evidence is more abundant. The new stage is best described as the Intermediate Early Bronze–Middle Bronze period, though others prefer Middle Bronze I, a label given when the significance of the period was not yet clear. The Early Bronze III period ends, as has been seen, *c.* 2300 BC, soon after the end of the 5th dynasty of Egypt. At Jericho there are clear signs of a complete destruction by fire of the final Early Bronze III town. The next houses are preceded by a period when there was only camping occupation, and houses, when they appear, are quite different from those of the Early Bronze Age; the town, moreover, was not walled, and the pottery and other equipment of its occupants were entirely different from that of their predecessors. The presence of the newcomers is, in fact, attested far more by their tombs than their houses, for some 400 have been excavated at Jericho, each containing a single or (rarely) a double burial, in marked contrast to the multiple burials of the Early Bronze Age.

Throughout southern and central Palestine the position is the same—almost no traces of buildings or villages, certainly no towns, but a multitude of tombs. The finds in the tombs and the method of burial fall into a number of groups. At Jericho itself, seven groups have been differentiated. The evidence suggests tribal groups only loosely attached to local centres, a suggestion supported by the practice of some groups of burying—in elaborately prepared rock-cut tombs—disordered and desiccated bones, evidence that the bodies of those who had died during the course of seasonal migrations were brought back in due course to the tribal centre for burial. An urban population had been succeeded by a pastoral, seminomadic population, loosely organized in tribal groups.

Burial rituals

The position is somewhat different at Megiddo and probably Bet She'an (Beth-shan) in the north of Palestine. The break with the Early Bronze Age is equally sharp. The pottery of the newcomers shows that they are linked with, and chronologically contemporaneous with, the groups further south. There seems, however, to be more in the way of town life. At Megiddo at least one of a succession of temples belongs to this period and probably some other buildings of importance. Both the pottery and the metal objects show contacts with Syria. It is probable that the newcomers reached Bet She'an and Megiddo after having passed through the settled areas of Syria and were thus more sophisticated, whereas those who appear further south came more directly from the desert fringes.

The picture is thus similar over the whole of northern Syria and Palestine. The preceding urban civilization was disrupted by wide-scale incursions of seminomadic Amorites. In Syria, the break may have lasted from *c.* 2200 to *c.* 2000. In Palestine, with poorer and weaker urban development, it may have lasted from *c.* 2300 to *c.* 1900.

Middle Bronze Age. In Palestine there is again a sharp break between this period and the Middle Bronze Age, when urban civilization reappears. This is because newcomers again appear, bringing with them a more civilized way of life developed elsewhere. The evidence suggests that the Middle Bronze Age of Palestine is closely linked with that of coastal Syria as far north as Ras Shamra. The evidence suggests that in the region around Byblos, with its urban tradition, the invading Amorites were assimilated into the existing patterns of town life and that the new urban civilization developed that, at least on the coast, can certainly be called Canaanite; it lasted until at least 1200 BC.

Literary evidence. At this stage Syria and, to a much lesser extent, Palestine enter into the light of written history. There is no evidence that the towns of Palestine that developed in the 19th and 18th centuries themselves kept written records, though this may be the accident of sur-

vival or discovery. The historical evidence for this area comes from Egypt. Trading relations with Byblos were resumed under Amenemhet I (1991–1962 BC), first king of the 12th dynasty, who also re-asserted control over the turquoise mines of Sinai and sent an expedition as far north as Shechem. Relations thereafter with Byblos were close. Gifts from Egyptian kings are found in the tombs of the rulers of Byblos, whose Semitic names are written in hieroglyphics. During the 12th dynasty (1991–1786 BC), Egypt maintained close relations with towns in coastal Syria and Palestine by means of representatives whose influence may have varied between that of ambassador and that of a governor.

Evidence from Egyptian records

Egypt thus provides the literary evidence for the coastal and southern areas. For the inland and northern areas there is much fuller evidence based on Mesopotamian contacts and local records of Mesopotamian type, which were kept on baked-clay tablets, thus surviving much better than records on other materials; this evidence interlocks on some of the northern coastal sites with the Egyptian evidence. The main sources from Syria itself come from the archives found at Mari on the Euphrates, which cover a period of about half a century, centred on the year 1800, and the archives of Alalakh ('Atshanah [Atchana]), which cover the period *c.* 1730 to 1655. The picture is one of a unified culture or at least way of life, Mesopotamian in inspiration, stretching from the Euphrates to the coast. Within this broad band, bounded by the Syrian Desert on the south and the plateau of Anatolia on the north, were a number of states of fluctuating importance, to which lesser states were loosely attached. The tie connecting the greater states together was trade. Mari, Carchemish, Aleppo, Qatna, Alalakh, and Ugarit (Ras Shamra) all formed links in a chain between Mesopotamia and the Mediterranean, while Byblos, to the south, played its part both in trade with Mesopotamia and with Egypt.

The princes and ruling classes of most of the states in the first half of the 2nd millennium had a not far-distant nomadic background, having established themselves in the period of disturbance just described following the breakup of the 3rd dynasty of Ur. Iakhdunlim, whose rule began *c.* 1830 BC, and who was the founder of Mari's greatness, was of West Semitic (Amorite) origin. Though Mari was on the right bank of the Euphrates, its territory lay mainly to the east, especially in the triangle formed by the River Khabur and the Euphrates. For a time, Mari fell under the control of Shamshi-Adad I of Syria but on his death was recovered by Zimrilim, son of Iakhdunlim. Though Zimrilim was constantly engaged in warfare against other states and against the ever-present menace of desert nomads, such as the Benjaminites, the records found in his palace show the wealth of trade that passed through his capital and the ambassadors that he maintained at foreign courts, while the remains of his enormous palace are one of the most impressive pieces of evidence recovered by archaeology as an illustration of the advanced urban civilization of the period.

Mari

One of the other most important states of the time was Iamkhad, with its centre at Aleppo, which rose to importance under Iarimlim, *c.* 1775 BC, also Amorite in origin. The kingdom of Iamkhad stretched from the Euphrates to the Mediterranean coast, with Alalakh and Ugarit as vassal territories. All trade from the Mediterranean countries to Babylonia that did not go by the desert route via Palmyra passed through Aleppo. Qatna, on the Orontes, the rulers of which again were Amorite, bordered Iamkhad to the south and was another independent and important state. Qatna was the southernmost of the major Syrian states. To the south was the general area of the Amurru, where petty Amorite princes ruled small areas.

From place-names and the names of their rulers, the states of north Syria can be identified as Amorite (West Semitic). There exists, however, a substratum of names of persons and places of which the ethnic significance is not clear; presumably this represents the indigenous population of the Neolithic and Chalcolithic periods for which the history, described above, can be based on archaeology alone. In addition, during the first half of the 2nd millennium a new element becomes increasingly important—that of the Hurrians. The Hurrians appear in Mesopotamia east of the Tigris, probably coming from the northeast, in the mid-3rd millennium. Their spread, from *c.* 1800 onward, is marked by an increasing number of names, and they seem to have secured positions of importance in the administrations of a number of states. They remain, however, a minority until the second half of the millennium.

Rise of the Hurrians

Archaeological evidence. The wealth of literary evidence for this period in Syria means that archaeology has not the importance there that it has, as will be seen, in Palestine. Only four sites have been excavated on a large scale: Mari, Ugarit, Alalakh, and Byblos. Mention has already been made of the great palace of Mari. All the sites excavated show royal buildings and town life on an imposing scale, though lesser than that of Mari. There are two aspects on which archaeology throws important light. The first is that there was a clear difference in culture between coastal and inland Syria. Evidence for this is provided by the pottery and other objects of common domestic use. The disruptions caused by Amorite movements at the end of the 3rd millennium brought about a complete break in the ceramic traditions. When urban life was re-established, a completely new repertory of pottery forms came into use, which probably developed in the neighbourhood of Byblos. Vessels closely similar in form came into use, from Ugarit in the north to the extremities of the Mediterranean. In inland Syria (*e.g.*, at Alalakh, Qatna, and Ḥamāh) the forms are for the most part quite different, being more closely allied to those of Mesopotamia. The coastal area where this new pottery appears is subsequently known as Canaan (though it includes an area to the north), and it is reasonable to give the new culture there the name Canaanite.

The second aspect upon which archaeology throws light is that of the defenses of a number of towns. It will be convenient to deal with this aspect in connection with the evidence from Palestine.

The history of Palestine at this time, in contrast to that of Syria, is based almost entirely on archaeology. The towns of Palestine were not of sufficient importance to receive much attention in the Mari archives, and the only site to be mentioned is Ḥazor. The evidence from Egyptian sources has already been mentioned, but it is slender in comparison with that for the Syrian states. On the other hand, the archaeological evidence is far more copious than in Syria.

Sometime after 1900 BC there is a break as sharp as that which brought the Early Bronze Age to an end. A completely new culture appears, that of the Middle Bronze Age. The direction from which it came is clear, for the new pottery's appearance in coastal Syria has just been described. The best example for the pottery in Syria is at Kafr Djarra. The newcomers were probably at first few in number, but they fairly rapidly stimulated a revival of town life. Almost all the old sites of the Early Bronze Age that had been deserted or sparsely occupied during the Intermediate period became walled towns again. The earliest city to regain its importance was Megiddo, where town life had not been completely interrupted. Excavations there have shown a long sequence of levels of well-built houses and fortifications, and mention of connections with Egypt stress its outstanding position.

The full urban development of the Middle Bronze Age seems to come only in the late 18th century. The most striking evidence of this is at Ḥazor, in the Jordan Valley north of Lake Huleh. The first Middle Bronze Age occupation there was confined to the area of the mound that marked the site of the Early Bronze Age town. To this town was added, probably in the second half of the 18th century, a vast new area, enlarging the site to about 182 acres. This area was built up with houses and temples and was defended by an entirely new type of fortification, consisting of a great earth bank with a wall on the top. Defenses of the same sort, an earth bank usually with a plaster facing, are found at many sites, such as Jericho, where it can be dated to the late 18th century BC, Megiddo, Tel Bet Mirsham (Tell Beit Mirsim), and Tel

New defensive works

Lakhish (Tell Dnweir), though at these sites the bank is for the most part backed against the earlier mound. Two important sites in the south Tell el-Ajjul and Tall al-Farʿah, seem first to have been occupied only when this new type of fortification was coming into use.

There is a particular interest attaching to this type of fortification, since it is found over a wide area in Syria and Palestine. At Carchemish on the Euphrates, at Ugarit on the coast, and at Qatna on the Orontes, a similar great expansion outside the area of the original town takes place, defended by similar massive ramparts. It will be noted that these sites include both the cultural areas (inland and coastal Syria) described above. The defenses are similar, but the culture is different. The clear suggestion is that when the important states of the 19th and 18th centuries were beginning to weaken, a new warrior aristocracy was acquiring influence and introducing new methods of warfare. There is a strong probability that these warriors came from the nomadic tribes of the Syrian Desert, the Semitic Benjamites, and the Ḫapiru (Habiru, ʿApiru) who may have been nontribal warrior bands, against whom Zimrilim of Mari, for instance, was continually at war.

The invasion of the Hyksos

This is, in fact, the period at which the 12th dynasty of Egypt succumbed to pressure of Asiatics, first perhaps infiltrators, then invaders—the so-called Hyksos, whose capital was established in the Delta by *c.* 1720. It is thus very significant that a site defended by earth ramparts appears at Tall al-Yahūdiyah (Tell el-Yahudiyah) near Cairo, together with pottery partly native Egyptian but partly linked with Palestine.

The flourishing period of states ruling large areas in Syria thus seems to come to an end in the 17th century. The kings and princes known from the written records are much less imposing. Town life goes on, and the towns of the end of the Middle Bronze Age in Palestine are certainly flourishing. It is reasonable, however, to conclude that it is a period when the warriors from the desert had succeeded in imposing their rule in many places, with effects extending from the Euphrates to Egypt.

(K.M.K.)

II. Syria and Palestine, c. 1550 BC–AD 634

THE ERA OF THE EGYPTIAN AND HITTITE EMPIRES, C. 1550–1200 BC

The struggle of the Great Powers for Syria and Palestine. When Kamose of Thebes raised the standard of revolt against the Hyksos—the hated foreign rulers of Egypt—in the second quarter of the 16th century BC, he could not have known the profound effect his action would ultimately have on the history and civilization of western Asia. For Kamose's successors, the first pharaohs of the 18th dynasty, pursued their erstwhile masters into Palestine and at the same time began to evince imperial ambitions of a totally new scale. Although close trade relations had existed between the Nile Valley and the countries of the Levant since about 3000 BC, and although during the Middle Kingdom (*c.* 2040–1786 BC) these relations had been reinforced by something approaching political control over such coastal cities as Byblos, it was not until the 18th dynasty that the Egyptian armies regularly treaded the roads of Syria and that Syrian taxes regularly swelled the Egyptian treasury.

Egyptian hegemony over Palestine and Syria

The Egyptians. The growth of Egyptian hegemony over Palestine and Syria is relatively well documented in the inscriptions with which the pharaohs embellished their temples, and the main stages of that growth are clear, though many problems of chronology and historical geography remain. To the first stage belong the activities of the first four rulers of the dynasty—Ahmose (reigned 1570–1546), Amenhotep I (1546–1526), Thutmose I (1525–*c.* 1512), and Thutmose II (1512–1504). The initial campaigns of Ahmose into Asia seem to have been on a relatively small scale, and progress was slow, despite the Egyptian chariotry. An indication of the Asians' resistance to the Egyptians is the fact that the town of Sharuhen in southern Palestine (probably Tall al-Farʿah near Gaza) withstood a siege of three years before it was taken, and it was probably not until the end of his reign that Ahmose reached northern Palestine. The pace of conquest, however, seems then to have accelerated. No information concerning the campaigns of Amenhotep I has survived, but the Egyptian position in Palestine must have been consolidated and some advance made into Syria, for, as early as the second year of Thutmose I, the Pharaoh claims to have made the Euphrates his frontier and is said to have erected a victory stela on the bank of that river. Thutmose's claim was clearly exaggerated and premature; Egyptian authority was by no means yet permanently established anywhere in Asia, and the records show that Thutmose's son, the second of that name, campaigned against rebellious native rulers in areas that his father had already tried to pacify. Egypt could not yet maintain permanent armies of occupation or establish an imperial administration in Syria and Palestine. Nevertheless, its achievement in Asia by 1500 was spectacular, reflecting the determination and dynamism that characterized the new royal house of Thebes.

The second stage in the establishment of Egyptian empire in Asia began with the assumption of power by Thutmose III in 1482 (after a coregency with his stepmother Hatshepsut) and covered the rest of the 15th century. Before turning to this, however, it is necessary to describe briefly the conditions found by the Egyptians in Palestine and Syria during the initial phase of conquest. Evidence for this is quite inadequate: the surviving written records are meagre and difficult to interpret, while the archaeological evidence is uneven and equally doubtful. It would appear that, although the whole area of Palestine and Syria consisted of more or less independent principalities centring upon strongly fortified cities, there were striking differences in ethnic composition and political organization between the north and south. In Palestine, the population was still almost exclusively West Semitic, speaking a language that scholars variously designate as either Amorite or Canaanite, and there is as yet little sign of the non-Semitic speaking peoples—Hurrians and Indo-Aryans—who were already well established farther north. Archaeology shows that the Palestinian towns were strongly fortified (witness the defense of Sharuhen, mentioned above), prosperous if not luxurious, and ruggedly independent in both their political life and their culture. Above all, there is no sign of external interference in their affairs prior to the Egyptian invasion, though lack of documentary evidence prevents scholars from knowing how much interstate rivalry and warfare existed. Many excavated towns show signs of having been destroyed about the middle of the 16th century and abandoned for a time thereafter. At some (*e.g.*, Tall al-Farʿah) this is clearly the work of the Egyptian armies, but at others, and especially those off the main routes (*e.g.*, Jericho, Tel Bet Mirsham [Tell Beit Mirsim]) the devastation could have been caused by marauding bands of Asians taking advantage of the troubled times.

Conditions during the initial phase of conquest

Mitanni. In Syria, the population on the eve of the Egyptian invasion was much more mixed, and political conditions were much less stable. From early in the 2nd millennium, people speaking a non-Semitic language known as Hurrian had been spreading from their homeland—probably in eastern Anatolia—and had established themselves alongside the older Semitic population in the northern Mesopotamian and Syrian cities. By the 16th century, the principalities of northern Mesopotamia seem to have coalesced to form a unified state, known as Mitanni, the rulers of which (judging from their names) belonged to yet another ethnic group, the Indo-Aryan. Mitanni soon became a powerful force, and it is generally supposed that one element of its strength was the progress made by the Hurrians in developing, if indeed not inventing, the light horse-drawn chariot as a weapon of war. The affairs of Mitanni belong properly to Mesopotamian history; but it is relevant to note that the 16th century in northern and central Syria was a period of political turmoil, in which the kings of Mitanni tried to assert their authority, by intrigue or by war, over such Syrian states as Aleppo, Mukish (in the Plain of Antioch), and Qatna (modern al-Mashrafah). It was no doubt because of the

Political turmoil

instability of the area that Thutmose I and II were able to bring Egyptian arms to the Euphrates with such apparent ease; but it was also because of the growing might of Mitanni that these same pharaohs were unable, by 1500, to consolidate their position satisfactorily in the north.

Dynastic quarrels within Egypt at the beginning of the 15th century were largely responsible for a hiatus in its Asian adventure, but, with the accession to full authority of Thutmose III in 1482, the situation changed. The Asian princes were aware of the challenge presented them by the young soldier-pharaoh, and a coalition was organized to oppose him. No fewer than 330 Palestinian and Syrian rulers were involved in the revolt, led by the Prince of Kadesh (modern Tall an-Nabī Mind, near Homs) and including many of the Hurrian and Indo-Aryan *mariyanna*, or warrior aristocracy, that by now were prevalent throughout the region. Such was the might of Egypt, however, that Thutmose had little difficulty in smashing the confederates at Megiddo in northern Palestine (1480). The ferocity of Thutmose's punitive measures is indicated by archaeological evidence that this site was probably completely deserted for most of the 15th century. With this battle it may be said that Egyptian authority in Palestine was firmly established, and it was to remain unchallenged for more than a century; this was the Golden Age of empire. The same was not true, however, of the northern marches. There the power of Mitanni continued to thwart the Egyptian design, and, although Thutmose III was able, in the years immediately following the fall of Megiddo, to defeat "the wretched Mitannian foe" at Aleppo and Carchemish, the situation in Syria remained unresolved, with the major cities changing hands almost annually. While Thutmose was alive, the balance of power was mostly in Egypt's favour, and it is possible that a treaty of peace between the Pharaoh and Saustatar of Mitanni at this time led to an uneasy relaxation of tension. But the old Pharaoh died in 1450, and this was the signal for a revolt by the cities of the Orontes Valley (*e.g.*, Kadesh, Tunip). The first campaign of Amenhotep II (1488) repressed this with savagery: the Pharaoh executed the rebel princes with his own hand, and their bodies were exposed in the Egyptian capital as part of the paean of victory. Such ferocity, however, had no lasting effect. In the seventh year of his reign, Amenhotep was obliged to march again against many of the cities that he had reduced only a few years previously; and, two years later, even Palestine seems to have been in revolt, and 70,000 captives are reported to have been sent to Egypt. These revolts were no doubt instigated and fostered by the Mitannian kings.

Revolts against the Egyptians

The Mitannian opposition to the Egyptian imperial design was ending, however, though through no wish of the Mitannian kings. A new power, that of the Anatolian state of Khatti, was rising on the northern horizon, and its threat to both Mitanni and Egypt induced the rulers of these empires—Thutmose IV and Artatama—to conclude (*c.* 1425) another treaty of peace, later sealed by the Pharaoh's marriage to a Mitannian princess. The empires agreed on respective spheres of influence; slightly later documents indicate that Egyptian control stretched as far as Ugarit on the Syrian coast and inland as far as Tunip (probably west of modern Ḥamāh) and Damascus. North and northeast of this boundary the Mitannian held sway, in such cities as Qatna, Aleppo, and Carchemish.

The Hittites. The history of the Egyptian Empire in Asia during the century following the détente with Mitanni was marked by the same kind of boundary fluctuations and internal revolts that had characterized its earlier development. There were, however, two important differences: the pharoahs of the 14th century were weak, whereas those of the 15th had been strong, and the enemy in the north was no longer Mitanni but the Hittite state. Before 1400 the Hittites had hardly impinged upon Syrian history, though as early as *c.* 1595 Mursilis I of Khatti had destroyed the cities of Aleppo and Alalakh and had marched as far southward as Babylon. These events had left little permanent trace on Syrian affairs, however, and the Hittites in the 16th and 15th centuries, preoccupied with domestic matters, played only a minor role in Syria compared with that of the Mitannians. The fact that Idrimi, king of Mukish, was able to attack with impunity a number of Hittite towns toward the end of the 16th century is illustrative of the prevailing situation. Despite some temporary success in the 15th century in imposing their authority over some of the most northerly Syrian towns, the Hittites at that time could hardly be considered a Syrian power.

The event that, more than any other, can be said to mark an end to this situation was the accession (1380) of Suppiluliumas to the Hittite throne. Suppiluliumas was a young, ambitious soldier who saw his imperial destiny in Syria. The immediate enemy was Mitanni, and the Hittite king took pains to preserve formally correct, though undoubtedly cool, diplomatic relations with Egypt. Having reorganized his homeland, he embarked, in about 1365, on his first Syrian campaign. Tushratta of Mitanni was unable to oppose him; most of the country from the Euphrates to the Mediterranean as far south as Lebanon fell. And, although the Mitannian king was the loser and the Egyptian vassal cities such as Ugarit and Kadesh seem to have remained loyal to Pharaoh, the potential threat posed to the Egyptian Empire could not be ignored.

The accession of Suppiluliumas

The threat, however, was not yet a direct one. The result of the Hittite victory in Syria was to upset the balance of power; it removed Mitannian control but did not replace it with equally strong Hittite rule. Although some of the Syrian principalities became Hittite vassals, others, particularly those in the south, took the opportunity to assert their independence and follow their own ambitions. The state that most clearly shows this development is Amurru, which had existed, apparently quietly, for many centuries between the southern Orontes and the Mediterranean, in what is now largely Lebanon. Since the time of Thutmose III, the princes of Amurru had been content with their vassalage to Egypt, but, at the beginning of the 14th century, the new ruler, Abdi-Ashirta, had begun to exert some independence and to extend his territories. The Hittite successes gave him further opportunities, and a number of cities loyal to Egypt were taken by him.

Abdi-Ashirta was also helped by internal difficulties in Egypt. In 1379 Akhenaton (Amenhotep IV) had come to the throne; he had soon shown himself to be untypical of the rulers of the 18th dynasty—he was a mystic rather than a soldier and a thinker rather than a doer. This was a time of religious revolution in Egypt, and the Pharaoh had to attend to things in the new capital Akhenaton (modern Tell el-Amarna) that were more important to him than the defense of his Asian provinces. Much detailed information is known of this period from an archive of diplomatic letters found at Amarna, many of which are either from or to the princes and the Egyptian officials in Palestine and Syria. In them are seen the continued appeals of loyalists such as Rib-Adda of Byblos to the Pharaoh for aid against rebels such as Abdi-Ashirta; rarely is there evidence of any such aid being given. In the circumstances it is not surprising that the spirit of independence and rebellion that had manifested itself in Amurru should spread farther southward also, into Palestine. The Amarna Letters show Labaya of Shechem and Milkilu of Gezer seeking to aggrandize themselves at the expense of their neighbours, while Shuwardata of Hebron is in conflict with Abdi-Kheba of Jerusalem, to the consternation of the Egyptian governor.

The Amarna Letters

This same Labaya is seen in the Amarna Letters to belong to a group called the Hapiru. There are many other references to this group. The same word, or an equivalent, is found in many documents, in many different languages, throughout the Near East, ranging from the 20th to the 12th centuries BC; and, although its precise meaning in any particular context is a matter for scholarly debate, there is general agreement that the word basically denotes a social class rather than an ethnic group and refers to people who were stateless or outside the law —*e.g.*, bandits, mercenaries, vagabonds, or peddlers. Clearly, the majority of such people can have had little influence on the course of history, though some few of

them—Labaya, for example—played an important role. But the word Hapiru is probably related to the word Hebrew (though there is no agreement on this, despite voluminous scholarly discussion), and it is possible that the troublemaking groups who appear under this name in the Amarna Letters are related in some way to the people who later settled in Palestine, as their Promised Land.

The troubles that disturbed Egyptian rule in Palestine were not resolved until the accession of Seti I at the very end of the 14th century; but meanwhile there had been developments adverse to Egypt in the north. Although Suppiluliumas had achieved a spectacular victory in his First Syrian War, it was not a permanent one; Mitannian influence was still strong and was able to foment a revolt of the major cities—*e.g.*, Aleppo, Alalakh, Qatna, and Kadesh—against the Hittites. The revolt was easily crushed by Suppiluliumas (*c.* 1360), and the triumphant Hittite progress, as far southward as Damascus, marked the final end of Mitannian aspirations in Syria, and indeed the end of the Mitannian empire. All Syria fell under Hittite sway, including Ugarit, which hitherto had been friendly if not wholly subservient to Egypt. In the south, the Hittite troops entered Damascus—a clear infringement of Egyptian suzerainty—while Suppiluliumas concluded a treaty with Aziru, Abdi-Ashirta's successor in Amurru, and encouraged him to wrest from Egypt the remaining coastal cities, as far south as Sidon and including Byblos, which had been the jewel of Pharaoh's Asian crown. Just before midcentury, a series of rather half-hearted attempts was made by the new pharaoh, Tutankhamen (reigned 1361–52), to reassert his authority in southern and central Syria. But the Hittite enemy was too strong, and Suppiluliumas consolidated his position on all sides. When Suppiluliumas died in *c.* 1336, all Syria was under firm Hittite control.

The end of the Mitannian empire

So affairs stood for another generation. Seti I, the second pharaoh of the 19th dynasty, shook off the torpor that had afflicted his predecessors and set about re-establishing Egyptian authority in Asia. His first concern was Palestine, which, although technically still an Egyptian province, was so unstable as to be more a liability than an asset. The fact that Seti was able to reach the northern part of the country during his first campaign, however, shows that many Palestinian cities had remained loyal to Egypt. Victory stelae erected at Bet She'an show that the Egyptian army relieved that city, under attack from an alliance of two neighbouring towns, and repulsed some bands of troublesome Hapiru from the mountains of Jordan. This campaign seems to have established Egypt's position once more in Palestine, but Seti's main purpose was to restore its position in the north. In this he achieved a certain measure of success, and, when he died, the effective boundary between the Egyptian and Hittite spheres of authority was probably as far north as Kadesh, while the King of Amurru had been forced to abrogate his treaty with the Hittites. Meanwhile, the Hittite king, Muwatallis, was planning to meet the renewed challenge to his empire. When the new pharaoh, Ramses II (reigned 1304–1237), advanced into Syria to carry on the work of his father, the Hittite forces were massed to meet him at Kadesh, and there they fought (*c.* 1300) perhaps the most famous battle of preclassical antiquity. Although militarily a draw, the battle represented a strategic defeat for the Egyptians, who retired to Palestine; and, although the Egyptians made extended raids back into northern Syria in subsequent years, the Battle of Kadesh had finally killed all chance of a northern Asian province being reactivated by them. Syria remained solidly under Hittite control.

The Battle of Kadesh

The final episode in the history of the Egyptian and Hittite rivalry in Asia was a peaceful one. The threat provided by a rising power, Assyria, led Ramses II and the Hittite ruler Hattusilis III to settle their Syrian dispute once and for all with a treaty of friendship (*c.* 1284) and subsequent dynastic marriages. The text of the treaty, which has survived, makes no mention of a frontier, but it can be safely assumed that the status quo was endorsed and that the effective boundary lay along a line from about Damascus to somewhere north of Byblos. The treaty ended the long series of imperial contests that had been waged over Syria; and, although the Egyptians were left to put down many a revolt in their Palestinian province, and the Hittites to defend their Syrian vassals from the nascent ambitions of Assyria, the Levant was to remain at relative peace until late in the century.

Organization and culture. The cultural history of the Levant during the 16th–13th centuries BC—the Late Bronze Age of the archaeologists—seems to disprove the theory that civilization requires peaceful conditions in which to flourish. Although Syria and Palestine were torn by imperial contests, the period witnessed remarkable achievements in art, architecture, and literature, and the general level of material culture was perhaps higher than it would be again in the region for more than 1,000 years. Before looking at this culture, however, it is necessary to consider the political, economic, and social organization of the region.

Political organization. At the beginning of the period, the basic political unit in both Syria and Palestine was the city-state. In some cases, particularly in the south, these comprised no more than the city itself and its immediate surroundings; but others, mainly in the richer, more fertile north, had already grown into sizable kingdoms, of which Iamkhad, with its capital at Aleppo, and Kinza, with its capital at Kadesh, were among the most important. As the Egyptians and Hittites extended their authority over the area, both allowed this political fragmentation to persist, while at the same time attempting to bring about some sort of centralized control into their own hands. Because of the greater volume of extant texts from Egypt, more is known about the administration of the Egyptian area than about that of the Hittite, and it is difficult to compare the two systems in detail. It seems that in both areas the local rulers became vassals of pharaoh or king, as the case might be, bound by written treaty to him. The local rulers had to help their overlord in time of war, pay tribute and organize forced labour, extradite fugitives and refugees, keep the central government informed of local events, and renounce all rights to an independent external policy. In return, the great king or the pharaoh confirmed them in their kingship and protected them from their enemies. If the local rulers fulfilled their obligations, renewed their oaths of allegiance, and did homage on the appointed occasions, they seem to have been left a considerable measure of independence in the conduct of their own affairs.

This essentially feudal system seems to have suited the Hittite kings; their Anatolian homeland was organized in much the same way—as a confederation of vassal states—and the administrative system of the Hittite Empire was feudalistic throughout. In the Egyptian territories the Asian lands were, in theory, an integral part of the pharaoh's realm, and, although it was clearly impossible in practice to integrate the African and Asian domains under one monolithic system of government, a much greater effort does seem to have been made by the Egyptian rulers than by the Hittite to keep the vassal princes under strict military and administrative control. To this end viceroys and governors were appointed, directly responsible to the pharaoh, and Egyptian Asia was divided into three provinces. In the north was the province of Amurru, covering modern Lebanon north of Byblos and the contiguous parts of Syria; its capital was Sumuru (identified with Tall Kazel, near modern Tripoli). East of this was Upi, extending from Kadesh to the northern part of Transjordan; Damascus was its principal city, but the administrative centre was Kumidu (today the village of Kāmid al-Lawz, in southern Lebanon). Finally there was Canaan, comprising all Palestine (though not Transjordan) and the coast as far as Byblos, where its boundary ran with that of Amurru; the capital of Canaan was Gaza (Tell el-Ajjul), in the south of the country. During the vicissitudes of the empire, the exact boundaries of the provinces changed, and eventually the province of Amurru was lost, as seen above, to the native dynasty of Abdi-Ashirta, while, before the end of the period, Upi seems to have been fused with Canaan to form a single province, sometimes called Huru. General names, impos-

Egyptian Asia

sible to locate precisely, used by the Egyptians for the whole of their Asian lands, were Retenu and Djahy.

The people of the Levant. During this time the population of the Levant began to assume the heterogeneous character it has had ever since. The Hurrian and Indo-Aryan elements that were already well established in the north in the 16th century, side by side with the older West Semitic stock, had, 100 years later, spread throughout Syria and appeared in Palestine. At the time of the Amarna Letters, many of the Palestinian rulers had Indo-Aryan names, while the name of the king of Jerusalem, Abdi-Kheba, is compounded of the West Semitic word for "servant" and the name of the Hurrian earth goddess Khebat. In general it seems that, just as the Indo-Aryans had established themselves centuries before in Mitanni as the ruling aristocracy of the Hurrian people, so now in southern Syria and Palestine they had achieved a similar position vis-à-vis the Semitic population. Many of the names used in the Old Testament to denote the pre-Israelite inhabitants of Palestine—*e.g.*, Hivites, Jebusites, Girgashites—can be assumed to refer to Indo-Aryan groups, while the Horites are almost certainly the Hurrians. Palestine never became so permeated with non-Semitic peoples, however, as did the region north of Damascus, as is proved by the language of the Amarna Letters. This is Akkadian, the diplomatic language of the time; but the letters written from Palestine are full of West Semitic (Canaanite) words, expressions, and syntax, reflecting the native tongue of the scribes. Far more Hurrian influence is discernible in the letters and other documents from farther north.

Agriculture and stock raising

The economy. The basis of the Levantine economy was agriculture and stock rearing. Although not as fertile as the Egyptian and Mesopotamian alluvial valleys, parts of Syria and Palestine were very favourably suited to the production of certain commodities, particularly grapes and olives on the seaward-facing hill terraces, barley and wheat on the plains of central Syria, and sheep and goats on the poorer steppelands of the interior. Cattle and (after their introduction early in the 2nd millennium by, probably, the Hurrians) horses were also raised. These products were traded widely. The northern part of the region was generally richer agriculturally than the southern, a fact reflected in the greater size and importance of the Syrian city-states as compared with those of Palestine. But this inequality should not be exaggerated. The vast booty taken by Thutmose III at the Battle of Megiddo included great numbers of cattle, sheep, and goats, and, even when allowance is made for Egyptian hyperbole, this suggests that the larger cities of Palestine were by no means economically backward.

The prosperity of the Levantine cities depended mainly upon trade, not only in agricultural products but also in raw materials, especially the timber of the Syrian and Lebanese mountains. The Syrian and Palestinian merchants were well placed to handle—or to hinder, if they so wished—the caravan traffic (which at this period still relied on donkeys) between Anatolia, Mesopotamia, and Egypt, and the relative status and prosperity of the cities varied according to the extent to which they controlled the major routes. Trading was nothing new to the Levant, and archaeology reveals evidence of such commerce from earliest times. In the 3rd millennium a flourishing sea traffic had developed along the Levantine coast, blessed with many natural harbours; and a new dimension was added to this maritime activity in the 2nd millennium, when contact was made with the Aegean world. Already as early as 2000 BC some exceptionally favoured towns on the Syrian coast—*e.g.*, Byblos and Ugarit—had had relations with Crete. But it was not until just before the beginning of the period just described that trade with the West became important, with progress in marine architecture and navigational science making longer voyages possible. As evidence for this, from about 1600 BC Cypriot pottery is found in increasing quantities on all excavated sites; it is accompanied in the 14th and 13th centuries by beautiful Mycenaean ware, probably exported from Greece itself. The importance of the Western trade is shown by the fact that colonies of Minoan, and later Mycenaean, merchants were to be found at Ugarit and probably elsewhere. Egyptian tomb paintings show that Palestinian and Syrian merchants commonly visited, and perhaps resided in, Egypt, and it is likely that some were also found in the ports and marts of Cyprus and the Aegean.

The expansionist policies of both the Hittite and the Egyptian states were largely the result of their desire to control the Levantine trade and to secure the natural wealth of the region for themselves. At the same time, the increasing needs and demands of the great empires produced very favourable economic conditions in Syria and Palestine, and in general terms the Late Bronze Age in the Levant can be considered a time of economic boom. It has been suggested, it is true, that the oppressiveness of the Egyptian administration, in particular, resulted in the impoverishment of Palestine during the latter part of the period; but, although there were undoubtedly economic fluctuations and although certain cities clearly suffered from the punitive measures of the pharaohs, it is likely that this suggestion is based on inadequate archaeological and textual evidence and that the general level of culture and prosperity at the end of the period in Palestine was higher than it had been at the beginning, as was clearly the case in Syria.

Economic development

Culture. The Levant of the Late Bronze Age was thus a region of prosperous commercial and agricultural city-states, normally in some sort of vassalage to either the Hittite or Egyptian empires, populated by a mixture of Semitic, Hurrian, and Indo-Aryan peoples, and constantly visited by foreign soldiers, administrators, and merchants. The hallmarks of both its material and its higher culture were therefore cosmopolitanism, eclecticism, and diversity. This last should be stressed first, for it explains why any attempt to generalize about the appearance of the Levantine towns of the period, or about the paraphernalia of life within these towns, is doomed to failure. From one end of the region to the other there was a bewildering variety of architectural styles, building materials, fashions in pottery and other utensils, burial customs, and the like, which defy categorization within the limits of a short article and which can only be studied in the archaeological handbooks. Temples, for example, varied in plan from the small rectangular structure outside the walls of Lachish (Tel Lakhish, in central Palestine), through the amorphous, extensive "courtyard" temple of Bet She'an and the massive monocellular "Fortress Temples" of Megiddo and Shechem, to the tripartite sanctuaries of Hazor and Alalakh, on which the Temple of Solomon in Jerusalem was later modelled. Even the siting of the temples varied from place to place: on the acropolis at Ugarit, for example, but in the centre of the flat "lower town" at Hazor. At Jericho the dead were commonly buried in rock-cut family vaults outside the city; at Ugarit, in beautifully constructed masonry chambers, perhaps of Aegean inspiration; at Megiddo, in small individual graves, beneath and between the houses. There was, perhaps, greater uniformity in the styles of such utilitarian objects as pottery, tools, and weapons, though even here it is possible to discern regional differences.

In face of such diversity, any brief review of the material culture of the Late Bronze Age Levant must confine itself to an indication of some of the more important surviving monuments and objects. Pride of place must go to the remains excavated at Ugarit, for these show what heights the Canaanite artists and architects could attain.

The royal palace at Ugarit

The royal palace at Ugarit—the residence of the king and the administrative centre of the state—was, in the 14th and 13th centuries BC, one of the most imposing and famous in all western Asia; the King of Byblos wrote his Egyptian masters that only the palace of Tyre could rival it. At its greatest extent it covered an area of some two and a half acres (one hectare); but it originated as a much smaller structure. In time the palace building was repeatedly enlarged; the final building was amorphous and irregular but of great charm and luxury. Many of its features—*e.g.*, courtyards, burial chambers, piped water, and drainage—were to be found also in the houses of the well-to-do inhabitants of the city, who lived around

the palace; their houses confirm the impression that Ugarit was a very wealthy city.

Nowhere else in the contemporary Levant is such luxury encountered, but this must be partly due to the chances of discovery: Tyre, at least, must have been as rich, if the King of Byblos is to be believed. At nearby Alalakh the slightly earlier palace of King Niqmepa was a much smaller and compact edifice, though based on the same basic plan of portico, main room, and courtyard. Only the lower parts of the walls were of stone—rubble faced with basalt slabs—and the superstructure was of mud-brick, strengthened by wooden beams. This style of construction may have been of Anatolian origin, though it had appeared in Syria, at Alalakh, as early as the 18th century, where King Yarim-Lim's palace is constructed in like fashion. It is found as far south as northern Palestine —*e.g.*, at Hazor and Megiddo—where the quality of the masonry in the temples and fortifications is little inferior to that of the Syrian towns. Farther south, the greater prevalence of simple mud-brick construction, with or without stone foundations, may suggest an indigenous tradition of building or perhaps one inspired by Egyptian contacts. Certainly the architectural forms and devices of Egypt were well-known in Palestine, particularly in the Egyptian garrison and government centres such as Bet She'an, where fragments of Egyptian cornices and papyrus capitals have been found in the ruins of the Late Bronze Age temples.

In Palestine, only at Megiddo has a building been discovered whose plan is at all comparable to the palaces of Ugarit and Alalakh, though it is much smaller than the former of these. Otherwise, the chief surviving monuments of Late Bronze Age Palestine are the temples, of which (as already indicated) there is a wide variety of types, reflecting the diversity of cults that existed.

In other fields of artistic expression, the Levantine peoples of the Late Bronze Age produced work of uneven quality. Sculpture in the round does not seem to have been a favoured art form; little survives, and what does is poor. Greater success was achieved in relief sculpture, though here, too, examples of first-class work are few. The stela of a weather god from Ugarit deserves mention, as does one with two scenes of combat between a lion and a dog from Bet She'an, showing that good quality work was not a prerogative of Syria.

Crafts

If carving in stone was not a Levantine forte, carving in ivory was. The origins of this craft must be sought long before the period being described, perhaps in an indigenous school of wood carving, perhaps stimulated by the ancient bone- and ivory-carving tradition of Egypt, going back to predynastic times. In the early 2nd millennium, bone inlay work was a flourishing craft in Syria and Palestine; the increased prosperity of the Late Bronze Age fostered the use of ivory, which was readily available in the herds of elephants that still roamed the valleys of the Euphrates and the Orontes, where the pharaohs were wont to hunt them for recreation. Ivory was used for ornaments, toilet articles, and furniture inlay, and a variety of techniques—*e.g.*, engraving, high- and low-relief carving, openwork—was developed. Most of the finest examples came from the 13th-century palace of Ugarit, and the actual amount of ivory used there (one openwork tabletop, for example, measures more than three feet [one metre] in diameter) testifies again to the extraordinary wealth of this city. But other specimens have been discovered—*e.g.*, at Megiddo, in a cache hidden under the floor of the palace already mentioned, indicating that such *objets d'art* were also prized in at least the more important Palestinian cities. Many pieces are first-rate works of art, worthy to stand beside anything the ancient world produced. But they are also the most striking evidence for the eclectic nature of Canaanite art, for often, in a single piece, are seen motifs and conventions derived from the art of the surrounding countries, combined with such skill and assurance as to produce a design that is homogeneous and uniquely Canaanite. Much of the originality and charm of Canaanite art lies, indeed, in the way in which Egyptian motifs were "misunderstood" in this way and used in manners that the convention-bound artists of the Nile Valley would have thought impossible (*e.g.*, the constant reproduction in Syro-Palestinian art of the sphinx—always male in Egypt—as female). The habit of looking at things in a different way is a characteristic of Canaanite art and gives it a freshness and unexpectedness unknown in Egyptian art before the 14th century, when, because of the Levantine influence that then began to stream back into the Nile Valley, Egyptian art also shook off some of the rigidity that it had acquired during the long centuries of its existence.

Fine metalwork and the engraving of cylinder seals were also art forms in which the people of Syria and Palestine excelled. The former craft arose, probably under Egyptian inspiration, at the beginning of the 2nd millennium. From the very beginning of the Egyptian–Hittite period, several hoards of fine gold jewelry from Gaza (Tell el-Ajjul) are distinguished by many fine specimens in granulation, cloisonné, and repoussé techniques. The designs, particularly pendants with female figures or heads on them, are strongly Egyptian in effect, though many of the details are un-Egyptian, and there is no doubt that they were made by local craftsmen. Similar ornaments come from Ugarit, but the most famous examples of goldwork from this site are decorated bowls of the 13th century. One of these shows a common western Asian theme—the chariot hunt—but treats it more realistically than did Egyptian and more decoratively than did Assyrian artists; it comes closest to the Mycenaean artists' conception of the hunt, though it is perhaps not quite so fine. Another bowl has a frieze in which animals, natural and unnatural, humans, plants, and magical symbols—all the iconographic gleanings of ancient western Asia—are loosely combined into an irregular, unbalanced design, the very uncanonicity of which defines it as Canaanite. The same could be said of most of the cylinder seals, though, because the vast majority of them come from the northern part of the region (the cylinder seal being a Mesopotamian form rather than an Egyptian, its equivalent in the south being the scarab seal), the influence of Assyrian and Mitannian styles and motifs can more clearly be discerned.

Religion

The religion of Syria and Palestine in the second part of the 2nd millennium also exhibits great diversity of beliefs, mythologies, and practices. From personal names and place-names, from representations of deities and cult scenes on cylinder seals and the like, and from cult objects found in excavations, it is clear that Egyptian, Babylonian, Assyrian, Hurrian, and Indo-European gods were familiar to the Levantine countries. Side by side with the foreign religions, however, there was also a body of indigenous religious beliefs and forms that, while they had much in common with those of neighbouring peoples, were distinct enough to merit the term Canaanite. This Canaanite religion is known primarily from two sources —the Old Testament, where it arouses the ire of the devout Hebrews, and a collection of clay tablets discovered in the excavation of Ugarit, containing part of its mythological and ritualistic literature. This literature, written in the local Ugaritic dialect of the Canaanite language, enables scholars to define the Canaanite pantheon, headed by El, who, however, played a rather passive and withdrawn role in the myths. The most active god was Baal, "the Lord of Earth," "the Victor," a deity associated in the myths with storms and rain and thus with vegetation and fertility. Baal's antagonist in the myths is Mot, the god of drought and death. Other important figures are Horon, god of the underworld, Resheph, the god of pestilence, and Koshar, patron of all kinds of craftsmanship. Of the goddesses, the three most prominent are Asherah, Astarte, and Anath; the first was the consort of El, and the two others apparently were sisters and wives of Baal. The roles played by these and other deities and their relationships with each other vary from myth to myth, thus complicating the task of defining their origins and functions. But the dominant part played by Baal and by the three goddesses is sufficient to establish the fact that Canaanite religion was primarily concerned with fertility. To a much greater extent than the inhabitants of either the Nile or Euphrates valleys,

where agricultural abundance was a product of never-failing annual floods, the Canaanites were at the mercy of an unreliable and fickle climate, whereby the tardy arrival of the winter rains or the unseasonal blowing of desert winds could ruin a crop and therefore a livelihood. The Canaanites desired a regularity of the seasons and of the natural forces of fertility, and their myths—whether stories to explain observed phenomena or the scripts of ritual dramas, enacted periodically to produce desired results (the two most widely held interpretations of the texts)—are overwhelmingly concerned with these matters. It was this emphasis on fertility, stronger than in either Egyptian or Mesopotamian religion, with its concomitant cultic practices of sacred prostitution, orgiastic rites, and perhaps human sacrifice, that provoked the fulminations of the Old Testament prophets.

Yet, although the Old Testament writers reacted strongly against the concepts and practices of Canaanite religion, the Canaanite mythological texts exerted a strong and positive influence upon Israelite literature, and its influence continues to be felt today wherever the Bible is read. The language of Canaanite religious literature is full of imagery and metaphor, which reappears time and again in the Old Testament, as (to cite but one specific example) the likening of Yahweh to a storm god, "The Rider on the Clouds" (Psalms 68:4; Isaiah 19:1), as is Baal in the Ugaritic tablets. Stylistic conventions well-known in the Bible are also derived from Canaanite poetry; most striking is the use of repetitive parallelism, in which statements are made two or three times for greater emphasis:

Canaanite influence on the Old Testament

> Thy right hand, O Lord, glorious in power,
> Thy right hand, O Lord, shatters the enemy.
>
> (Ex. 15:6–7)

So close is the poetic diction of some of the early Hebrew literature to that of the Ugaritic texts that, were it not for its religious content, it could properly be classed as Canaanite. Similar stylistic conventions and imagery also occur in the Homeric poems, and these may well have been inspired by a Mycenaean tradition that itself owed something to Canaanite literature. Thus, both because of its own intrinsic quality and its far-reaching influences, the literature of Syria in the 2nd millennium BC must be considered one of the most important legacies of the ancient world.

But the Levant's most important single contribution to civilization lay in writing—the art that made literature possible. By the beginning of the Egyptian–Hittite period, most writing for business, administrative, and diplomatic purposes was carried on, in the Levant, in the Babylonian cuneiform script, although the Egyptian hieroglyphic script was also undoubtedly known in the areas where Egyptian contacts were strong. Both scripts were cumbersome, however, with their hundreds of complicated signs, many of which often represented several different objects, concepts, and, sometimes, sounds. The busy Canaanite merchants would have preferred a simpler method of writing down their language, and several attempts seem to have been made in the 2nd millennium to invent one, based on the phonetic principle, whereby each symbol represented one distinct sound and nothing else. Such a principle marks a great step forward in the history of writing and stands at the beginning of the true alphabetic system, even though (because of the nature of the Semitic languages, where vowels play a less important role than consonants) the Canaanite systems should strictly be termed syllabaries because each sign stood for a syllable of a consonant and vowel.

Alphabetic system

The Ugaritic mythological texts were themselves written in a syllabary of 30 signs, based on cuneiform symbols; because these still proved tedious to write, this script, although probably widespread in the region, did not gain much popularity. In Byblos, about the middle of the millennium, a script based on the Egyptian hieroglyphs was evolved, but this, too, failed to prosper. Credit must go to the inhabitants of Palestine for inventing a syllabary that was to succeed. Sometime before the middle of the 2nd millennium, cursive characters, at least in part derived from Egyptian, were adopted to represent about 30 of the basic sounds of the Canaanite tongue. The earliest examples of this Proto-Canaanite alphabet (its most common designation) are short words, mostly names, on a few objects such as potsherds, a dagger blade, and a gold ring, and a series of dedicatory inscriptions roughly carved on the rocks of the Sinai Peninsula, in the vicinity of the Egyptian mines. Originally the symbols were still pictograms, though simplified and standing for sounds, but, by the end of the millennium, they had evolved into a linear script, easier to write and to read. By 1000 BC they were in use, with minor regional variations, among the Phoenicians on the Syrian coast and the Hebrews in Palestine. From this linear Canaanite alphabet were to develop the true Phoenician, Aramaic, and Early Hebrew alphabets of the 1st millennium BC; and from these all the alphabets in use throughout the world are derived, directly or indirectly. No other invention in the history of mankind, unless perhaps the invention of the wheel or the discovery of fire, has had so lasting an effect upon the human race.

The coming of the Hebrews. During the course of the events described above, there occurred in Palestine a different series of events, which find no mention in the multifarious historical documents surviving from the great Near Eastern empires but which, without doubt, had a greater effect on the history of the area than did any action of the Egyptian, Mitannian, or Hittite kings. These events were the arrival and settlement of the Israelites; they are recorded only in Hebrew folklore and are deducible only with difficulty from archaeological data. Were it not for the Old Testament, the process by which Israel first became associated with its Promised Land would have passed unnoticed by ancient historians.

Evidence of early Israelite history

The books of the Old Testament that deal with the early history of Israel are not historical narratives in the usual sense of the term. Rather, they are collections of reminiscences, of greater or lesser reliability, written down several centuries after the events they describe and rearranged and edited many times since. As they stand, therefore, they contain many anachronisms, contradictions, and obscurities; and, although modern scholarship has made progress in solving some of the more important problems of interpretation, there are probably as many interpretations of detail as there are Old Testament scholars. Even on the main outlines and chronology of Israel's early history there is not complete agreement, and, although the summary that follows seems to reflect a certain consensus, it should nevertheless be borne in mind that individual scholars of great repute have very different views on major points, of which limitations of space prevent discussion.

In the Old Testament, the earliest representatives of the Hebrews are the patriarchs, who are said to have been of Aramaean stock and to have come to Palestine from the East and who are pictured as leading a wandering life, searching for pasture for their flocks, and occasionally travelling southward as far as Egypt. Some of these statements are open to criticism. The reference to the Aramaeans, for example, is an anachronism, because that people did not emerge until toward the end of the 2nd millennium, when Israel was already settled in Palestine. Nor is there any certainty that the town of Ur, from which Abraham's father is said to have come, can be identified with the Babylonian city of that name. There is no proof, even, that the patriarchs are historical figures at all; many scholars regard them as personifications of tribal or other groups (such as the 12 sons of Jacob almost certainly are), while others see them as former Canaanite gods, shorn of their divinity and incorporated into a new religious mythology. Yet whatever their true nature, there is enough authenticity about the patriarchs—*e.g.*, their legal and social customs and their semi-nomadic way of life, as revealed in the narratives pertaining to them—to make it reasonably certain that the narratives reflect a genuine memory of tribal groups that were present in Palestine long before the invasion of the historical Israelite tribes and whom these later Israelites considered to be their true ancestors. It is not known when these early patriarchal groups first arrived. Most scholars

would place them in the 19th and 18th centuries BC, at a time when it is postulated from other evidence that West Semitic peoples were moving en masse into the Levant from the northeast. But the infiltration of semi-nomadic pastoralists into Palestine is a constant feature of its history and cannot be related to any one period, while the analogies between patriarchal customs and those of other Near Eastern peoples, for example the Hurrians or the Amorites, although they indicate a date before about 1400 BC, are not sufficiently close to establish anything more precise. In short, the first Hebrews in Palestine, as evidenced by the patriarchal stories, could have appeared at any time between about the 20th and the 14th centuries BC.

It is in the 14th century that, in the search for Hebrew origins, one treads firmer ground, though it is only a relative firmness. As mentioned above, there are reasons, mainly philological, for equating the word Hapiru of the Amarna Letters ('Apiru in Egyptian) with the biblical word 'Ivri (Hebrew). Not all scholars accept this, however, and the question must be left open until more evidence is available. Yet there are other reasons for supposing that there were Hebrews in Palestine by the 14th century, closely related to those who eventually occupied the whole country. To understand these reasons requires a glance forward to consider the nature of the event or events that, in the Old Testament, are subsumed under the terms Exodus and Conquest.

Biblical accounts

For reasons described below, it is virtually certain that the major phase of the Israelite occupation of Palestine, with which the Bible associates the name of Joshua, had been completed by the end of the 13th century. A careful reading of the biblical narrative reveals that, although an attempt has been made by later editors to arrange all the events and incidents relating to the Exodus, the wanderings in the desert, and the conquest and settlement of Palestine into a logical and coherent sequence, the attempt is far from successful, and inconsistencies, duplications, and contradictions abound. There are, for example, two conflicting accounts of the route the Israelites took through Transjordan, one (Num. 33) suggesting a direct route through Edom and Moab, the other (Num. 20:14 ff. and Judg. 11:17) telling of a long detour through the desert to the east of these countries. Similarly, in Num. 21 and Judg. 1 the conquest of southern Palestine is attributed to the tribes of Judah and Simeon, while elsewhere it is ascribed to Joshua. Examples could be multiplied. Given the fact that, when studied in detail, most of the various narrative strands have a definite ring of truth about them, it must be inferred that, far from being a single sequence of events under one or two successive leaders, the actual process by which the Israelites reached Palestine and settled therein was complex and piecemeal, extending over a long period of time and involving many different groups, acting independently and with varying degrees of success.

One part of this process could have involved the Hapiru of the Amarna Age, and there is evidence that makes this hypothesis attractive. For example, in the Bible there is no mention of the capture of Shechem in central Palestine during Joshua's campaigns of the late 13th century, yet Shechem was, from the very beginning of Israelite settlement, one of their most important centres. In the Amarna Letters Shechem and its vicinity is shown to be in the control of Labaya, a Hapiru, and it is tempting to assume that this region was already in "Hebrew" hands long before Joshua's time. The archaeological evidence from Jericho may also point to "Hebrew" conquests in Palestine in the 14th century. This site has always been a problem for Old Testament historians because, although the Bible makes much of Joshua's capture of the town, it was almost certainly destroyed not later than 1350 BC and then abandoned, more than a century before the date usually, and on good grounds, given to Joshua. It is true that some scholars, largely on the Jericho evidence, would date Joshua's activities and the activities of his predecessor as Israelite leader, Moses, to the 14th century, while a very few others would consider that the archaeological evidence from Jericho is incomplete or unsound. Yet these solutions fly in the face of other evidence, and a more likely solution might be that Jericho was in fact destroyed by Hapiru in the troubled 14th century but that, because of the strategic importance of the site on the main ford over the river Jordan and because of the symbolic importance to the Israelites of the crossing of that river into the Promised Land, its capture was erroneously attributed to Joshua, who became a semimythological hero to the later Israelites.

The capture of Jericho

If the Hebrews were already conquering and settling parts of Palestine as early as the 14th century BC, as many scholars now believe, then the Exodus and Conquest traditions associated with Moses and Joshua in the Old Testament must be revised. Yet, although scholars can no longer think in terms of one Conquest (and probably not of one Exodus), there is no good reason to doubt the basic historicity of the activities attributed to Moses and Joshua and their companions by the biblical authors. To begin with, although the Egyptian records never mention the presence of Israelites by name in the Nile Valley, there is ample documentary evidence to show that Semites from Asia were constantly entering and settling in Egypt, not only in the Hyksos period (when the rulers of Egypt themselves were Semitic) but at all other times as well. Nothing is more likely than that these Semites included, in the mid-2nd millennium, groups identical with or related to the Hapiru and the later Hebrews and that some of them were in a state of slavery. Nor is there anything unlikely about the Mosaic Exodus, and a date for this event can, with great probability, be given. The Bible tells (Ex. 1:11) that the Hebrews were forced to labour at the construction of the royal Egyptian cities of Pithom and Raamses (Pi-Ramesse). The latter was the former Hyksos capital Avaris, in the eastern Delta, rebuilt by the 19th-dynasty pharaohs, Seti I (reigned 1318–1304) and Ramses II (1304–1237), and called by the latter the House of Ramses. For such large-scale building works the pharaohs would have used slave labour and very likely foreign slaves. It seems virtually certain, therefore, that Exodus 1:11 refers to these activities at Avaris, and it can be reasonably postulated that Ramses II was the "pharaoh of the oppression" and that the Exodus under Moses took place in his reign. A *terminus ante quem* for the event can also be deduced from an extant document from the reign of Ramses' successor Merneptah; an inscription commemorating a successful raid by the Egyptian army into Palestine during the fifth year of the reign (*c.* 1231) states that, as a result of the Egyptian action, "Israel is laid waste and has no seed." The Egyptian word used refers to Israel as a people, not as a country, and the inference is that, at this time, the Israelite tribes were present in Palestine in sufficient strength to be considered a national group but had not yet wrested political control from the existing inhabitants. It is a reasonable assumption that such conditions pertained at about the time of Joshua, and the resultant central date of *c.* 1230 for the Conquest would fit perfectly with a date somewhere in the middle of Ramses II's reign, *c.* 1270, for the Exodus, allowing the traditional 40 years for the wanderings between the two events.

Archaeological evidence

The above reconstruction of events relating to the arrival of the Hebrews and Israelites in Palestine is based entirely upon documentary evidence. Corresponding archaeological evidence is practically nonexistent, but what little there is can at least be said not to conflict with this reconstruction, provided that the problem of the fall of Jericho is interpreted as above. This archaeological evidence concerns the destruction of a number of towns in Palestine at about the time of the Israelite invasion. There is clear evidence that many sites were destroyed then, and a number of them are towns specifically mentioned in the Old Testament as having been captured by the Israelites —*e.g.*, Hazor, Debir (Tel Bet Mirsham), and Lachish (Tell Duweir). Moreover, at these sites the archaeological evidence reveals either a period of abandonment or of very poor occupation following the destruction—circumstances that agree with their having been captured by the Israelites, who had no urban traditions. Convincing though this interpretation is, however, the destruction of

these Palestinian cities could, with equal justification, be attributed to armies other than that of the Israelites: the Egyptians were engaged in punitive raids (as Merneptah's inscription proves), while other invaders, notably the Philistines, were responsible for widespread ravaging of Levantine cities about the same time. As long as archaeologists cannot prove any one particular destruction to be the work of the Israelites rather than that of the Egyptians or the Philistines, the bearing of archaeological data upon the problems of the Israelite conquest of Palestine must be seen as minimal.

The Sea Peoples and the advent of the Philistines. Had all been well with the Egyptian Empire of the late 13th century BC, it is inconceivable that the Israelites would have been able to establish themselves in Palestine, and thus the whole future history of Judaism and of the world would have been different. But all was not well, and the ease with which the newcomers captured towns and settled the country was largely due to the fact that Egypt was weakening and was beset on all sides by enemies, compared with whom Israel was seemingly so unimportant as to merit but one single mention in the Egyptian records (in the Merneptah stele already noted). Other inscriptions of the same pharaoh point to the real source of danger to Egypt and indeed to the whole of the Levant: in the fifth year of his reign, Merneptah records that he successfully defended his kingdom from an attack from the west, in which Libyan tribes were allied with certain "Northerners from all lands," peoples "of the Sea." The ethnic names of some of these latter are recorded, and it appears that they were mostly of Indo-European stock and probably came from the islands and coastlands of the Aegean and southern Asia Minor, though the matter is still highly controversial. Merneptah's success held good for a generation, but in the eighth year of Ramses III (1190), these Sea Peoples were threatening again and on a wider front. In the words of the Egyptians: "The foreign countries made a plot in their islands, and the lands were dislodged and scattered by battle all at one time, and no land could stand before their arms—Khatti, Kode, Carchemish, Arzawa, and Alashiya." The Egyptian statement is confirmed by other evidence, especially archaeological. It was just about 1200 BC that the Hittite Empire collapsed, never to rise again, with its cities in ruins. In Cyprus (Alashiya), southern Anatolia (Kode and Arzawa), and throughout the Levant, site after site reveals evidence of catastrophic destruction—Enkomi, Ugarit, Alalakh, Carchemish, Ḥamāh, Tall Abū Hawam, Ashkelon (Ascalon) Tall Jammah, to name but a few. The entire eastern Mediterranean was in turmoil, and, although it is probable that deep-seated environmental factors, still imperfectly understood (*e.g.*, climate deterioration, famine, or even such geophysical calamities as earthquakes), lay at the root of the trouble, there can be little doubt that the cities were actually destroyed by marauding Sea Peoples, as the Egyptian texts specify.

Assault on Egypt

From these texts it is deducible that the assault on Egypt came from two directions—one group of raiders attacking the delta by sea, the other entering Egypt by land from the northeast, from the direction of Palestine. Two battles were therefore fought, and these are depicted in beautiful reliefs that accompany the commemorative inscriptions at Madīnat Habu. The Sea Peoples are clearly distinguished from the Egyptians by their facial characteristics, dress, and equipment; the most distinctive feature is the helmet, of which two types are shown, one with horns and the other with an upstanding circlet of feathers or reeds. The ships and chariots of the Sea Peoples are also distinctive and suggest Anatolian prototypes, confirming the evidence of the ethnic names and pointing to an Anatolian origin for at least some of the raiders. Not all these chariots were vehicles of war; some are heavy carts and were drawn by slow oxen and carried women and children. This was clearly a migratory movement, therefore, and not merely a pirate raid.

The victory that Ramses claimed over the Sea Peoples was a Pyrrhic one. His effort proved too much for Egypt, and from this time can be dated the effective end of the Egyptian Empire in Asia. The real victors seem to have been that section of the raiders whom the Egyptians called Peleset and whom we know from the Bible as the Philistines. They probably formed the bulk of the migrants who had attempted to invade Egypt by land, for, either just before or immediately after the battle with Ramses, they settled on the southern coastal plain of Canaan, a region that was to become known as the Plain of Philistia and from which derives the name Palestine. Although the Egyptian account of these events makes it seem as though Pharaoh deliberately promoted this settlement, he more likely found himself unable to prevent what amounted to a dismemberment of the Asian province, with even the former provincial capital itself, Gaza, in Philistine hands. For perhaps another two centuries, Egypt continued to maintain isolated garrisons in Canaan —*e.g.*, at Bet She'an and Gezer—but they were poor reflections of former imperial glories, anachronisms in a world that had entirely changed.

SYRIA AND PALESTINE, C. 1200–C. 330 BC

The incursions of the Sea Peoples upset the balance of power in the Levant and enabled other groups, such as the Hebrews and the Aramaeans, to establish themselves. Geopolitically, therefore, the region was fragmented, and the following two centuries saw the foundation of the new states and peoples that were to dominate the history and culture of the 1st millennium BC.

The Philistines. Knowledge of the Philistines after their settlement comes both from the Bible and from archaeology. They ruled as a military aristocracy over a predominantly Canaanite population, and their territory comprised a federation of five city-states—the Pentapolis —each ruled by a king or tyrant. The capitals of these five states were Gaza, Ashkelon, and Ashdod, on or near the coast, and Gath and Ekron further inland. The port of Tel Qasila, on the outskirts of modern Tel Aviv-Yafo, seems to have been the northern extent of Philistine territory; between it and the Phoenicians to the north there seems to have been another group of Sea Peoples, the Tjekker, about whom little is known.

The Pentapolis

The Philistines preserved certain distinctive cultural traits for a century or so. These included their attractive pottery, whose designs and shapes are closely related to contemporary Mycenaean pottery from Cyprus and the Aegean and indicate the direction from which the Philistines continued to draw their artistic inspiration.

Little is known of Philistine religion. Biblical references to flies and bees in the cults seem to indicate Greek and Minoan influences. The Philistine gods, however—Dagon, Ashtoreth, and Baal—are Semitic in origin and must have been taken over by the newcomers, perhaps replacing their own deities. Indeed, perhaps the most striking fact about the Philistines is their rapid assimilation to the Canaanite civilization. Only one Philistine innovation had a lasting effect on the civilization of Palestine: the working of iron. The Bible credits the Philistines with introducing this metal into the country and retaining a monopoly, at first, in its use. The resultant superiority of Philistine weaponry and armour helps explain their early success in defeating Israel. It is from *c.* 1200 BC that the archaeologist's Iron Age conventionally begins. Knowledge of this metal must have been acquired by the Philistines in Anatolia. It remained a rare and valuable metal for several generations, however, and not until the 1st millennium did iron weapons and tools become common in Palestine and Syria.

Beginning of the Iron Age

Until about the mid-11th century the Philistines evinced no expansionist tendencies. Not until the growing power of the Israelites seemed to threaten them did they assume an aggressive role, and the second half of the 11th century saw a decisive struggle. At the Battle of Ebenezer (*c.* 1050), the Israelites suffered a severe defeat in which the ark of the Covenant was captured. A number of Israelite towns were destroyed, and Philistine control was extended into the hill country. By the beginning of Saul's reign in Israel (*c.* 1020), the Philistines were clearly in the ascendancy, and Saul could not check them. Following the Battle of Mt. Gilboa, in the Plain of Esdraelon, Saul

took his own life, and Israel was at the mercy of the Philistines. But David, Saul's successor, defeated the Philistines, and by the end of his reign Philistine princes were paying tribute to him. The Pentapolis ended as a political entity; the Philistine city-states survived for almost three centuries, and there was constant border friction between them and the Hebrew states. In the 8th century, when Tiglath-pileser III of Assyria subjugated the northern kingdom of Israel, he first conquered the Philistine cities; his successor, Sargon II, reorganized northern Philistia into the Assyrian province of Ashdod, while the southern cities remained semi-independent Assyrian vassals. This reorganization seems to have survived into the Neo-Babylonian and the Persian periods.

The Syro-Hittite states and the Aramaeans. The destruction of the Hittite Empire in *c.* 1200 BC coincided with a period of Assyrian weakness. Because of a lack of textual evidence and unreliable archaeological evidence, it is possible to discern only the outlines of the history of the next few centuries.

The neo-Hittites. The southeast Hittite provinces were protected by the Taurus and Amanus mountains from the western invaders who, in conjunction with Sea Peoples, overran the central Anatolian plateau; in these districts some old city-states survived and new ones were created, becoming the legatees of Hittite culture and power. Most rulers of these neo-Hittite states were neither Hittites nor descendants of the Hurrians of northern Syria. The language of their earliest monumental inscriptions is related to the Luwian tongue of the southern Anatolian seaboard, and there must have been a migration of people eastward from the coast to the northern Syrian plains. This influx added another element to the racial mixture of northern Syria.

About 20 of these neo-Hittite states are known. Together they formed an important bloc in the Syrian power structure. At the end of the 12th century Tiglath-pileser I brought about a short-lived Assyrian revival in Syria; but the resistance of the Syro-Hittite states helped frustrate Tiglath-pileser's ambitions, and the re-emergence of the Assyrian Empire was delayed another century.

The Aramaeans. A new force now appeared on the scene—the Aramaeans. The first known mention of these people appears in the records of Tiglathpileser I, where it is implied that they are desert nomads. Their language, Aramaic, was a dialect of North West Semitic, closely allied to Canaanite and Hebrew; they may have originated in southern Syria. The biblical account of wars between the Israelites and Aramaean states in southern Lebanon and Syria indicates that these states had been established south of the neo-Hittite area by the 11th century. During the 10th and 9th centuries, many of the neo-Hittite states were taken and renamed, and south of the Anatolian mountains only the plain of Antioch and Carchemish remained Hittite. A brief period of stability and even prosperity then ensued, only to be ended by the Assyrian recovery (*c.* 900).

The Assyrian king Ashurnasirpal II appeared at Carchemish in 876, met no resistance, and led his army right through Syria to the coast. Some years later, Shalmaneser III, following the same route, defeated a coalition of the northern Syrian states. The southern states were more successful against the Assyrian threat. At Qarqar (near Ḥamāh) in 853, the Aramaean kings of Ḥamāh and Damascus, together with 12 subject princes, sustained heavy losses in a battle that, however, forced the Assyrians to halt their advance. But Assyria could not be thwarted. In 804 Adad-nirari III reduced Damascus and claimed mastery over all inland Syria, taking tribute also from Phoenicia, Israel, and the Philistines. Constant revolts forced the Assyrian rulers to introduce a policy of direct annexation, and by 709 all the former Hittite and Aramaean states had become an integral part of the Assyrian Empire.

Battle of Qarqar

Culture. The motivation for Assyrian expansion west of the Euphrates was mainly economic. The routes west to the Mediterranean, north to Anatolia, and south to Egypt ran through the Syrian plains, and along them flowed valuable trade. The Assyrian tribute lists testify to the wealth of Syria—mainly metals (iron, copper, silver, gold) and timber. The economies of the states that provided this tribute were undoubtedly founded on a solid basis of agriculture and stock rearing.

In the 1st millennium the population of inland Syria was even more mixed than before. Linguistic evidence shows that the predominant Hurrian population still survived, as did the Hittite aristocracy in some areas. But the migration of Luwian-speaking people from the west had added a strong new element, at least to the ruling class, while, most important, Semitic Aramaeans had spread from the south. The region also acquired its share, in time, of Assyrian officials and soldiers and of Phoenician merchants and craftsmen.

This mixture of races is paralleled by and explains the mixture of religions. The Hurrian element was apparently strongest: the gods worshipped in the northern states remained for a long time those venerated throughout the Hurrian lands for more than 1,000 years. The Aramaeans, however, introduced a mixture of East and West Semitic deities into their states. Thus, the religious life of the Syrian towns must have comprised a rich and colourful medley of cultic observances, rites, and beliefs.

The prosperity of the neo-Hittite and Aramaean states was considerable and gave rise to rich artistic production. A summary of this art is difficult because of the heterogeneity of races and religions and because there is controversy over the dating of much of the evidence. The main points at issue are the date of the earliest neo-Hittite art and the source of its inspiration. Some authorities argue that northern Syrian art arose after the Assyrian expansion in the 9th century and under eastern stimulus; others stress the preservation of the imperial Hittite artistic tradition in some neo-Hittite states and date the earliest work to the 11th and 10th centuries. Whatever the truth, Hittite influence is clearly very strong on some of the artistic productions. In time, however, Assyrian conventions developed, and there thus arose a composite Hittite-Assyrian style. The contribution of the Aramaeans to this art was probably slight; their role was primarily that of patrons (the princes of Damascus and Arslan Tash employed Phoenician ivory carvers, and these and similar artists must have introduced Canaanite and therefore Egyptian motifs into northern Syrian art).

The most important artistic achievement of northern Syria at this time lay in architecture, particularly in the development of a type of building called the *bit hilani* by the Assyrians. Its basic plan seems to have been a Syrian design. It did not become standard in the neo-Hittite period until the mid-9th century, however. From the time of Tiglath-pileser III it became one of the most characteristic elements of Assyrian architecture.

Achievements in architecture

The major cultural achievement of the Aramaeans and their major contribution to world civilization lay in the field of writing. The Aramaeans adopted the Canaanite alphabetic script, which had already developed from a pictographic to a simpler linear form both on the Levantine coast (Phoenician) and in Palestine (Early Hebrew). Their rapid movement throughout Syria and Mesopotamia, as well as their commercial contacts even farther afield, soon spread the new writing and the language that went with it. During the 7th century the Aramaic language and script were widely adopted for international correspondence and even for private communication among the Assyrians. In *c.* 500 BC the Achaemenian kings chose Aramaic as the lingua franca of their vast empire, and it long remained unchallenged over the entire Near East. The Aramaic script is the progenitor of Arabic and of all the alphabetic scripts used in India and the Far East today.

The Phoenicians. Even after the break-up of the Late Bronze Age around 1200, enclaves of Canaanite population retained their independence and culture in northern Palestine and along the coast of Lebanon and Syria. In Palestine the cities of Megiddo and Bet She'an survived for a time; at Bet She'an an Egyptian garrison may still have been stationed during the 12th century, and a local prince may have ruled as late as *c.* 1000, when the town was captured by the Israelites. But the survival of Canaa-

nite culture was most significant on the coast, and from it grew the civilization of Phoenicia.

The name Phoenicia derives from the Greek word *phoinix,* meaning "purple"; many scholars believe the name Canaan comes from a Semitic word also meaning purple, because from at least the mid-2nd millennium the Levantine coast was famous for the purple dye of the murex whelk, used in the manufacture of fine cloths. The words Phoenician and Canaanite may be synonymous in origin, and some modern scholars see the Levantine culture of the 2nd and 1st millennia as Phoenician. But, because the word does not seem to have been used in antiquity before the time of Homer, it seems best to confine it to those elements of Canaanite population and culture that survived the late 13th century.

The development of Phoenicia. Canaanite survivors on the Syrian coast, hemmed in by the neo-Hittite and Aramaean states on the north and east and by the Philistines and Israelites on the south, soon looked westward for opportunity and advancement. The high Lebanese mountains that protected the coastal cities from the Aramaean bedouin also restricted their access to the rich agricultural lands of inland Syria. Yet these same mountains provided timber, and the coast was blessed with many good harbours. The prerequisites of shipbuilding and sailing were thus at hand, and Phoenician skill in these things was a legacy from the Canaanite past. The collapse of Egyptian and Mycenaean sea power left only the Sea Peoples as rivals in the eastern Mediterranean. By the time of the visit to Byblos by an Egyptian envoy, Wen-Amon, in *c.* 1075, Phoenician ports were already busy, and less than a century later David's defeat of the Philistines cleared the way for its commercial and colonial expansion westward.

The legacy of shipbuilding and sailing

At first, the leading cities were Aradus, Byblos, Sidon, Tyre, and Akka. Sidon probably dominated until the 10th century (hence the use of the word Sidonians in the Bible and in Homer to denote all Phoenicians), when Tyre became the chief city, perhaps at times heading a confederacy of the less important city-states. Because relations with the Philistines were bad, there developed amicable relations with the Israelites, although some of the southern cities, including Akka, were victims of David's expansionist policy. For a time, even Tyre may have been an Israelite vassal, and it was perhaps in this capacity that its king, Ahiram, sent David timber and craftsmen to help build the palace at Jerusalem. Solomon returned the southern cities and cooperated with Ahiram in various commercial undertakings on an equal footing. Following a period of civil strife in both Israel and Phoenicia, these good relations were re-established by Omri of Israel in *c.* 870 with the marriage of Omri's son Ahab to Jezebel, daughter of King Ethbaal of Tyre.

By the 9th century the threat of the Assyrian army loomed over the Phoenician coast. Ashurnasirpal II received tribute from Tyre and Sidon and the other Phoenician cities in 876, but the first military confrontation apparently occurred in 853, when small Phoenician contingents joined the allied forces that halted Shalmaneser III at Qarqar. Shalmaneser claimed tribute from the Phoenicians later in his reign, however, as did Adad-nirari III when he reduced Damascus in 804. Tiglath-pileser III's policy of direct annexation affected the coastal cities, and, through the internecine strife and anti-Assyrian rebellion, scholars can trace the destruction of Phoenician cities by the Assyrians, the deportation of the inhabitants, and the imposition of direct Assyrian rule over the coast in the late 8th and 7th centuries. When Assyria fell to the Babylonians (late 7th century), only Aradus, Byblos, and Tyre remained autonomous.

Colonization. The Assyrian invasion must have stimulated the Phoenicians to colonize the Mediterranean basin in an effort to find safer homes and new markets. Their colonizing activities had, in fact, started earlier, though exactly when they had begun is controversial. According to classical historians—*e.g.,* Pliny, Diodorus Siculus—colonizing began late in the 12th century: the foundation of Utica (in modern Tunisia) is attributed to *c.* 1100, of Gades (Cádiz, Spain) to *c.* 1110, and of Lixus (on the Atlantic coast of Morocco) to an earlier date. There is no archaeological evidence to support such high dates, however. Even in the eastern Mediterranean, archaeology suggests that the first colonies, probably in Cyprus, do not antedate the 10th century. This, the time of Ahiram and Solomon, was the golden age of Phoenicia and may also have seen the establishment of the earliest western colonies. These western bases were established by the 9th century; the traditional date for the foundation of Carthage, 814, has been adequately confirmed. The 8th and 7th centuries saw many foundations; some of these, especially after the mother cities began to fall, were colonies of Carthage rather than of Phoenicia proper.

The total number of Phoenician colonies is not known, but evidence indicates at least 50. Phoenician expansion was primarily commercial, with no intent of conquest and no large-scale emigration from the homeland. The importance to Phoenicia of this expansion lay in new markets and ports and new sources of wealth, particularly in such metals as copper from Cyprus and silver, tin, and iron from Spain. Its importance to the rest of the world lay in the channel it provided by which the culture of the Orient was transmitted to the West.

Phoenician civilization. Phoenician civilization was a continuation and development of Canaanite civilization. Despite the more exotic produce that came to Phoenicia from its western colonies or from expeditions to Ophir, its main resource was still timber, supplied as tribute to the Assyrian kings as it had been earlier to the pharaohs. Agriculture was also important, with cereals, vines, olives, and dates carefully cultivated on the hillsides and the narrow plain with the help of irrigation. The availability of iron helped exploit these agricultural and natural resources more efficiently. And the relatively small area available for agriculture not only stimulated overseas expansion but also must largely account for the development of industries in the Phoenician cities that were famed in Greek literature. The Phoenicians apparently excelled in textiles, especially the manufacture of cloth coloured with the murex dye, and in glassmaking. Fine metalwork, ivory carving, quarrying, masonry, and carpentry were also notable. In all these industries the Phoenicians simply—and excellently—carried on the traditions of an earlier age and became famous for their skill because of their greater contact with the Greek world.

Phoenician industries

The same may be said of their art and architecture, which shows the same eclecticism and syncretism that had characterized Late Bronze Age art in the region. Thus, in their ivory carving and jewelry Egyptian influence is strong, while on fine engraved metal bowls Mesopotamian and Anatolian influences predominate. This is not to deny originality and genius to the Phoenician craftsmen, who used the artistic devices of their neighbours in new and exciting ways and produced eminently successful works of art. But the Phoenicians' main achievement lay in preserving the artistic traditions of the Bronze Age through the Dark Age at the end of the 2nd millennium and in passing those traditions to the West.

There was an even greater Phoenician legacy, especially to Greece. Just as the Aramaeans spread the Canaanite alphabet to the East, so did the Phoenicians to the West, where it is the source of all modern scripts. By about the 11th century the Canaanite alphabet had been simplified by the use of linear characters, and in this form it became standardized in Phoenicia. The Greeks adopted it, with minor changes, probably around 800. Shortly afterward —either directly borrowed from the Phoenicians or through the Greeks—a very similar script appeared in Italy for use with the Etruscan language, and from there it passed to the Romans and to posterity.

The Hebrews. The only evidence for the history of the Hebrews' first two centuries in Palestine is from the Bible, which presents a collection of legendary and etiological stories impossible to construe correctly. Three things are certain: by 1200 BC the Hebrews were organized into a number of tribes—traditionally 12—bound together only loosely by their common faith in Yahweh; they were culturally inferior to the existing inhabitants of the land; the task they set themselves, one of conquest, was diffi-

cult. The earliest phase of settlement, in Gilead, east of the Jordan, and in the central Palestinian hill country (though not including Jerusalem), was apparently accomplished without much difficulty; but then the Hebrews began to compete for the land with the powerful Canaanites and Philistines. Thereafter successive crises gave rise to successive leaders—called Judges in the Bible—who united the tribes and delivered them from danger; such deliverers were Barak, who with Deborah defeated a Canaanite confederacy in Esdraelon (Judg. 4–5), and Gideon, who defended the Israelites from an attack by Midianite nomads from across the Jordan (Judg. 6–8). Once a danger had passed, however, the tribes would drift back to their separate camps and villages; only gradually and reluctantly did they realize the need for a more permanent leader and a more unified government. Thus arose the monarchy. Gideon himself was invited to be king, but he refused, doubtless because the concept of an earthly monarch was inconsistent with Israel's covenant with God. But by *c.* 1020 Saul had been made king. Opposition to the idea of kingship was still strong, however, and Saul clearly lacked the support needed to defend Israel against the Philistines. Moreover, a young and popular rival had appeared, David, of the tribe of Judah, who, though Saul's son-in-law, incurred the King's jealousy and was forced into exile, serving for a time in the Philistine army as a mercenary. Upon Saul's death David, with Philistine approval, established himself as leader of a coalition of southern tribes; and for a few years bloody rivalry ensued between him and the leaders of those tribes, mostly in the north, loyal to Saul's son Ishboseth (Ishbaal). In *c.* 1000 David was acclaimed king over all Israel.

The rise of the monarchy

David's reign. Such unification displeased the Philistines, and they launched an attack on the new kingdom near Jerusalem, still a Canaanite city, where David defeated them decisively, forcing their withdrawal to the coastal plain. David then consolidated the union of the two parts of his kingdom by capturing the central town of Jerusalem and making it his new capital. By moving the ark of the Covenant to Jerusalem, David also made it the religious centre of the nation. David then embarked upon a series of campaigns against his neighbours, which rapidly enlarged his territory. By the end of his reign he controlled all the remaining Canaanite cities, the Aramaean city-states of southern Syria, and the whole of the fertile land east of the Jordan, comprising the princedoms of Amon, Moab, and Edom. David ruled from the Gulf of Aqaba to Damascus and beyond; and the Aramaean princes to the Euphrates may have been his vassals, as were the Philistine princes.

David firmly believed in the institution of monarchy and in the centralization of government, and he was wise enough to realize that, although Israel's religion set it apart from the previous occupants of the land, it could not disavow the political and cultural legacy of its predecessors. Thus, he based the governmental machinery and the military organization of his kingdom on those of the Canaanites, though he also preserved the Israelite tribal structure. Nor did he turn his back on the more material aspects of Canaanite culture. The fact that Ahiram of Tyre sent wood and craftsmen to help build his palace in Jerusalem suggests that it conformed to Phoenician and so to Canaanite fashions. In the Israelite literature—for example, in the poetry of this and the immediately preceding periods, which included such masterpieces as the "Song of Miriam," the "Song of Deborah," and some of the Psalms (certain of which David may well have composed himself, as tradition maintains)—are found close analogies in imagery and diction to the Ugaritic epics. Thus, by the time of David's death (*c.* 960), Israel had been transformed from a loose confederation of tribes into a powerful empire and had, along with the Phoenician and Aramaean states, adopted the cultural mantle of the old Late Bronze Age civilization of Syria and Palestine.

Solomon's reign. David's latter years were troubled by intrigue and violence, mainly caused by the problem of the succession. But in a final act of statesmanship David had Solomon anointed king, and for a short time father and son reigned together as co-regents. On David's death Solomon acted swiftly and ruthlessly to secure his hold on the throne. The state was preserved and entered what is commonly regarded as its golden age.

Solomon's reputation for wisdom is clearly founded upon his genuine skill in diplomacy and in his ingenuity in handling difficult situations. Having inherited an overly large state, comprised of many disparate parts, he saw that its survival depended on internal consolidation and economic development. His reign was not marked by costly military campaigns, not even when the Edomites or the Aramaeans of Damascus revolted, though these acts reduced the boundaries of Israel. Solomon built his foreign policy upon amicable relations, promoted by a number of dynastic marriages, which introduced many foreign princesses into his harem. Commercial relations were promoted, especially with Tyre. Trade played a large part in Solomon's conception of government; he exhibited interest in the overland route to southern Arabia, as the story of the visit to Jerusalem by the Queen of Sheba (Saba', in southwest Arabia) proves. He also traded with the north, particularly with Asia Minor, where he bought horses for his army. Though his rule was not militaristic, Solomon realized that his government needed the twin supports of centralized administration and a standing army (which for the first time in Israel was equipped with chariots). As for the administration, Solomon broke completely with the past; he reorganized the entire kingdom into 12 provinces, few of which bore any relation to the old order. This reorganization led to more efficient government, especially in tax collection and the imposition of forced labour, essential though much disliked features of Solomon's government.

Palestine was again a wealthy commercial, cosmopolitan country, as is reflected in its material culture, in which the indebtedness to Canaan and to Phoenicia is clear. Particularly is this true of Solomon's famed architectural monuments. The style of fortifications and administrative buildings he erected owes much to comparable structures of the Late Bronze Age in Syria and Anatolia. Even more striking, the Temple he built at Jerusalem (thereby carrying out a plan his father had been forbidden by prophetic injunction to undertake) was, from its description in the Bible, planned and executed in traditional Canaanite manner. Whether Solomon obtained all his ideas and his craftsmen for his Temple from Phoenicia, as is usually assumed from the account of the help he received from Ahiram, or whether there still survived in Palestine a tradition of such art and architecture, is debatable. What is important is that the Temple, with its adjacent palace and administrative buildings, must have seemed to the poorer Israelite peasantry and tribesmen more the resurrected symbols of the old Canaanite priest-king than the house of God and his anointed.

Israel's culture

Outwardly Solomon's reign was marked by relative peace, prosperity, magnificent achievements in architecture, and probably a flowering of literature (at this time the first attempts were probably made to commit to writing the early tribal traditions, using the Canaanite linear script now common throughout the Levant). But there was much disaffection among the lower orders of society, on whom the burdens of taxation and forced labour bore heavily and who obtained no benefit from the ostentation of the court or from Solomon's prestige among his fellow kings. Particularly in the north, where old antagonisms toward the house of David and hereditary kingship still lived, there was a tendency toward separatism.

Separate kingdoms. Solomon was succeeded (922) in Jerusalem by his son Rehoboam, but the northern tribes, whose requests for administrative reform had been refused, repudiated him and chose Jeroboam, who had earlier led a revolt against Solomon. The united kingdom thus ended and was replaced by two smaller kingdoms—Judah in the south and Israel in the north. The accompanying internal strife enabled the neighbouring vassal princes to revolt, and the Israelite Empire dissolved practically overnight, leaving two second-rank states. Although the actual boundaries fluctuated from time to

time, Israel (until its destruction by the Assyrians in the late 8th century) always included the fertile northern coastal plain and the Plain of Esdraelon and was therefore the richer of the two; its population was diversified, and its boundaries touched those of Phoenicia and the Aramaean states, which often led to warfare but which also exposed Israel more to foreign cultural influences than was the case with Judah, thus making Israel more the true heir of the defunct united kingdom. Judah possessed a more homogeneous population and retained Jerusalem, but it was cut off from the sea by the Philistine cities and comprised only the relatively barren hill country and the Negeb, though for a while it controlled Edom and the Arabian trade route. Judah's relative poverty and isolation helped it to survive, however, until its final destruction in 587 BC.

The dissolution in 922 of Israel's fledgling empire coincided with a revival of Assyria and Egypt, and imperial rivalry for control of the Levant was renewed. The history and culture of Israel and Judah in the 9th–7th centuries follow very closely that of their neighbours; only the Israelites' religion kept them distinct. Thanks to the Bible, scholars know much more about the affairs of the Palestinian states than, for example, about Carchemish, Tyre, or Ashkelon (Ascalon).

External affairs

The external affairs of the two kingdoms were dominated, first, by their own rivalry, particularly by constant friction along their common border, which ran not far north of Jerusalem, Judah's capital. Second, but increasingly important, was the foreign threat, from the north and from Egypt. Shortly after Solomon's death the pharaoh Sheshonk invaded Palestine in an effort to restore Egypt's authority, but he was prevented from following up his success by the chronic weakness of Egypt itself. As it was, both Judah and Israel were devastated but soon revived.

In the north, Israel was concerned mainly with the Aramaean state of Damascus, its rival for the Syrian and Transjordanian trade. This rivalry led the sixth king, Omri (reigned 876–869 or *c.* 884–*c.* 872), to conclude an alliance with Ethbaal of Tyre, marrying his son Ahab to the Phoenician princess Jezebel, thereby restoring close ties with Phoenicia. At the end of the 9th century, Israel profited from the Assyrian defeat of Damascus, and for the next half century it enjoyed a period of comparative peace, coinciding with the long reign of Jeroboam II. Judah benefitted from the relaxation of tension in the north and from the strong rule of Amaziah (reigned 800–783) and Uzziah (783–742). The latter re-established the Red Sea trade, even to the extent of obtaining Phoenician help. The Assyrian danger was never far away, however, and with the Syrian states weakened the next blow fell on Israel (738). Israel was forced to pay tribute; and six years later, having joined Damascus in an abortive revolt against the Assyrians, it was devastated, most of its territory being annexed to the Assyrian Empire. Only the capital, Samaria, was spared; and in 722 Samaria itself fell to Sargon II, its inhabitants deported and replaced by settlers from Syria and Babylonia. The Northern Kingdom ceased to exist.

In the south, Judah had refused to join the rebellion, and it was spared, but only as a vassal state. It remained so for most of the 7th century. Rebellion under Hezekiah led to the destruction of the Judaean cities by Sennacherib in 701. Jerusalem itself survived, and from it the last kings of Judah ruled a much-reduced kingdom, subservient to Assyria until 625, when Josiah shook off the yoke.

Another, more powerful vassal of Assyria also established its independence—Babylon. Nabopolassar of Babylon (reigned 625–605) and his son Nebuchadrezzar II (604–562) overthrew the Assyrian dynasty and took control of its empire. A series of rebellions by the last kings of Judah early in the 6th century led to the Babylonian capture of Jerusalem in 597; the royal house was deported, and a puppet king was installed. He too rebelled, and in 587 the city was captured a second time and utterly destroyed, together with the remaining town of Judah.

The Babylonian exile

The wholesale deportation of the inhabitants of the country to Babylon and elsewhere—the Exile—ends the history of the southern kingdom of Judah and is the most important watershed in the history of the Jewish people, with profound consequences for its future development and its psychology.

Two conflicting tendencies may be noted in the internal development of the Hebrew kingdoms. One was the tendency to make the Hebrew states nations such as others were, and this involved, first, the fostering of the principle of hereditary monarchy. In Judah, where loyalty to the house of David was strong, this was never a serious problem. But in the northern kingdom, with its tribal jealousies, it led to dynastic instability. Only briefly under Omri and Ahab (*c.* 874–*c.* 853) and more lengthily under the Jehu dynasty (842–746) did Israel enjoy stable government; significantly, these times coincided with periods of economic prosperity. Secondly, it involved the desire to become a part of the surrounding world —economically, socially, and culturally. Thus, the rulers of Israel and Judah adopted the administrative machinery of Solomon's state and followed, when circumstances permitted, his example in fostering trade with Syria and with Arabia and in maintaining cultural contact with Phoenicia. The tangible results of this are to be seen most clearly in architecture and art. At about the time of their alliance with Tyre, Omri and Ahab built at Samaria and at Megiddo and Hazor royal quarters and garrison buildings based on Phoenician traditions. At Samaria the biblical reference to Ahab's "House of Ivory" is substantiated by the discovery of hundreds of fragments of beautifully carved and inlaid ivory pieces, direct stylistic descendants of Canaanite ivories of the 2nd millennium, testifying to the wealth and taste of the Israelite court. Less is known of the southern capital, though repairs and improvements to Solomon's Temple and royal buildings probably lived up to the finest precedents. As late as the 7th century fine "Phoenician" masonry was employed for a royal villa at Ramat Raḥel, south of the capital.

The less tangible results of this tendency toward syncretism with the outside world are seen in the Bible. The 8th-century prophets Amos, Hosea, and Isaiah castigate the Israelites for luxury and indolence and for overconfidence, arrogance, and wrongdoing. As prosperity increased, moral, social, and religious standards fell. (Ahab's wife, Jezebel, had brought into Israel the cult of the Phoenician god Melqart [Malkart]; his sister, or possibly daughter, Athaliah, married to Jehoram of Judah, fostered the worship of Baal in Jerusalem; Ahaz, when a vassal of the Assyrians, was compelled to erect an altar to the Assyrian gods in the temple itself.) The real and lasting importance of the tendency toward syncretism, therefore, is that it gave rise, in the prophetic preaching, to the opposite tendency—a rejection of contemporary foreign standards and of worldly values and an insistence upon uniquely high moral and religious ideals. In the prophetic movement Israelite religion reached its apogee, with right conduct and personal morality stressed at the expense of mere formal observance of the cult.

The era of the Assyrian, Neo-Babylonian, and Achaemenian empires. By the end of the 8th century practically all of Syria and Palestine had fallen to Assyria. But constant revolts during the next century show that the people of the region did not readily accept the Assyrian yoke. Hopes that an Egyptian revival would release the Levant from Assyrian rule were not fulfilled, though for a few years (609–605) the pharaoh Necho II controlled the entire region. It was to its vassals that the Assyrian Empire finally fell: Nineveh was destroyed by the Medes and Babylonians in 612, in 609 the Assyrian royal line ended, and in 605 Nebuchadrezzar's defeat of the Egyptians at Carchemish put the western part of the Assyrian domains into Babylonian hands. But Babylonian rule was as oppressive as Assyrian, and revolt following revolt was met with destruction and depopulation. Not until the Neo-Babylonian Empire was itself overthrown by the Achaemenian Persians in 539 was the Levant again to enjoy prosperity.

The main focus during the Neo-Babylonian and Achaemenian periods must again be on Palestine because, thanks to the Bible, scholars know most about that coun-

try; making allowances for geographic and religious differences, it can be assumed that parallel conditions prevailed elsewhere in the Levant. The amount of destruction wrought in Palestine after the fall of Jerusalem in 587 is controversial, but there can be no doubt that a significant proportion of the wealthy and official classes were removed. Archaeology, too, proves that many towns were razed and were not rebuilt for a long time. Perhaps as important was the introduction of new peoples; the Edomites especially moved westward from Transjordan and settled in southern Palestine, in what was later to be called Idumaea, named after them.

The Babylonians. Babylonia seems to have treated the victims of its deportation policy more leniently than had Assyria; some of the exiles became prosperous in their new lives as farmers, tradesmen, and merchants in Babylonia. After Nebuchadrezzar's death (562), the exiled king of Judah, Jehoiachin, was honoured at the Babylonian court. The fact that the Babylonians permitted the exiles to retain their religious and national identity provided conditions in which Israel could take stock of its past and make preparations for a new and formative stage of its history. During the Babylonian Exile many of the historical books of the Old Testament (Deuteronomy, Joshua, Judges, Samuel, Kings) and some of the finest theological writings (particularly the second part of the book of Isaiah) were composed.

Persian rule

The Achaemenids. A new chapter began in 538, when the Achaemenid ruler Cyrus II, having gained control of the Neo-Babylonian Empire, ordered the restoration of the Jewish community and cult in Palestine. Only a few Jews actually took advantage of this, and those who did found too much opposition from the new settlers there and from government officials to rebuild more than the foundations of the Temple. Although the exile was over and Yahweh was once more worshipped in Jerusalem, it was not until Darius I (reigned 522–486) established firm control over the Levant and re-issued Cyrus' edict that the Jewish leader Zerubbabel was able to complete the Temple. Conditions improved gradually, and during the 5th and early 4th centuries the Jewish leaders Nehemiah and Ezra enjoyed excellent relations with the Persian kings and acted as semi-autonomous governors. Nehemiah rebuilt the walls of Jerusalem and began reforms that strengthened and purified Jewish social and religious life. Ezra continued these measures and stressed the reading of the Law, the observance of the sabbath, and the prohibition of mixed marriages. Thus, the separation of the Jews was ensured, and the uniqueness of their faith was maintained.

Outside Judah, the Persian period in Syria and Palestine is one of the most obscure in all their history. It seems clear, however, that it was a time of relative peace and prosperity. The toleration toward the Jews also operated elsewhere. Darius I assigned all Syria and Palestine to one province (or satrapy) called "Beyond the River"—*i.e.*, west of the Euphrates—with a provincial capital at Damascus. This area was subdivided into smaller provinces, including Judah and Samaria. The Achaemenians carefully balanced central control with local autonomy; the governors of the provinces were often natives of the area. Darius' excellent road system, legal reforms, and the introduction of coinage (based on an idea developed in the Greek colonies of Asia Minor in the 7th century) made the Achaemenian Empire one of the most successfully governed in the ancient world. Not only is there no record of rebellion among the Phoenician cities against the Persians during the 6th and 5th centuries, but they actually helped their new masters in a conflict with the Greeks, who were fast becoming Phoenicia's rivals in Mediterranean trade and colonization. Only in the 4th century did the Phoenician cities adopt a pro-Greek policy, resulting in an abortive revolt by Tennes, king of Sidon, in 346.

It is hard to estimate the effect of Persian rule on the civilization of the Levant because of the scarcity of archaeological and literary evidence. A few architectural fragments from Phoenicia are typically Achaemenian, and the standard feature of the Achaemenian palace plan—a square pillared hall—may have influenced later temple buildings of the Roman period, particularly in Syria and Transjordan. The first indigenous coinage to appear in the Levant (in Judah and Phoenicia in the 5th century) was clearly the result of Persian stimulus, though the coins themselves are modelled on Greek counterparts. The main new cultural influences in Syria and Palestine were probably Greek rather than Persian, and perhaps the main contribution of the Achaemenian rulers was the peace and stability that allowed these Western influences to permeate. Settlements of Greeks were already spreading along the coast of Palestine and Syria, and it is in the Persian period that the Hellenization of the Near East can be said to have begun.

SYRIA AND PALESTINE IN THE HELLENISTIC AND ROMAN PERIODS, C. 330 BC–AD 634

Alexander's invasion

The Macedonian conquest. In 333 BC Alexander the Great of Macedon routed the Persian army and invaded Syria. Before pursuing the enemy eastward, he elected to visit Egypt. His march down the Syro-Palestinian coast met with opposition only at Tyre and Gaza (it was at this time that Alexander joined the island of Tyre to the mainland with an artificial mole, so making it the peninsula it is today). Meanwhile, his general Parmenio went to Damascus to secure the satrapic capital, and Macedonian governors were appointed to the provinces. Apparently only Samaria resisted the change of rule; a rebellion in that city was easily put down, and a colony of Macedonian veterans was established there.

Alexander died before he could attend to the organization of his new empire and to the problem of succession, though he appointed Perdiccas regent. No one man, however, could fill the position he had held, and his empire was shared out among his friends and generals—the so-called *diadochoi* ("successors"). Syria and Palestine fell to Laomedon and Egypt to Ptolemy I Soter; but in 320 the latter, anxious to secure his kingdom from attack, seized Syria as well. Meanwhile another general, Antigonus I Monophthalmus, tried to take over the entire empire. The next 20 years saw a struggle of Antigonus and his brilliant son Demetrius I against the other successors, with the Levant changing hands several times. Ptolemy defeated Demetrius at Gaza in 312, enabling another member of the anti-Antigonid coalition, Seleucus I, to establish a kingdom in Babylonia. In 301 Antigonus was killed at the Battle of Ipsus, and a settlement was achieved by which Seleucus occupied Syria and built himself a new capital at Antioch on the Orontes, while Ptolemy retained control over Palestine, Transjordan, and the southern Phoenician coast.

The Ptolemies and Seleucids. Ptolemaic rule of the southern Levant lasted about a century. The Seleucids, who considered this region a part of their inheritance, made several unsuccessful attempts to dislodge the Ptolemies; but not until Seleucid fortunes revived under Antiochus III the Great did the Syrian kings make headway. In 198 the Egyptian army was shattered at Panias, and Ptolemaic rule in Asia ceased; Phoenicia, Transjordan, and Palestine were annexed to the Seleucid Empire.

Roman involvement

Antiochus sought to extend his influence westward, into Greece, but there met with a new power, that of Rome, which had secured its position in the western Mediterranean by defeating Carthage and was beginning to take an interest in eastern affairs. Antiochus' army was defeated by the Romans at Magnesia, and by the Treaty of Apamea (188) he was forced to cede all his territories in Asia Minor beyond the Taurus. Antiochus thus opened the Levant to Roman intervention. In 168, when his successor, Antiochus IV Epiphanes, was about to occupy Egypt to stem a threatened invasion of Palestine, the Roman legate forced him to withdraw to Syria.

After the death of Antiochus IV (164), the entire Levant suffered from internal dissension, family quarrels, and native revolts. Because of Seleucid weakness, the eastern and northern parts of the kingdom fell to Parthian and Armenian invaders; Transjordan and southern Syria (including Damascus) went to the Nabataean Arabs; the Ituraean Arabs founded a principality in Galilee

and Lebanon from which they raided the Phoenician coast, and even individual cities proclaimed their independence and began to issue their own coins. Such turmoil led to the increasing involvement of Rome. First in Asia Minor, where Mithradates VI of Pontus was defeated, then in Syria, where Tigranes II of Armenia was forced to retreat, the Roman legions restored order. In 64 Rome refused to recognize Antiochus XIII as king and annexed Syria. The next year Palestine followed.

Hellenization. The 2nd-century revolts against Seleucid rule were partly a reaction against Hellenism. Greek influence in the Levant had been felt from very early times. But in Hellenistic times the rulers, especially the Seleucids, embarked on a deliberate policy of hellenization in the Near East, founding new cities, Greek in appearance and in their semi-autonomous status. The Ptolemies seem to have been content to leave things much as they were (though they inherited from Alexander the finest Hellenistic city in the world, Alexandria). In their Asian province they founded few, if any, new cities, though they gave new Greek names and new constitutions to some of the older ones. They looked on Palestine as an appendage to their kingdom, to be exploited for the good of Egypt. There was more centralized bureaucratic control of trade, agriculture, industry, and local affairs in Ptolemaic Palestine than in Seleucid Syria, and the level of prosperity, though higher than it had been for centuries, did not reach that attained in Seleucid lands.

But Syria was the heart of the Seleucids' domain, and their missionary zeal in spreading Greek culture therein was unbounded, especially during the first century of their rule. Seleucus I alone founded no less than 16 cities (though not all in Syria); most of them were named Antioch, in honour of his father, Antiochus, or Seleucia, in honour of himself. Little remains of these cities, rebuilt many times since; even those sites that have been excavated—*e.g.*, Jarash, Bet She'an, Antioch, Apamea—exhibit few pre-Roman monuments.

Archaeology thus provides little evidence for the early progress of Hellenization in the Levant. Judging from ancient descriptions and from analogy, however, the first Hellenistic cities in Syria and Palestine were undoubtedly magnificent places, conducive to the sort of Greek life the Hellenistic rulers so ardently hoped to propagate.

The cities testify to the wealth and productivity of the Hellenistic period. Alexander had put into circulation a vast amount of precious metals, which the Persian kings had hoarded, and this provided a remarkable stimulus to trade and industry. Close contacts with the Mediterranean world improved markets, while Ptolemaic enterprise extended commercial relations on the Red Sea and in Arabia. In this prosperity the Nabataean Arab caravan traders laid the foundations of their national state at Petra, while their Syrian cousins did the same at Palmyra.

Many Greek colonists came to the region, bringing the Greek language, philosophy, and religion. As always before, the foreign fashions were partly adopted, partly changed, and partly rejected. This was true of race (many Hellenistic kings and their Macedonian and Greek followers married native women and so helped to mix still further the Levantine ethnic pool), of language (for Greek never replaced Aramaic as the common language of the people), and especially of religion (for in the symbiosis of religions that followed the conquests of Alexander, the oriental cults and deities often proved the more persistent, though frequently under new names and in new temples). Among the educated classes, however, Greek literature and philosophy were generally acknowledged to be superior to anything the Orient had produced. Thus, some of the finest thinkers and writers of the Hellenistic Age were Levantine: Zeno of Sidon, who taught his namesake, Zeno of Citium, founder of the Stoic school of philosophy; Diodorus the Peripatetic of Tyre; Antiochus of Ascalon, one of Cicero's teachers; Poseidonius of Apamea, the historian; Meleager, the poet of Gadara.

The Hasmonean state in Palestine. Many Jews had been attracted by the new Greek customs and had sought to foster them in Judah. A gymnasium was built in Jerusalem, in which Greek games and their attendant religious ceremonies took place. Even young priests wore Greek dress. A rift between these Hellenizers and the more conservative Jews showed itself in rivalry over the office of high priest; the two main contenders during Antiochus IV's reign were Jason and Menelaus. Antiochus not only wanted to support the more Hellenizing candidate, but he also hoped to gain financially by selling the office to the highest bidder. This contest prompted Antiochus to visit Jerusalem on his way back from Egypt in 167. When his soldiers plundered the city and tore down many of its buildings and he himself—in flagrant disregard of Jewish law—entered the Temple, Antiochus could not understand the Jews' reaction to this profanity.

Antiochus was probably a sincere universalist in religious matters, hoping that the syncretism of Greek and Oriental faiths would help unify his realm. To this end he accorded to himself divine status, and he represented himself to his subjects as Zeus on Earth. The monotheistic Jews could not accept this. When, following his devastation of Jerusalem, he turned the sacred precinct over to the cult of Zeus Olympius, proscribed all Jewish practices and observances, and built a fortress overlooking the Temple area, religious Jews had no alternative but to revolt.

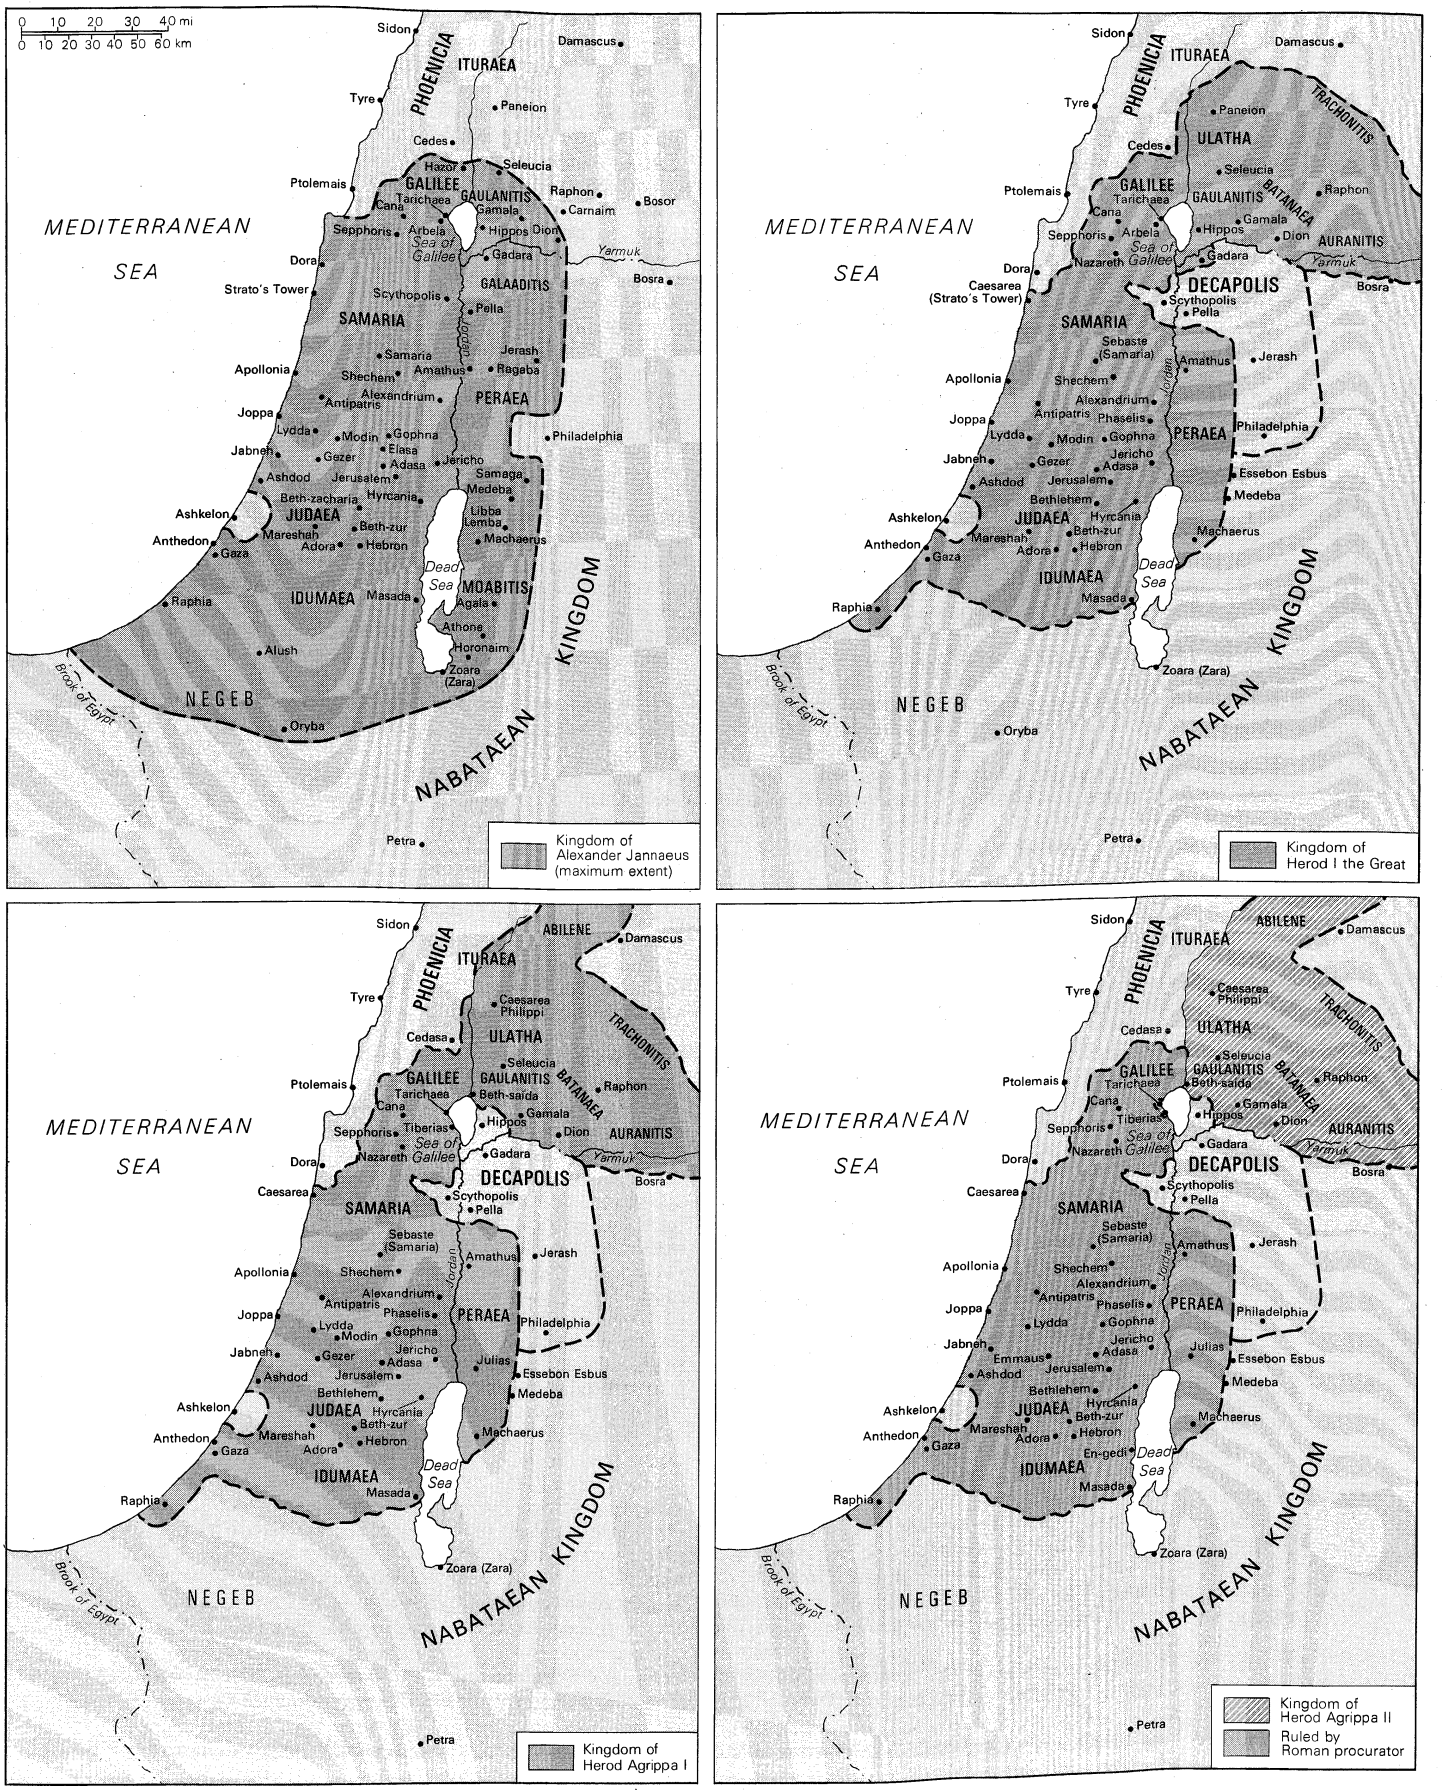
The rebellion of Judas Maccabeus

The rebellion was begun by Mattathias, of the priestly Hasmonean family. At first the rebels confined themselves to tearing down heathen altars and other signs of Greek religion and to harassing the Hellenizing Jews. When Mattathias died (166), he was succeeded by his son Judas, a brilliant military leader called Maccabeus (the Hammer). As the rebel numbers grew, particularly by the adherence of those pious Jews called Ḥasidim, the conflict became one of total war against the Syrian king. Judas won a number of victories, helped by his knowledge of the terrain and by massive local support. In 164 the rebels took Jerusalem, although the Syrian garrison in its fortress remained. The Temple was cleansed of every Hellenistic feature and was rededicated to Yahweh. The next year Antiochus died and was succeeded by his son Antiochus V, who tried to restore Seleucid authority in Palestine. He reoccupied Jerusalem but made no attempt to renew religious persecution or to profane the Temple. A legitimate high priest was appointed, and a Syrian general was stationed in Jerusalem to uphold the new regime.

With religious freedom won, many pious Jews were prepared to submit once more to alien rule. Not so was Judas; convinced that religious freedom could only be assured by political independence, he continued his war. Judas died in battle in 160 and was replaced by his brother Jonathan. For a time the Syrians were in the ascendancy in Palestine, but at home the dynasty was torn by family rivalry. By skillfully playing off one faction against the other, Jonathan retrieved the Jewish position and was recognized as de facto ruler of Judah. The rival Seleucid princes now vied for his support, and his position became correspondingly powerful: in 152 he assumed the office of high priest (although not of the Zadokite family), and, when Alexander Balas emerged victor of the dynastic conflict in 150, Jonathan was appointed general and joint ruler within the Seleucid kingdom. The struggle did not cease, however; and not until 141 was Jonathan's successor, Simeon, granted independence of Seleucid rule, with the right to mint his own coins. His territory comprised the old province of Judah, a part of Samaria, Joppa on the coast, and a large area east of the Jordan; most important, the Syrian garrison was finally removed from Jerusalem. Thus began the period of independent Hasmonean rule.

Expansion under the Hasmoneans

The period of the next three Hasmonean rulers—John Hyrcanus I (reigned 135–104), Aristobulus I (104–103), and Alexander Jannaeus (103–76)—was a time of territorial expansion. The Jewish rulers conquered practically all of Palestine and Transjordan; only the Greek cities of Ascalon on the coast and Philadelphia in Transjordan and their environs remained outside Jewish control, and the two most important neighbouring states—the Naba-



Palestine (top left) under the Hasmoneans, 168–63 BC; (top right) under Herod the Great, 40–4 BC; (bottom left) under Herod Agrippa I, AD 41–44; and (bottom right) in the time of Herod Agrippa II and the Roman procurator, AD 54–66.

From G. Wright and F. Filson (eds.), *The Westminster Historical Atlas to the Bible* (rev.); The Westminster Press; Copyright 1956 by W.L. Jenkins, used by permission

taean in the east and the Ituraean in the north—were severely weakened. But the Hasmonean state was itself weakened internally by the conflict of the opposing secular and religious tendencies. As the state grew in size and complexity, the old problem reappeared of how to govern successfully without adopting the military and administrative techniques of the outside world. It was impossible, and the Hasmonean kings soon became as manifestly Hellenizers as had been those Jews against whom Mattathias had revolted.

During John Hyrcanus' reign the Pharisees—the Separated Ones—opposed the Hasmoneans both as illegitimate high priests and as Hellenistic rulers. The Hasmoneans looked for support to another sect, the Sadducees. The rivalry of Pharisees and Sadducees and their vying for position within the state contributed to internal dissension that split the Hasmonean house after the death of Jannaeus in 76.

For nine years Jannaeus' wife held the reins of government, but on her death civil war broke out between their sons Hyrcanus and Aristobulus. Hyrcanus was supported by Antipater, an Idumaean, and by the Nabataean king Aretas III. In 65 Aretas and Hyrcanus were beseiging Aristobulus in Jerusalem. The Romans, restoring order in Syria, commanded the Nabataeans to withdraw, thus for the moment saving Aristobulus. The next year the Roman general Pompey arrived in Damascus; taking a dislike to Aristobulus, he reversed the Roman position and gave his support to Hyrcanus. Aristobulus resisted, and the Roman legions marched on Jerusalem; the city was taken with little trouble, but the Temple was fiercely defended and fell only after a three-month siege. The Temple was not plundered, and the traditional observances were resumed on Pompey's command. Hyrcanus was appointed high priest, and Aristobulus was taken captive to Rome. The Jewish kingdom was now under Roman hegemony.

The Romans in Syria and Palestine. Pompey's settlement of the Levant was based as much on the status quo as was consistent with the establishment of peace and order and with maintenance of Roman supremacy. All western Syria and Palestine became the new province of Syria, with its capital at Antioch; the Ituraean and Nabataean states suffered losses of territory and became vassals; Palmyra in eastern Syria was left alone for the moment. The Greek cities were freed from the control of local dynasts, their original semi-autonomous status restored under the general control of the provincial governor. The most important cities east of the Jordan were organized into a league of ten—the Decapolis. Judaea lost most of the territory conquered by the Hasmoneans, and the former kingdom was reduced to its original core in central Palestine, together with Galilee and Peraea. Hyrcanus II remained high priest, but much of the secular power was wielded by his minister, Antipater, under Roman supervision.

The province of Syria

Rome considered the Syrian province so important that it was placed under the direct rule of a proconsul. The first governor, Gabinius, had to suppress a revolt in Judaea of the dispossessed Aristobulus. Under the second governor, Crassus, the Romans were confronted by the Parthian kings of Persia and Mesopotamia; the Roman army was beaten and Crassus slain at the Battle of Carrhae (53). Two years later, the Parthians invaded as far as Antioch but then withdrew. A civil war in Rome between Pompey and Julius Caesar, followed by a period of anarchy after Caesar's assassination in 44, gave rise to unstable conditions in the East; the Parthians invaded again in 40, dislodging the Romans from most of the province. Only with difficulty did Mark Antony restore order. In Palestine, Antipater was made procurator of Judaea and was allowed to make his sons Phasael and Herod governors of Jerusalem and Galilee, respectively. Antipater was murdered in 42, but Mark Antony made Phasael and Herod tetrachs. The Parthian invasion enabled the Hasmonean party, now represented by Aristobulus' son Antigonus, to seize power; and Phasael and Hyrcanus were both captured. Herod escaped to Rome and appealed for help, and the Senate, judging that he would help Rome against Parthia, named him king of the Jews. Herod returned to Palestine with Roman help and began to fight for his kingdom. Jerusalem fell in 37, after an enormous and deliberate slaughter; Antigonus was executed in Antioch at Mark Antony's command, and Herod the Great's reign began.

The kingdom of Herod the Great. Herod's position was not completely secured for several years. Mark Antony was vanquished at Actium (31), leaving Octavian (later Augustus) sole ruler in Rome. Herod met Augustus and convinced him of his loyalty. His kingship under Rome was confirmed, and during the succeeding years he proved his ability as an administrator and in maintaining law and order on Rome's eastern frontier, and he was permitted to make important additions to his kingdom. At its greatest extent, in 20 BC, Herod's kingdom stretched from Idumaea in the south to Galilee in the north and included most of southern Syria and much of Transjordan (Peraea).

Herod ruled as a confederate king, directly responsible to the emperor. He provided auxiliary troops to protect the empire's eastern frontier but paid no tribute, and in internal affairs he was largely independent. He murdered several members of the Hasmonean house, whom he suspected might still threaten his position. His enthusiasm for Hellenistic culture led him to spend more of his country's resources on vast building programs than was economically wise. Jerusalem itself was entirely changed by his massive building programs.

Yet Herod was aware of the peculiar problems of his kingdom, with its mixed Jewish and gentile population, and he probably genuinely wanted to bridge the gap between the two. Within the Jewish parts of his realm he was careful to observe the Jewish law, and thus he managed to prevent a recurrence of a wholesale rebellion against Hellenism and gave Palestine a few decades of relative tranquillity in which the material benefits of Greco-Roman civilization could be felt.

Herod's successors. Herod died in 4 BC, a year or so after the birth of Christ, and his realm was divided between three of his sons: Archelaus received Judaea, Samaria, and the coastal towns; Antipas, Galilee and Peraea; and Philip, southern Syria. But the Romans deposed Archelaus in AD 6 and replaced him with a series of Roman prefects (the most famous of whom is Pontius Pilate). Philip died in 34, and his territory was soon given to one of Herod's grandsons, Agrippa, who had secured the confidence and friendship of the emperor Caligula. In 39 Antipas was also removed, his domain given to Agrippa, and two years later Archelaus' former territory was also given to Agrippa. Thus, until Agrippa's death (44), most of Herod's kingdom was reconstituted. Agrippa ruled much as Herod had, as a rich Hellenistic king in the gentile areas and as a devout Jew in the Jewish. Yet, unlike Herod, he was popular with the Jews (the majority of whom were becoming less averse to Hellenism) and less so with the Romans, who considered him too independent and arrogant. When he died the emperor Claudius refused to accept his son, a minor, as king and turned the realm into the procuratorial province of Judaea.

Jewish resistance

Herod and his successors could not wipe out all resistance to Hellenism among the Jews. There were, of course, varying degrees of resistance. Herod's supporters sought to bridge the gap between the two cultures and thus have the best of both worlds; the Sadducees combined a strict adherence to the Mosaic Law with at least a partial acceptance of Hellenism; the Pharisees were sterner opponents of foreign culture but more flexible in their attitude toward Judaism; the Essenes and other groups hoped for a messiah to deliver them from Roman domination and restore an independent Jewish nation. The Zealots had the most important influence on political events. They condemned anything foreign and insisted that force was the only weapon with which to combat it. At first only a minority, they grew powerful as Roman policy toward the Jews changed. The mad Caligula reversed the formerly tolerant Roman policy by attempting to install his own statue in the Temple, and only his timely murder saved the day. After Claudius' inauguration

of the province in 44, conditions worsened under a series of greedy and incompetent procurators, and in 66 revolt broke out (the First Jewish Revolt—66–77).

The governor of Syria could not quell the uprising, and the emperor Nero entrusted the campaign to the veteran commander Vespasian. With superior forces Vespasian slowly and effectively subdued Galilee and Judaea. When he was recalled to Rome to become emperor himself, he gave his army to his son Titus. In 70 Titus captured and completely destroyed Jerusalem with great slaughter. In 73 the last flames of revolt were put out at Masada, where the last rebels committed suicide rather than fall into Roman hands.

The Jewish nation was not destroyed, however, and the Romans behaved with remarkable moderation. Except in Jerusalem and a few other cities, little material damage was inflicted, and life went on very much as before. Even in the capital, where a Roman legion was stationed, Jews continued to live among the ruins. Although the Romans strengthened their hold on the country and to this end elevated it to the status of a praetorian province, they continued not to interfere in purely Jewish affairs.

In 115–116 rebellions by the Jewish communities in Egypt, Cyrene, and Cyprus were only prevented from spreading to Palestine by the savage measures taken by the governor, Lusius Quietus. In 130 Hadrian, an ardent philhellene, rebuilt Jerusalem as a Roman colony, called Aelia Capitolina, with a shrine to Jupiter on the site of the Temple. But revolt broke out again. Bar Kokhba was proclaimed messiah and commander, and the Romans, taken by surprise, were forced to abandon their new colony. The Temple was partly restored and was rededicated to Yahweh. But Roman might was restored in 135, thus ending the Second Jewish Revolt. Jewish captives were executed or sold into slavery, and the survivors were forbidden to assemble for prayer, practice circumcision, or visit Jerusalem. The colony of Aelia Capitolina was re-established, and Judaea was renamed Syria Palaestina.

Roman Syria and the Palmyrene episode. The rebellions faced by the Romans in Palestine were exceptional for their eastern domains; elsewhere, the population of Syria was glad to accept the benefits of Roman government and the security it brought. Following the wars of the 1st century BC, the security of the eastern frontier was entrusted to a number of client kingdoms: Nabataea and Judaea in the south, Palmyra in the east, Commagene and Cappadocia in the northeast and north. By the early 2nd century AD, these kingdoms had all been absorbed into the empire, and Hadrian strengthened the imperial border with Parthia by a network of roads and fortresses, the remains of which are a conspicuous feature of the landscape of western Palestine and Syria today. In about 193 the emperor Lucius Septimius Severus reorganized the Syrian province, dividing it into two by making the Phoenician coast the separate province of Syria Phoenice.

Client kingdoms

In the 3rd century the Parthians were replaced as rulers of Iran by the more aggressive Sāsānians, who in 260 overran northern Syria, destroyed Antioch, defeated the Roman legions at Edessa, and captured the emperor Valerian himself. From this crisis the empire was saved by a native Syrian prince, Odaenathus of Palmyra. Although within the empire Palmyra had been granted a measure of independence by Septimius Severus, and a line of native rulers had emerged, honoured by the Romans for their loyalty. Odaenathus succeeded in throwing the Sāsānian forces back across the Euphrates and laid siege to the Persian capital at Ctesiphon. In gratitude for his services, Rome granted him the title *dux orientalis* ("commander of the East"). He died soon after, leaving a widow, Zenobia, who exceeded him both in talent and ambition. Shaking off Roman tutelage altogether, she assumed the title Augusta and, in the manner of a completely independent ruler, invaded Anatolia, western Syria, Palestine, and even Egypt, where a Palmyrene garrison was stationed in Alexandria. Her "empire" was short-lived; in 272 Aurelian restored Roman authority throughout the eastern provinces, destroyed Palmyra, and sent Zenobia to Rome as a prisoner.

The effects of Roman rule. Syria, one of the wealthiest of the Roman provinces, was an important supplier of grain to the rest of the empire. Fruits, nuts, and other tree products were also sent to Rome. Palestine was, as always, less favoured agriculturally but shared with its northern neighbour the benefits of a thriving eastern Mediterranean trade. Commerce continued to be the primary activity of the Levantine peoples; the many Syrian merchants who settled in Rome and other western cities brought eastern culture and religion with them.

The process of Hellenization continued under the Romans; Greek continued to be the language of a flourishing literature and philosophy. The emperors, especially Hadrian, Antoninus Pius, and Septimius Severus, founded and embellished cities (Antioch, Baalbek, Palmyra, Jarash, Bozrah, and Petra) in the manner of Alexander and the Seleucids. Although these were given some measure of Roman administrative machinery, they remained both in external appearance and in internal character essentially Greek. As under the Seleucids, Aramaic remained the language of the common people.

Culture under the Romans

Syria and Palestine in the late Roman and Byzantine periods, c. 300–634. *The Christian Golden Age.* The 3rd and 4th centuries were, on the whole, as prosperous as the two preceding ones, and the Byzantine period was to prove a Golden Age for Syria, and especially for Palestine. The emperor Constantine I (306–337) embraced Christianity and made it the favoured if not the sole religion of the empire. As protectors of the new religion, he and his successors evinced a special interest in Palestine, the land of its origin. Constantine's mother, Helena, visited Jerusalem, beginning the cult of pilgrimage to Christian shrines, which contributed greatly to the country's prosperity. The desert fringes of the country in the south and in the east, settled in Nabataean times but then neglected during the 2nd and 3rd centuries, became the scene of intense agricultural and urban development. Churches were built everywhere in the existing towns and in numerous new villages. Syria, especially the north, between Antioch and Aleppo, shared in this prosperity.

Christianity was not without its rivals, both in Syria and Palestine. In the north, pagan cults and Greek philosophy persisted; in Palestine, the Jews, although suffering from the official recognition given to their Christian rivals and (after 428) from exclusion from civil and military posts in the empire, benefitted from the prosperous times and continued to build synagogues in defiance of the law; these, while less assuming and conspicuous than the churches, vied with the latter in the splendour of their interior decoration, particularly in mosaic work, the art form *par excellence* of the period.

Sāsānian and Muslim invasions. Secure from attack in the 4th and 5th centuries, Syria and Palestine suffered from renewed Persian inroads in the 6th century. In 540 the Sāsānian king Khosrow I invaded Syria, sacking Antioch, Apamaea, and other Christian cities. The Byzantine emperor Justinian strengthened Syria's defenses following this incursion, but in the early 7th century the Sāsānians ravaged Syria once more and extended their activities farther south; Damascus and Jerusalem were both taken (614) and Egypt was occupied by the Persian army (616). Byzantine fortunes revived when the emperor Heraclius invaded Persia and forced the Sāsānians to sue for peace. In 629 Heraclius entered Jerusalem in triumph and restored the "True Cross," carried off by the Sāsānians 15 years previously. But while Heraclius was ridding his empire of the Persian foe, the southern borders of that empire were being harassed by groups of Arabs. This was nothing new and hardly gave cause for concern. These Arabs, however, were Muslims, followers of Muḥammad, who had founded a new religion in the Hejaz. Hardy fighters, united in their creed, and boundless in their ambition, they permanently removed Syria and Palestine from Byzantine control in the decade following Heraclius' triumph. (P.J.Pa.)

Heraclius' counter-attack

III. From the Islāmic conquest to 1920

MEDIEVAL PERIOD

The conquest and its sequence. The Arab–Muslim conquest of Syria was accomplished easily. Begun in 634,

it was practically completed by 636. Weakened by the Persian invasion, but, above all, morally and socially alienated by Byzantine domination, by interchurch struggles, and by the ethnic and social gap between a hellenized aristocracy and a subordinate Aramaean population, individual regions never really resisted their new masters and sometimes even welcomed them. As far as is known, there had been Arabs within the borders of Syria for a long time. And accommodation to the new rulers was also made easier by the fact that Islām remained a remote entity—the native population was able to keep its religious freedoms and social customs. The majority of them bent to the new regime and helped to strengthen it by supplying it with administrative staff and by participating in cultural developments. The change in administration resulted in only a partial economic separation from Constantinople, and although coastal ports lost, the towns of the interior gained.

Because it was the passageway to Mecca and to Medina, Syria became the principal political and military centre of the newly conquered area. And its importance in the Muslim empire was further increased when the third caliph (successor to Muḥammad), ʿUthmān, was assassinated by a group that brought ʿAlī (the cousin and son-in-law of Muḥammad) to power; a leading member of ʿUthmān's family, Muʿawiyah, governor of Syria, defeated ʿAlī's forces (657) and became the first of the Umayyad line of caliphs. He kept his seat of government among the Syrian Arabs who had been responsible for his victory; Damascus replaced Medina as the political capital of an empire whose new conquests soon extended from the Aral Sea to the Pyrenees. To the north, only Byzantium resisted, and Syria, as the base for operations launched against it, was of particular strategic importance. The 90 years of the Umayyad dynasty were thus for Syria years of considerable development. Little is known of how Arab–Christian cohabitation was organized in Damascus during the Umayyad period, although it is known that in Syria the Arabs rejected the special town-garrisons (that is, segregation) they had resorted to elsewhere. The evidence suggests that, except under ʿUmar II, Christians were at least well tolerated.

The Umayyad caliphate

The Umayyad period is remembered for cultural, especially architectural, achievements. In Damascus was constructed the Great Mosque, and in Jerusalem the Mosque of ʿUmar and the Dome of the Rock. On the edges of the desert elegant residences permitted the caliphs and the Arab chiefs to link ancestral Bedouin life with that of the new Syrian society. In intellectual life, Arab culture, which was particularly focussed on poetry, was also juxtaposed with the indigenous culture. Meanwhile, both Islām and the Arab language had slowly begun to gain native adepts; they did not, however, expand at the same rate. Even in the second half of the 20th century, in Iran, there are nonarabicized Muslims. And in Syria there are still important Christian communities within a population that is entirely arabicized linguistically.

Under the later Umayyads the strength of the central government declined. There were factions and feuds inside the ruling group: the Arabs of Iraq resented the domination of Syria; the non-Arab converts to Islām (*mawālī*) resented the social gap between them and the Arabs; devout Muslims regarded the Umayyads as too worldly in their lives and policies. After the defeat and death of ʿAlī's son Ḥusayn at the Battle of Karbalāʾ in 680, sentiment in favour of the family of ʿAlī was still strong. The later Umayyads could not control these discontents. Their rule was finally overthrown and the family virtually destroyed by the new ʿAbbāsid caliphate in 750.

From the 8th to the 12th century. The end of the Umayyad dynasty meant a shift in power from Syria to Iraq. Syria returned to the rank of a simple province, of secondary importance and held in suspicion because of its Umayyad attachments. Even its military role decreased since the war against Byzantium was no longer anything more than a matter of local raids carried out by the frontier people of Cilicia or the Middle Euphrates. Important commerce abandoned it, sucked up by Alexandria, Constantinople, and Baghdad.

The ʿAbbāsid dynasty found itself faced with difficulties that undermined it in its turn. Little by little its most remote provinces began to separate themselves politically, and the army, up to then its source of strength, began to turn into an instrument of disorder.

Starting in the last third of the 9th century and then again, after an interruption, in the second third of the 10th century, Egypt became the seat of certain powerful dynasties: the Tūlūnids, the Ikshīdids, and, most importantly, from 909 to 1171, the Fāṭimids. Syria then became a battlefield for the rival ambitions of these dynasties; first those of the Tūlūnids, who secured control of it from the ʿAbbāsid caliphate; then those of the Ikshīdids and the Fāṭimids, who took control of the centre and the south but had to abandon the north to other Arab dynasties, including the Ḥamdānids and the Mirdasids. The Fāṭimids reintroduced the religious doctrine of Ismāʿilism, to which their rivals the Qarmaṭians, who were influential in the subdesert zone between Iraq and Syria, also adhered. These two sister but enemy sects came into conflict, notably over the control of Damascus, at the end of the 10th century. The Ḥamdānids were established in the north and had the city of Aleppo as their capital. They engaged in war with Byzantium, but their early successes were followed by the Greek recovery of Antioch and its province in 969. Although practically deserted by the rest of the Muslim world, the leading prince of Aleppo, Sayf ad-Dawlah, was able to mobilize the enthusiasm of the Bedouins, his principal supporters, by organizing the only form of war to which they were adapted—counter-raids in depth against the enemy's rear. He could not put off the end indefinitely, however, and Aleppo became for a century thereafter a kind of protectorate, alternatively under the control of the Byzantines and the Fāṭimids.

The beginning of Egyptian domination

But Aleppo has remained famous in the eyes of posterity, for around the court of the Ḥamdānids lived some of the greatest Arabic writers: the poets al-Mutanabbi and Abū-Firās, the philosopher Al-Fārābī, and the anthologist Abū al-Faraj al-Iṣbāhanī. For a brief period Aleppo became a cultural centre that attracted many people—even the Iraqis.

Certain developments that were to mark Syria for a long time to come occurred during the 10th and 11th centuries. Tribes moving from Arabia or driven from Egypt and Mesopotamia increased the Bedouin element. Among the Christians, a group that had been looked down upon by the other sects retrenched itself on the western slopes of Lebanon. These were the Maronites, who were to become of increasing importance. The Muslim population was affected by the schism found throughout the Muslim world between two Islāmic sects—the orthodox Sunnites and the Shīʿites. Damascus and southern Syria, with Palestine, were primarily Sunnite; Aleppo and the Arabs who dominated the region around it were Shīʿite. At the end of the 10th century, Syria was threatened by the Qarmaṭians, who had established a state in the Persian Gulf. The danger was beaten back, but it returned in a more insidious form as an esoteric doctrine spread by the Ismāʿilis from their centre at Salamīyah (Selemīya) in northern Syria. In southern Lebanon another offshoot of Shīʿism took root: the Druze religion, preached by missionaries sent from Egypt by the Fāṭimid caliph al-Ḥākim.

At the beginning of the 11th century, life in Jerusalem was temporarily affected by Ḥākim's unusual persecution of the Christians, knowledge of which was brought back to the West by Pilgrims. The Church of the Holy Sepulchre was destroyed, but Ḥākim's successors returned to the previous policy of tolerance and, desiring a political reconciliation with Byzantium, even gave the Byzantines a kind of protectorate in the holy places over Christians, particularly those of the Greek rite. In this atmosphere of toleration flourished persons touched by a kind of religious skepticism, such as the great blind poet Abū al-ʿAlāʾ al-Maʿarrī.

Not of central importance to the great powers, and often

fought over by their dependents or other local potentates, Syria was able to become an area conducive to the development of certain new forms of autonomy. Various types of local militia appeared in many of the Near Eastern towns before the middle of the 11th century. These militias sometimes took the form of secret societies (*futūwwah*) or were sometimes representative of town interests. Of the latter type were the *aḥdāth* (young people) of Damascus, Aleppo, and other towns of Syria and Upper Mesopotamia, who shared effective power with helpless princelings, at least within the town walls. The leader of the *aḥdāth*, the *ra'īs al-balad*, or town leader, was for some time close to being the equivalent of mayor. Tripoli in Syria offers an example of another tendency toward autonomy and independence. Throughout the Muslim world, justice was dispensed locally by the *qāḍī*, who theoretically represented the law but in actuality was closely tied to the local "bourgeoisie." Just as the families of bishops dominated the towns of southern Italy, the family of the *qāḍī* Ibn ʿAmmār founded a prosperous dynasty in Tripoli, one that would probably have lasted much longer if the Crusades had not put an end to it.

The 11th-century coastal towns, such as Tripoli, benefitted from the commercial revival that was taking place in the Mediterranean area, one that involved relations with the Maghrib and, increasingly, with southern Italy. In addition, pilgrims from the West were arriving in greater and greater numbers. Thus Europe and the Near East were in the process of being brought into contact.

Invasion by Turks and crusaders

In the middle of these events Syria fell into the hands of the Seljuq Turks, who had established a sultanate in Western Asia Minor. They occupied Jerusalem and then Damascus, later Aleppo. But after the death of the sultan Malik-Shāh in 1092, the Seljuq Empire fell to pieces; and between 1098 and 1124 the crusaders occupied Antioch, Jerusalem, al-Karak in Transjordan, and the coast. The crusaders organized their conquests into four states, the most important of which was the kingdom of Jerusalem (see CRUSADES). Their situation was precarious, however. The crusaders were always a minority in their states, and they never penetrated far into the interior. They could maintain their position only as long as the surrounding Muslim states were weak and divided. Zangī, the Turkish ruler of Mosul, occupied Aleppo in 1128 and recovered Edessa from the crusaders in 1144. His son Nureddin united inner Syria and annexed Egypt.

Nureddin was also the animator of a program that appealed directly to the pietist sentiments of all Muslims. Under his direction, holy war again became the official and prime task of the regime. Annexation of Muslim territory was presented as necessary to the battle against the infidel, a device that was helpful in discrediting any independently minded princes in the common military action. The triumph of Nureddin's career was the dispatch of an army to Egypt, where the factions around the last Fāṭimids were disintegrating.

Victories of Saladin

Nureddin's campaign was completed by the man who was at the head of the victorious army in Egypt—Saladin. Saladin was one of the numerous Kurds enrolled in the Turkish armies. He put an end to the Fāṭimid rule (1171) and created a strong kingdom of Egypt and Syria. The states established by the crusaders were encircled, and Egypt's resources were put to the service of the holy war. He then defeated the crusaders at the great Battle of Ḥiṭṭīn (1187). He recovered all Palestine and most of the inland strongholds of the crusaders. Soon afterward, however, the Third Crusade recaptured part of the coast, where European rule lingered for another century.

(C.C.)

The Ayyūbids and Mamlūks. After Saladin's death his kingdom was split up among members of his family, the Ayyūbids, who established principalities in Aleppo, Ḥamāh, Homs, Damascus, Baʿlabakk, and Transjordan and ruled them until 1260. The period of Nureddin, Saladin, and their successors was of great importance. Thanks largely to the establishment of Italian trading centres on the coast, and better security, economic life recovered and Syria reached a level of prosperity such as it had not enjoyed for centuries. The Ayyūbid rulers stimulated culture and architecture. Following the Seljuqs, they created a new land system based on the grant of rights over land in return for military service. They were champions of Islāmic orthodoxy against the sects that had gained ground in the previous era. They supported orthodox theology and law and built colleges of a new type, the *madrasah*, as centres of orthodox learning. Their efforts to stamp out heterodoxy were not completely successful. The Ismāʿīlīs kept their strongholds in the mountains, and their secret organization, the Assassins, had some political importance. The Druze religion also spread.

Although strong internally, the state was still in danger from the Bedouin tribes of the desert and from the Mongols, who invaded Syria for the first time in 1260 and sacked Aleppo. They were driven back not by the local rulers but by a new Egyptian military group, the Mamlūks, a self-perpetuating elite of slaves and freedmen, mainly of Turkish and Caucasian origin, who had replaced the Ayyūbids as rulers of Egypt in 1250. In 1260 they defeated the Mongols at the Battle of ʿAyn Jālūt in Palestine; the victorious Mamlūk general, Baybars I, made himself sultan of a reunited kingdom of Syria and Egypt, which he ruled until his death in 1277. This state continued to exist for over two centuries. In 1291 it won back Acre and other coastal towns from the crusaders, who were expelled; and a few years later it took the last crusading stronghold, the island of Ruad (Arwād). The Mamlūks reorganized the Ayyūbid principalities as six provinces, of which Damascus was the largest and most important. Political power was in the hands of the Mamlūk elite, who held land in virtual ownership in return for military service in the cavalry. But there was a local element in the government, the civil servants being drawn mainly from Syrian Arab families with their tradition of religious learning. Local rulers such as the Buhturids of Lebanon were recognized and absorbed into the "feudal" system.

Like the Ayyūbids, the Mamlūks were strictly orthodox in religion. Religious culture flourished and produced a number of great scholars such as the Ḥanbalī jurist Ibn Taymīyah. For religious and political reasons, the Mamlūks dealt severely with the religious minorities living in the coastal mountain ranges: Druze, Maronite Christians, Ismāʿīlīs, and ʿAlawites (or Nusayrīs; adherents of another creed derived from extreme Shīʿism and living in the Jabal an-Nuṣayrīyah). One of the principal reasons for this severity was the fear of the Mamlūks that these minorities might cooperate with the crusaders, should they attempt to return.

In the early Mamlūk period, Syria remained prosperous; the rulers constructed public works, and Venetian merchants carried on their coastal trade. But in 1401 came a blow to economic life: a new Mongol invader, Timur (Tamerlane), sacked Aleppo and Damascus. His empire did not long survive his death in 1405, but the damage had been done. The cities had been burned, a large part of their population killed, and many craftsmen taken away to Central Asia.

Invasion of Timur

OTTOMAN PERIOD

Ottoman government, 16th–17th centuries. Throughout the 15th century, Mamlūk Syria continued to decline, while a new power was growing to the north, that of the Ottoman Turkish sultanate in Asia Minor. Having occupied Constantinople and the Balkans, it began to look south-southward. In 1516 Sultan Selim I defeated the Mamlūks in the Battle of Marj Dābiq and occupied the whole of Syria that year and Egypt the next. While Egypt later recovered some autonomy under the Mamlūks, Syria remained for 400 years an integral part of the Ottoman Empire. It was divided into provinces, each under a governor: Damascus, Aleppo, and later Tripoli and Ṣaydā, or Sidon, of which the administrative centre was later moved to Acre. Damascus, the largest, had special importance as the place from which the pilgrimage to Mecca was organized every year. The governor of Damascus led the pilgrimage when possible, and most of the revenues of the province were earmarked for its expenses.

The tax system continued in principle to be that of

Muslim law—land tax, poll tax on Christians and Jews, and customs duties. But the Ottomans, like their predecessors, gave the right to collect and keep the land tax in return for military service and thus created a virtual land-owning class. Later, this system was allowed to decay, and tax collection was turned over to tax farmers (*mültezim*), who themselves became in the course of time a land-owning class. Another official hierarchy, the religious hierarchy of judges, jurisconsults, and preachers, served as an intermediary between government and subjects.

Within this framework of law, order, and taxation, the local communities were left to regulate their own lives. In the desert, the Bedouin tribes were controlled to some extent by gifts, the encouragement of factions, and occasional military expeditions but otherwise were not interfered with. In the mountains, the Maronites and other Christians, Druze, Shīʿite Muslims of Lebanon, the ʿAlawites, and Ismāʿīlīs of Jabal an-Nuṣayrīyah, were watched by the Turkish governors of Tripoli, Sidon, and Damascus, but they were not interfered with so long as they paid their taxes. The Druze princes of Lebanon, first of the Maʿn and then of the Shihabid family, were recognized as governors and chief tax collectors. In the Jabal ad-Durūz south of Damascus there grew up a community of Druze farmers under no control and paying no taxes. The authority of the Christian patriarchs over their communities was recognized. In the corps of *ʿulamāʾ* (learned Muslims holding government appointments) most positions except the highest were held by members of local families having a tradition of religious learning. They continued to be, as under the Mamlūks, spokesmen and leaders of the Muslim citizens.

Economic life

The early Ottoman governors paid much attention to agriculture, and their fiscal system was designed to encourage it. In parts of Syria it flourished during the 16th and 17th centuries, and, apart from cereals for local consumption, cotton and silk were produced for export. Aleppo and Damascus not only were important centres of handicrafts but also served as market towns for the desert and countryside and as stages on the desert routes to the Persian Gulf and Persia. Aleppo and Sidon were also important centres of trade with Europe; French and English had largely replaced Italian merchants, and there grew up also a class of Syrian Christian and Jewish merchants who developed contacts with Egypt, Italy, and France.

Throughout the 17th and 18th centuries the position of the Christians improved. Catholic missions, protected by France, enlarged the Catholic communities of both Latin and Eastern rites, founded schools, and spread knowledge of European languages. The Oriental colleges in Rome produced an educated priesthood, and the Christian communities in Aleppo and Lebanon brought forth scholars such as the famous Joseph Assemani, Vatican librarian, and Arabic writers such as Germanos Farhat, Maronite archbishop of Aleppo. The traditional Muslim Arab culture could still produce a theologian of some originality in ʿAbd al-Ghanī an-Nābulusī and a systematic jurist in Ibrāhīm al-Ḥalabī.

Decline of Ottoman authority. In spite of a widespread revolt in the early 17th century, Ottoman rule was in general stable and effective until the end of that century. After that it declined rapidly, in Syria as elsewhere. Control by the central government weakened; the standard of administration sank; the Janissaries (the elite troops of the sultan) lost their discipline and became a menace to order. The result was a shrinkage of agricultural production, as the villages suffered from the depredations of soldiery and tax collectors and from Bedouin incursions. This was a period of activity in the Syrian desert, and Bedouin tribes, moving northwest from Arabia, extended their control far into the settled land. In the towns there was also a decline. The desert routes were unsafe, and the European merchant colonies were shrinking. But there was still a vigorous commercial life; the standard of craftsmanship was high, and the great tradition of Islāmic architecture was continued.

Ottoman authority did reassert itself to some extent, but in a new form. For most of the 18th century, Damascus was ruled by governors belonging to the ʿAẓm family, loyal to the sultan but with more independence than earlier sultans would have allowed. They controlled the Janissaries, kept back the Bedouin, maintained security, and sometimes extended their authority to other provinces. In the province of Sidon, power was held on similar terms by a ruthless and able Bosnian governor, Aḥmad al-Jazzār (1775-1804), and his group of Mamlūks. Such rulers raised their own armies, but this involved additional taxation and further depressed the condition of the peasants. Agriculture flourished only in the hilly districts, which were virtually beyond Ottoman control, free from Bedouin attacks, and ruled by strong local rulers who protected agriculture and made Acre a prosperous centre of trade.

At the beginning of the 19th century, the population of Syria was perhaps 2,000,000. There were some islands of prosperity: Aleppo and Damascus (each with roughly 100,000 inhabitants), Mt. Lebanon, and certain other secluded districts. In general, however, the country was in decay, the small towns subsisting on local trade, the villagers receding in face of the Bedouin. The Ottoman hold on the country was at its weakest. At Acre, it is true, al-Jazzār maintained his strong rule and was able, with the help of a British fleet and the Turkish army, to hold back Napoleon when he invaded Palestine in 1799. But in Damascus and Aleppo the governors were scarcely able to control the population of city or countryside. The prince of Lebanon, Bashīr II (1788–1840), who had been installed by al-Jazzār and remained quiet while al-Jazzār was alive, gradually extended his control over districts beyond Lebanon. In 1810 the Wahhābīs from central Arabia threatened Damascus.

Egyptian domination. In 1831 the ruler of Egypt, Muḥammad ʿAlī, sent his son Ibrāhīm Pasha at the head of his modern army into Palestine. Helped by Bashīr and other local leaders, Ibrāhīm conquered the country and advanced into Asia Minor. He ruled Syria for almost ten years. The whole country was controlled from Damascus. There and in the provincial centres the governors were Egyptians, but they were assisted by councils representing the population. In political matters Ibrāhīm relied largely on Bashīr, and in financial concerns on a Syrian Christian adviser. New taxes were introduced and strictly collected, agriculture was encouraged, and the Bedouin pushed back. After an abortive attempt to introduce trade monopolies, Ibrāhīm encouraged European traders by maintaining better security and creating special commercial courts. It was in this period that Beirut became important as a centre of trade with Europe. The Christian and Jewish populations were treated with consideration.

European intervention in Syria

After a time, Ibrāhīm's rule became unpopular because his taxes were heavy and because he disarmed and conscripted the population. The European powers (except France) also objected to Egyptian rule in Syria because it was a threat to the Ottoman Empire, the weakness or disintegration of which might cause a European crisis. In 1839 war broke out between Muḥammad ʿAlī and his suzerain, the Sultan. Ibrāhīm defeated the Turkish army, but in 1840 the European powers intervened. After an ultimatum, a British, Turkish, and Austrian force landed on the Syrian coast; there was a local insurrection encouraged from outside, and the Egyptians were forced to withdraw from Syria, which reverted to the Sultan's government.

Ottoman rule restored. The next 20 years were a period of mounting crises. Bashīr II was deposed by the Ottomans because of his support of the Egyptians; his successor was in turn soon deposed. Lebanon became the scene of a struggle for power between Druzes and Maronites, with undertones of social conflict. In the rest of Syria, an attempt was made to apply the new Ottoman administrative system. But the new system of taxation and conscription caused unrest. This situation was worsened by the growth of European influence; the Muslim majority became aware of the weakness of the Islāmic community, and the connection of France with the Catholics and of Russia with the Orthodox both encouraged the minorities

to hope for a more favourable position and focussed on them the hostility of their Muslim compatriots. There was also economic unrest. From the 1820s, European goods flooded the market and replaced the products of local craftsmen. This diminished the prosperity of the artisan class, largely Muslim, but increased that of the import merchants, mainly Christians and Jews.

The tension thus generated burst out in 1860 when a civil war of Druzes and Maronites in Lebanon touched off a massacre of Christians by a Muslim mob in Damascus. The Ottoman government sent a special commissioner to punish the guilty and suppress disorder. France sent an expeditionary force, and a European commission discussed the future of the country, coming to the conclusion that Lebanon (the mountain itself but not the coastal towns) should be an autonomous district (*mutaṣarrifīyah*) but that no change should be made in the rest of Syria.

From then until the collapse of the Ottoman Empire, Syria continued to be governed as a group of Ottoman provinces. From 1888 there were three: Damascus, Aleppo, and Beirut. The new administrative and legal system was more carefully applied, and a new type of educated official gradually raised its standards. The introduction of railways and telegraphs made possible a stricter control. A French-built railway linked Beirut and Damascus, with a later extension running north to Aleppo, and in 1908 the Hejaz Railway was opened to take pilgrims from Damascus to Medina. Railways and better security encouraged agriculture. Transjordan and al-Jazīrah, the district between the Upper Euphrates and Tigris, ceased to be wholly nomadic. In other parts, however, the growth of population outran the increase of production, and there began a large-scale emigration to North and South America. The trade of Beirut increased steadily; its modern harbour was built by a French company, and by 1914 its population had grown to about 150,000. Aleppo (population about 200,000) and Damascus (250,000) both had a flourishing trade, but the crafts declined, and the desert routes suffered from the opening of the Suez Canal.

In Beirut and other cities there was a considerable change in social life. The upper and middle classes adopted the clothes and social customs of western Europe, and Western-style schools flourished. In 1866 the American Protestant Mission opened in Beirut the Syrian Protestant College (later the American University of Beirut), and in 1881 the French Jesuits opened the Université Saint-Joseph in the same town. The government opened schools, and young men of the great Arab families of the towns began to attend the higher schools in Constantinople and to go on to civil or military service.

Under Sultan Abdülhamid II (1876–1909) the Muslim Arabs of Syria were reasonably content. His emphasis on Islāmic solidarity frightened the Christians, but the Muslims on the whole still regarded the Ottoman Empire as the political embodiment of Islām. Syrian Arabs played a leading part at the Sultan's court.

Emergence of Arab nationalism

After the Young Turk revolution of 1908, relations between Arabs and Turks grew worse. Power fell into the hands of a Turkish military group whose policy stimulated the growth of opposition. Arab nationalist feeling became more conscious, and political parties, both open and secret, were organized by Syrians in Cairo, Constantinople, and Paris as well as in Syria itself. Their explicit demand was for improved status within the empire and some local autonomy, but there was a growing feeling in favour of independence and the establishment of a Syrian or Arab state. This was the aim of the secret Fatāt Party founded in 1911. Many Christians, particularly Maronites and other Catholics, wanted an independent Lebanon with extended frontiers and under French protection. Among the nationalists were some who looked to England and France for allies in the struggle for independence, but others were conscious of the danger of domination by those countries. France had paramount influence on the Syrian coast and in Lebanon, while in Palestine all the powers competed for influence. And in the 1880s there had begun Jewish immigration from Russia and eastern Europe, aiming to create a national home for the Jews under international guarantee.

World War I. When the Ottoman Empire entered World War I in 1914, Syria became a military base. In 1915 an Ottoman army under German command attacked the British position on the Suez Canal, and from 1916 a British and imperial force based in Egypt, with a French contingent, undertook the invasion of Palestine. By the end of 1917 Gen. Sir Edmund (later Field Marshal Viscount) Allenby had occupied Jerusalem and by November 1918 the rest of Syria. Most Christians and Jews welcomed the occupation; among the Muslims a large proportion had remained loyal to the empire, as being all that was left of the political independence of Islām, but the nationalist societies had made common cause with the ruler of the Hejaz, Sharīf Ḥusayn, forming an alliance with Britain against their Turkish suzerain. An Arab army under the command of Ḥusayn's son Fayṣal was formed in the Hejaz, with Syrian and other Arab officers and British help led by T.E. Lawrence. It took part, under Allenby's general command, in the Syrian campaign, operating on the east flank in Transjordan and helping to capture Damascus.

Allied vacillation over Syria's future

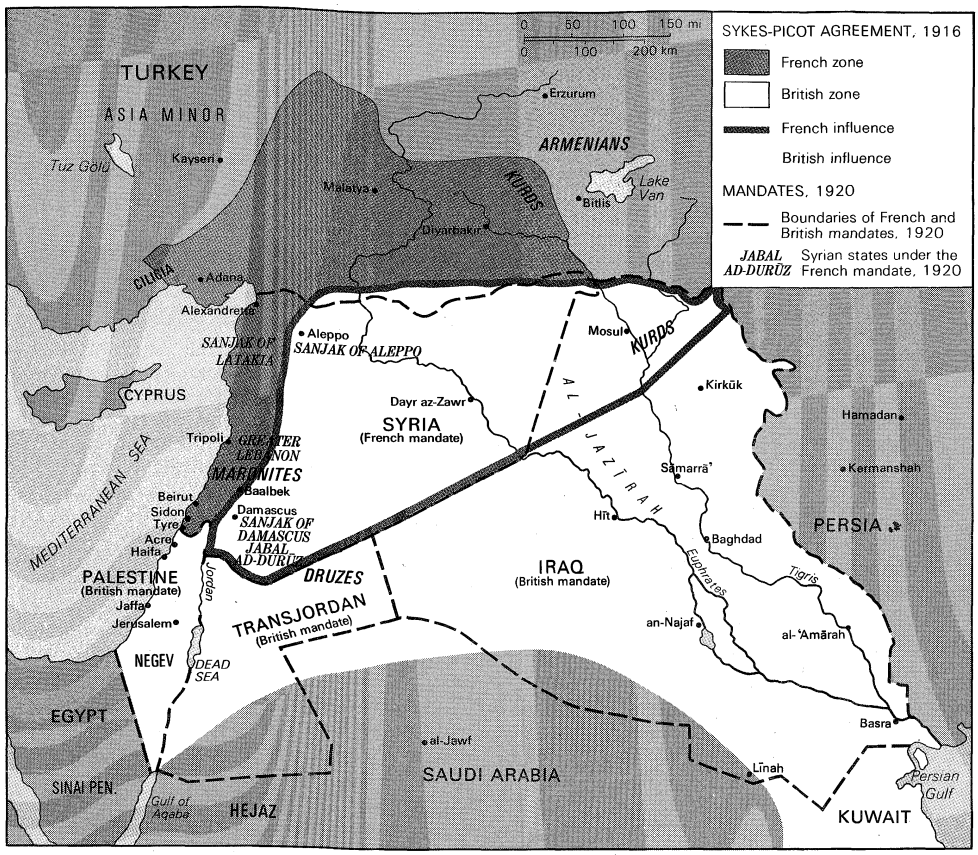
When the war ended, Allenby installed an Arab military administration, under Fayṣal, in Damascus and the interior. The French took over the coast, with Beirut as their centre, and the British took over Palestine. There followed four unsettled years while the fate of Syria was being decided. During the war the British government had made promises, to Ḥusayn and other Arab leaders, that the Arabs would be independent in those countries that they helped to liberate, subject to certain reservations, the precise extent of which has never been clear. Then, in November 1918, Britain and France declared their intention of establishing in Syria and Iraq "national governments drawing their authority from the initiative and free choice of the native populations."

By the Sykes-Picot Agreement of 1916, France was to be free to establish its administration in Lebanon and on the coast and to provide advice and assistance to whatever regime existed in the interior; Britain was to have similar rights in Transjordan and Iraq. Palestine was to be under international control, but France later agreed that it should be in the British sphere, while Britain had already, by the Balfour Declaration of November 1917, pledged conditional support for the establishment of a Jewish national home. It proved impossible to reconcile the various claims and pledges. (A.H.Ho./V.E.I.)

IV. Syria and Palestine since 1920

Events of the war and postwar negotiations had made the *amīr* Fayṣal, the most widely known and respected leader. The government he established in Damascus, although rudimentary, unfamiliar in form, and weak, appeared almost the only rallying point for nationalists. There, in July 1919, a national congress met to demand independence for Syria. Strongly opposed to the French, the nationalists were willing to settle for an interim mandate by the Americans or the British. Just 10 weeks later, Britain turned over effective control of what subsequently became Syria and Lebanon to the French, and Gen. Henri Gouraud was appointed French high commissioner there. By December fighting had broken out between the French and Fayṣal's forces on the frontier between the west and east zones.

On March 8, 1920, the Arab nationalists held a second congress in Damascus, again declaring for complete independence. Three days later, on March 11, 1920, Fayṣal was proclaimed king of Syria as Fayṣal I, but neither France nor Britain would recognize him. In April the Allied supreme council, meeting at the Conference of San Remo, ignored Syrian sentiment and offered the mandate for "Syria and Lebanon" to France. General Gouraud, faced with the problem of imposing the mandate upon the interior, took advantage of a frontier clash to crush the Arab army and occupy Damascus. Fayṣal was dethroned and forced into exile. In Syria, while he had not yet won the esteem of the whole community, the manner of his overthrow left a legacy of bitterness.



Projected and actual divisions of Syria and Palestine by the World War I Allies.
From Z. Zeine, *The Struggle for Arab Independence*

SYRIA AND LEBANON UNDER FRENCH MANDATE, 1920–41

The French organized Syria into four states: Aleppo; Damascus; the ʿAlawite country (the Latakia region); and Jabal ad-Durūz (the predominantly Druze mountain region to the south of Damascus). The state of Greater Lebanon was created from parts of the former Ottoman vilayet of Syria and of the former Ottoman vilayet of Beirut, together with Mt. Lebanon, which had enjoyed autonomy as an Ottoman sanjak since 1861. A high commissioner for Lebanon and Syria resided in Beirut. In 1922 a decision of the high commissioner established a loose federation between the four Syrian states; Lebanon was treated thereafter as a separate entity.

The new administrative organization, although obviously designed to divide and weaken opposition to French rule, had some historical justification. The ʿAlawites (or ʿAlawīs; also called Nuṣayrīs) of the Latakia region and the Druzes of Jabal ad-Durūz, both offshoots from Islām, had for centuries led an existence separate from the majority Sunnites. The provinces of Damascus and Aleppo were distinct under the Ottoman Empire and had a strong sense of local pride. Mt. Lebanon, nucleus of the French-created Greater Lebanon, was geographically and politically separate. And, finally, the province of Alexandretta, with a sizable Turkish population, was in 1923 made a sixth division of the mandate.

Whatever the rationale, however, these divisions were immediately opposed by the Syrian nationalists. In partial concession, the French reunited Aleppo and Damascus in 1925. This only encouraged the nationalists, who then formed the People's Party to demand complete national unity.

Formation of the People's Party

The Druze revolt. Minor outbreaks occurred in various parts of Syria throughout the first five years of the mandate. The first major rising against the French began in 1925 in Jabal ad-Durūz. A large French force sent against the Druzes was defeated, and the revolt spread to other parts of Syria and to the Druze portions of Lebanon. When the insurgents secured a foothold in Damascus, the French bombarded the city. A major military campaign was required to subdue the revolt in 1927.

Establishment of the Lebanese Republic. Developments were quieter in Lebanon, where the Christians, who had formed the overwhelming majority in the old sanjak of Mt. Lebanon, hailed the establishment of the state of Greater Lebanon as an achievement of Lebanese national aspirations. The territories annexed to the old mountain sanjak were preponderantly Sunnite, Shīʿite, or Druze in population; of these three non-Christian groups, only the Sunnites raised serious objections to being included in the Lebanese state.

With the support of a substantial majority of the population, the French were able to introduce numerous administrative reforms. The French governor was assisted by an elected council drawn from the country's major religious sects. The Lebanese leaders who sat in the council demanded a larger measure of self-rule, but in other respects they cooperated with the authorities and accepted the many important reforms the French introduced.

Lebanese administration

In response to the Lebanese demands, the French authorities convened the council toward the end of 1925 to draft a constitution. Upon its adoption in May 1926, the state of Greater Lebanon became the Lebanese Republic. Three days later the legislature elected Charles Dabbas, a prominent Greek Orthodox lawyer and former journalist, as first president of Lebanon.

Constitutional developments in Syria. Achievement of a constitution took longer in Syria. In 1928, a year after the suppression of the Druze revolt, a constituent assembly was summoned. This assembly, in which the People's Party and other nationalists had a large majority, drafted a constitution giving no recognition to the French mandate. The draft was therefore rejected and the assembly prorogued. Further negotiations with the nationalists ended in deadlock, and the French finally introduced a constitution that organized the state of Syria (Damascus and Aleppo) as a republic similar to that of Lebanon. The ʿAlawite state was established as a separate republic, and the Druze state maintained administrative autonomy. The first parliamentary elections in 1932 yielded, under French pressure, a majority of moderates,

but even this hand-picked assembly refused French terms for a treaty until 1936, when a treaty acceptable to both sides was finally concluded. Subsidiary agreements and letters permitted the inclusion in the Syrian republic of the ʿAlawite state, the Druze state, and the sanjak of Alexandretta, with special status. Rioting among the Turkish population of the sanjak of Alexandretta over proposed inclusion in Syria caused the French to permit the Turks to send troops to help supervise elections. Their presence secured a bare victory for the Turks in the elections. Two years later, on September 2, 1938, the sanjak of Alexandretta was proclaimed the autonomous Republic of Hatay. It was subsequently incorporated into Turkey, and its loss became a new Syrian grievance against France. The Franco-Syrian Treaty of 1936 was never ratified by France. Upon the outbreak of World War II in 1939, the French took measures to freeze the situation both in Syria and in Lebanon.

Problems and crises in the Lebanese Republic. While the politics of Syria, from the suppression of the Druze revolt until World War II, were dominated by the conflict between the nationalists and the French, the politics of Lebanon following the proclamation of the constitution were more concerned with personal and factional rivalry focussing on Émile Eddé and Bishara al-Khuri, two Maronite leaders. The internal struggle led the French to dissolve the Chamber of Deputies and to suspend the constitution in May 1932.

This provided the French with the opportunity to complete the work of administrative, fiscal, and judicial organization begun in the early years of the mandate. It also provoked a strong Lebanese opposition under the leadership of Bishara al-Khuri. When the French announced that a new president would be elected in 1936, the two men were again the rival candidates. Eddé won with a majority of one vote. Later in the year, following the conclusion of the Franco-Syrian treaty, Lebanon concluded a similar treaty with the French, envisaging complete independence for Lebanon before the end of 1939. In correspondence subsidiary to the treaty, Eddé agreed to observe certain principles, foremost among which was the equitable representation of the various religious sects in government and administration. Accordingly, Eddé asked Khayr ad-Dīn al-Ahdab, a Sunnite Muslim notable and journalist, to form a government in January 1937, thereby establishing the precedent for Sunnite premierships under Maronite presidents.

PALESTINE AND TRANSJORDAN UNDER BRITISH MANDATE, 1920–48

When the Conference of San Remo established the French mandate for Syria and Lebanon in 1920, it gave the British a mandate in Palestine, including Transjordan. When the French overthrew Fayṣal and his Arab regime in Damascus, his brother Abdullah recruited a private army in the Hejaz and announced his intention of marching on Syria to expel the French. On his way north, in January 1921, he entered Transjordan and established political dominance over its tribes and villages, with his seat in the city of Amman. The British recognized him as *amīr* (prince or governor), and in return he affirmed the British mandate, subsequently split from the rest of the Palestine mandate in 1923, and renounced his declared intention of invading Syria.

The state of Transjordan

The Balfour Declaration. In "Palestine," the definition of which was a part of the controversy, the British were committed to the establishment of a Jewish "national home." The strangeness of the term provides a hint of the complexity of the background. Zionism, like other movements of national self-expression, was a product of the political stirrings of the 19th century; like many others, it arose from bitter experiences in eastern Europe. A Zionist movement of considerable influence was created in England, America, Germany, and France, and before 1914 settlers had been sent to establish communities in Ottoman territory and attempts had been made to win approval for special status for a Jewish community there. Attempts were also made to enlist the support of the German government, which then enjoyed close ties with the Sublime Porte, to promote the scheme. When the first Russian Revolution occurred in 1917, the British believed that much of its leadership was Jewish and sympathetic to Zionism; to keep Russia on the British side and in the war seemed vital. In America (upon which war-impoverished Britain was increasingly dependent for financial support), the British government believed, supporters of Zionism were powerful and influential. For these reasons, the British Cabinet devoted much time and talent during 1917 to planning how to win Jewish sympathy. The result was a declaration, published in Europe in November 1917 as a statement from the British foreign secretary, Arthur James (later Lord) Balfour, to Lord Rothschild, head of the English branch of the banking family. This declaration, subsequently incorporated in the mandate document, was one of the most remarkable exercises in English of the 20th century; just 67 words long, it formed the starting point for political controversy for the next 30 years. It contained two juxtaposed, balanced, but—as history was to show—mutually exclusive parts: "His Majesty's Government views with favour the establishment in Palestine of a national home for the Jewish people, . . . it being clearly understood that nothing shall be done which may prejudice the civil and religious rights of existing non-Jewish communities."

Balfour Declaration

While the declaration was actively publicized in America, in Russia, and on the battlefronts, it was withheld by censorship in the Middle East. When, after the Allied victory, it was published there, and the scope of Zionist ambition was made clear, storms of protest followed. Public opposition forced Fayṣal, who had flirted with the Zionists in his more urgent fear of the French, to denounce the Zionist movement. Even when Fayṣal was overthrown and the mandate system was established, the Palestine Arab community felt so assured of general Arab support and was so encouraged by the private sympathies of British officials as to see no need to make concessions to Zionism beyond accepting the Jews already established in Palestine as a minority with guaranteed rights.

In September 1921 the British promulgated a constitution that provided for the establishment of a Palestinian state based upon the expectation of Arab-Zionist cooperation; since the constitution made concessions to Zionism that the Arabs were unwilling to accept, however, it was not applied.

Since no constitutional Palestinian state could be established, the British continued direct rule. They also continued, however, to seek ways to create auxiliaries or partners in government, and in 1923 they offered each of the two major communities an "agency." The Jewish community accepted and formed the Jewish Agency, but the Arabs refused. As so often in the following years, the Arabs' political action amounted to abstention, while the Jewish community profited by creating a shadow government that enabled them to concentrate their efforts on achievement of their major objectives.

Zionists and Arabs

Until 1925, Jewish immigration steadily increased, but from 1926 it fell, and in 1927 there was a net emigration. The Palestinian Arabs relaxed in the belief that the Zionist movement was melting away to nothing. The economic shock of 1929 suddenly reversed the trend and shattered the calm. A demonstration in Jerusalem at the Wailing (Western) Wall—which was also the outer wall of the Muslim Ḥaram (al-Ḥaram ash-Sharīf) area—was followed by the first large-scale attacks upon Jews by Arabs. In the course of the troubles, the *muftī* of Jerusalem, Amīn al-Ḥusaynī, emerged as the leader and champion of the Palestinian Arab cause.

The troubles of 1929 led the British to establish a special commission under Sir Walter Shaw, which reported in March 1930 that the conflict was mainly the result of the disappointment of Palestinian Arab hopes for independence and of the fact that Jewish expansion was creating a "landless and discontented" Arab class in the country. The Shaw Commission urged that restrictions be imposed on the management of the Jewish national home. In May 1930 the British sent a commission under

a senior civil servant, Sir John Hope Simpson, to study the whole scope of the mandate and recommend a solution to the conflict. The commission, noting Arab fears of losing the country, urged an immediate halt to immigration. The British government accepted the advice and issued the so-called Passfield White Paper to implement it. Zionist reaction was immediate, angry, and effective. Ignoring the mandate government, leaders of the movement concentrated their efforts on London and forced cancellation of the White Paper.

The Palestine revolt and the Peel Commission and later commissions. In February 1931 the British prime minister had stated, in a letter to *The Times* of London, that continued Jewish immigration "can be fulfilled without prejudices to the rights and positions of other sections of the population of Palestine." It was not this statement, however, but the election of Adolf Hitler in Germany that was to play the vital role in the years ahead. From 1933 the growing Nazi persecution increased the flow of Jewish refugees into Palestine. The Arabs there, not involved and mainly ignorant of German politics and feeling justified by the Shaw, Hope Simpson, and Passfield episodes, lapsed into a moody and sullen abstention, noncooperation, and boycott of British goods. Meanwhile, the Jewish community, chafing under existing restrictions and increasingly fearful of the rise of Nazism, about which they were better informed, protested and rioted. The British found themselves caught in an impasse.

Nazi persecution

In April 1936 an Arab High Committee was formed to unite the Palestinian Arabs in opposition to the Jews; its formation was followed by a renewal of Arab attacks on Jews, which soon developed into a civil war that was to last three years. In November 1936 a new commission, under Lord Peel, arrived to study the situation. The Arab leaders boycotted the commission until just before its departure. The report, published in July 1937, concluded that cooperation between Arabs and Jews in a Palestinian state was impossible; to the dismay of the Arabs, it recommended the partition of Palestine. Partition, it made clear, was no easy solution, since the establishment of a Jewish state would involve radical movements of population to secure the necessary Jewish majority, even in the parts of Palestine where the Jewish population was largest.

In September 1937, nonofficial representatives from the various Arab countries met at Blūdān in Syria and announced the complete rejection of the Peel proposals. In Palestine, the publication of the Peel report was followed by intensified Arab terrorism and violence. The British thereupon outlawed the Arab High Committee and arrested and exiled its leading members. The *muftī* and a few others escaped arrest and fled to Syria, which became the headquarters of a continuing Palestinian Arab insurrection.

In despair, the British government appointed a new commission under Sir John Woodhead to reconsider the partition plan suggested by the Peel Commission. The Woodhead report, published in November 1938, proposed a reduction of the Jewish share of Palestinian territory to about 400 square miles (1,000 square kilometres) around Tel Aviv—the only area where the Jews constituted a majority. The Woodhead scheme was completely rejected by both Zionists and Arabs. To seek an exit from the impasse, the British convened a conference in London, where the British conferred separately with Arab and Jewish delegations in February 1939.

When no common ground was found, the British government decided to impose its own terms, which were set forth in a White Paper published in May 1939. It stated that there would be no partition and that it was not British policy that the country should become either a Jewish or an Arab state. It envisaged the establishment within 10 years of an independent "Palestine State." In the intervening period, Jews and Arabs would be invited to take an increasing share in the administration. Jewish immigration into Palestine would be limited to a total of 75,000 persons during the next five years, after which no further immigration would be allowed without Arab consent. Land purchases by Jews from Arabs would be prohibited in some areas and restricted in others, in accordance with regulations to be published by the high commissioner.

The British White Paper of 1939

As a proposal for the final settlement of the Palestine question, the White Paper was opposed by both the Zionists and the Arabs. As a means for freezing the situation for the duration of the war, however, it succeeded. Between 1939 and 1945, Palestine was relatively quiet; both the Arab and Jewish communities, for the most part, cooperated with the British, though extremists in both communities carried on their anti-British wars.

THE ACHIEVEMENT OF SYRIAN AND LEBANESE INDEPENDENCE

In Syria and Lebanon, stability was precluded by the fate of France in the war. After that country's fall to the Germans in June 1940, a regime collaborating with Germany was established by Marshal Philippe Pétain at Vichy, while in London Gen. Charles de Gaulle formed a government in exile to cooperate with the Allies. Vichy control of Syria and Lebanon proved dangerous to the British positions in Iraq, from which vital oil was flowing, and in June 1941 British and Free French forces, proclaiming the two mandates' sovereignty and independence, invaded them. By mid-July the Allied occupation of Syria and Lebanon was complete. Gen. Georges Catroux, the representative of the Free French government in Cairo, took over control in Syria and Lebanon as delegate general rather than as high commissioner, to signify the proclaimed new order, and in February 1942 Britain appointed Maj. Gen. Sir Edward Spears as minister to Syria and Lebanon.

World War II and independence

Syria, 1941–43. In September 1941 Catroux formally proclaimed the independence of Syria as a sovereign and politically and territorially indivisible unit including the ʿAlawite and Druze territories; its independence was something less than complete, however, since it was committed to a policy strictly in alignment with that of France. In February 1942 the ʿAlawite and Druze territories were transferred to Syrian authority. Not until March 1943 did Catroux yield to British and Syrian nationalist pressure and decree the full restoration of the Syrian constitution. Elections for a new Chamber of Deputies, held in July, returned the National Bloc to power with a substantial majority; the chamber elected Shukri al-Kuwatli president. The new government demanded complete independence at once, but the Free French authorities declined to transfer powers and services to the Syrian government unless it agreed to enter into special treaty relations with France.

Lebanon, 1941–43. In September 1939, following the outbreak of war in Europe, the French had dissolved the Lebanese Chamber of Deputies, dismissed the Cabinet, suspended the constitution for a second time, and confirmed Émile Eddé as president and head of state by appointment. In April 1941 Eddé, who had quarrelled with the Vichy French authorities, was forced to resign; a Maronite judge, Alfred Naccache, replaced him as chief of state and was still in power when General Catroux formally proclaimed the independence of Lebanon. Subsequently Naccache was appointed president. In March 1943 the Lebanese constitution was restored along with that of Syria; Naccache was removed from his position and replaced by a Protestant notable, Ayyub Thabit, pending general elections.

Meanwhile, political developments had been taking place in Lebanon at a more fundamental level. After the proclamation of Lebanese independence in November 1941, and particularly after the arrival of Sir Edward Spears in Beirut as British minister to Lebanon and Syria, the nationalist leader Bishara al-Khuri and his Constitutional Bloc, backed by the British, began to press for full independence. The Christians of the Constitutional Bloc were joined by prominent Sunnite Muslim leaders of Arab nationalist persuasion, and together they reached a gentleman's agreement on the principle of Christian–Muslim cooperation in the country after independence—an agreement later known as the National Pact. By the unwritten terms of this pact, the Muslim Lebanese were

Christian–Muslim cooperation in Lebanon

to accept the independence, sovereignty, and territorial integrity of Lebanon and cease to demand union with Syria or inclusion in a pan-Arab state; the Christian Lebanese were to admit that Lebanon has an Arab character and agree to cooperation with the Arab states to the greatest possible extent.

By the summer of 1943, as the time for elections approached, the question of how to distribute the parliamentary seats among the various sects became pressing. When President Thabit, whose sympathies lay with the National Bloc, announced that the number of seats would be fixed at 54, allowing 32 for the Christians and 22 for the Muslims and Druzes, strong Muslim protests forced his removal from office. He was replaced as chief of state by a Greek Orthodox notable, Petro Trad, who raised the number of parliamentary seats to 55, giving 30 seats to the Christians and 25 to the Muslims and Druzes. This 6:5 ratio, it was understood, would be maintained in subsequent Lebanese parliaments.

In the ensuing elections the Constitutional Bloc and its allies won an overwhelming victory. The new chamber elected Bishara al-Khuri president, and Riad as-Sulh became premier. On November 8 the Sulh Cabinet presented the chamber with a special bill proposing an amendment of the constitution to remove all references to the French mandate. The bill was unanimously passed, in the absence of the pro-French National Bloc leader Eddé. On the morning of November 11, however, French marines and Senegalese troops arrested President Khuri and his ministers, and the French delegate general, Jean Helleu, announced the suspension of the constitution, the dissolution of the chamber, and the appointment of Émile Eddé as chief of state.

A general strike, angry demonstrations and riots, and the establishment of a temporary Lebanese government in a mountain hideout near Beirut, all with open encouragement from the British, forced the French to reverse themselves, and President Khuri and his party returned to Beirut in triumph. The Free French government then terminated the mandate in both Lebanon and Syria.

While the war continued and French troops remained stationed in the two countries, the French continued to press to secure French interests by special treaty relations. In May 1945, clashes between French troops and rioters in Syria, culminating in a third bombardment of Damascus by the French, led to further British intervention. In the course of the following year, the French forces were compelled to evacuate Syria and Lebanon, which finally became completely independent.

THE PARTITION OF PALESTINE AND THE EMERGENCE OF ISRAEL

Between 1922 and 1939 the Jewish population in Palestine had risen from 83,790 to 445,457 (30 percent of the total inhabitants). Tel Aviv had become a Jewish city of 150,000. Until 1939 the plans to establish a Jewish state in Palestine had been compromised by the fact that there were not enough Jews there to secure a majority in a portion of Palestinian territory of the required size. As eastern Europe fell under German domination, however, Nazi persecution drove many more Jews to seek refuge in Palestine by illegal immigration; and when the systematic slaughter of the Jews of Europe began in 1942, the flow of immigrants became a flood.

Jewish militance

As the Jewish population swelled with this influx of fugitives, the nature of Zionist activity in the country began to change and to tend more toward violence. Following the first Arab attacks on the Jews in 1921, a secret Jewish army called Haganah (Defense) had been formed. Until 1936 Haganah restricted itself to purely defensive action, but during the years of the Arab revolt it became more aggressive; it also received some legal recognition when the British administration formed a Jewish Settlement Police drawn exclusively from Haganah and placed nominally under British command. In 1937 a more clandestine Jewish militia representing the extreme revisionist party within the World Zionist Organization had been formed—the Irgun Zvai Leumi (National Military Organization). During the early years of the war, Irgun followed the lead of the Jewish Agency and cooperated with Haganah; it soon resumed its old extremist course, however, as Jewish fugitives freshly arrived from Poland joined its ranks and took over its control. The Irgun leaders were convinced that Britain had betrayed the Zionist cause—an opinion that was shared by another fanatical organization, the Stern Group, or Gang, whose leader, Abraham Stern, was killed in a police raid in 1942. In the last years of the war, the Irgun and the Stern Group began resorting to terror to remind the British of their commitment to Zionism.

Meanwhile, the Jewish Agency, under its veteran leader Chaim Weizmann and younger leaders such as David Ben-Gurion, tried to maintain British goodwill by offers of help to the British war effort. They proposed formation of a Jewish Legion to defend Palestine, and when Britain showed a disinclination to accept this proposal Palestinian Jews joined the British forces as volunteers.

Pressures for a Jewish state. A new Palestine policy was decided upon at a Zionist conference held in May 1942 at the Biltmore Hotel in New York City; it called for unrestricted Jewish immigration into Palestine and for the ultimate establishment of the country as a Jewish commonwealth. By the end of the war, Zionist political activity in the United States had succeeded in winning the U.S. government's support for Zionism, and Britain, unable to resolve the predicament on its own, was pleased to admit American involvement.

Biltmore Resolution

At the end of the war in Europe, the Jewish Agency addressed a memorandum to Britain demanding the full and immediate implementation of the Biltmore Resolution. Another memorandum followed in June 1945 demanding that immigration visas be issued for 100,000 European Jewish refugees awaiting admission into Palestine. By the time Japan surrendered in September, Haganah had gone into alliance with the Irgun and the Stern Group to present a united front in Palestine. The Jewish Agency stood ready to assume the provisional government of the Jewish state. In the absence of a unified Arab leadership in Palestine, Arab leaders from the neighbouring countries of Egypt, Syria, Lebanon, Transjordan, Iraq, Saudi Arabia, and Yemen, which in March 1945 had formed the League of Arab States, proclaimed their intent to take up the defense of the Arab cause in Palestine.

In the United States, Pres. Harry S. Truman took up the Zionist cause and urged that the European Jewish refugees be immediately admitted into Palestine. Beset by U.S. pressure, fighting a costly and unpopular war against Zionist guerrillas in Palestine, and seeing no practical solution, Britain participated in yet another commission, the Anglo-American Committee of Inquiry, which published its conclusions in April 1946. In essence, it recommended the immediate admission to Palestine of 100,000 Jewish refugees from Europe, the withdrawal of all restrictions on Jewish purchase of land, and the eventual incorporation of both communities in a binational state under United Nations trusteeship. The British government refused the central and immediate demand, admission of 100,000 refugees, and suddenly found itself involved in a war. Forced to maintain a large and costly military establishment when its electorate demanded demobilization and easement of the tax burden, with no end of the bloodshed in sight and with all its practical political and diplomatic ploys used and options closed, the British referred the question to the United Nations.

The General Assembly voted on May 15, 1947, to create a Special Committee on Palestine (UNSCOP) to submit "such proposals as it may consider appropriate for the solution of the problem of Palestine." When it arrived in Jerusalem, UNSCOP was boycotted by the Arabs but actively aided by the Zionists. Few issues had been more studied than Palestine, and UNSCOP found nothing new but urgency. The only solution, it suggested, was partition, but it urged that the consequences of partition be mitigated by the maintenance of economic union. On November 29 the UN General Assembly approved, with slight frontier modifications, the UNSCOP recommendations.

UNSCOP

The Palestine war. The UN decision was a major Zionist victory. Not only did it affirm the Zionist right—the fundamental point at issue and bitterly opposed by the Arabs—to establish a Jewish state in Palestine, it gave the state a territory that, although smaller than that proposed by the Jewish Agency, was far out of proportion to the relative numbers of Jews to Arabs in the country. It comprised more than half the territory of Palestine, including the greater part of the valuable coastal area. Shocked and angry, the Arab leaders refused to recognize the validity of the UN decision and declared their determination to oppose it by force.

By January 1948, volunteers were arriving from the Arab countries to help the Palestinian Arabs; but these irregulars, unorganized and poorly led and equipped, were soon overwhelmed by the superior Zionist forces. By May 13 the latter had secured full control of the Jewish share of Palestine and captured important positions in the areas allotted to the Arabs. The Irgun stormed and captured the village of Deir Yāsīn and massacred much of the population, terrorizing the Arab villagers, who began a mass exodus from Palestine.

Deir Yāsīn

On May 14 the State of Israel was proclaimed and immediately recognized by the Soviet Union and the United States. On the following day, as the British announced the end of their mandate in Palestine, troops of the new, poorly trained, shoddily equipped, and uncoordinated armies of Egypt, Transjordan, Syria, Lebanon, and Iraq entered the country.

They were no match for Israel, and the separate armistice agreements that were finally signed in 1949 by Egypt, Lebanon, Transjordan, and Syria left Israel in possession of all the areas it had won by conquest: the whole of Galilee, the whole of the Palestinian coast minus a reduced Gaza Strip (now occupied by Egypt), all of the Negev, and a strip of territory connecting the coastal region to Jerusalem, including the northwestern section of Jerusalem. The remaining parts of Jerusalem (including the Old City), along with what remained of the Arab share of Palestine, were taken over by Transjordan, which then became the Hashemite Kingdom of Jordan. No entity remained that was officially called Palestine. The departure of nearly 1,000,000 Palestinian Arabs had meanwhile left Israel with the substantial Jewish majority it urgently required.

SYRIA AFTER INDEPENDENCE

The humiliating failure of the Arab intervention in Palestine brought serious discredit to the governments of the Arab countries involved, but nowhere more than in Syria. There it provided the excuse for the first of a series of military coups.

Syria's heterogeneous population

Fundamental to the Syrian problem was the ethnically, religiously, and socially heterogeneous nature of the emerging republic. The new state united the ʿAlawite and Druze territories, which had formerly enjoyed separate status, with the predominantly Sunnite regions of Damascus, Homs, Ḥamāh, and Aleppo. While the ʿAlawites and Druzes formed compact communities in their respective regions, they were not the only religious minorities in the country. In northern Syria there were communities of Ismāʿīlī Muslims. Throughout the country, and particularly in the cities, there were large communities of Christians. Kurds and other less important ethnic minorities, notably the Armenians and the Syriac-speaking Christians, were to be found in various parts.

In addition to this religious and ethnic heterogeneity, there was an equally important social heterogeneity; the population of Syria was composed of townsmen, peasants, and nomads, three groups with little in common. Economic differences added further complexity; in the cities the ostentatious wealth of the notables contrasted sharply with the poverty of the masses. Those same notables were also the owners of large agricultural estates on which the peasants were practically serfs. It was the Sunnite landowning notables of Damascus, Homs, Ḥamāh, and Aleppo who had organized themselves as the People's Party, and later as the National Bloc, and led the resistance to the French. When Syria achieved independence, they took over power and endeavoured to forge a unitary state. They proved unequal to the task.

By 1949 the small but rising middle class, among which new social ideas were developing, and minorities, mainly the ʿAlawites and Druzes, who resented the growing threat to their particularism, were increasingly opposed to the government. The rulers, having tasted power after so long a struggle for independence, self-righteously refused those concessions that might have saved them. Moreover, they appeared to be more devoted to achieving pan-Arab goals than to solving the problems closer to home. In the years immediately following World War II, Iraq and Saudi Arabia were making rival bids for pan-Arab leadership. The ruling National Bloc in Syria readily divided into two new parties: a National Party headed by Shukri al-Kuwatli, which represented the business interests of the Damascus notables and supported Saudi Arabia; and a resuscitated People's Party, which represented the interests of the Aleppo notables and supported Iraq. The Socialist and secular Arab nationalist Baʿth party was recruiting followers among students and army officers, winning support particularly among the ʿAlawite, Druze, and other minorities that were strongly represented in the army.

The colonels. The end of the short-lived civilian order in Syria came in March 1949 when Col. Husni az-Zaim overthrew the Kuwatli government in a bloodless coup. Zaim was himself overthrown in August by Col. Sami al-Hinnawi. A third coup, led by Col. Fawzi Salu in conjunction with Col. Adib ash-Shishakli, followed in December; by November 1951 Shishakli had removed his associate by a fourth coup.

Military dictatorships in Syria

The first four military dictators of Syria were officers of no particular ideological commitment, and the regimes they led may be described as conservative. All four ruled in association with veteran politicians of the former civilian regime. Among the politically minded army officers at the time, many were Baʿth Socialists, while others were followers of the Arab Socialist Union of Akram al-Hourani. Colonel Shishakli was a first cousin to Hourani and came to power with his assistance. Opposing the Baʿth and pro-Hourani Socialist officers were officers of a radically different political persuasion, who followed the Syrian Social Nationalist Party (the Parti Populaire Syrien, or PPS), an authoritarian party of the Fascist type devoted to the establishment of a pan-Syrian national state that would include Syria, Lebanon, Palestine, Transjordan, Iraq, and Cyprus. Because its concept of the Syrian nation included Iraq, it received strong backing from the Iraqi government. After coming to power, Shishakli parted company with Hourani and turned to the PPS for support.

Shishakli was overthrown in February 1954 by a military coup led by Col. Faisal al-Atasi. The PPS forthwith lost its influence in Syrian politics, and an attempt to regain it by violence in the following year led to the suppression of the party and the purging of PPS elements in the army. From that time the Baʿthists in the army had no serious rival, although the party was not yet in a position to take power alone. In the four years that followed, it had to associate itself in rule with civilian leaders of the old school and also with the Communists.

The union with Egypt, 1958–61. The years that followed the overthrow of Shishakli in Syria saw the rise of Pres. Gamal Abdel Nasser of Egypt to uncontested leadership of the pan-Arab unity movement. As a party committed to pan-Arabism, the Baʿth could not dissociate itself from this movement; and the veteran pan-Arab Syrian politicians found themselves in the same position. The Arab world was meanwhile being drawn into the Cold War. The continued interference of pro-Western Iraq in Syrian affairs forced the coalition regime in Syria to turn more and more to Egypt for support and also to establish the first friendly contacts with the Communist countries. By 1958 the fear of Iraq and its Western involvements, on the one hand, and a growing reluctance to become committed to the Communist countries, on the other, convinced the Syrian coalition that the only way out was union with Egypt. In February 1958 Syria gave up its

sovereignty to become, for the next three and one-half years, the "Northern Province" of the United Arab Republic (U.A.R.) of which Nasser was president.

The union of Syria with Egypt, though widely acclaimed, proved a bitter disappointment. Far from accepting the Syrians as full partners, the Egyptians tended to treat them as subordinates. In September 1961 a coup led by rightist Syrian army officers, in league with a coalition of civilian leaders, re-established Syria as a sovereign and independent state.

The "secessionist" regime, 1961–63. The coup of 1961 paved the way for a return of the old class of notables to power. Parliamentary elections were held, and Nazim al-Qudsi of the People's Party was chosen president. The "secessionist" regime, though civilian at the surface, was still under army control, and in the army the Ba'th was still powerful. The regime had made hardly any concessions to the Socialism of the Ba'th and the pro-Nasser pan-Arabists. While the latter approved of the Socialist measures introduced under the union with Egypt (such as the land reforms and the nationalization of banks and large business enterprises), the secessionist regime set out quickly to undo or at least amend them, thus playing into the hands of the Ba'th. In March 1963 the Ba'th and their supporters in the army seized power.

Ba'thist Syria after 1963. The new government was a coalition that included pro-Nasser elements who demanded reunion with Egypt. A month before the Ba'th coup in Syria, however, the Iraqi branch of the party had seized power in Baghdad. A Ba'thist union between Syria and Iraq seemed imminent, but it was opposed by Egypt and by the pro-Nasser Arab unionists in Damascus and Baghdad, and the Ba'thists were unable to establish a union that would exclude Egypt. The Ba'th leaders of Iraq and Syria flew to Cairo for unity talks with President Nasser, but Nasser would agree to a union only on his own terms, and the talks failed. The Ba'th regime in Iraq did not outlive the year. In Syria the pro-Nasser Arab unionists were thrown out of power by an eighth coup in October 1964, and a Ba'th military dictatorship was established.

The Ba'thists in Syria were soon faced with a serious problem. Although their party was led by Syrians, it was pan-Arab in ideology and organization and had branches in Iraq, Lebanon, and Jordan. Non-Syrian Ba'thists were members of the central committee of the party, which had its headquarters in Damascus; the continued subordination of the Syrian branch of the party to the central committee gave non-Syrian Ba'thists a considerable say in Syrian affairs. Thus it was necessary for the Syrian branch of the party to become independent of the pan-Arab central committee. In May 1965 the party split. A ninth coup in February 1966 set up a new military regime in the name of the Syrian Ba'th. The central organization of the Ba'th was reconstituted in Lebanon.

Ba'th split

For some years the Syrian branch of the Ba'th party, with its 'Alawite leadership, successfully maintained itself in power. Nureddin al-Atassi, a Sunnite notable from Homs, served as chief of state until November 1970, while Col. Salah al-Jadid wielded ultimate power. Salah al-Jadid was then deposed in favour of Hafez al-Assad, who on March 14, 1971, was sworn in as president. (For the Syrian role in the Lebanese civil war, see below.)

LEBANON AFTER INDEPENDENCE

For many years Lebanon successfully maintained its parliamentary democracy, despite serious trials. The main problem for Lebanon was to implement the National Pact between the Christians and Muslims. In the early years of independence, so long as no urgent call for pan-Arab unity came from outside, the National Pact faced no serious strains.

The Khuri regime, 1943–52. Under Pres. Bishara al-Khuri, there was close cooperation between the Maronite president and the Sunnite leader Riad as-Sulh, who was premier most of the time. So successful was the partnership that an attempt was made to perpetuate it by seeking a temporary amendment of the constitution to permit the president, in 1949, a second six-year term. The parliamentary elections of 1947 were blatantly rigged to produce a Parliament favourable to the amendment. This, together with the open favouritism of the president toward his family and friends, and the gross corruption he allegedly condoned, made Khuri increasingly unpopular after his re-election in 1949.

The military coups that overthrew the Kuwatli regime in Syria in March 1949 and the monarchical regime in Egypt in July 1952 encouraged the opponents of Khuri in Lebanon. In July 1949 the Syrian Social Nationalist Party (PPS) tried to overthrow the regime by force. The coup failed and its leaders were seized and shot. The PPS took its revenge by securing the assassination of Khuri's premier in 1951. The mounting opposition to the Khuri regime culminated in September 1952 in a general strike that forced his resignation. Camille Chamoun was elected by the Parliament to succeed him.

The Chamoun regime and the 1958 crisis. The presidency of Camille Chamoun coincided with the rise of Nasser in Egypt. During the Suez war (October–December 1956), Chamoun earned Nasser's enmity by refusing to break off diplomatic relations with Britain and France, which had joined Israel in attacking Egypt. Chamoun, known for his pro-Western leanings, was accused of seeking to align Lebanon with Iraq, Turkey, Iran, and Pakistan in the Western-sponsored Baghdad Pact.

Lebanon's difficult position

Matters came to a head following the parliamentary elections of 1957, which allegedly were manipulated to produce a Parliament favourable to the re-election of Chamoun. In the summer sporadic troubles occurred in the Druze area of ash-Shūf. When Syria entered the union with Egypt in February 1958, the Muslim opposition to Chamoun in Lebanon hailed the union as a triumph for pan-Arabism, and there were widespread demands that Lebanon be associated in the union. In May a general strike was proclaimed, and the Muslims of Tripoli rose in armed insurrection. The insurrection spread, and the army was asked to take action against the insurgents to prevent the overthrow of the Chamoun regime by force. The commanding general, Fuad Chehab, however, refused to attack the insurgents for fear that the army, which was composed of Christians and Muslims, would split apart. United Arab Republic units from Syria took over peripheral parts of the country to help the insurgents. The Chamoun government took the issue to the United Nations, accusing the U.A.R. of intervention, and UN observers were sent to Lebanon. When in July the pro-Western regime in Iraq was toppled in a coup by apparently pro-U.A.R. forces, President Chamoun immediately requested U.S. military intervention, and on the following day U.S. marines began to land outside Beirut. The temporary presence of U.S. troops had little immediate effect on the internal situation, but the insurrection slowly faded out. To succeed Chamoun as his term ended, Parliament turned to the commander of the army, General Chehab; Rashid Karami became the new premier.

The Chehab and Hélou regimes, 1958–70. The crisis had been resolved by judicious compromise, and the Chehab regime was successful in maintaining the compromise and promoting what was renamed the National Unity (rather than National Pact) of the Lebanese People. By his refusal as army commander to take offensive action against the insurgents in 1958, Chehab had earned the confidence of the Muslims as no Christian leader had before. Once in power, he proceeded to allay the long-standing Muslim grievances by associating the Muslims more closely in the government and administration and by attending to neglected peripheral areas of Lebanon where Muslims predominated. Internal stability was further promoted by the re-establishment and maintenance of good relations with the U.A.R. (which, even after the Syrian secession in 1961, remained highly popular with the Muslim Lebanese). The economic boom that had begun under the Chamoun regime as the result of the flight of capital from the unstable Arab world into Lebanon continued under the Chehab regime.

National Unity of the Lebanese People

Charles Hélou, a former journalist and member of Khuri's Constitutional Bloc, was elected to succeed Che-

hab in 1964. His government was essentially a weaker version of the Chehab regime, but it managed to keep the internal peace and to thwart attempts to draw Lebanon into military alignment with Syria and Egypt.

ISRAEL AND THE ARAB STATES

Jordan and the Palestine question after 1949. When King Abdullah concluded his armistice with Israel in 1949, he incorporated into his kingdom the area of the old Palestine mandate held by his troops. In the eyes of many Palestinians, Abdullah appeared as the ultimate enemy, and on July 20, 1951, he was assassinated in Jerusalem by a Palestinian terrorist. The brief reign of his mentally unbalanced son Talal was followed by that of his grandson Hussein, from his coming of age in 1953.

The reign of King Hussein

Hardly had King Hussein taken the oath of loyalty to the constitution when the Ba'thists and their associates began to foment trouble among his discontented Palestinian refugee subjects. They also encouraged military plots against the King. After the establishment of the U.A.R. in 1958, fear of the consequences for his country and regime led the King to conclude a federal union with Iraq. The overthrow of the Iraqi monarchy in the same year brought a quick end to this federation; subsequently, British paratroops had to be flown to Jordan to prevent a Nasserist overthrow of the monarchy there.

Syria's secession from the U.A.R. in 1961 brought temporary relief to the regime in Jordan. During the years that followed, United States aid made it possible for Hussein to promote considerable economic development in his country, which, apart from the Palestinian West Bank, was composed mainly of desert. There was also a boom in tourism, centred on the Old City of Jerusalem. Hussein's Palestinian subjects, though a source of political trouble, included some of the best educated and talented elements in the Arab world.

Formation of PLO and al-Fatah

Until 1964 the Palestinians were the object of actions by the Arab states; largely leaderless and unorganized, they were recipients of United Nations aid and a source of cheap labour in the "host" countries. Their cause was argued for them by others, and such political activity as they evinced was in relationship with one or other of the Arab states or leaders. In 1964, however, the Arab summit meeting that proposed the United Arab Command also led to the formation of a Palestine Liberation Organization (PLO). About the same time, Palestinians living in various Arab countries formed a secret organization called the Palestine National Liberation Movement, known from a reversal of its Arabic initials as al-Fatah ("the Conquest"). Both the PLO and al-Fatah undertook the training of guerrilla units for raids on Israel. Until 1967 these raids emanated mainly from Jordan. The distribution of the refugee camps focussed attention on Jordan and Lebanon and created tensions in both countries that were to explode in later years.

Israel after 1948. The emergence of Israel as a Jewish state on the former territory of Palestine was the central political issue of the Middle East from the end of World War II. Viewed from any perspective, it was a remarkable achievement. The energy, enthusiasm, and skill of the Zionists were unmatched among the Arabs. Essentially, Israel represented the coming of a modern, European state into an underdeveloped area, and in that fact lies the crux of its achievement and its problems.

Deriving proportionally huge external financial and military support from Western governments (its relations with the Soviet Union, despite immediate recognition in 1948, have been strained), the Israelis also benefitted from a highly trained and motivated citizenry to create a unique nation-state. Ironically, they were assisted in this process by the hostility of the surrounding Arab countries, because the state of siege in which they were forced to live helped to unite them against the common danger and gave them a sense of mission. And, finally, hanging as a tragic backdrop to the state was the memory of the Nazi holocaust, both a justification and a cause of the final push to success of the Zionist movement.

In 1948 Israel emerged as a parliamentary republic, with David Ben-Gurion, the head of the Jewish Agency, as premier of the provisional government. Parliamentary elections held in January 1949 yielded a Knesset (Parliament) in which the Mapai (Labour Party) of Ben-Gurion had the ascendancy. The Knesset elected Chaim Weizmann, president of the World Zionist Organization, as the first president of Israel (he was succeeded, upon his death in 1952, by Itzhak Ben-Zvi, who was succeeded in turn, upon his death in 1963, by Schneor Zalman Shazar). In keeping with Zionist principle, the Knesset proclaimed Jerusalem the capital of Israel (only a section of the new city was actually held by Israel) and passed the Law of Return, which gave every Jew the right to immigrate. Ben-Gurion formed a succession of coalition governments that kept him in power continuously (except in 1953–55, when his Mapai associate Moshe Sharett was premier) until his resignation in 1963. Levi Eshkol (also of the Mapai) succeeded him at the head of another succession of coalition governments. Upon Eshkol's death in 1969, the Israel Labour Party, which had been formed in the previous year to unite the Mapai with the more leftist Ahdut Avodah and the Rffi (a splinter party of the Mapai founded in 1965 by Ben-Gurion in association with Maj. Gen. Moshe Dayan), chose Golda Meir, former foreign minister and secretary general of the party, to succeed Eshkol as premier. Labour remained in power till 1977.

Israel Labour Party

To large numbers of Jews throughout the world the state of Israel symbolized the hopes and aspirations of the Jews as a people. To its neighbours, Israel remained an alien presence forcibly established on formerly Arab soil and consequently unacceptable. At a minimum, they demanded a return to frontiers fixed by the 1947 UN partition and repatriation of the Palestinian Arab refugees who had fled the country after 1948; to neither condition was Israel prepared to yield. Because of Arab hostility toward Israel, the government had to maintain restrictions on the civic and political liberties of its Arab minority—a blemish on Israel's democracy, which was otherwise the most successful in the Middle East.

The frontiers of Israel were periodically exposed to guerrilla raids from one or another of the neighbouring countries. Even more important, Israel's access to the Red Sea, essential for trade with East Africa and the Far East and for receiving needed oil supplies from Iran, was barred by Egypt's control of the Suez Canal and by the Egyptian and Saudi Arabian control of the Strait of Tiran at the mouth of the Gulf of Aqaba. After the Suez war of 1956, Israel secured a guarantee for passage through the Strait of Tiran in return for its retreat from Sinai and the Gaza Strip, occupied in the course of that war. The port of Elat was enlarged to handle the Red Sea trade.

The Arab–Israeli War of 1967 and after. While the direct cause of the Six-Day War of June 1967 was Egypt's closure of the Strait of Tiran, the war was, in a more profound sense, another battle of the wars of 1948–49 and 1956, focussed on the issue of Israel's legitimacy in the Middle East. Inexorably, also, it was coloured and magnified by the global confrontation of the United States and the Soviet Union.

From time to time, Israeli forces took reprisals for attacks on Jewish settlements by Arab guerrilla bands—attacks that became particularly frequent after 1964 and that came mostly from across the Syrian border. Tension had been building up on the border from the early 1960s as Israel asserted its control over the demilitarized zones. In November 1966 Nasser pledged his support for Syria if Israel should invade; subsequently, Syrian bombardment of Israeli villages from across the border was intensified, as were the Israeli reprisals and warnings. In May 1967 Syria announced that Israel was massing troops on its border; Nasser thereupon called for the immediate withdrawal of the UN Emergency Force from the Israel–Egypt border and closed the Strait of Tiran to Israeli shipping and to all other vessels carrying strategic material to the Israeli port of Elat; he also secured a promise of solidarity from Jordan and received promises of support from Saudi Arabia, Algeria, and Iraq. In Israel, Premier Levi Eshkol, under popular pressure, handed over the Ministry of Defense to Maj. Gen. Moshe Dayan.

Withdrawal of the unarmed UN troops after May 16 signified to the Israelis that ultimately they were alone. On May 30, King Hussein signed a mutual defense pact with Nasser, convincing the Israelis that they were surrounded. Two hours before dawn on June 5 the Israeli Air Force caught on the ground and largely destroyed the Arab world's only effective military force, the Egyptian Air Force. In Sinai in the following days, the Israeli Army smashed the Egyptian troops. Caught by its five-day-old pact with Egypt, Jordan also was sucked into the war. Israel offered Jordan a sort of informal separate peace, but Hussein realized that he could not accept and survive. The price he paid for survival was loss of the bulk of his kingdom, the whole of the West Bank of the Jordan. Syria in its turn was the object of a furious frontal assault that cleared the Golan Heights and threatened Damascus.

Jordan–Egypt pact

By the time the UN Security Council managed to effect a cease-fire (June 11), the Arab states had lost huge territories, much of their productive capacity, perhaps 5 percent of their best labour force, millions of dollars worth of industrial equipment, and untold amounts of potential tourist and other revenues; much more importantly, they lost psychologically and politically. That fact was to set the tone for the events of the following years. Central to the history of the Middle East, the defeat of the Arab governments gave a powerful impetus to the Palestine guerrilla movement.

Militancy of the Palestinian refugees. Following the cease-fire, the more militant members of the Palestine Liberation Organization (PLO) took over its leadership and began making guerrilla raids into Israel and Israeli-occupied territory. In riposte, Israeli forces attacked the "host" countries, and Lebanon and Jordan found themselves paying the bill for the policies of the Palestinians. The Palestinians, moreover, increasingly insisted upon their right to act as an independent state, under arms and immune from the laws of Jordan. Clashes and confrontations punctuated the months leading up to the high point of Palestinian power in 1970. In June a Palestinian group apparently tried to assassinate King Hussein and fired on his palace with rockets. Next, they demanded the arrest and dismissal of the King's uncle, who was commander of the armed forces. Surprisingly, King Hussein announced his decision to bow to most of the guerrilla demands, that concession, he said, to be his last. But the guerrilla groups, never really effectively coordinated, much less centralized, continued to push their program, and by August the country was an armed camp or, more accurately, a collection of armed camps, in which the government appeared to be but one among many rival powers. The situation obviously could not continue, and the spark that set off the explosion, known among the Palestinians as "Black September," was the most flamboyant of the Palestinians' acts, the hijacking on September 6–9 of four commercial airliners, three of which were flown to northern Jordan and there held hostage with their passengers and crews. Humiliated, the King resolved to destroy the guerrillas as a contender for power in Jordan. The Jordanian Army, given its head in mid-September, swept through the refugee camps, wiping out all resistance, disarming the guerrillas, and deporting many of the leaders. Driven from Jordan, the PLO focussed its activities upon Lebanon.

Black September in Jordan

Israel, confident that its policy had worked in Jordan, naturally turned similar pressure upon Lebanon. Already, in December 1968, an Israeli Army airborne group had seized Beirut International Airport and blown up most of the Lebanese commercial air fleet; this spectacular raid was followed by others, particularly along the southern frontier. Perhaps the most dramatic of these took place in April 1973, when Israeli commandos spent almost a complete day in Beirut hunting down and killing some of the best known leaders of the PLO. Outraged, the Palestinians accused the Lebanese of complicity.

The war of 1973. When Gamal Abdel Nasser died in September 1970, he was succeeded by Anwar as-Sadat. Few expected from Sadat a continuation of Nasser's strident pan-Arab policies, and the Egyptian offensive of October 6, 1973, thus came as a shock to many who had overlooked the clear signs that war was about to break out. During 1973 the Soviet Union increased arms deliveries to both Egypt and Syria; Syria alone received in the first six months of 1973 almost $200,000,000 worth of arms and aircraft. By the end of June, Sadat of Egypt and Assad of Syria had formed a rough plan of operations. In September King Hussein apparently was informed in general terms and approved the plan. A major air battle off the Syrian coast, in which Israeli planes shot down at least eight Syrian aircraft, appears to have resolved all Syrian doubts on Sadat's conditions for cooperation. Ironically, Sadat himself publicly warned that war was imminent in a speech on September 28.

Fighting started almost simultaneously on the Syrian and Egyptian fronts at about 2 PM local time on October 6—for the Jews, Yom Kippur, the holiest day of the year, and for the Muslims, the anniversary of the crucial battle for the conquest of Mecca by the Prophet Muḥammad, the 10th of Ramaḍān. The war ended on the Egyptian front effectively on October 24 but dragged on on the Syrian front until a cease-fire was achieved in May 1974. Except for action by a Jordanian unit in Syria, Jordan was not directly involved in the fighting, and Lebanon managed to stand aloof. The Palestinians, as before, were ignored in the formal military engagement.

The Syrians were by no means so successful as the Egyptians, either in the fighting or in the cease-fire negotiations. They ended the war with a net loss of territory and with appalling losses of men and material. Bitter because the Egyptians had signed a separate cease-fire, they felt that the Egyptians were being wooed away from the Arab cause by the United States. The Soviet Union, feeling outmanoeuvred and in danger of losing its diplomatic position in the Middle East, encouraged the Syrian "hawks." The cease-fire on the Syrian front was thus more difficult to achieve than that in Sinai. Negotiations were hard, and the U.S. secretary of state, Henry A. Kissinger, spent 28 days travelling back and forth between Israel and Damascus to achieve acceptable results. In the cease-fire, Syria regained 300 square miles of territory lost in the war, together with small but symbolically important pieces of ground lost in the fighting of 1967; Israel retained the Golan Heights and an observation post on Mt. Hermon; and a complex buffer zone under UN supervision was established around the Syrian town of al-Qunayṭirah.

CIVIL WAR IN LEBANON, 1974–76

Events in Lebanon meanwhile were moving toward the outbreak of one of the most destructive civil wars in modern history. The essential issues were separate but strongly and immediately affected one another. First came the fact that the political structure of Lebanon was based on a sort of floating consensus—an agreement among leaders of the various religious and ethnic minorities over their respective roles in the state. Under the strong regime of Pres. Fuad Chehab and his somewhat weaker successor, Charles Hélou, the personal and group ambitions of the various sectors of society were held in check, and the organs of the state, especially the army and the security police, were employed to prevent recourse to violence. The immediate result was a long period of domestic calm, stretching from the civil war of 1958 to 1969.

Background to the war. During that period, however, major changes were taking place in Lebanese society, most significantly urbanization, which brought 40 percent of the Lebanese population to the city of Beirut. But the city, like the country, failed to make its people homogeneous; Beirut became a reflection of Lebanon as a whole. Each quarter took on a religious affiliation, with virtually every village having an outpost established in one suburb or more. And the newcomers suffered from deep and growing social and economic contrasts with their more affluent close neighbours. Those who remained in the rural areas lost even more ground, relatively speaking. By the early 1970s, agriculture, in which nearly half the population was employed, accounted for less than 11 percent of the country's gross domestic product, while the

Lebanese social change

share of urban commerce was rising. An already existing schism was deepened between the groups, which increasingly took on an urban Christian *versus* rural Muslim coloration.

A second factor, the role of Lebanon in the Arab world, was an issue almost as complex as that of Israel. Many Syrians still felt that the French decision to separate Lebanon from Syria in 1920 was invalid and an affront to the very idea of pan-Arabism; many in Lebanon, often for different reasons or only temporarily, agreed or professed to agree. Lebanon's noninvolvement in the wars of 1967 and 1973, its strong and often heavy-handed security policies, and rumours of its secret understandings with Israel all focussed attention on this issue.

Third, the Palestinians thought of Lebanon, after the ruinous Jordanian campaign against them in September 1970, as their last refuge, and by 1973 roughly one person in each 10 in Lebanon was a Palestinian. Yet the Palestinians were constantly made aware of their separate and inferior status; landless and mostly poor, they were exploited as a source of cheap labour. Increasingly their politics became radicalized, and they found common cause with those Lebanese who were poor, rural, and mainly Muslim. As they acquired structure, motivation, and arms during the period after the fall of their base in Jordan, they were gradually sought out as allies by radical groups in Lebanon. Faced, finally, in September 1975, by an Egyptian–Israeli interim agreement on Sinai, the Palestinians concluded that they were being deserted by the Arab states and would shortly be suppressed in Lebanon by a second Black September.

Palestinian radicalization

Beginning of the war. Toward the end of the presidency of Charles Hélou, the Palestinians began to clash with Lebanese security forces. The situation was increasingly complicated by the inability of the PLO to control the more radical of the factions into which the Palestinians were divided. Under an agreement announced in Cairo on November 3, 1969, the Lebanese government gave the Palestinians virtually a free hand in the refugee camps and at forward posts in the south along the Israeli frontier. In return, the PLO promised not to intervene in Lebanese politics; this, for reasons noted above, was impossible for the Palestinians and not desired by the Lebanese left. It was particularly significant that at this period the minister of the interior, charged with police functions, was the leftist leader Kamal Jumblatt. When the Lebanese failed to restrain the Palestinians, the Israelis began to raid the south with increasing severity, and this fact encouraged the Lebanese Christian right, particularly the militant Phalangist Party (with discreet army backing), to attack the Palestinians with its well-organized and well-armed militia.

It was in this atmosphere that Suleiman Franjieh was elected president, by only one vote in the Parliament, on August 17, 1970. Franjieh was known as a man of personally violent tendencies, and the Lebanese right looked to him to suppress the left and their Palestinian allies. In his first acts, he seemed to justify that hope. Economic events, however, soon got out of control. Lebanon was caught in a severe inflation that enriched those on one side of the social chasm while it exacerbated the distress and bitterness of those on the other side. The government appeared incapable of addressing this problem; in its attempt to make an appearance of reform, it discarded or destroyed the strong instruments of state control that it had inherited from the aftermath of the civil war of 1958. The more radical of the guerrilla groups, angered by failure of the Lebanese to prevent Israeli incursions and encouraged by the vacillation of the regime, determined upon a series of dramatic terrorist attacks. When their plots were foiled, they retaliated by abducting several Lebanese soldiers. Heavy fighting then broke out between the army and the armed refugees in May 1973, and thereafter, despite a series of truces, events moved rapidly toward civil war. By early 1974 the Palestinians were providing the force for the Lebanese National Movement led by Kamal Jumblatt. Into this arena then stepped the relatively deprived Shī'ite Muslims, especially those of the rural area of al-Biqā' (Beqaa) valley, under the leadership of a Muslim *imām*, Sayyid Musa as-Sadr; his Movement of the Deprived was based on a call for Shī'ite political rights, economic justice, and defense against Israeli raids in the mainly Shī'ite south.

Franjieh election

Hardly a day passed during the rest of 1974 and 1975 without a battle somewhere in Lebanon. The country was torn apart, and the central government virtually ceased to exist. The army, long the mainstay of the government, was immobilized by the nature of the conflict. And the combatants, amply supplied by various foreign groups, turned upon one another with a ferocity—and firepower—almost unequalled in such a small area of the world.

Final phases of the war. During the early phases of the civil war, the Christians had received encouragement from President Sadat of Egypt, while President Assad of Syria had encouraged and aided the left and the Palestinians. The Lebanese and resident Palestinians fought furiously, and gradually the left and the Palestinians began to win the war. By the early months of 1976, it seemed clear that the Christians were losing and that either they would be defeated (so that Lebanon would be reconstituted as a left-dominated, Palestine-oriented state) or Lebanon would be partitioned. Either case appeared to the Syrians likely to bring Israeli intervention. This realization forced a reversal of Syrian policy, first toward restraint on the left and then toward support for the Christians. Ironically, both the Syrians and the Israelis, so opposed to one another on other issues, took up the cause of the Lebanese Christians with essentially the same tools: Syria supplied arms and prevented the Palestinians from taking strategic points, while Israel blockaded Sidon and Tyre, through which arms to the left and the Palestinians had arrived, trained a large military contingent in Israel and supplied it with tanks, and shipped tanks and other equipment into the Christian sector. During the summer of 1976, the Israeli defense minister, Shimon Peres, paid at least four clandestine visits to the de facto Christian capital at Jūniyah, and the Israeli Army occupied sizable parts of southern Lebanon; from the east, beginning in early June, Syrian military units entered the country with about 450 tanks and 20,000 soldiers.

Syrian reversal of position

This realignment led to two new developments. First, the non-Syrian left, represented by Iraq and Libya, resumed close contacts with the PLO, which earlier it had denounced as conservative and ineffectual, and this, in turn, caused President Sadat of Egypt to seek closer relations with the PLO leader Yasir Arafat in order to win Palestinian support for his claim to Arab leadership and to prevent attacks on the Egyptians' separate disengagement agreement (September 1975) with the Israelis. Second, the Christians, with strong support from Syrian tanks and soldiers, began to win the civil war. In late June, Christian forces launched attacks on the two huge Palestinian refugee camps of Jisr al-Bāshā, which fell after one week, and Tall az-Zaatar, which, becoming a symbol of Palestinian resistance, withstood a tragic and bloody siege until mid-August.

In April Pres. Suleiman Franjieh had signed a constitutional amendment to permit the Parliament to elect a new president. Elias Sarkis was elected on May 8 but was not inaugurated until September 23, and then in a Syrian-held town. Meanwhile, Lebanon was effectively partitioned along the "Green Line," which passed through the centre of Beirut (east–west) along the main road to Damascus: to the north was a Christian government, to the south a leftist (Druze–Muslim–Palestinian) government led by Kamal Jumblatt. Repeated attempts were made to bring the fighting to an end, until finally a formal "summit" meeting, held in Cairo on October 25–26 established an Arab League peace-keeping force of 30,000 troops (of whom about 70 percent were Syrian), under the overall command of President Sarkis and headed by a Lebanese Sunnite officer. By the end of November, despite continued minor clashes, the civil war came to a close.

Consequences of the war. The civil war was a catastrophe for the Lebanese, whose country now lay in ruins. For the Palestinians, it not only cost perhaps 20,000 killed and twice that many wounded but also shattered

their leadership and placed in jeopardy alliances and friendships—even in distant Kuwait—upon which they had relied for the 30 years of their dispersion. The Syrians appeared stronger than before, but their victory could turn out to be almost worse than defeat; having got into Lebanon, they faced the problem of extricating themselves without leaving behind strong and enduring enmities. Egypt, whose leadership of the Arab world was certainly endangered by the war, emerged with the divisive separate truce (September 1975) with Israel all but forgotten and with general respect for its role in making peace. Jordan, likewise, found the tragic memory of its Black September overshadowed by not one but many incidents, each blacker than Black September. Only Israel among the states of the Middle East appeared to have "won." The unity of its enemies appeared to be shattered. The Palestinians lost their major bid; Syria acted, apparently, out of fear of their intervention and against its fellow Arabs, virtually in concert with Israel; the Lebanese Christians, likely to regain much of their former power, were in Israel's debt; and the modus vivendi with Egypt was more secure than before. More important, the revulsion and horror of the war had caused Arabs everywhere to question, as never before, the very dream of pan-Arabism. (K.S.S./W.R.P.)

BIBLIOGRAPHY

Syria and Palestine to c. 1550 BC: The following chapters in *The Cambridge Ancient History*, 3rd ed. (1970–), summarize the evidence for Syria and Palestine available up to *c.* 1965–69. All have a full bibliography that can supplement the titles given here. In volume 1, see SIR MAX MALLOWAN, "The Development of Cities from Al-'Ubaid to the End of Uruk 5"; ROLAND DE VAUX, "Palestine During the Neolithic and Chalcolithic Periods," and "Palestine in the Early Bronze Age"; MARGARET S. DROWER and JEAN BOTTERO, "Syria Before 2200 B.C."; and GEORGES POSENER, JEAN BOTTERO, and KATHLEEN M. KENYON, "Syria and Palestine, *c.* 2160–1780 B.C." In volume 2, see JEAN R. KUPPER, "Northern Mesopotamia and Syria"; and KATHLEEN M. KENYON, "Palestine in the Middle Bronze Age." ROBERT J. BRAIDWOOD, "Near Eastern Prehistory," *Science*, 127:1419–30 (1958), provides a description of the Pre-Pottery Neolithic site of Jarmo in northeastern Iraq. J.B. HENNESSY, *The Foreign Relations of Palestine During the Early Bronze Age* (1967), analyzes objects traded among Palestine, Egypt, and western Asia, and thereby establishes a chronology for the Palestinian Early Bronze Age. KATHLEEN M. KENYON, *Amorites and Canaanites* (1966), deals with the breakup of the Early Bronze Age civilization of Syria and Palestine and the development of the Middle Bronze Age culture. The same author's *Archaeology in the Holy Land*, 3rd ed. (1970), a summary of the archaeological evidence for Palestine from the beginning of settlement down to the postexilic period, includes a bibliography of the main excavated sites. JAMES MELLAART, *Earliest Civilizations of the Near East* (1965), is a popular account of the earliest settlements in Anatolia, Iraq, Iran, Syria, and Palestine—includes accounts of the author's finds at Hacilar and Çatalhüyük in Anatolia.

From c. 1550 BC to AD 630: (*Syria and Palestine in the era of the Egyptian and Hittite empires*): PAUL GARELLI, *Le Proche-Orient asiatique, des origines aux invasions des peuples de la mer* (1969), the best one-volume history, covers the entire Near East but should be used selectively for the Levant (very full bibliography). J.B. PRITCHARD (ed.), *Ancient Near Eastern Texts Relating to the Old Testament*, 2nd ed. (1955) and *The Ancient Near East in Pictures Relating to the Old Testament* (1954), are excellent source books of translated texts and annotated illustrations, covering a wider period and area than this article does. JOHN BRIGHT, *A History of Israel* (1959); and MARTIN NOTH, *Geschichte Israels*, 3rd ed. (1956; Eng. trans., *The History of Israel*, 2nd ed., 1958), are the two best single-volume histories of ancient Israel in the English language, approaching the subject from rather different viewpoints. HAROLD H. ROWLEY, *From Joseph to Joshua* (1950), although rather out of date, contains a valuable discussion of all the various theories concerning the Patriarchal and Exodus narratives. The conclusions are not always reliable. ARVID S. KAPELRUD, *Ras Sjamra-funnene og det Gamle Testament* (1953; Eng. trans., *The Ras Shamra Discoveries and the Old Testament*, 1963), is a brief introduction to the subject. (*Syria and Palestine from c. 1200 to c. 330 BC*): For this period, see BRIGHT and NOTH (*op. cit.*); and ANDRE DUPONT-SOMMER, *Les Araméens* (1949). DONALD B. HARDEN, *The Phoenicians*, 2nd ed. (1963); and SABATINO MOSCATI, *Il mondo dei Fenici* (1966; Eng. trans., *The World of the Phoenicians*, 1968), are both good, well-illustrated accounts of Phoenician history and civilization. LUDWIG KOHLER, *Der Hebräische Mensch* (1953; Eng. trans., *Hebrew Man*, 1956), is a brief, but stimulating and scholarly, survey of Hebrew life and thought. ROLAND DE VAUX, *Les Institutions de l'Ancien Testament*, 2 vol. (1958–60; Eng. trans., *Ancient Israel: Its Life and Institutions*, 1961), is a thorough and detailed study of the civil, military, and religious institutions of ancient Israel (very full bibliography). EKREM AKURGAL, *Die Kunst Anatoliens von Homer bis Alexander* (1961; Eng. trans., *The Art of Greece: Its Origins in the Mediterranean and Near East*, 1968), is a profusely illustrated study of Assyrian, Aramaean, and Phoenician art and their influences. (*Syria and Palestine in the Hellenistic and Roman periods*): For these periods, see ROBERT M. GRANT, *A Historical Introduction to the New Testament* (1963); AVIGDOR TCHERIKOVER, *Hellenistic Civilization and the Jews* (1959; orig. pub. in Hebrew, 1930), a fairly detailed study by one of the foremost authorities on the subject; A.H.M. JONES, *The Herods of Judaea* (1938), still one of the best and most reliable sources, despite the vast number of more recent books on the Herodian family; and the same author's *Cities of the Eastern Roman Provinces*, 2nd ed. (1971), the standard work on the subject, with full bibliography.

From the Islāmic Conquest to c. 1920: MARIUS CANARD, *Histoire de la dynastie des H'amdanides de Jazîra et de Syrie*, vol. 1 (1951), a detailed study of the Ḥamdānid dynasty; MARSHALL W. BALDWIN and KENNETH SETTON (eds.), *A History of The Crusades*, 2 vol. (1955–62; 2nd ed., 1969–), contains chapters by leading scholars on all aspects of the Crusades, particularly good on the Muslim viewpoint—covers the Seljuqs, Ayyūbids, and Fāṭimids in detail; STEVEN RUNCIMAN, *A History of the Crusades*, 3 vol. (1951–54), a sound general history of the Crusades; A.S. ATIYA, *The Crusades in the Later Middle Ages* (1938), a very useful and readable account; CLAUDE CAHEN, *La Syrie du nord à l'époque des Croisades et la principauté franque d'Antioche* (1940), a detailed account of Syria at the time of the Crusades, intended for the serious student; MAURICE GAUDEFROY-DEMOMBYNES, *La Syrie à l'époque des Mamelouks d'après les auteurs Arabes* (1923), another detailed work; NICOLA ZIADEH, *Urban Life in Syria Under the Early Mamlūks* (1953), a useful supplement to the political histories, more general in scope than its title implies; PETER M. HOLT, *Egypt and the Fertile Crescent, 1516–1922* (1966), the best work on Syria for the Ottoman and early modern periods; A.N. POLIAK, *Feudalism in Egypt, Syria, Palestine, and the Lebanon, 1250–1900* (1939), useful for the study of institutions; HENRI LAMMENS, *La Syrie, précis historique*, 2 vol. (1921), a useful outline of events that tends to be rather controversial; PHILIP K. HITTI, *History of Syria*, 2nd ed. (1957), a general history that includes Lebanon and Palestine; and *The Origins of the Druze People and Religion* (1928), a good general account of this important minority; IRA M. LAPIDUS, *Muslim Cities in the Later Middle Ages* (1967), a penetrating introduction to the Mamlūk period; ABDUL-KARIM RAFEQ, *The Province of Damascus*, 1723–1783 (1966), covers some of the same ground for the Ottoman period; MOSHE MA'OZ, *Ottoman Reform in Syria and Palestine, 1840–1861* (1968), for 19th-century political and administrative change.

Syria and Palestine since 1920: STEPHEN H. LONGRIGG, *Syria and Lebanon Under French Mandate* (1958), tells in detail the story of the two countries from 1918 until 1947 and is indispensable as a reference on the subject. KAMAL S. SALIBI, *The Modern History of Lebanon* (1965), traces the history of the country from the 18th century to date and deals with the period since 1918 in pt. 2, entitled "Greater Lebanon." There is no survey of the history of Syria since 1920, but useful information on the subject is found in PATRICK SEALE, *The Struggle for Syria* (1965), which gives an intelligent and vivid account of the peculiar developments in the Syrian Republic between 1943 and 1958. ALBERT HOURANI, *Syria and Lebanon: A Political Essay* (1946), retains its importance as a sensitive and well-thought-out study of the two countries as they emerged into independence. The material available on the Palestine question, Israel, and Arab–Israeli relations is vast, but hardly any of the accounts available are objective. CHRISTOPHER SYKES, *Crossroads to Israel* (1965), tells a convincing story of the developments that led to the establishment of Israel on the former territory of Palestine. NORMAN BENTWICH, *Israel* (1952), considers the developments in Israel during the early years after its establishment. See also KAMAL S. SALIBI, *Crossroads to Civil War: Lebanon 1958–1976* (1976), dealing with the events leading up to the civil war and the war; and WILLIAM R. POLK, *The United States and the Arab World*, 3rd ed. (1975).

(K.M.K./P.J.Pa./C.C./A.H.Ho./V.E.I.)

Syrian and Palestinian Religions

Syrian and Palestinian religions, originating in the Stone Age and continuing into Hellenistic times, absorbed religious beliefs and practices of ancient Near Eastern religions—as well as their own indigenous cultic phenomena—and transmitted them to biblical, Greek, and Roman religions. The Syrian and Palestinian religions influenced Judaism, Christianity, and Islām insofar as these religions reacted to Syrian and Palestinian religious beliefs and practices.

NATURE AND SIGNIFICANCE

At least as early as the 3rd millennium BC, the area comprising what was later known as Syria and Palestine was the home of a linguistically and ethnically mixed population and the meeting place of cultural influences from all sides: Egypt, Mesopotamia, and Asia Minor. This complexity increased in later centuries and had as its counterpart a very complex religious picture. The typical political unit in the area was a city-state of limited geographic extent. Each of these states had its own pantheon and cult, and within the larger states there might be different ethnic and social groups carrying on their distinct religious beliefs and practices.

Common features

Certain common features can be discerned, however. The religion of each of these peoples was characterized by the worship of numerous gods. These gods were mostly conceived in anthropomorphic terms and images and were identified with, or guardians of, important elements of the universe and vital aspects of nature and of human society. The competing powers in the divine world were thought to be organized, rather loosely, into a council of gods, in which the storm god played an especially dominant role. Images of the gods stood in their houses, the temples, where organized priesthoods saw to it that they were supplied with food and clothing. Important conceptions as to the nature of the world, and of human society, were embodied in myths, which often took the form of narrative poems of considerable length and complexity. The dominant concerns of official religion were for the economic bases of society—that is, for abundant crops and fertility of herds and flocks—and for the state, especially for the well-being of the ruling king and the continuance of his line. Scholars have reasonably full information only about the religion of the Canaanites—one of the ancient peoples of Palestine–Syria—as attested in the Ugaritic texts (see below *Sources*) from the Late Bronze Age (15th–13th centuries BC), supplemented by other materials; hence, for practical reasons, Canaanite religion must occupy a central place in a description of the area's religions. Fortunately, there is good reason to suppose that Canaanite religion was typical and representative and maintained its dominant characteristics through the centuries, so that knowledge of that religion probably indicates the general nature and features of most of the other religions of the area.

The religions of ancient Syria–Palestine are of great intrinsic interest because of the variety of phenomena they encompass and because of the great antiquity of the conceptions they preserve, some of which doubtless derive from the Stone Age (*c.* 4000 BC). But beyond this interest, these religions are of extraordinary importance to the student of ancient Israelite religion. On the one hand, Canaanite religion constituted the antithesis to Israelite religion; and, on the other hand, it supplied a rich heritage of religious language, ideas, and ritual practices on which the Old Testament writers drew to an extent that is only beginning to be realized. Furthermore, Syrian religion enjoyed a vogue not only in the Hellenistic world (3rd century BC–3rd century AD) but centuries earlier, in the Minoan–Mycenaean age (*c.* 3000–*c.* 1100 BC), it exercised an influence on early Greek religion.

SOURCES

Evidence for reconstruction of the ancient Syrian and Palestinian religions has increased astonishingly within the last 50 years, due to materials recovered by excavation; even so, however, the record is full of gaps. Moreover, ancient religious texts tend to be more difficult to interpret than historical records, business documents, or other such recovered materials.

Old Testament, Greek, and Roman sources

The Old Testament was, until comparatively recent times, the most ancient of sources available to scholars for study of the religions of Syria–Palestine. It supplies the names of some major deities, such as Baal (male fertility god) and Asherah (female fertility goddess); some cultic terms; and evidence for the major concerns of the native religion. The story of the Israelite prophet Elijah's contest with the prophets of Baal on Mt. Carmel (I Kings 18) is especially rich in information. But biblical evidence is scattered, fragmentary, and limited in value by its polemical character. Greek and Latin sources have long been drawn on to fill in the gap in knowledge of this subject, especially for Punic religion—referring to the Syrian-derived religion of Carthage in North Africa—and for Syrian religion in the Hellenistic world. Along with inscriptions and coins, scattered passages in classical writers shed light on Syrian religion. Thus, the Roman historian Dio Cassius (*c.* AD 150–235) describes the devotion of the Syrian-born Roman emperor Elagabalus (reigned AD 218–222) to the sun god of his native Emesa, and Apuleius (flourished 2nd century AD) paints a vivid picture of the obscene rites that attended the worship of the Syrian Goddess (*Metamorphoses* 8–9). *De Dea Syria* (On the Syrian Goddess), attributed to the satirist Lucian (*c.* AD 120/125–*c.* 190), describes the temple and cult of the goddess at Bambyce (Hierapolis) in Syria. The 4th-century Christian historian Eusebius in his *Praeparatio evangelica* (Preparation for the Gospel) gives extensive extracts from the "Phoenician History" of Philo of Byblos (2nd century AD), who in turn claims to have translated the work of one Sanchuniathon, a Phoenician priest. The work is a treatise on Phoenician religion, especially cosmogony (origin of the world) and theogony (origin of the gods). As long as no independent confirmation of its authenticity was available, it was possible to dismiss Philo's work as a farrago of elements current in Hellenistic religious syncretism, until the Ugaritic evidence referred to above confirmed its authenticity and antiquity. One can scarcely accept Philo's dating of Sanchuniathon to before the Trojan War (*c.* 12th century BC), but a leading biblical archaeologist, W.F. Albright (1891–1971), has dated him to about the 6th century BC.

Phoenician, Punic, and Ugaritic sources

Phoenician and Punic inscriptions were first effectively deciphered in 1837 by the German linguist H.F.W. Gesenius (1786–1842). Punic inscriptions are very numerous but are mostly votive and provide little beyond the bare names of deities and a few epithets, plus theophoric names (those including the name of a god) of the offerers and some sacrificial terms. An inscription called the Sacrificial Tariff of Marseilles (2nd or 3rd century BC) lists various sorts of offerings and the payment due to the officiating priest in each case; a similar tariff from Carthage is also extant. Phoenician and Aramaic funerary, votive, and building inscriptions, the earliest of them dating to the 10th century BC, have been discovered in Syria–Palestine itself. Egyptian texts of the New Kingdom (18th–20th dynasties, *c.* 1567–*c.* 1085 BC) make fairly frequent mention of Syrian deities who had come to be venerated inside Egypt. A text in the Hittite language contains an originally Canaanite myth concerning Ilkunirsha (perhaps "El, Creator of the Earth") and his consort. Evidence for a very early stage of Semitic religion (early 2nd millennium BC) can be gleaned from Amorite theophoric personal names that have been preserved in cuneiform texts from Mari on the mid-Euphrates and from Alalakh in North Syria.

By far the most extensive and most important sources, however, are the Ugaritic texts. Since 1929, excavations at Ras Shamra on the Syrian coast opposite Cyprus have been yielding texts written in an alphabetic cuneiform script on clay tablets; the language—a Semitic tongue closely related to Phoenician and Hebrew—and the script are called Ugaritic from Ugarit, the ancient name of the city. Many of the tablets contain religious texts, myths, incantations, rituals, offering lists, and lists of gods. The tablets date from the Late Bronze Age, but the mythological texts may have been composed centuries earlier.

Written evidence is supplemented by a great quantity of strictly archaeological material from numerous excavations in Palestine and Syria: temples, cultic utensils, amulets, and images and symbols of the gods.

HISTORICAL AND SOCIAL BACKGROUND

Prehistory through the 3rd millennium BC. Behind the history of religion in Syria–Palestine stretches a long prehistory that is known only in fragments from the evidence of archaeology. By the 7th millennium BC, at Jericho, some characteristic elements of later religion can be discerned. British excavations of the prepottery Neolithic phase of the city discovered animal figurines that were probably votive offerings, and a figurine of a mother goddess proffering her breasts. A small shrine held a sacred standing stone, a type of cult object used very widely in later ages. Veneration of ancestors is attested for Stone Age Jericho in the groups of carefully preserved skulls, with plaster molded over the bones to reproduce the features of the living person.

Evidence of ancient religion at Jericho

By the 3rd millennium BC, when written evidence begins to be available in meagre quantity, Syria–Palestine was already inhabited by speakers of a Semitic language of a Canaanite type. Moreover, a large share of the ancient place-names are Semitic. Some, such as Beth Yerakh (House of the Moon god), shed a bit of light on the religion of this early time. Other place names suggest occupation of some areas by non-Semitic groups. Moreover, there is evidence that the Egyptians in the Old Kingdom (*c.* 2686–*c.* 2160 BC) already controlled Byblos on the Phoenician coast and exercised cultural and political influence over much of Syria–Palestine. Characteristic features of the religious history were thus already present—that is, a mixed population and an openness to foreign influence.

2nd millennium BC. In the early centuries of the 2nd millennium, the Amorites, a Semitic people, pushed into the centres of civilization all around the Fertile Crescent. At Mari on the Euphrates and also at many other sites in Syria and Mesopotamia, Amorites had gained the upper hand. The Egyptian Execration Texts (documents by means of which the Egyptians cursed their enemies) show that groups of Amorites also dominated throughout Palestine. Since many of the Amorite personal names—the only source for knowledge of the Amorite language—contain the name of a god and an assertion about the god, a reconstruction of some aspects of the religion is possible, though the limitations of the evidence are obvious.

Following the wave of Amorite settlement came a period of incursion by Hurrians and Indo-Europeans, beginning about the 18th century BC. By the 15th century BC, northern Syria was dominated by these elements, and many cities even in southern Palestine had kings with non-Semitic names. In the 15th century BC, kings with Indo-European names ruled a strong Hurrian state known as Mitanni, which controlled all of north Syria. The rise of the Hittite Empire spelled the end of Mitanni, and through the remainder of the Late Bronze Age, Syria–Palestine was the scene of a struggle for domination between Egypt and the Hittites. At the same time, the Akkadian language was in widespread use for communication between states throughout the Near East, and scribes in Syria–Palestine were trained in the literary, religious, and scholarly works of Mesopotamia. Trade by sea with Cyprus, Crete, and the Aegean flourished. As might be expected, then, the Late Bronze Age presents a complex religious picture: a great many local cults were scattered throughout Syria–Palestine, and the possibilities for transmission and borrowing from one area to another were practically unlimited. A treaty (*c.* 1380 BC) of the Hittites with Mitanni illustrates the complexity in its list of the gods of Mitanni who are regarded as witnesses to the treaty, for the deities named include Hurrian figures such as Teshub, the storm god, and Shimegi, the sun god; the Indian gods Mitra, Varuṇa, Indra, and the Nasatyas; and originally Mesopotamian deities, such as Anu and Enlil.

Syncretistic developments

The political picture changed decisively at the transition from the Late Bronze to the Iron Age (*c.* 1200 BC). At about that time, certain peoples with ties to older nomadic groups established themselves as independent kingdoms in various parts of the region: the Aramaeans in various cities in Syria, down as far south as Damascus; the Ammonites, on the highlands east of the Jordan; Moab, east of the Dead Sea; and Edom, south of the Dead Sea. The Hittite Empire disintegrated, leaving behind a number of states in Syria that maintained Hittite cultural traditions. The "Sea Peoples," among them the Philistines, established themselves along the Mediterranean coast from the Egyptian border north to Dor on the coast of Palestine. Israel became master of most of Palestine west of the Jordan and held some lands east of the river. The direct descendants of the ancient Canaanites, the Phoenicians, were left in control of a small strip along the Syrian coast.

Only meagre evidence exists for the religion of the Aramaeans, Ammonites, Moabites, Edomites, and Philistines. Such evidence as survives suggests that they continued the traditions of Late Bronze Age polytheism in various ways, with no fundamental change in type. Even the non-Semitic Philistines worshipped gods under names familiar in the region for centuries before their arrival, such as the grain god Dagon and the fertility goddess Astarte. Israel introduced a new element, an exclusive monotheism that brought it into a life-and-death struggle with local religions.

1st millennium BC. The Phoenicians found an outlet for their energies in trade and colonization of lands bordering the Mediterranean, especially in Spain, Sardinia, and North Africa. Carthage, founded in the late 9th century BC according to tradition—a date that agrees well with modern research—became the principal Phoenician foundation. Carthage fell to Rome in 146 BC, but veneration of the old gods survived for centuries thereafter. In Syria–Palestine, although the old independent city-states were incorporated in successive empires—Assyrian, Neo-Babylonian, Persian, Hellenistic, and Roman—the local cults survived. At famous centres such as Baalbek, Emesa, and Hierapolis, a descendant of the ancient Canaanite religion flourished, and the Syrian goddess Atargatis was widely worshipped in the Eastern Roman Empire. After the triumph of Christianity, and later of Islām, vestiges of Syrian religion survived only at the level of folk religion.

MYTHOLOGY AND RELIGIOUS PHENOMENA

The gods. Ancient Ugaritic scholars prepared ordered lists of their gods, and one such order is followed here, omitting numerous minor figures. The first in the series of divine names is Il-a-bi, which admits various interpretations: "the god of the (or my) father(s)" or "the father god" or still others. The lack of certainty on this point leaves open the question as to whether this figure is in any way related to the "god of the fathers" or "the god of my father" frequently mentioned in the Old Testament stories of the patriarchs Abraham, Isaac, and Jacob.

El. The next deity is El, whose name is the same as the common noun "god," a word that appears in varying forms in most Semitic languages. El is the titular head of the pantheon and as such is called king. He is the father of the gods (except for Baal) and is also the creator of man. Phoenician and Aramaic texts give him the title Creator of the Earth, a title expanded in the Bible to "maker of heaven and earth" (Gen. 14:19). He is identified with the Hurrian Kumarbi and with Greek Cronos. El is thought of as an old man with a long gray beard and as such has the title "father of years" (other translations of the epithet have been preferred). As another epithet, "Bull," suggests, he was renowned for his sexual powers, both in myth and in artistic representations, where he is depicted with the attributes of the ithyphallic (having an erect penis) Egyptian god Min. As the "Kindly One, Merciful El," he is the bestower of good gifts on men in various mythic episodes. In one strange burlesque, he is almost a figure of fun, roaring drunk at his own party. In Ugaritic religion, El is relatively inactive compared to the storm god, Baal; but in Sanchuniathon, El is more active and rather sinister. Like the Greek Cronos (Saturn), he emasculates his father, Heaven, and he slays some of his children.

The Creator God

Dagon. Dagon (Dagan) comes next in the list, presumably because he, not El, was thought of as the father of Baal and because of his great importance in the city's cult, even though he plays no role in extant myth. The original meaning of the name is uncertain, but it became a common noun in Ugaritic and Hebrew for "grain," which sufficiently indicates that he was associated with fertility of crops. Worship of Dagon is attested at Mari almost a millennium earlier than at Ugarit, and Dagon later became the chief god of the Philistines.

Baal. Baal was the storm god and as such occupied a prominent place in both cult and myth. The ancient proper name of the deity is Hadad, but this title is much less common at Ugarit than Baal, which is also a common noun meaning "Lord, Master." As storm god, Baal is called "cloud rider," a title adopted in Israel for Yahweh (Ps. 68:4). He is also "the Prince" and "the Conquering One." His residence is on a mountain north of Ugarit on the Syrian coast whose Semitic name was Zaphon. The Hittite name was Khazzi, which becomes Kasios in later

Importance of the storm god

Giraudon

Storm god riding on a bull, brandishing a mace and thunderbolt. Relief from Arslan Tash; 8th century BC. In the Louvre, Paris.

Greek references to the god and the mountain, the Canaanite Olympus. Under the title Baal Zaphon, the god was worshipped as a patron of sailors, a cult transferred to a site in the Egyptian delta near Pelusium. Though there is now no doubt that Baal/Hadad was a great god, comparable to Zeus in nature and importance, the situation is complicated by a number of factors. Since *baal* means "lord," it is often combined with place-names to form divine names of the pattern "Lord of such and such a place" (*e.g.*, Baal-peor, "Lord of Peor"). In some cases these names may designate a separate minor deity rather than the great storm god; on the other hand, the "baals" of various localities may in other cases be local manifestations of the one major figure. In a given case, it is often impossible to decide. In the Old Testament, a plural form, *ha-bealim* ("the Baals"), is of frequent occurrence. It may refer to a variety of local deities, but in many cases the plural is a "plural of majesty" referring to a single god; an honorific plural, *baaluma*, occurs at Ugarit.

Yarikh and Kothar. Yarikh, "Moon," was a male deity widely and very anciently worshipped, but little mythological detail survives. In general, the sun—a goddess at Ugarit—and the moon and stars play relatively minor roles at Ugarit. Kothar was the Canaanite craftsman god, similar to the Greek Hephaestus. The name means "skillful," and his other title is Khasis, "clever."

Fertility goddesses

Asherah, Anath, and Astarte. Three goddesses are especially prominent: Asherah, Anath, and Astarte. Asherah, the consort of El at Ugarit, has the fuller name "She who walks in the Sea" and is also called "Holiness." The Old Testament uses the name Asherah frequently, but usually for a wooden cult object associated with her worship rather than for the goddess herself. Astarte (Ashtoreth in the Old Testament) is a goddess of love and war, the approximate equivalent of Mesopotamian Ishtar. Overshadowed by Anath in Ugaritic mythology, she is much more prominent in cultic texts. In the Old Testament, she is the most frequently mentioned of the pagan goddesses; and her name is also a common noun, "sheep breeding."

Anath is the chief Ugaritic goddess of love and war. The consort of Baal, she plays an important role in the myth of Baal's death and resurrection—that is, in the cycle of fertility and infertility in nature. Her outstanding trait is her ferocity in battle. In one scene, she wades in blood and wears heads and hands as ornaments. There is evidence that suggests a connection between Anath and the ferocious Indian goddess Kālī. In the Hellenistic period, Anath and Astarte are blended into a single figure, Atargatis. She is the "Syrian Goddess," whose cult was famous for its *galli*, devotees who voluntarily emasculated themselves for the goddess and thereafter dressed as women.

Mot, Melqart, Adonis, and other gods. Mot is what his name, "Death," implies, god of the dead and of all powers that oppose life and fertility. Resheph is a related figure, a god of the underworld and of pestilence. Some abstractions were deified and occur in the god lists, notably Mishor and Suduk, approximately "Justice" and "Righteousness." Many other deities are attested at Ugarit, and other sites swell the list of names.

Carthaginian deities

The chief god of Tyre was Melqart, who was also head of the pantheon at Carthage. The name means "King of the city"—that is, "of the underworld city" in the most plausible interpretation. Greeks and Romans identified him with Hercules. Baal Hammon, perhaps "Lord of the Incense Altar," is mentioned only very rarely in inscriptions from Syria but becomes very important at Carthage, where the name occurs in hundreds of dedicatory inscriptions. Little is known of his nature. The principal Carthaginian goddess is Tanit (or Tinnit). No explanation of the name is generally accepted; usually it occurs in the form "Tanit face of Baal." Little of a positive nature can be asserted as to her nature, though, not surprisingly, she seems to have to do with the heavens and with fertility.

Adonis, whose name is a Semitic word, "Lord," is known only from relatively late non-Semitic sources. A youthful god of vegetation beloved of the goddess of love, he is according to one myth killed by a boar, his blood staining the river Adonis. Women took part in rites of mourning for him and set out ephemeral "Adonis gardens" in his honour. The cult reached Athens by the 5th century BC from Cyprus and was widespread in the eastern Mediterranean.

The chief god of Moab was Chemosh; his name occurs also in a list of gods at Ugarit, but little can be said about his nature; still less is known of Milkom, god of the Ammonites.

Myths and legends. *Theogony and cosmogony.* Philo of Byblos gives Sanchuniathon's account of the origins of the cosmos, the gods, and the arts of civilization. Many of the figures in the latter portion of the account can now be identified with ancient Canaanite deities, and in the sequence of divine generations, the account is strikingly like that of the Greek poet Hesiod's (flourished *c.* 800

BC) *Theogony* and the Hittite–Hurrian creation myth of Kumarbi, but sufficiently distinct to provide assurance that it is an ancient and independent variant of a common tradition. Thus, Sanchuniathon tells of four generations of gods: Eliun or Hypsistos ("the Most High"), Uranos, El (=Kronos), who castrates his father, and Demarus (=Zeus), all of this very like the *Theogony* and Kumarbi, but with numerous differences in details. This very archaic theogony is preceded by an atheistic cosmogony that is probably the product of later Phoenician speculative thought; it resembles the cosmogonies of the Pre-Socratic philosophers.

The Baal epic. From Ugarit comes the longest of known Canaanite myths, the Baal epic, probably composed in the early 2nd millennium BC. (The order of the separate tablets is not completely certain.) Baal is challenged to battle by the god Yamm (Sea). Equipped by Kothar with special clubs, Baal defeats Yamm. Baal, though supreme in power, has no house like those of the other gods; finally Kothar builds and equips a house for him, magnificent with gold and silver. After a gap in the text comes an episode in which Baal descends into the jaw of death, the god Mot. When the news reaches El, he mourns extravagantly, as does the goddess Anath, who then sees to the burial of Baal's body. She seeks out Mot and cuts him to pieces. Then Baal is resurrected and "the heavens rain oil, the watercourses flow with honey."

Other myths. Briefer myths recount the wedding of Nikkal, a moon goddess, to the moon god Yarikh, and El's seduction of two females, who bear the children Dawn and Dusk. Creatures of voracious appetite, they are driven into the wilderness; at this point the text breaks off. In one mythological fragment, Anath espies the beauty of her brother, then "she eats his flesh without a knife; she drinks his blood without a cup"—a striking parallel to the omophagy (eating of live victims, occasionally human) practiced by raving devotees of the Thracian and Phrygian god Bacchus. Elsewhere there is an allusion to Baal's defeat of Lotan, "the primeval serpent . . . the twisting serpent." Lotan is the same as the Hebrew Leviathan, and the same motif occurs in the Old Testament (*e.g.*, Isaiah 27), with Yahweh as the dragon slayer.

Legends. Other Ugaritic epics are less strictly mythological in that they involve human characters. The Keret epic concerns a king Keret whose sons have all died. In a vision Kindly El advises him to undertake a military campaign to get a new wife. After careful preparation, Keret besieges the city Udum and compels its king, Pabel, to grant him his daughter Hurriya in marriage. Hurriya bears Keret many children. In the last episode of the extant story, Keret falls ill and is saved only by El's healing intervention. The so-called *Aqhat Epic* concerns the sage, Danel (the ancient worthy Daniel mentioned in Ezekiel 14), who has no son. In response to Danel's prayer and offerings, El grants him a son, Aqhat. Later Danel gives Aqhat a marvellous composite bow made by Kothar. The goddess Anath covets it, but Aqhat spurns her and she arranges for him to be killed. Danel and his daughter Paghat discover the crime and take steps to avenge it; here the text breaks off.

PRACTICES AND INSTITUTIONS

The importance of sacrifice

Sacred customs and ceremonies. Animal sacrifice occupied a central place in the religion. Few details about the rites observed are known, but since much of the Ugaritic terminology is the same as later Israelite terminology (*e.g.*, "sacrifice," "burnt offering," "peace offerings," "wave offerings"), scholars contend that they are justified in conceiving Canaanite sacrificial practices to be similar in many respects to those of the Israelites. The animals commonly presented were sheep, goats, cattle, and birds; the Marseilles Tariff (see above) mentions also young deer and other game. The extent to which human sacrifice was carried on is uncertain, but there is no doubt that it was practiced to some extent, judging from biblical allusions and evidence for human sacrifice at Carthage. Sacred prostitutes, both male and female, were among the personnel of some shrines, but details as to the extent and significance of this institution are lacking.

Kings, priests, and prophets

Religious authorities. The king and queen were important religious figures, both because offerings and prayers were made for them and because they took a leading part in certain rituals, to judge from brief references in Ugaritic texts. The relatively elaborate official cult at Ugarit was led by a "chief priest" and by several lesser orders of priests. There were special temple singers and "drawers of water for the sanctuary" (compare the role of the biblical Gibeonites). The temples were economic as well as cultic centres. Estates were assigned to orders of priests, and a certain chief priest is said to have been also "chief of the shepherds"—that is, overseer of the temple flocks.

Prophets—that is, persons inspired by a god to deliver a message in his name—were a very ancient feature of the religion. In the Mari texts (dated *c.* 18th century BC), there are repeated references to ecstatics, some of them women, who appear unsolicited in the temples to deliver messages from the gods to the king. A similar phenomenon is attested for Byblos in the Wen-Amon report, an Egyptian text of about 1100 BC: a youth falls into an ecstatic state and delivers an oracle on behalf of the Egyptian envoy, which is respected by the ruler of Byblos. The prophets of the Tyrian Baal used dancing and self-laceration to achieve a state of frenzy (I Kings 18). A long charm against snakebite from Ugarit suggests that not only this variety of incantatory magic but others as well were cultivated in Syria–Palestine.

Shrines and festivals

Sacred places and sacred times. The temple, or house of god, was the place where the god, symbolized by his image, dwelt and thus the point at which heaven and earth met. Since, according to biblical tradition, Solomon's Temple was built by a Phoenician architect, the biblical descriptions apparently give us the fullest and most coherent idea of Syrian temple architecture. The basic tripartite plan, with porch, holy place, and most holy place, is illustrated in the small temple excavated at Tall Tainat in north Syria (9th–8th century BC). In addition to the elaborate temples in the cities, there were the more rustic shrines known as "high places" (Hebrew *bamot*), built on natural ridges or artificially built up and often associated with the cult of dead heroes. The principal cult objects were statues of the gods, but typical also is veneration of various deities in the form of unshaped stones, well exemplified in the black stone of Emesa that Elagabalus brought to Rome.

Very little is known about the sacred calendar of the region. At Ugarit, important sacrifices were offered on the day of the new moon and on the 14th of the month. Since the three great feasts of ancient Israel—that is, Unleavened Bread, Weeks (Pentecost), and Booths—were evidently native agricultural feasts originally, it is probable that from time immemorial the farmers of Syria–Palestine kept a spring festival at the beginning of barley harvest, a feast at the end of the grain harvest, and a fall vintage festival.

RELIGIOUS ART AND ICONOGRAPHY

Though excavations have yielded statues and reliefs depicting gods or symbols of the gods, it is frequently difficult to be certain about identification of a given representation with a particular deity known from written evidence. Baal and similar storm gods are frequently shown as riding on a bull and brandishing a mace or thunderbolts. The symbol of Tanit, very commonly found on Punic steles, is basically a triangle having a disk at its apex, with a horizontal bar in between; this basic form is often embellished. The source of the symbol and its significance are not known. In Syria–Palestine the most commonly found religious artifacts are small terra-cotta figurines depicting females, often naked and with exaggerated sexual characteristics. Some of these are probably intended to represent fertility goddesses, but none can be certainly identified with any one goddess. Winged human-headed lions (cherubim) and similar composite creatures are very frequent in Canaanite religious art, as in the cultic stand from Taanach (Palestine; 10th century BC).

BIBLIOGRAPHY. For translations of Ugaritic texts and major Phoenician inscriptions, see J.B. PRITCHARD (ed.), *An-*

cient Near Eastern Texts Relating to the Old Testament, 3rd ed. (1969). For the material remains of Canaanite religion, see Pritchard's *The Ancient Near East in Pictures,* 2nd ed. (1969). A one volume condensation of the earlier editions of both these works is available in paperback, *The Ancient Near East: An Anthology of Texts* (1958). G.R. DRIVER, *Canaanite Myths and Legends* (1956); and T.H. GASTER, *Thespis: Ritual, Myth and Drama in the Ancient Near East* (1950), contain some Ugaritic materials not in the Pritchard volume. E.H. GIFFORD, *Eusebius, Praeparatio Evangelica,* 4 vol. (1903), may be consulted for Philo of Byblos' Phoenician History in English. For the historical background, see W.F. ALBRIGHT, "The Role of the Canaanites in the History of Civilization," in G.E. WRIGHT (ed.), *The Bible and the Ancient Near East* (1961), and *Archaeology and the Religion of Israel* (1953), for an excellent summary sketch of Canaanite religion, rich in detail. M.H. POPE, *El in the Ugaritic Texts* (1955), is an important study of a major god. All the gods and myths are treated authoritatively by M. POPE and W. ROLLIG in H.W. HAUSSIG (ed.), *Wörterbuch der Mythologie,* vol. I (1965).

Systems Engineering

Systems engineering, a relatively new field, is not so much a branch of engineering as it is a technique for applying knowledge from the older branches in effective combination to solve a multifacetted engineering problem. It is related to operations research (*q.v.*) but differs from it in that it is more a planning and design function, frequently involving technical innovation, whereas operations research concentrates on the analysis of how existing systems work. Probably the most important aspect of systems engineering is its application to the development of new technological possibilities with the specific objective of putting them to use as rapidly as economic and technical considerations permit. In this sense it may be seen as the midwife of technological development.

The word systems is frequently used also in other combinations, especially when elements of technological advance are not so important. Systems analysis is an example. Systems theory or sometimes systems science is frequently applied to the analysis of physical dynamic systems, usually linear or nearly so. An example would be a complex electrical network, perhaps with one or more feedback loops, characterized by the partial reversion of the effects of a process to their source.

In the development of the various engineering disciplines in the 19th and 20th centuries, considerable overlap was inevitable among the different fields; for example, chemical engineering and mechanical engineering were both concerned with heat transfer and fluid flow. Further proliferation of specializations, as in the many branches of electrical and electronic engineering, such as communications theory, cybernetics, and computer theory, led to further overlapping. Systems engineering may be seen as a logical last step in the process. Systems engineers frequently have an electronics or communications background and make extensive use of computers and communications technology. Yet systems engineering is not to be confused with these other fields. Fundamentally a point of view or a method of attack, it cannot be identified with any particular substantive area. In its nature and in the nature of the problems it attacks, it is interdisciplinary, a procedure for putting separate techniques and bodies of knowledge together to achieve a prescribed goal in an effective manner.

Systems engineering as a point of view

In general, a systems engineering approach is likely to differ from a conventional design approach by exhibiting increased generality in its basic logical framework and increased concern with the fundamental objectives to be achieved. Thus, at each stage the systems engineer is likely to ask both why and how, rather than merely how.

In addition to systems engineering, it is important to define systems themselves. The systems with which a systems engineer is concerned are first of all man-made; second, they are large and complex; their component parts interact so extensively that a change in one part is likely to affect many others. Unless there is such interaction, there is little for the systems engineer to do, at least at the systems level; he can turn immediately to the components themselves. Another important characteristic of systems is that their inputs are normally stochastic, that is, the inputs are essentially random functions of time, although they may exhibit statistical regularities. Thus, one cannot expect to foresee exactly what the system will be exposed to in actual operation, and its performance must be evaluated as some sort of statistical average of the responses to a range of possible inputs. A calculation based on a single precisely defined input function will not do.

Systems may also vary depending on the amount of human judgment that enters into their operation. There are, of course, systems such as electrical circuits or automated production equipment that may operate in a completely determinate fashion. At the other extreme, there are management and control systems, for both business and military purposes, in which machines in a sense do most of the work but with human supervision and decision making at critical points. Clearly these mixed human-machine systems offer the greatest variety both of possibilities and problems for the systems engineer.

THE DEVELOPMENT OF SYSTEMS ENGINEERING

The systems approach stems from a number of sources. In a broad sense it can be regarded as simple extension of standard scientific methodology. It is a common procedure in science (and elsewhere) to list all of the factors that might affect a given situation and select from the complete list those that appear critical. Mathematical modelling, perhaps the most basic tool in systems engineering, is a technique encountered in any branch of science that has become sufficiently quantitative. Thus, in this broad sense, the systems approach is simply the inheritor of a tradition that is generations, if not centuries, old.

In looking for more recent and more specific sources for the systems approach, on the other hand, there are two in particular that stand out. First is the general field of communications, particularly commercial telephony, where systems engineering first appeared as an explicit discipline in its own right. Traces of the systems approach are to be found in telephone engineering at least as far back as the beginning years of the century, and systems ideas were fairly common in telephony by the 1920s and 1930s. When Bell Telephone Laboratories, the research arm of the American Telephone & Telegraph Company, was officially incorporated in 1925, its two principal engineering divisions were called respectively Apparatus Development and Systems Development. A complete formal doctrine of the role of systems engineering, however, first emerged in the years after World War II, as part of an effort to redefine the policy and structure of the research and development. This doctrine set the engineering effort on a level of logical parity with the research and development efforts and made it of almost comparable actual size, at least with research. The systems engineer had a multitude of functions, with special emphasis on effective utilization of scientific and technical advances in planning new communications systems. This particular set of ideas, of course, reflected the special needs of telephony. Nevertheless, as an example and a point of departure, it had a wide effect. It seems to be one of the reasons why so esoteric a subject as systems engineering advanced as rapidly as it did.

Relation to operations research

A second major source for systems engineering is operations research, which originated in a recognizable form in Britain during World War II and initially was concerned with the best employment of military equipment. Typical examples included determining the best employment of a given number of bombers, the best way of arranging convoys against submarine attack, and the best way of using interceptors against a bombing attack. Operations research was effective in such cases and has flourished ever since in both civilian and military contexts.

There exists a clear distinction between operations research and systems engineering. Because operations research is concerned with the best employment of existing equipment, technological uncertainties do not arise. Systems engineering, on the other hand, is normally concerned with the planning of new equipment and such uncertainties may be important. In practice, nevertheless,

systems engineering and operations research have a good deal in common. In particular, they share many of the same analytic techniques. This results in large part from the fact that a systems engineer is likely to evaluate the effectiveness of a tentative design by the same methods an operations research man would use with actual hardware.

Another reason for overlap is the fact that the distinction between new and existing equipment is not quite clear-cut. Newness in equipment is a relative matter. If the new equipment is sufficiently well based on existing design techniques and seems to involve few enough technical uncertainties, the issue becomes unimportant. The question is one of degree and, to an extent, of judgment.

Most of the present character of systems engineering derives historically from the early 1950s. There were some noteworthy events in the years just after the war, including, for example, the discovery of linear programming in 1947 and the founding of various organizations for continued development of the field in the late 1940s. On the whole, however, this was a period of consolidation of earlier advances. Thus, in the communications field, the principal systems were some long-distance transmission systems that had been initiated before the war and had been interrupted by war activities.

In the 1950s the pace of growth accelerated appreciably. The first general textbook on systems engineering appeared in 1957 and was followed by a number of other works that treated both industrial and military applications. These publications proved sufficient to establish systems engineering as an accepted academic discipline, and courses in it are now taught in many universities throughout the developed countries of the world. Professional societies and journals exist in France, Great Britain, India, Japan, West Germany, and the United States.

The development of systems engineering after 1950 stemmed, in large part, from the impact of great advances in adjacent fields, notably communications and electronics. An automatic control system is a good example. A control system has the prime characteristic that the components interact extensively and that the system as a whole has certain properties—*e.g.*, stability—that cannot be said to adhere to any individual component. Thus control systems furnished convenient textbook examples for systems engineering.

The development of information theory as a basic starting point for communications engineering, in the years just after World War II, was also influential in shaping the evolution of systems engineering. The various subsystems in many complete systems were found to be held together by what were, in effect, communication channels. Thus ideas of information transfer from one part of the system to another proved useful in understanding the operation of the structure as a whole.

Use of the computer

Systems engineering also profited from the advent of computers (*q.v.*), which affected the field in two principal ways. In the first place, they were a powerful tool for analyzing complex systems by means of extensive calculations or direct simulation. In the second place, they could be used to digest large amounts of data or as actual constituents of complex systems, especially those concerned largely with information transmission. This opened up the possibility of processing information as well as simply transmitting it in such systems.

The impact of military weapons problems on systems engineering began soon after World War II. A landmark date was 1945, when development of Nike Ajax, a United States air-defense missile system, was initiated.

In 1945, available rocket propulsion seemed barely sufficient to give the missile a satisfactory tactical range. It was discovered that achievable range depended on several parameters, such as the weight and size of the warhead, fineness of the missile's aerodynamic design, degree of manoeuvrability provided by the control system, the shape of the trajectory, and the average speed along it. Thus an effective systems-engineering effort could be mounted, in which a variety of combinations of the missile's properties could be explored, with the objective of achieving the best balance between range and other tactical characteristics.

Control and feedback questions were also important aspects of the overall systems problem. The whole system was in fact a gigantic feedback loop because the missile was controlled by orders sent it from a ground computer, and the computer input included information on what the tracking radar observed the missile to be doing. Thus there was a closed feedback loop from missile to computer and back to the missile again. There were in addition such subsidiary feedback loops as that through the autopilot controlling the attitude of the missile, and the dynamical response of the system was further affected by the need to process the radar signals to remove radar "jitter." The analysis of such elaborate dynamical systems involving interlaced feedback paths has become an important special part of the general systems area.

In the 1950s and 1960s systems engineering also grew in other directions, largely as a result of weapons systems projects associated with the Cold War. Thus the Ajax study was concerned with the dynamics of a single isolated missile. On the other hand, the defense systems that grew up in the 1950s involved the coordinated operation of a large number of missiles, guns, interceptors, and radars scattered over a considerable area. These were all held together by a large digital computer, which thus became the central element of the system. The SAGE system in the United States (for semiautomatic ground environment) is a good example.

During the same years the systems approach also became increasingly identified with management functions. Thus the phrase "systems engineering and technical direction" came into use to describe the role of a systems engineer responsible both for the initial planning of a project and its subsequent management. So-called planning, programming, and budgeting techniques (PPB) were developed to provide similar combinations of systems engineering and financial management.

In nonmilitary fields, systems engineering has developed along similar though more modest lines. Early applications were likely to stress feedback control systems in large-scale automated production facilities, such as steel rolling mills and petroleum refineries. Later applications stressed computer-based management information and control systems somewhat like those that had earlier been developed for air defense. In recent years the systems approach has occasionally been applied to much larger civilian enterprises, such as the planning of new cities.

SYSTEMS ENGINEERING TECHNIQUES, TOOLS, AND PROCEDURES

Techniques. If a system is both large and complex in the sense in which we have defined these terms, it may be difficult to find out how it works. In a substantive sense, a large part of the content of systems engineering consists of techniques for the investigation of such relatively complex situations.

Modelling and optimization. Perhaps the most fundamental technique is the flow box diagram, a graphical display composed of boxes representing individual components or subsystems of the complete system, plus arrows from box to box to show how the subsystems interact. Though such a representation is very useful in an initial study, it is, of course, essentially qualitative. A more effective approach in the long run is construction of a so-called mathematical model, which consists of a set of equations, or sometimes simply of tables and curves, describing the interactions in quantitative terms. It is not necessary for the mathematical model to be exact, as long as it serves its purpose. It frequently consists of piecewise linear approximations to basically nonlinear situations (*i.e.*, a series of short straight lines that roughly approximate a curve). After the model has been constructed and checked, a number of mathematical techniques can be employed (including straightforward computing) to find out what it says about the actual operation of the system. Often these calculations will have a probabilistic or statistical flavour.

When the components or subsystems interact signifi-

cantly, it may be possible to achieve essentially the same final level of performance in many different ways. Limited performance by one subsystem may be offset by superior performance somewhere else. These optimization studies, called trade-offs by people in the field, are important in suggesting how to achieve a given result in the most economical manner. They are, however, at least equally valuable in suggesting whether or not the proposed result is in fact a reasonable goal to aim for. It may be found, for example, that a modest reduction in performance will permit radical savings in overall cost or, conversely, that the postulated equipment is capable of much better performance than is asked of it, at only nominally greater expense. (It may also turn out that the equipment can supply useful functions not originally contemplated. Computing systems, for example, can usually perform extra chores of record keeping at little increased cost.) For all of these reasons, studies of such variables are an important part of systems engineering, both in the early exploratory phases of the project and in the final design.

Optimization studies

Identifying objectives. The formulation of suitable objectives for the final system is so important a part of the systems-engineering process that it deserves special attention. It is, of course, always possible to state the general objectives of a system in vague or perfectionist terms. A sufficiently clear, precise, and comprehensive statement to serve as a basis for engineering studies, however, is another matter. Unless the situation has been well explored in the past, the real choices are not likely to be obvious when the work begins. Thus, the first task of the systems engineer is to develop as clear a formulation of objectives as possible. This will usually involve computations and consultation with others interested in the system. Because the final statement must reflect value judgments as well as purely technical considerations, the systems engineer does not try to do this thinking entirely by himself but attempts to serve as a working focus and catalyst. Although issues of this sort naturally present themselves with particular force near the beginning of a systems study, they may recur in subsequent steps. The question of objectives is never really out of the systems engineer's mind.

The principal reason why a satisfactory statement of objectives may present such a problem is simply that most systems have multiple objectives, often in conflict with one another. In airplane design, for example, there are a multitude of desirable characteristics, such as range, speed, payload, and safety to be maximized, as well as undesirable characteristics, such as noise generation and air pollution, to be minimized. Because the same design cannot do the best job in all of these directions, a compromise achieving the most desirable overall performance is required. The most attractive compromise, which may require both study and ingenuity, is not likely to be found at all until some hard thinking has been done about what characteristics are really needed.

Especially difficult problems in defining objectives may arise when an existing technology is transplanted to some new disciplinary area. An example might be the application of electronics, perhaps computer techniques, to medicine and education. It seldom happens in such cases that the best system is based on a simple one-for-one substitution, such as direct replacement of the teacher by electronics. It is much more likely that the most effective plan will turn out to be a rather complicated mixture of the old and the new. This conclusion, however, is likely to raise basic issues about the actual objectives of the new system, issues made no simpler by the interdisciplinary nature of the situation.

To make adequate comparisons between competing objectives, a logical frame of reference, broad enough to include both, is needed. Thus, the systems engineer may study many situations in the framework of more than one system or a whole hierarchy of systems of steadily increasing generality. In the airplane example, the airplane itself is a possible system, as are the group of planes owned by one airline, the total number of airplanes in a particular country, and all that nation's transportation facilities. Though the simplest system—the airplane itself—is a satisfactory reference for specific design problems, a more general framework may be needed to approach broader problems. Thus the individual airplane designer may seek to ameliorate air-traffic congestion by improving airplane takeoff and landing characteristics, permitting better utilization of existing airports. The airlines in turn may suggest construction of more and better airports. From the point of view of the transportation system as a whole, the best step might be to invest more money in high-speed rail facilities, to carry part of the air-traffic load. In systems engineering, the error of studying the problem within too narrow a framework is called the error of suboptimization.

Work at different levels of generality

The stress on systems objectives has one further consequence worth mentioning; *i.e.*, that systems engineering is likely to be strongly user-oriented. This results naturally enough from the fact that systems objectives usually relate to overall performance, which is what the final user is interested in. The identity of technical interest between the systems engineer and the final user is usually marked; systems engineering is likely to give special consideration to such qualities as reliability, ease of maintenance, and convenience in operation. Moreover, the final step of a systems-engineering project is typically an evaluation phase that attempts to find out how well the system works in the hands of the user.

Design considerations and examples. Chemical-processing plants usually consist of many different items of equipment. A typical plant, for example, might include distillation columns, heat exchangers, absorption columns, and chemical reactors. These feed each other; in addition, partially processed material may be recycled. Thus, the different pieces of equipment interact extensively, and many opportunities exist for improving efficiency by rational compromise. An inefficient reactor, for example, can be balanced against high-efficiency absorption and distillation columns. An adequate systems-engineering study takes account of still other considerations, which go beyond the individual physical plant. Capital demands must be balanced against operating costs. Moreover, the plant under study may be one of a complex of plants at the same site, dependent on common feedstocks and common utilities, and this in turn may be only one of several complexes at different sites, manufacturing the same or related products. Thus, the best design for an isolated plant may by no means be the best when all of these other facilities are taken into consideration. The idea of a hierarchy of systems applies here because it is only by going to a sufficiently general system, perhaps the operations of the company as a whole, that one can expect to deal satisfactorily with all of these considerations.

Another example is furnished by the design of the commercial transport plane mentioned above. In such a design, the aerodynamic lift, the drag of fuselage and wings, the control apparatus, the propulsion system, and such auxiliary hardware as the landing gear all interact substantially. One cannot be disturbed without affecting the others. Thus, if designers make the fuselage fatter and the wings smaller in an effort to carry more payload at the same or higher speeds, a new control system might be needed because of the changes produced in the overall mechanical and aerodynamic characteristics of the vehicle. Stronger and heavier landing gear might be needed to withstand higher landing speeds. Almost surely, the new design would call for larger engines and fuel tanks to compensate for greater aerodynamic drag. Thus the designers would have lost ground in some respects and gained in others. The new plane might be more useful for short flights when not much fuel must be carried but less useful for long ones. Obviously, the system objective—the kind of airplane actually wanted—must control the direction of any such study.

The study becomes more interesting if a possible advance in basic technology is considered, such as an improvement in propulsion or aerodynamics, and it is desired to determine how it might best be applied in a new airplane design. The central systems-engineering question

then would probably encompass the relation between the available new plane characteristics and the needs of the existing air-transportation system. Clearly, such an investigation can be made only by going to one of the upper levels in the systems hierarchy.

Finally, to operate the new airplane successfully, a whole series of supporting functions may be required, including routine checkout, maintenance, and spare parts supply, in addition to functions directly involved in the plane's flight. Though, under normal circumstances, these might readily be handled by the existing operating staff, it is part of the user orientation of the systems approach that the systems engineer is expected to anticipate any new requirements here and make sure they are properly planned for.

There exist entire areas of technology that, from a present-day point of view, have an obvious systems flavour. Examples are transportation, electric-power supply, and communications. Communications was the area in which systems engineering first developed. Telephone engineering exhibits most of the characteristics that have been associated with systems problems. A national or international telephone network is inherently large and complex. Moreover, there are many ways in which its function might be accomplished. In addition, telephone traffic—the number of connections that must be set up simultaneously and their geographical dispersion—is essentially random in character, so that a statistical or probabilistic approach is mandatory. Furthermore, man–machine relations are particularly conspicuous in telephony because the customer participates in every call. Finally, the field is abnormally responsive to advances in electronics, so that an orderly approach toward the utilization of new technology by means of systems engineering is particularly rewarding.

Systems engineering in telephony

Tools. The most obvious aspect of systems-engineering tools is their great diversity. A leading text in the field states that "there is virtually no scientific discipline which may not be used in the design of some large-scale system" and singles out probability, mathematical statistics, computing, system logic, queuing theory, game theory, linear programming, cybernetics, group dynamics, simulation, information theory, servomechanism theory, and human engineering. To this list might also be added decision theory, nonlinear programming, some elements of econometrics, and communications theory as related to random processes.

In spite of this diversity, many of the tools of systems theory can be grouped under a few major headings. The analytic problems associated with optimization, for example, are a recurrent theme. Probability and statistics are also major areas that carry with them numerous more specialized topics, such as queuing theory and much of communications theory. Finally, computing is a major field for the systems engineer. If all else fails, he can still mount an attack by direct calculation or simulation.

These fields are all essentially mathematical in nature. The systems engineer may need knowledge and skills of other sorts as well. The mathematical model and associated objective functions that conventionally begin a systems analysis, for example, are only satisfactory to the extent that they adequately represent the real physical situation. The adequacy of a mathematical model in this sense, however, is a matter of physical or engineering rather than mathematical judgment. In some circumstances, the systems engineer may also need to know something about experimental procedures in general and, in particular, about ways of maximizing the amount of information from a given testing program. This is particularly likely to happen in urgent high-risk projects, like weapons-system programs, in which intermediate testing failures are bound to occur, and the systems engineer, as part of his overall responsibility, must decide what to do next. Even in simpler cases, in which the project should close in a final test and evaluation phase, the systems engineer is responsible for ensuring that this work is adequately carried out. A closely related question is the monitoring of testing procedures for routine quality-control purposes. This also is logically part of the systems engineer's duties, a reflection of his basic user orientation. When reliability is very important, as in space programs, it may be a major responsibility.

The systems engineer in testing programs

When the systems engineer's job is defined as including significant management responsibility, some acquaintance with modern management techniques is an obvious requirement. The techniques of particular importance are those that bear most directly on cost figuring and scheduling technological developments.

Finally, systems engineering is used in new situations that may involve the application of new discoveries in science or technology to existing technical areas or the application of known science or technology in new contexts. In either case the systems engineer obviously needs considerable substantive knowledge of the fields involved if he is to make reliable plans.

It is apparent that no single person is likely to meet all of these qualifications. Thus, systems engineering on any significant scale almost invariably involves a team approach.

Procedures. Not all systems-engineering projects follow exactly the same course. Too much depends on the nature of the problem and of the specific organizational setting in which the work is done. Nevertheless, if such variations are ignored, a sort of general pattern of procedures for systems-engineering studies can be perceived. Most authorities recognize a sequence of about five major steps, including systems studies, exploratory planning, development planning, studies during development, and current engineering (individual nomenclatures differ somewhat).

In a broad sense the activities reflected in the early phases (systems planning; exploratory planning) are obvious. The starting point is a recognized need or requirement and the end point a preliminary design of a system to satisfy that need. Mathematical modelling and so-called trade-off studies are used to find efficient proportions for such a system.

When the situation is sufficiently simple, the systems engineer's task may be almost as straightforward as this suggests. In other circumstances, however, the job may be much more difficult. Five points requiring special attention follow.

Exploration of objectives. It is particularly important that the objectives of the system be thoroughly explored and carefully stated. An offhand statement of a requirement seldom is complete or quantitative enough to serve as a basis for design. The desirability of going to a higher level in the systems hierarchy may need to be evaluated. Questions of economic constraints, even if they cannot be fully explored in the preliminary design, are introduced at this time. Finally, the preliminary study must take adequate account of the conditions to be met by the system in actual use. Many systems, such as telephone, highway, and air-defense systems, must be evaluated ultimately by the amount of traffic they can carry. It would not be sufficient, then, to stop the preliminary design with a demonstration in principle, by showing that the proper sequence of operations can be realized for a single telephone call or a single vehicle or enemy intruder. The traffic problem must be met head-on. Similarly, the preliminary study should deal explicitly with such questions as the extent to which the system should be expected to keep operating under conditions of damage or other departures from nominal operating conditions.

Systems involving traffic

Consideration of other possible systems. In many situations there may be more than one possible systems answer to a given need. The systems engineer tries to avoid settling prematurely on one design without giving other possibilities adequate attention, particularly when dealing with systems that depend on radical breaks with past technology. If radical new systems work at all, they are likely to lead to much greater advances than slight improvements of an old system.

Data collection. The systems-engineering team is likely to find that it needs data it does not have. Thus data collection begins as soon as these needs can be foreseen. It is usually more economical in the long run to make the effort ambitious enough to provide a data base through-

out the life of the project and not just in the preliminary phases. As a closely related issue, physical information may be lacking on components or phenomena that may become important in a proposed system. The systems engineer attempts to foresee such needs in order to initiate a suitable experimental program as quickly as possible.

Organization of the team. The internal organization of the systems-engineering effort may also raise unexpected problems. Because the group must cover so much ground, it is natural to make it fairly large, to include all of the necessary kinds of expertise. On the other hand, if the group becomes too large (perhaps seven to ten members), it begins to lose internal coherence. The members tend to pursue their individual interests and may become overly active partisans of particular systems concepts. The close-knit integration of the parts with the whole, on which the whole systems idea depends, begins to fail. Later on, as the system develops, it will naturally begin to subdivide into somewhat independent pieces, and larger numbers can be accommodated.

These phases of the project culminate in the generation by the systems-engineering group of a preliminary design for the proposed system. The preliminary design is supposed to be a feasibility demonstration, to show at least one way to realize the proposed system physically. It is also supposed to show that the system will be feasible economically in the sense that it will not be impossibly expensive.

Review and development. With the preliminary design in hand, the appropriate authority decides whether or not to proceed with the project. If the decision is made to go ahead, responsibility begins to shift from the systems engineers to the development engineers, until the development engineers soon carry the principal work load.

The first step in this shift is a detailed review of the ground already covered in the preliminary design, with the objectives of establishing a detailed blueprint for the development and of providing enough information for satisfactory forecasts of schedules and expenses. In the course of this review, the development engineers may find improved or cheaper ways of accomplishing some of the functions in the preliminary design. If the systems engineer has done his planning well, it will generally be possible to adjust the system to take significant advantage of these possibilities.

After this detailed review, actual development may proceed directly to the final goal, or, depending on circumstances, may be interrupted by the construction of development test models and prototypes. In either case, the development engineer rather than the systems engineer is the central figure in the effort. The systems engineer, however, is responsible for seeing that the original aim of the system is maintained and that intermediate test results are consistent with the overall plan. These stages in the effort correspond approximately to the phases labelled "development planning," "studies during development."

Production and operations

After the development phase comes production and operations. This corresponds approximately to the item, "current engineering." Production and operating people dominate, although the systems engineer also has important responsibilities. He devises tests to find out to what extent the final product does indeed realize the initial systems objectives. Occasionally, readjustments in the design may be necessary. It usually turns out that the apparatus in the field is not used in exactly the way the designer intended. The systems engineer must be alert for such situations and their causes. This becomes particularly important information if there is likely to be a successor design sometime in the future.

APPLICATIONS OF SYSTEMS ENGINEERING

The procedures just described do not distinguish between relatively new technical situations and somewhat older ones. Many useful systems are, in effect, modifications of previous designs. The proportions of the subsystems may be changed, but no substantial function has been added or left out. Chemical-processing plants and information systems, for example, are likely to be of this sort. The basic task of the systems engineer in such a situation is relatively straightforward; it is essentially a matter of reoptimizing the existing design to meet the new conditions.

In other circumstances, however, the basic systems concept represents a more radical break with the past. The new concept may involve the introduction of new functions or the realization of old functions in new ways. On the other hand, it may merely involve a radical change in system parameters (constants). Many complex systems are sensitive in one way or another to changes in scale. A systems concept that seems awkward and uneconomic for certain ranges of basic parameters may be quite inviting for others. Sometimes it is enough just to understand clearly what physical factors are holding the system back. Formal optimization procedures are normally better suited to small, continuous variations in linearized or nearly linearized systems (systems the operation of which can be graphically represented as a straight line). In any of these cases there is a key idea or a key technical decision—to follow one given technical path and not some other—that needs to be isolated and thoroughly understood, because it has a decisive effect on the final system.

The development of radically new systems. Radically new systems concepts are like inventions in ordinary engineering. Usually offering a substantial advance in overall performance, more than would be expected from a modest reproportioning of a known system, these clearly deserve special attention. On the other hand, in many cases it is impossible to predict accurately in advance of the development just what performance may be achievable in one or more of the critical elements of the new system. This leaves the systems engineer with a special problem in planning, which is usually addressed by establishing a minimum acceptable level of performance for the critical elements, with the rest of the system so arranged that whatever is realized beyond this level will appear as growth potential in the overall capabilities of the system. Thus definitive optimization studies may be postponed until the system is better understood.

Microwave-radio relay system. An illustration of this is furnished by the development of a microwave-radio relay system begun in the early 1940s and finished after the war. The possibility of using radio instead of wire lines for long-distance commercial communications had long been recognized. Beginning at quite low frequencies with Marconi, the transmission capability had crept up the radio spectrum to slightly beyond the high-frequency band, but the band width was still very small and most of the frequency spectrum in this range had to be conserved for vital services. Near the end of the 1930s, it was suddenly realized that many difficulties could be overcome by taking a large jump upward in the frequency spectrum. The system invention, then, consisted of a frequency jump of the order of 100 to 1 or more, from the high-frequency band (3–30 megahertz) to squarely in the middle of the so-called microwave range (about 4,000 megahertz). In this range, adequate frequency space was available and external interference comparatively low. Furthermore, at these wavelengths moderate-size antenas could be made highly directive, thus leading to efficient transmission links without mutual interference, even when they were physically close together and operated on the same wavelengths.

A systems analysis of radio waves

A preliminary systems analysis revealed that the microwave system itself was efficient only for rather broad transmission bands. Moreover, because a large part of the cost of the final system was for towers, access roads, power supplies, and other equipment, it was advantageous to provide numerous separate links at each site. Thus, everything pointed to a system of very high capacity, and high capacity became a necessary part of the total system concept. The advent of network television, which could readily be foreseen, provided an obvious justification for the provision of such broad bands and resultant high capacity. Growth potential was easy to achieve.

Nike Ajax missile system. The Nike Ajax missile system provides another example of the application of a radically new systems concept. The simple realization that the technology was available to provide a missile that could outmanoeuvre an enemy bomber taking evasive

action was perhaps the systems invention in this case. (Guided missiles had been thought of before, but only for use against simpler targets than a rapidly manoeuvring airplane.) In a more limited sense, however, the key idea in the overall systems concept was probably the decision to use a command-guidance system, as opposed, for example, to a homing system.

In the command system, both the radars used for tracking the aircraft and the intercepting missile and the computer that calculates how the missile should change course are on the ground. Such a system requires a minimum of control apparatus in the missile. It also allows the missile to follow computer-determined paths that are aerodynamically favourable. This was an especially important consideration at the time in maximizing the range achievable with available propulsion systems. It also allows, through the computer, maximum flexibility in dealing with evasive action by the target. On the other hand, adequate accuracy from the ground-tracking system becomes increasingly difficult in a command system as the range is increased, whereas a homing system is not so limited. Thus the adoption of the command system implied a belief that the ground radars would be accurate enough to provide satisfactory interception even at the limits of the expected field of fire. As the development turned out, tracking accuracies were more than adequate for the purpose, and the surplus provided growth potential toward still longer ranges and higher probabilities of interception. (In other circumstances, of course, a different choice might have been better.)

Long-term systems development. Thus far the description of systems engineering may seem to suggest that systems-engineering efforts are essentially episodic and that to the individual systems engineer successive studies may have no special connection with one another. In many situations, however, there are important elements of continuity in what the systems engineer actually does. He is likely, in fact, to work on a series of similar problems as part of a long-term effort. This happens frequently, for example, in the weapons-system field or in the design of refineries or other chemical-processing plants. In the case of telephone engineering, systems-engineering groups have been set up formally as permanent parts of the overall organizational structure, each group having cognizance over some wide area of telephone technology. Thus continuity in this case may extend over many years.

Permanent systems-engineering groups

Such elements of continuity have a major impact on the systems engineer's job. He can work more efficiently and expeditiously on each new task if he can draw upon relevant experience. More to the point, however, the efficient solution of any particular problem, using familiar tools, begins to be something that can be taken more or less for granted. Attention almost inevitably begins to centre on the relation these solutions have to general technical progress in the field. Systems engineering thus tends to shift away from operations research and toward long-range technical and economic planning.

Telephone engineering makes a particularly good example of this because of the importance of long-range forecasting for the telephone plant. One of the important responsibilities of the systems engineer in this field, for example, involves establishment of performance standards for new items in the plant. In most fields, the systems engineer's role in this respect is comparatively modest because performance standards represent value judgments established by others. In telephony, the systems aspects are more conspicuous because, at any given instant, the plant is a composite of new and old items, designed at different times in different ways to meet a variety of assumed operating conditions. The pieces must all work together. Any new apparatus or system must be compatible with what already exists. In addition, however, if an orderly evolution of the plant is to continue, the new apparatus must also be suited to the traffic and service needs of the future. Thus the systems engineer's responsibility, to provide a sort of long-term doctrine of performance standards, becomes very important.

Somewhat the same considerations affect the economics of new telephone systems. Here again a carefully developed forecast is essential. On the one hand, there are usually substantial economies of scale in communication apparatus. Thus it pays to take big steps in installing new equipment. On the other hand, capital charges on underutilized equipment are likely to be excessive. Because the successive steps of design, production, and installation of a complicated system may take years, and because meanwhile both technology and service demands may change materially, the situation may increase in complexity, and the systems engineer may find that the choice of the most inviting system is not an easy one to make. Indeed, the best choice may involve a calculated risk. He is responsible for judging the degree to which new possibilities should be exploited at any time. The principal result of assigning the telephone-systems engineer a continuing organizational position and function is to put him into much more intimate contact with the technical frontier in communications. His prime responsibility becomes that of monitoring the technical frontier to see what can be put to use in new operating systems.

Major technical advances may, of course, require many years between the original discovery or conception and the time when a practical design is feasible. The systems engineer keeps in touch with the work throughout this period. He can exercise a valuable if indirect influence on the investigation simply by noticing weaknesses and errors that need correction for a successful project. It frequently happens that a program of systematic measurements is called for before a new systems conception can be implemented, even when the basic conception is well established.

Competitive approaches to problems

In many cases, technology suggests two or more competitive approaches to the same problem. If a continuing systems-engineering organization exists, there is generally no need to make a premature choice between them. Rather, both lines can be followed until it is clear that one is superior or, perhaps, that each has its place. In telephony, for example, this was the case in the long-continued rivalry between microwave transmission systems and those based on transmissions by a coaxial cable.

New fields of application: future possibilities. Thus far, systems engineering has been dealt with in relation to two principal fields of application. One field is industry, in which the prospects of a further expansion of systems engineering appear bright. Existing applications furnish many good models, and it seems likely that such extensions can take place without raising many unusual problems. The other major field of application has been in military and space systems, and this may have been the principal force in shaping the systems-engineering field. Although techniques learned here are still valuable, interest in applications of systems ideas to military and space problems seems likely to decline as activities in both fields taper off somewhat. In their place may appear new applications of systems ideas in the nonmilitary side of government. There appear to be many such possibilities in the realm of worldwide basic social and economic problems. On the other hand, systems engineering as practiced in other contexts does not automatically transfer easily to this new environment. General interest in the subject dates, however, only from the rather late 1960s, so that the field is incompletely explored.

Systems approach in government

In one experiment in the conversion of military systems-engineering techniques, a U.S. state government contracted with four large aerospace companies (each of which had a substantial capability in systems engineering) to study the following four topics: (1) a statewide information-handling system, including a plan for implementation, (2) a program for the prevention and control of crime and delinquency, (3) a waste-management problem, and (4) a systems approach to basic transportation problems.

None of the four studies led to proposals that seemed attractive enough to be implemented by the state, and, in this respect, the experiment was a mild disappointment, although in view of the wide scope of the problems attacked and the limited effort called for by the study contracts, the result is not surprising. On the other hand, the

experiment was useful in advertising the possibilities of systems analysis as applied to civil problems and in illuminating difficulties that may be encountered in making such applications. The experiment stimulated interest in the civil uses of systems methods both inside and outside the United States. A survey made in 1967 listed more than a hundred studies then current. By the early 1970s there were several times as many.

The potential applications of the systems approach to governmental activities are so numerous and so varied, in both the developed and developing worlds, that an exhaustive catalog would be out of the question. Nevertheless, it may be worthwhile to list a few of the most conspicuous possibilities. The most obvious class is made up of massive engineering attacks on very broad socio-economic problems. These are the situations that seem to have most in common with the applications of systems methods in the weapons sphere. New transportation systems, comprehensive attacks on pollution, and radical reconstruction of urban areas belong here. A concrete issue is the problem of power-plant location, an urgent question in many advanced and developing countries. The systems overtones are obvious. Generating stations are customarily interconnected so that a new plant has an impact on the availability of power over a considerable region, and, of course, the effects of thermal and atmospheric pollution from a given plant may also be widespread.

Other applications of systems analysis in the social sphere tend generally to be smaller and more easily treated. One class consists of the extension of military budgeting and methods of financial control to the nonmilitary world. Another application has been the use of systems analysis to support the technical side of foreign-aid programs. Other fields include the possible application of specific items of new technology in such areas as crime detection, fire fighting, and traffic control. Still other current studies involve specific aspects of such subjects as housing and other types of building construction. Such studies attempt to be useful rather than broad or necessarily definitive for all time to come.

The applications of systems analysis in civil government obviously still have far to go before their potentialities are exhausted. On the other hand, there are many reasons why these potentialities can be realized only slowly, if at all. Some of them are related to the inherent difficulty of the problems presented—the wide range of both technical and social considerations that may enter certain decisions, for example. Others reflect some of the common characteristics of governmental structure, the necessary bureaucratization of functions, for example, or the frequent problem of overlapping jurisdiction. Still other problems reflect the fact that existing systems analysts are trained preponderantly in the physical sciences and engineering and thus may not be well matched to the socio-economic issues they are likely to confront, though most systems-analysis groups working in socio-economic questions try to balance their strength by adding appropriate missing skills. The most common problem, however, is probably simply the need to build up an adequate basis for mutual cooperation between systems analysts and government.

As such an evolution proceeds, there may be an increasing tendency for the individual systems analyst to become identified with the substantive area in which he works and to lose his special relation to systems analysis as a distinctive field. Thus, it may be the ultimate fate of systems analysis to disappear as a separate field and instead become an important constituent of the planning function required in many parts of modern society.

BIBLIOGRAPHY. The systems engineering field is so broad and so diffuse that one should not expect to find a complete treatment in any single work. A well-rounded picture requires several sources.

Because systems engineering and operations research overlap extensively, one possible source is simply a good account of operations research. The classic starting point here is PHILIP M. MORSE and GEORGE E. KIMBALL, *Methods of Operations Research*, rev. ed. (1951). The introductory discussion in this book is still useful for orientation, but the specific examples, dating mostly from World War II, are too limited to be of much value now. The book *Operations Research for Management*, vol. 1 by JOSEPH F. MCCLOSKEY and FLORENCE N. TREFETHEN (1954), and vol. 2 by MCCLOSKEY and J.M. COPPINGER (1956), on the other hand, give a broad range of examples, many of which are still of interest. Because, in addition, most of the examples are developed with a minimum of mathematics, the book is well suited to the general reader interested primarily in a broad understanding of the field.

Later books have tended to place more stress on mathematical techniques. Thus, *Introduction to Operations Research* by CHARLES WEST CHURCHMAN, RUSSELL L. ACKOFF, and E. LEONARD ARNOFF (1957), gives a fair survey of the field but is more useful for its description of operations research methodology. Recent books such as FREDERICK STANTON HILLIER and GERALD J. LIEBERMAN, *Introduction to Operations Research* (1967), put still more emphasis on methodology (and probabilistic techniques in particular) and are less suited to the general reader.

Among books more directly related to systems engineering, the earliest significant work is HARRY HERBERT GOODE and ROBERT ENGEL MACHOL, *System Engineering* (1957), followed by Machol's *System Engineering Handbook* (1965). These give substantial treatments of both the philosophy and methodology of systems engineering, and the second in particular is a mine of background information. On the other hand, both books are clearly directed primarily at large military systems and are less useful for other applications. A somewhat more recent book that also attempts to cover both philosophical and technical aspects of systems engineering is A.D. HALL, *A Methodology for Systems Engineering* (1962). It takes its inspiration largely from the author's experience with television and similar broad-band circuits. HAROLD CHESTNUT, *Systems Engineering Tools* (1965) and *Systems Engineering Methods* (1967), deal largely with methodology and overlap corresponding books in operations research extensively.

Among shorter works, an article by H.W. BODE, "The Systems Approach," in the NATIONAL ACADEMY OF SCIENCES, *Applied Science and Technological Progress* (1967), may be mentioned. It furnishes a broad discussion of the field along lines similar to those followed in the present treatment. Another article with the same title, by G.M. JENKINS, in the *J. Systems Engng.*, 1:3–49 (1969), furnishes a valuable elementary introduction to systems engineering, especially for cases in which technical uncertainties are not serious. C.J. HITCH, "Sub-Optimization in Operations Problems," *J. Ops. Res. Soc. Am.*, 1:87–99 (1953), is a classic.

(H.W.B.)

Szechwan

Szechwan (Si-chuan in Pin-yin romanization), the second largest province of China, is located in the Upper Yangtze Valley in the southwest part of the country. It covers an area of 219,700 square miles (569,000 square kilometres) and is bordered by the provinces of Kansu and Shensi to the north, Kweichow and Yunnan to the south, the Tibetan Autonomous Region to the west, Tsinghai to the northwest, and Hupeh and Hunan to the east. One of the most populous regions in China, in the early 1970s it had an estimated population of between 70,000,000 and 84,000,000. The name Szechwan means Four Streams and refers to the four main tributaries of the Yangtze River, which flows through the province. The capital, Ch'eng-tu, is located in the centre of the province.

From economic, political, geographical, and historical points of view, the heart and nerve centre of Szechwan is in the eastern basin area, commonly known as the Szechwan, or Red, Basin. Its mild and humid climate, fertile soil, and abundant mineral and forestry resources make it one of the most prosperous and economically self-sufficient regions of China. The area has been seen by some as China in a microcosm and is often viewed as a country within a country. The Chinese call the basin Tien Fu Chih Kuo, which literally means Heaven on Earth. (For an associated physical feature see YANGTZE RIVER; see also CHUNGKING.)

HISTORY

Early history. Apart from the Upper Huang Ho (Yellow River) Valley provinces, Szechwan was the first area of China to be settled by the Chinese, or Han, people. The first organized Chinese migration took place in the 5th century BC.

Szechwan was known as the Shu Pa territory during the Chou dynasty (1122 to 221 BC). During the Ch'in dynasty (221 to 206 BC) the territory was incorporated within the Ch'in Empire and began to assume considerable importance in China's national life. It was at this time that the Tu Chiang-yen irrigation system was built to control the Min Chiang and to water the Ch'eng-tu Plain. In the time of the Three Kingdoms Period (AD 220 to 264) the Szechwan region constituted the Shu Kingdom. From the end of this period until the 10th century, Szechwan was known by various names and administered through various political subdivisions. During the Sung and Southern Sung dynasties (AD 960 to 1279), it was known as Szechwan Lu ("Szechwan Province"). Szechwan was established as a province during the Ch'ing, or Manchu, dynasty (1644 to 1911).

The Chinese Republic. During the early years of the Chinese Republic (1911 to 1930) Szechwan suffered seriously from the feudal warlord system; at one time it was divided into as many as 17 independent military units, and not until 1935 was it unified under the Nationalist Party government. During the Sino-Japanese War of 1937 to 1945, there was a great influx of people and of new ideas from coastal China—a development that resulted in extensive economic development. A large number of factories, or trading posts, were moved from the coastal area into Szechwan, and a number of industrial centres were established, especially in Chungking and at Ch'eng-tu.

Because of its geographic isolation, inaccessibility, extensive area, large population, and virtual economic self-sufficiency, Szechwan has served periodically as a bastion in its own right. Because the area is easily defensible, geography has encouraged political separatism. During the war with Japan, the province served as the seat of the Nationalist government from 1938 to 1946; the Japanese were never able to penetrate the area.

THE NATURAL ENVIRONMENT

Relief. Szechwan is bordered on all sides by lofty highlands. To the north, the Tsinling Shan (Tsinling Mountains) extend from east to west and attain an elevation between 11,000 and 13,000 feet above sea level. The limestone Ta-pa Shan rise to approximately 9,000 feet on the northeast, while the Ta-lou Shan, a lower and less continuous mountain range with an average elevation of 5,000 to 7,000 feet, border the south. To the west, the Ta-hsüeh Shan—the Great Snowy Mountains or Azure Mountains of the Tibetan borderland—rise to an average elevation of 14,500 feet; to the east, the rugged Wu Shan, rising to about 6,500 feet, contain the spectacular Yangtze Gorges.

The Szechwan Basin

In general, the relief of the eastern region of the province is in sharp contrast to that of the west. An extensive depression—known as either the Szechwan or the Red Basin—and its peripheral highlands predominate in the east; the land slopes toward the centre of the basin from all directions. This basin was a gulf of the China Sea in the later Paleozoic Era from 225,000,000 to 570,000,000 years ago; most of it is underlain by soft sandstones and shales that range in colour from red to purple. Toward the west there is a generally horizontal rock structure, while to the east there is considerable discontinuity and deformation.

Within the basin, the surface is extremely uneven and gives a general appearance of badland topography. Numerous low, isolated, and rolling hills are interspersed with well-defined high ridges, flood plains, valley flats, and small, local basins. The most impressive portion of the basin's surface is the Ch'eng-tu Plain—the only large continuous tract of relatively flat land in the entire province.

The land forms of western Szechwan include a plateau in the north and mountains in the south. The northern area is part of the edge of the Plateau of Tibet, which consists of highlands over 12,000 feet above sea level and higher mountain ranges. There is also an extensive plateau and some swampland. To the south, the transverse mountain belt of eastern Tibet and western Yunnan Province rises to an average of between 9,000 and 10,000 feet above sea level. Trending from north to south is a series of parallel lofty ranges with narrow divides and canyons more than a mile deep. The Minya Konka in the Ta-hsüeh Shan, is the highest peak in the province; it rises to a height of 24,900 feet (7,590 metres).

Drainage. Seen from the air, the principal drainage pattern of the eastern section of the province has the appearance of a leaf with a network of veins. The Yangtze—flowing from east to west—is conspicuous as its midrib, and the main north and south tributaries appear as its branch veins. Especially important are the Chia-ling and Min river systems in the north and the Wu Chiang system in the southeast. The distribution of these veins is primarily concentrated in the upper, or northern, half of the leaf.

The name Szechwan (Four Streams) refers to the four main tributaries of the Yangtze. These are the Min, T'o, Chia-ling, and Fou rivers, which flow from north to south. Most of the major streams flow to the south, cutting steep gorges in the west or widening their valley floors in the soft sediments of the Szechwan Basin; they then empty into the Yangtze before it slices its precipitous gorge, 150 miles due east, through the Wu Shan below Wan-hsien. Within the basin most of the rivers are navigable and are a common means of transportation.

Soils. There are six major soil regions—three in the east and three in the west. In the east, they include the highly fertile, purple-brown forest soils for which the Red Basin is named. This group of soils rapidly absorbs and loses water; one evening's thick fog may cause the entire depth of the surface soil to be thoroughly moistened, while a half day's torrential rain may cause the soil to be completely saturated and washed away. The other eastern soils consist of the noncalcareous alluvium and rice-paddy soils of the Ch'eng-tu Plain and other river valleys and the yellow earths of the highlands and ridges. From the standpoint of agricultural land use, the alluvial soils are the most important group. They are very fertile and are formed mainly from the rich black soils that are washed down from the Tibetan borderlands. The yellow earths are usually gray brown in colour; they are generally less fertile and are agriculturally unimportant.

The three major groups of soils in the west are the degenerated chernozem (dark-coloured soils containing deep, rich humus) soils of the Sung-p'an Grassland, the alluvial soils of the numerous valleys, and the podzolized (leached), gray-brown soils of the mountain slopes.

The problem of soil creep

In Szechwan, a form of soil erosion known as soil creep has developed. On hillsides where the surface slopes are composed of smooth sandstones, the covering soil gradually slides downward under the influence of gravity. In many places the thin surface soils have been completely removed, leaving only bare rocks. When the surface rock is composed of comparatively rougher shales, the soil is less easily moved.

Climate. The eastern basin area and the lower western valleys are sheltered from cold polar air masses by the surrounding mountains. The climate is therefore milder than would be expected and is similar to that of the Yangtze Delta region. There are 350 frost-free days in the east, and the growing season lasts nearly all year round. In the west, the sheltering effect of the mountains is evident from the contrast between the perennially snow-capped peaks and the mild weather prevailing in the valleys beneath them. During the summer, in the month of July, the mean temperature is about 84° F (29° C) at Chungking in the southeast and less than 68° F (20° C) in most parts of the west. During the winter, the mean temperature in the west decreases northward from 54° F (12° C) in Hsi-ch'ang to 18 ° F (−8° C) in Ch'ien-ning.

The eastern rainy season begins in April and reaches its peak during July and August. Annual rainfall and precipitation measures about 40 inches annually. The east is noted for its frequent fogs, its many cloudy days, the relative absence of wind, and the high relative humidity. The extent to which the region is overcast with clouds is reflected in the saying "Szechwan dogs bark when they see the sun."

Precipitation is lower in the west than in the east. The average total of about 20 inches falls mainly during the summer, and there is heavy snowfall in the mountains during the winter.

Vegetation and animal life. There are four major vegetation regions—the pine–cypress–banyon–bamboo association of the basin area, the dense mixed association of coniferous and deciduous trees in the eastern highlands, the grasslands of the northwest, and the dense coniferous forests of the western highlands. Its great altitudinal differences, low latitudinal position, diversified topography, and high rainfall, make the area what has been called a paradise for botanists. Extensive forests grow on the upper slopes, and rich rhododenderons are found at higher elevations; arid vegetation prevails on many canyon floors.

One of the outstanding features of vegetation of Szechwan Province is its division into vertically differentiated zones. Cypress, palm, pine, bamboo, tung-oil, and citrus-fruit trees grow below 2,000 feet, while, between 2,000 and 5,000 feet, there are evergreen forests and oaks. From 5,000 to 8,000 feet, the vegetation is characterized by dense groves of mixed coniferous trees. Between 8,500 and 11,500 feet, there is a sub-Alpine zone of coniferous forest, while above 11,500 feet there are Alpine zones of scrub and meadow up to the snow line, which occurs at 16,000 feet.

One of the unique vegetational features is the presence of the dawn redwood, or *Metasequoia*—a tree previously believed to be extinct.

Two of the most interesting indigenous animal species are the *hsiung-mao* (the bear cat or panda) and the ling yang (a special species of antelope), both of which frequent the highlands of western Szechwan.

POPULATION

Population groups. *Ethnic composition and distribution.* Szechwan Province has one of the most diversified range of ethnic groups in all China. They include the Han, or Chinese, people, the Yi (Lolo), the Tibetans, the Miao, the Hui (Chinese Muslim), and the Ch'iang. Most of the Han people—who comprise about 96 percent of the population—live in the basin region of the east. The Yi reside in the Liang-shan Fi area of the southwest, while the Tibetans are distributed in the plateau region of the west. The Miao people live in the mountains of the southwest near Kweichow and Yunnan provinces. The Hui are concentrated in the Sung-p'an Grassland of the northwest and are also scattered in a number of districts in the east. The Ch'iang are concentrated in the Mao-wen area on both banks of the Min Chiang.

The minority peoples

The majority of the non-Chinese ethnic groups are fiercely independent and have maintained their traditional way of life. In most cases, they practice a mixture of agriculture, animal husbandry, and hunting.

Among the Chinese, there has been an influx of people from various neighbouring provinces, and particularly from Hupeh in the east and Shensi in the north. This immigration was especially intensified in the early part of the 18th century, as a result of the massacre of the Szechwanese by a local warlord. The immigrants brought with them agricultural techniques that are reflected in the heterogeneity of present cultivation patterns.

Linguistic groups. There are three major linguistic groups—the Chinese, who speak southern Mandarin; the Tibeto-Burman group including the Tibetans and the Yi; and the Muslims who speak southern Mandarin but use Turkish or Arabic in their religious services.

Religious affiliations. The Chinese practice a mixture of Confucianism, Buddhism, and Taoism. They do not maintain rigid boundaries in religious belief. The Tibetans follow a form of Buddhism in which the lamas are spiritual authorities. Many people in the northwest profess Islām, while some hill tribes of the southwest may be classified as animistic.

Patterns of human settlement. *Population density.* As one of the most densely populated provinces of China, Szechwan may be compared to the Yangtze Delta and the North China Plain. Given the larger estimated population of 84,000,000, it has an average density of over 717 persons per square mile. The population, however, is unevenly distributed. About 95 percent of the total population is concentrated in the eastern part of the province. The number of persons per square mile of cultivated land varies from about 26,000 persons in the Ch'eng-tu Plain to fewer than 130 persons in the west.

Rural settlement. As in most of China, about 85 percent of the population is rural. There are comparatively few large villages and nucleated hamlets, except for the provincial capitals. In the hilly regions, farmsteads are scattered through generally small and irregular terraced fields. In the Ch'eng-tu Plain, the larger field units are commonly square or oblong in shape, and the farmsteads are surrounded by groves of banyan, cypress, mimosa, palm, or bamboo.

Urban settlement. One of the outstanding features of urban settlement is the concentration of cities on river terraces. Along the Yangtze River from Feng-chieh to I-pin, there are no fewer than 15 urban centres, including the most populous cities and trading towns of the province. Because water transportation is vital, large cities are always found wherever two major streams converge. Chungking is located at the confluence of the Yangtze and the Chia-ling rivers, Lu-chou on the Yangtze and the T'o, I-pin on the Yangtze and the Min, and Lo-shan on the Ta-tu and the Min.

The relation between cities and rivers

The principal disadvantage of these urban sites is that their areas are limited by their locations, so that development is hindered. Because of the fluctuations of high and low water levels in most of the rivers of the basin, the hazards of flood are great. Many houses are perched on understructures of poles and posts.

Chungking, located in the southeast, is the largest city of the province and the most important trading, transportation, industrial, and cultural centre of southwestern China. Ch'eng-tu is located in the centre of the Ch'eng-tu Plain. It is the provincial capital, and Szechwan's second largest city. Other important urban centres in the east are Tzu-kung on the T'o Chiang, I-pin in the southeast, and Nan-ch'ung on the upper Chia-ling Chiang. The chief western cities are Ya-an on the Ching-yi Chiang, K'angting near the Ta-tu Ho, and Hsi-ch'ang on the An-ning Ho.

Most urban settlements give the appearance of being compactly built. Generally, the houses have only one story. There are no yards or sidewalks in front of the houses, which abut the street. The streets are narrow and in most cases not over ten to 12 feet wide; they are paved with limestone slabs. Like many other long established and unplanned urban communities in the Orient, most of the cities have no sharply delineated functional areas.

ADMINISTRATION AND SOCIAL CONDITIONS

Government structure. *Provincial administration.* Szechwan is one of the 21 provinces forming the first-order administrative units of China. In 1955, former Sikiang Province at the edge of the Plateau of Tibet was incorporated into Szechwan Province, doubling its area and making it the second largest province of China. The province is divided into three municipalities (*shih*) of Ch'eng-tu, Chungking, and Tzu-kung; 12 special districts (*chuan-ch'ü*); and three autonomous districts (*tzu-çhih-chou*).

Administrative subdivisions

The autonomous districts are the A-pa Tibetan Autonomous District with its headquarters at Ma-erh-K'ang; the Tibetan Kan-Tzu Tibetan Autonomous District with its capital at K'angting; and the Liang-shan Yi Autonomous District with its capital at Chao-chiao. As a rule, the districts are inhabited by sizable groups of non-Chinese peoples, and they represent little more than a symbolic cultural indulgence of local minorities. The actual control of the units is exercised by the central government at Ch'eng-tu. The ethnic groups, however, enjoy their own mode of life and preserve their cultural traditions with a minimum of interference by the Chinese-controlled provincial government.

Local administration. There are 181 counties (*hsien*) in the province. They are the most important administra-

tive units because the government exercises control over the rural masses through them. Normally, the county headquarters is not only a political centre but also an economic, cultural, transportation, and market focus of the county. It also represents the county's largest congregation of people.

Social conditions. *Education.* The educational system was restructured as a result of the Cultural Revolution of the late 1960s. It consists of preschool classes, or kindergartens; six-year primary schools; and six-year secondary schools. Vocational schools usually include work-study programs, but there are also several full-time vocational schools with two- or three-year courses.

Ch'eng-tu and Chungking are centres of higher education. Institutions include Chungking University, Szechwan University, Che'eng-tu Technical University, Szechwan Agricultural Institute, Southwestern Institute of Law, Ch'eng-tu Chinese Medical College, Szechwan Medical College, and various engineering institutes.

Health. Because of the warm and wet climate of most of the province, respiratory ailments are a major health problem. Despite the rich agricultural production of the region, malnutrition is fairly common, although famine is rare.

Welfare. Because of the severe pressure of the people on the land, the Szechwanese farmer must work extremely hard to eke out a living. The farmers of the Ch'eng-tu Plain are the most prosperous and have the highest standard of living. Rural life is harder in the hills surrounding the basin, and the standard of living is considerably lower in the west, where pastoral activities predominate. In the western mountains, many of the people practice transhumance—*i.e.*, seasonal migration from the lowlands to the highlands in search of pasturage.

THE ECONOMY

Szechwan Province has a varied economy based on agriculture, valuable forestry products, mineral deposits, and diversified branches of industry.

Agriculture. Approximately 85 percent of the population of the province earn their livelihood from agriculture, and most of the provincial exports are agricultural products. Cultivation is characterized by the diversity of crops, intensive land use, the extensive practice of terracing, the use of *tung-shui-t'ien* (or fields that are flooded in winter in order to store water), the cultivation of *tsai-seng-tao* (or "rebirth" rice), and the special methods of soil culture, fertilization, composting, and crop rotation.

Agricultural practices

Agricultural products. Crops range from those of subtropical climates to those of the cool temperate zone. Although Szechwan is generally classified as a rice region, it is also a prominent producer of such crops as corn, sweet potatoes, wheat, rapeseed (the oil seed of the rape plant), kaoliang (drought-resistant sorghum), barley, soybeans, and millet. Tropical fruits—such as litchi (the oval fruit of a soapberry tree) and citrus—grow together with the apples and pears of cool temperate climates.

Szechwan leads all of China in production of rice, corn, sweet potatoes, and rapeseed and ranks second in the production of barley and soybeans. Other principal economic crops include sugarcane, cotton, tobacco, silk, hemp, and tea. Szechwan has a long history of silk production; its hemp and other fiber crops normally occupy second place in the total production of the nation.

Livestock. Szechwan leads the nation in the total number of its cattle and pigs. It is the only region in China in which both water buffalo of South China and oxen of North China are found together. Pig bristles from Szechwan are of international repute and have been an important item of foreign trade for years.

About half of the inhabitants of the west are pastoral. Their animals include cattle, sheep, horses, donkeys, and yaks (long-haired oxen from Tibet). The most important animal products are butter, cheese, fur, and hides.

The "land of 1,000,000 steps"

Terracing and irrigation. The basin area of eastern Szechwan is extensively terraced and is often known as a "land of 1,000,000 steps." The terraces are of varying dimensions. They are commonly long narrow strips of land and frequently have rather steep slopes. They are easy to construct because the bedrock is soft and weathers easily. Even 45 degree slopes have tiny steps of terraced land.

A special landscape feature of the eastern basin is the *tung-shui-t'ien* (literally "winter water-storage field") system. In spite of the favourable climate and the fertile soil, large tracts of terraced fields—estimated to amount to 25 to 50 percent of the total area of rice fields under cultivation—are left fallow during the winter season. They are used for the storage of water that will be needed in the paddy fields the following spring; from the air they give the appearance of a mosaic of broken mirrors.

Irrigation is widely practiced in the terraced fields and numerous methods and devices are employed. Among the most spectacular is the Tu Chiang-yen system of the Ch'eng-tu Plain, which captures the torrential flow of the Min Chiang and guides it through an artificial multiplication of channels into numerous distributaries along the gently graded plain. The river level is kept constant by the removal of excess silt through annual dredging. The system is not only the oldest but also the most successful and easily maintained irrigation system in China. It has freed the Ch'eng-tu Plain from the hazard of floods and droughts and insured the unbroken agricultural prosperity of the basin. Since 1950, the Szechwan provincial government has initiated numerous engineering improvements of the project.

Forestry. Valuable forests are located in the east, on the peripheral highlands which surround the basin area, and on the numerous hills within the basin. Because of its high elevation and plentiful humidity, Szechwan is second only to Manchuria as a lumber region. It still has much of its original forest cover, with a predominance of spruce, fir, and birch trees. The most important products from the forests are tung oil, white wax, various kinds of herbs, and some animal products, including antelope horn and *hsi-hsiang* (a special perfume extracted from deer secretions).

Mining and quarrying. Mineral deposits are abundant and varied. They include both metallic and nonmetallic deposits, such as those of iron, copper, gold, silver, aluminum, salt, coal, petroleum, asbestos, and marble. Among them, salt, coal, and iron were by far the most important in the early 1970s. The production of brine salt is the most extensive mining activity; the province is the only large producer of this commodity in China.

Petroleum and natural gas are often located together and are widely spread throughout the province, especially in the Tzu-kung area. Natural gas has been used for centuries in the production of brine salt. There are also more natural gas deposits being exploited in the Pa-hsien area and elsewhere.

Most coal fields are located in the eastern and southern mountain areas; those of the Hua-yang Shan area are the richest, and production there is the largest. The most important iron deposit is in the Ch'i-chiang area, and those of the western plateau area are of high quality. Placer gold along the Chin-sha Chiang (Gold Sand River) is important. Other valuable minerals include tin, zinc, and sulfur.

Industries. There has been considerable industrial development since the 1950s and Szechwan has become the most industrialized province of southwestern China. The most important industries include iron and copper smelting, the production of machinery and electric power, coal mining, petroleum refining, and the manufacture and processing of chemicals, textiles, and food. Chungking is the most important industrial centre, and other industrial areas include those centred on Ch'eng-tu, Nei-chiang, I-pin, and Lo-shan.

Szechwan is also known for its cottage industries. These include the handweaving of cloth, the production of silk products, silversmithing and coppersmithing, and embroidery.

TRANSPORTATION

Overall problems. Among the problems facing the province, none is more important and more acute than

the problem of transportation. For centuries, travel into the province has been extremely difficult; the main entrances to it were the dangerous Yangtze Gorges in the east, the treacherous Chang Tao road across the mountains in the north, and the deep canyons and swift currents of the Ta-tu Ho and Chin-sha Chiang in the west. Since the 1950s, both the central government and the provincial government have made great efforts to improve transportation. Numerous dangerous shoals along the Yangtze Gorges routes have been destroyed, a railway has been built across the northern mountains, and steel bridges have been constructed over the Ta-tu Ho and other rivers in the west.

Component systems. *Inland waterways.* Water routes are the most important means of transportation. There are about 300 streams in the province, with a total length of more than 8,000 miles. The mighty Yangtze River, the most significant, traverses the entire width of the basin from the southwest to the northeast. It is the spinal cord of the river transportation system; steamboats of 1,000-ton capacity can negotiate its waters between the gorge section and Chungking during the high-water season. Smaller steamers ply the river between Chungking and I-pin throughout the year and travel on various tributaries, such as the Chia-ling, the Min, and the T'o.

In the west, water transport is difficult and limited except for the lower reaches of the An-ning Ho and the Ta-tu Ho.

Railways. Railways are important for the transport of bulky products. Until the 1950s, only a small railroad that ran for 47 miles between Hsiu-shan and Pai-miao-tzu near Chungking served the province. Since then, facilities have been greatly improved. The Ch'eng-tu–Pao-chi railroad—which crossed the lofty Tsinling Shan for the first time in Chinese history—links with the principal east–west Lunghai Railway. Szechwan is thus connected to both northwest and coastal China. The Ch'eng-tu–Chungking railroad, completed in the 1950s, links the rich Ch'eng-tu Plain with the industrial and navigation hub of the Yangtze River at Chungking. A Szechwan–Kweichow railway is planned to connect the province with its southern neighbours.

Roads. Because of the thoroughly dissected terrain and the easily weathered rock structures, the building of highways is attended with serious difficulties. The constant threat of landslides, the presence of numerous steep slopes and hairpin turns, and the necessity of constructing many solid embankments make road construction and maintenance costly and hazardous.

Principal highways

Ch'eng-tu and Chungking form the two principal highway focuses of the province; Nan-ch'ung, Ya-an, and San-t'ai are secondary centres. Major highway routes that connect with bordering provinces run to Shensi in the north, Hupeh in the east, Kweichow and Yunnan in the south, and Tibet in the west. The Ch'eng-tu–A-pa–Lan-chou highway and the Ch'eng-tu–Tibet routes cross lofty and rugged mountains, broad deep valleys, and vast high plateaus. Within the province, the most important highways are the Ch'eng-tu–Chungking route and the Ch'eng-tu–Wan-hsien-shih route.

In the west, Ya-an is the only major highway centre. From there routes radiate into Ch'eng-tu in the east, Tsinghai Province in the north, Yunnan Province in the south, and Tibet in the west.

Air services. The Shanghai–Ch'eng-tu airline, initiated in 1937, was the province's first commercial air service. Since then, commercial flying has grown steadily. From Chungking, the principal air-transportation centre, there are regular flights to Han-k'ou and Wu-chiang in the east, Sian in the north, K'un-ming in the south, and Ch'eng-tu in the west. The airlines engage principally in passenger and mail service. Freight capacity is limited.

CULTURAL LIFE

Rural culture. The village fair is an important institution in the rural life of eastern Szechwan. The fairs are widespread and colourful and attract great interest. Because of the isolated character of the settlements in many parts of the province, these fairs fulfill a pressing need. In many cases, the village fair—locally known as *chang* meaning "enclosure"—is the only place where a farmer can buy and sell his products, and is, thus, essential to the rural economy.

Village fairs

Urban culture. Ch'eng-tu has always played a vital role in the cultural and intellectual life of the Szechwanese people. Some of the streets are lined with two-story buildings that boast elaborate carvings. The city is a haven for intellectuals and scholars, and—with its heavy traffic, rich night life, and luxurious suroundings—is sometimes called the "Little Paris" of China.

Architecture. The unique form of architecture of the eastern basin is characterized by projecting eaves, gracefully curved roofs, and rich, elaborate roof ornaments. As there is little wind and practically no snow in the basin, these fragile and extraordinarily beautiful structures and decorations can safely be constructed. The frequent misty rains make it necessary to project the roof eaves over the walls to protect them from the rain.

(C.Hu./Y.-G.G.H.)

Ṭabarī, aṭ-

Abū Jaʿfar Muḥammad ibn Jarīr aṭ-Ṭabarī, whose academic endeavours spanned most of the Muslim sciences of his day, is remembered today chiefly for his enormous compendia of early Islāmic history and Qur'ānic exegesis. Aṭ-Ṭabarī was born, probably in 839 (AH 224/225), at Āmol in Ṭabaristān, now in Iran. He demonstrated a precocious intellect and journeyed from his native town to study in the major centres of learning in Iraq, Syria, and Egypt. Over the course of many years he collected oral and written material from numerous scholars and libraries for his later work. Aṭ-Ṭabarī enjoyed sufficient financial independence to enable him to devote the latter part of his life to teaching and writing in Baghdad, the capital of the ʿAbbāsid caliphate, where he died in 923 (AH 310). The times in which he lived were marked by political disorder, social crisis, and philosophical-theological controversy. Discontent, of diverse cause and circumstance, brought open rebellion to the very heart of the caliph's empire, and, like all movements of socio-economic origin in medieval Islām, sought legitimacy in religious expression directed against the official credo of Sunnī (major Muslim sectarian division) orthodoxy. Aṭ-Ṭabarī rejected out of hand the extreme theological positions of these opposition movements but at the same time he also retreated from the embrace of the ultra-orthodox Sunnī faction, the Ḥanbalites (a major school of Islāmic law), represented most powerfully in the capital itself. An independent within orthodox ranks, he established his own school of jurisprudence, which did not long survive his own death. He nevertheless made a distinct contribution to the consolidation of Sunnī thought during the 9th century. What aṭ-Ṭabarī accomplished for historical and Qur'ānic studies consisted less in the discovery and initial recording of material than in the sifting and re-organiza-

tion of it. His achievement was to condense the vast wealth of exegetical and historical erudition of the preceding generations of Muslim scholars (many of whose works are not extant in their original form) and to lay the foundations for both Qur'ānic and historical sciences.

Major works

His life's labour began with the *Qur'ān Commentary* and was followed by the *History of Prophets and Kings* (*Ta'rīkh ar-Rusūl wa al-Mulūk*). Aṭ-Ṭabarī's *History* became so popular that the Sāmānid prince Manṣūr ibn Nūḥ had it translated into Persian (*c.* 963).

In the *Commentary*, aṭ-Ṭabarī's method of composition was to follow the Qur'ān text word by word, juxtaposing all of the juridical, lexicographical, and historical explanations transmitted in reports from the Prophet Muḥammad, his companions, and their followers. To each report (Ḥadīth) was affixed a chain of "transmitters" (*isnād*) purporting to go back to the original informant. Divergent reports were seldom reconciled, the scholar's only critical tool being his judgment as to the soundness of the *isnād* and not of the content of the Ḥadīth. Thus a plurality of interpretation was admitted on principle.

The *History* commenced with the Creation followed by accounts regarding the patriarchs, prophets, and rulers of antiquity. The history of the Sāsānian kings came next. For the period of the Prophet's life, aṭ-Ṭabarī drew upon the extensive researches of 8th-century Medinan scholars. Although pre-Islāmic influences are evident in their works, the Medinan perspective of Muslim history evolved as a theocentric (god-centred) universal history of prophecy culminating in the career of Muḥammad and not as a continuum of tribal wars and values.

The sources for aṭ-Ṭabarī's *History* covering the years from the Prophet's death to the fall of the Umayyad dynasty (AD 661–750) were short monographs, each treating a major event or the circumstances attending the death of an important person. Aṭ-Ṭabarī supplemented this material with historical reports embodied in works on genealogy, poetry, and tribal affairs. Further, details of the early ʿAbbāsid period were available to him in a few histories of the caliphs that unfortunately have come down to us only in the fragments preserved by aṭ-Ṭabarī. Almost all of these accounts reflected an Iraqi perspective of the community; coupled with this is aṭ-Ṭabarī's scant attention to affairs in Egypt, North Africa, and Muslim Spain so that his *History* does not have the secular "universal" outlook sometimes attributed to it. From the beginning of the Muslim era (dated from 622, the date of the *hijrah*—the Prophet Muḥammad's migration from Mecca to Medina), the *History* is arranged as a set of annals according to the years after the *hijrah*. It terminates in the year 915.

Views of history

Obviously, aṭ-Ṭabarī could not sustain his preference for reports originating with the Prophet and the pious scholars of the early community known as *as-salaf*. His judgment of a report's reliability was now based upon the largely theoretical criterion that it should originate either with an eyewitness or a contemporary informant. This posed a problem for which aṭ-Ṭabarī had no practical solution. Oftentimes he placed separate accounts of an event side by side without editorial comment. He saw no relevance in searching for the nature and causes of events, for any ultimate explanation lay beyond history itself and was known to God alone. Prophetic tradition, like the Qur'ān, provided positive commands and injunctions from God. History pointed to the consequences of heeding or ignoring Him. For aṭ-Ṭabarī, therefore, history was the Divine Will teaching by example.

BIBLIOGRAPHY. FRANZ ROSENTHAL, *A History of Muslim Historiography*, 2nd ed. (1968); O. LOTH, "Tabari's Korankommentar," *Zeitschrift der deutschen Morgenlandischen Gesellschaft*, 35:588–628 (1881). A French translation of the abridged Persian version was made by H. ZOTENBERG, entitled *Chronique de Tabari* (reprinted 1958). E. MARIN translated a portion of the *History* into English, entitled *The Reign of al-Mu'tasim* (1951). The *Commentary* has been edited by M.M. and A.M. SHAKIR, 13 vol. (1954–) under the title *Tafsir al-Tabari*. M.J. DE GOEJE *et al.* edited the *History*, known as the *Annals*, 15 volumes with index and glossary (1879–1901, reprinted 1964).

(D.Wa.)

Table Tennis

Table tennis, an indoor ball game similar in principle to lawn tennis, is played on a flat table divided into two equal courts by a net fixed across its width at the middle. The lightweight hollow ball is made of celluloid or a similar plastic and is propelled back and forth across the net by small rackets (bats or paddles) held by the players. The game is popular all over the world. In most countries it is very highly organized as a competitive sport, especially in Europe and Asia, particularly in China and Japan.

History. Invented in England in the early days of the 20th century, the game was originally called Ping-Pong, which was a trade name. The name table tennis was adopted in 1921–22 when the old Ping-Pong Association formed in 1902 was revived. The original association had broken up about 1905, though apparently the game continued to be played in parts of England outside London, and by the 1920s was being played in many countries. Led by representatives of Germany, Hungary, and England, the Federation Internationale de Tennis de Table (International Table Tennis Federation) was founded in 1926, the founder members being England, Sweden, Hungary, India, Denmark, Germany, Czechoslovakia, Austria, and Wales. By the 1970s more than 90 national associations were members and there were six Continental Federations: Europe, Asia, Africa, North America, South America, and Oceania.

First world championships

The first world championships were held in London in 1927, and from then until 1939 the game was dominated by players from Central Europe, the men's team event being won nine times by Hungary and twice by Czechoslovakia. There was no competition during World War II, but from 1946 to 1953 Czechoslovakia won four times and Hungary twice. These two countries produced some of the greatest players in the game. Victor Barna (five times world singles champion), Laszlo Bellak (twice a finalist), Mike Szabados (once winner and twice finalist) all came from Hungary, as did Ferenc Sido, winner in 1953. From Czechoslovakia came Bohumil Vana, twice world champion and twice a finalist, and Ivan Andreadis, who was a great stylist and four times world doubles champion.

Another Central European, recognized as one of the

K. Johansson and H. Alser of Sweden, world men's doubles champions in 1967 and 1969, face opponents J. Stanek and V. Miko of Czechoslovakia in a Vanderbilt Cup match, New York, 1970.

greatest champions of all time, was Richard Bergmann of Austria, who won the world singles title four times (twice as a naturalized English citizen). In the women's team event, Central Europe has also been prominent. Of the 16 championships played between 1934 and 1956, Romania and Czechoslovakia won eight times. Great women players have been Maria Mednyanszky (Hungary) who won the ladies singles title each year in the first five years, Gizi Farkas (Hungary) who won the title three years, and Angelica Rozeanu (Romania) with the record of six world singles titles.

The 1953–54 season saw the emergence of Asia as a breeding ground of champions, and from that time the men's team event has been won either by Japan or China while the women's event also has been dominated, though to a lesser extent, by Japan and China. Japan has produced many great players, in particular Ichiro Ogimura and Toshiaki Tanaka, both twice world champions, and China, too, had a three times consecutive winner in Chuang Tse-tung.

At world championships, held biennially since 1957, players compete for:

The Swaythling Cup	Men's team event. The best of nine singles matches.
The Corbillon Cup	Women's team event. The best of four singles and one doubles matches.
St. Bride's Vase	Men's individual singles.
G. Geist Prize	Women's individual singles.
Iran Cup	Men's doubles championships.
W.J. Pope Trophy	Women's doubles championships.
Heydusek Prize	Mixed doubles championships.

For world championship winners see SPORTING RECORD in the *Ready Reference and Index*.

The game. Table tennis equipment is relatively simple and inexpensive. The table is rectangular 9 ft by 5 ft (2.74 m by 1.52 m), its upper surface a horizontal plane 30 in (76 cm) above the floor. The net is 6 ft (1.83 m) long and its upper edge along the whole length 6 in (15.25 cm) above the playing surface. The ball, which is spherical, hollow, and made of white celluloid or, since 1969, a similar plastic, weighs about .88 oz (2.5 gm) and has a diameter of about 1.5 in (3.81 cm).

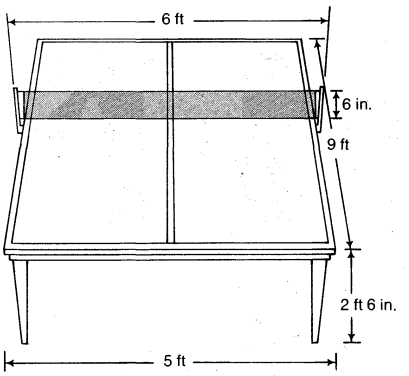

Table tennis table.

The racket or bat is of wood, flat and rigid, and may be either plain uncovered wood, or wood covered with a thin layer of ordinary stippled or pimpled rubber, which may be laid over a thin layer of sponge rubber and may have the pimples reversed; whatever combination is used, the colours on both sides must match and the total thickness must not exceed 0.37 in (4 mm).

Scoring

A match consists of the best of three or the best of five games, each game as in handball being won by the player who first reaches 21 points, or who after 20 points each, wins two clear points ahead. A point is scored when the server fails to make a good service, when either player fails to make a good return, or when either player commits a specified infraction; *e.g.*, touches the playing surface with his free hand while the ball is in play. Service changes hands after every five points until 20-all is reached, when it changes after every subsequent point.

The serve is made from behind the end of the table, the server projecting the ball upward from the palm of his free hand and striking it as it descends so that it first touches his own court and then, passing over the net, touches his opponent's court. In serving no spin may be imparted to the ball by the fingers. This was not always so. Finger spin, especially in the U.S., reached a stage where the experts could produce untakable services and the game became farcical. Finger spin was universally banned in 1937.

Interest to the spectator lies in observing the ability of one player to defeat his opponent by out-manoeuvring him by well-thought-out strategy and by superior fitness, footwork, and stroke repertoire. Increasing the speed of the game, slowing it down, varying the direction of or imparting different spin or pace to the ball, and employing gentle drop shots over the net when the opponent is out of position, are some of the tactics that may be used to support the strategy planned.

Slow or defensive play at one time reached the stage that, at the 1936 world championships in Prague, an hour was needed to decide a single point. Play is now restricted. If a game is unfinished 15 minutes after it has begun, the rest of that game and the remaining games of the match proceed under the Expedite System. Thereafter if the service and 12 following strokes of the server are returned by the receiver, the server loses the point. The service changes after each point.

Variants

Table tennis may be played as a game of singles with one player at each end of the table, or as doubles with two players at each end who may be both men or both women or one of each. Worldwide, the women's game is comparable in organization to the men's, and women take part in world championships and all other organized events. Table tennis as well as being fully organized is also extremely popular as a recreational game and is so played in all types of sports clubs, social clubs, game rooms, in the home, and even out-of-doors when conditions are reasonably calm.

National handbooks can be obtained from the various national Table Tennis Associations.

(V.B.)

Tacitus, Cornelius

Renowned as a public orator and high official in Rome's imperial administration, Tacitus achieved lasting fame with the historical writing of his later years, in which his political experience and literary skill combine to describe the character of 1st century Roman rule. Though soundly based, this work was often adapted, even distorted, to fit his own view of the empire, which he saw as a study in the pathology of tyranny, where power corrupted and impotence had led to degeneration. Tacitus exploited a brilliant style to emphasize, as well as to record, his interpretation. Hence, his descriptions of policy and persons, especially of the imperial court, are often highly ironic. The political tone did not suit later Roman sentiment, though he was still read for his Latin style. When statecraft again became a subject of interest in the Renaissance, his work was re-examined, as it was, once again, after the French

Revolution. In modern scholarship Tacitus' writings are studied seriously—with critical reservation—to reconstruct the early history of the Roman Empire. On the literary side it is appreciated as a stylistic masterpiece.

Family and early career. Tacitus was born *c.* AD 56, perhaps in north Italy (Cisalpine Gaul) or, more probably, in southern Gaul (Gallia Narbonensis, or present southeastern France). Nothing is known of his parentage. Though Cornelius was the name of a noble Roman family, there is no proof that he was descended from the Roman aristocracy; provincial families often took the name of the governor who had given them Roman citizenship. In any event he grew up in comfortable circumstances, enjoyed a good education, and found the way open to a public career.

Tacitus studied rhetoric, which provided a general literary education including the practice of prose composition, learning the concentrated and pointed style of the 1st century. This training was a systematic and fair preparation for administrative office. Although often artificial, this course of study would, along with conscious effort, enable a talented writer to express himself well. Tacitus studied to be an advocate at law under two leading orators, Marcus Aper and Julius Secundus; then he began his career with a "virgintivirate" (one of 20 appointments to minor magistracies) and a military tribunate (on the staff of a legion). In so doing he followed the traditional course for young men of social standing, and it may be assumed that he displayed his ability and promise at each of these early stages of his career.

Marriage

In 77 Tacitus married the daughter of Gnaeus Julius Agricola. Agricola had risen in the imperial service to the consulship, in 77 or 78, and he would later enhance his reputation as governor of Britain. Tacitus appears to have made his own mark socially and was making much progress toward public distinction; he would obviously benefit from Agricola's political connections. Moving through the regular stages, he gained the quaestorship (often a responsible provincial post), probably in 81; then in 88 he became a praetor (a post with legal jurisdiction) and a member of the priestly college that kept the Sibylline Books of prophecy and supervised foreign-cult practice. After this it may be assumed that he held a senior provincial post, normally in command of a legion, for four years. When he returned to Rome, he observed firsthand the last years of the emperor Domitian's savage oppression of the Roman aristocracy. By 93 Agricola was dead, but by this time Tacitus had achieved distinction on his own in the imperial service. In 97, under the emperor Nerva, he rose to the consulship and delivered the funeral oration for Verginius Rufus, a famous soldier who had refused to compete for power in 68/69 after Nero's death. This distinction not only reflected his reputation as an orator but his moral authority and official dignity as well. For an ambitious man there remained only appointment to a high provincial governorship, and Tacitus had to await his turn; in the meantime he turned to literary composition.

First literary works

In 98 Tacitus wrote two works: *De vita Julii Agricolae* and *De origine et situ Germanorum* (the *Germania*), both reflecting his personal interests. The *Agricola* is a biographical account of his father-in-law's career, with special reference to the governorship of Britain (78–84) and the later years under Domitian. It is laudatory yet circumstantial in its description, and it gives a balanced political judgment. Agricola (as Tacitus depicts him) was a man of true Roman virtue who defended the empire without either reckless defiance or craven servility toward an evil emperor, and he recognized that Rome was greater than its rulers. One may sense the tone of administrative apologia, for the fact that the political martyrs of Domitian's reign were now being glorified may have tarnished (if only by implication) the reputation of those who had advanced their careers during this period. And both Tacitus and Agricola had done well.

The next work, the *Germania*, is another descriptive piece, this time of the Roman frontier on the Rhine. Tacitus emphasizes the simple virtue as well as the primitive vices of the Germanic tribes, in contrast to the moral laxity of contemporary Rome, and the threat that these tribes, if they acted together, could present to Roman Gaul. Here his writing goes beyond geography to political ethnography. The work is hardly, as has been argued, a pamphlet about Roman strategy in the West: it gives an administrator's appreciation of the German situation, and to this extent the work serves as a historical introduction to the Germans.

Ancient literature had already provided models of style for biography, geographical description, and ethnographical study. Tacitus knew these conventions and adapted them to his new writing. What, then, of his celebrated oratory? He still practiced advocacy at law—in 100 he, along with Pliny the Younger, successfully prosecuted Marius Priscus, a proconsul in Africa, for extortion—but he felt that oratory had lost much of its political spirit and its practitioners were deficient in skill. This decline of oratory seems to provide the setting for his *Dialogus de oratoribus*. The work refers back to his youth, introducing his teachers Marcus Aper and Julius Secundus. It has been dated as early as *c.* 80, chiefly because it is more Ciceronian in style than his other writing. But its style arises from its form and subject matter and does not point to an early stage of stylistic development. The date lies between 98 and 102; the theme fits this period. Tacitus compares oratory with poetry as a way of literary life, marking the decline of oratory in public affairs: the Roman Republic had given scope for true eloquence; the empire limited its inspiration. The work reflects his mood at the time he turned from oratory to history.

Historical writing. There were historians of imperial Rome before Tacitus, notably Aufidius Bassus, who recorded events from the rise of Augustus to the reign of Claudius, and Pliny the Elder, who continued this work (*a fine Aufidii Bassi*) to the time of Vespasian. In taking up history Tacitus joined the line of succession of those who described and interpreted their own period, and Tacitus took up the story from the political situation that followed Nero's death to the close of the Flavian dynasty.

The *Histories*

The *Historiae* began at January 1, 69, with Galba in power and proceeded to the death of Domitian, in 96. The work contained 12 or 14 books (it is known only that the *Histories* and *Annals*, both now incomplete, totalled 30 books). To judge from the younger Pliny's references, several books were ready by 105, the writing well advanced by 107, and the work finished by 109. Only books i–iv and part of book v, for the years 69–70 are extant. They cover the fall of Galba and Piso before Otho (book i); Vespasian's position in the East and Otho's suicide, making way for Vitellius (book ii); the defeat of Vitellius by the Danubian legions on Vespasian's side (book iii); and the opening of Vespasian's reign (books iv–v). This text represents a small part of what must have been a brilliant as well as systematic account of the critical Flavian period in Roman history, especially where Tacitus wrote with firsthand knowledge of provincial conditions in the West and of Domitian's last years in Rome. The narrative as it now exists, with its magnificent introduction, is a powerfully sustained piece of writing that, for all the emphasis and colour of its prose, is perfectly appropriate for describing the closely knit set of events during the civil war of 69. Tacitus found the opening of the *Histories* well within the scope of his political and military experience and his literary training; he displays his firm control of the incisive Latin style of his time.

This was only the first stage of Tacitus' historical work. As he approached the reign of Domitian, he faced a Roman policy that, except in provincial and frontier affairs, was less coherent and predictable. It called for sharper analysis, which he often met with bitterness, anger, and pointed irony. Domitian's later despotism outraged the aristocratic tradition. It is not known, and it is the most serious gap, how Tacitus finally handled in detail Domitian's reputation. Perhaps his picture of the emperor Tiberius in the *Annals* owed something to his exercise on Domitian.

It is necessary to keep the dating of Tacitus' work in mind. He had won distinction under Nerva and enjoyed

the effects of liberal policy; at the same time he had lived through the crisis of imperial policy that occurred when Nerva and Trajan came to the succession. Under Trajan he retained his place in public affairs, and in 112–113 he crowned his administrative career with the proconsulate of Asia, the top provincial governorship. His personal career had revealed to him, at court and in administration, the play of power that lay behind the imperial facade of rule. He was especially familiar with the effect of dynastic control, which tended to corrupt the rulers, as it had in the period from Vespasian to Domitian, and to reduce the supporting nobles to servility, while only military revolt within Rome or from the frontier legions could change the situation—as it had done at the end of Nero's reign.

From what can be reconstructed from his personal career along with the implications of his subsequent historical thought, it is possible to mark an intellectual turning point in his life after which he began to probe deeper into the nature of the Roman Empire. Although in the *Agricola* he had lightly promised to continue his writing from the Flavian years into the new regime, he now moved not forward but backward. He was no longer content to record the present but to interpret the political burden of the past from the time when Tiberius consolidated Augustus' policy of imperial government. It was for these reasons that he wrote the *Annals*.

The *Annals*

The *Annals* (*ab excessu divi Augusti*), following the traditional form of yearly narrative with literary elaboration on the significant events, covered the period of the Julio-Claudian dynasty from the death of Augustus and the accession of Tiberius, in 14, to the end of Nero's reign, in 68. The work contained 18 or 16 books. There is some evidence that he organized his books into groups of six: books i–vi on Tiberius (subdivided into books i–iii on Tiberius and Germanicus, books iv–vi on Sejanus and Tiberius), and books vii–xii on Caligula (Gaius) and Claudius. To judge from references to Parthia that reflect its power before Trajan's invasion, Tacitus had written most of books i–vi by 114. If a reference in book ii, 61 to Mare Rubrum ("Red Sea") as the Roman frontier means the Persian Gulf, he was touching up these books in 116–117, after Trajan's victory and before Hadrian's withdrawal; but the term refers rather to the Red Sea as we know it, after the annexation of Arabia in 105–106. In any event he probably completed the work early in Hadrian's reign. Only books i–iv, part of book v, most of book vi (treating the years 14–29 and 31–37 under Tiberius), and books xi–xvi, incomplete at beginning and end (on Claudius from 47 to 51 and Nero from 51 to 66), now exist.

In casting back to the early empire Tacitus did not wish necessarily to supersede his predecessors in the field, whose systematic recording he seemed to respect, judging from the use he made of their subject matter. His prime purpose was to reinterpret critically the Julio-Claudian dynasty, when imperial rule developed a central control that, even after the complex military coup d'etat of 68–69, would continue under the Flavians. In effect, the *Annals* represents a diagnosis in narrative form of the decline of Roman political freedom, written to explain the condition of the empire he had already described in the *Histories*. Tacitus viewed the first imperial century as an entity. There was (in his eyes) a comparison to be made, for example, between the personal conduct of Tiberius and that of Domitian, not that they were the same kind of men but that they were corrupted by similar conditions of dynastic power. Yet he did not begin with Augustus, except by cold reference to his memory. The modern world tends to think of Augustus as the founder of the empire. The Romans—one may cite Appian and Florus alongside Tacitus—regarded him, at least during the first part of his career, as the last of the warlords who had dominated the republic.

Criticism of the imperial system

In opening the *Annals* Tacitus accepts the necessity of strong, periodic power in Roman government, providing it allowed the rise of fresh talent to take over control. That was the aristocratic attitude toward political freedom. But to secure the continuity of personal authority by dynastic convention, regardless of the qualifications for rule—he could quote the examples of Caligula, Nero, and Domitian—was to subvert the Roman tradition and corrupt public morality. If Augustus began as a warlord, he ended by establishing a dynasty. But the decisive point toward continuing a tyrannical dynasty was Tiberius' accession. One may, indeed, believe that Tiberius was prompted to assume imperial power because he was anxious about the military situation on the Roman frontier; but Tacitus had no doubts about the security of the Roman position, and he considered the hesitation Tiberius displayed on taking power to be hypocritical; hence, the historical irony, in interpretation and style, of his first six books. Here, perhaps, Tacitus had some support for his interpretation. A strong, dour soldier and a suspicious man, Tiberius had little to say in his court circle about public affairs. On his death he was blamed for never saying what he thought nor meaning what he said, and Tacitus elaborated this impression. His criticism of dynastic power also stressed the effect of personality: if Tiberius was false, Claudius was weak, Nero was not only unstable but evil, and the imperial wives were dangerous. With regard to provincial administration, he knew that he could take its regular character for granted, in the earlier period as well as his own.

Sources

For the period from Augustus to Vespasian, Tacitus was able to draw upon earlier histories and monographs that contained material from the public records, official reports, and contemporary comment. It has been noted that the work of Aufidius Bassus and its continuation by the elder Pliny covered these years; both historians also treated the German wars. Among other sources Tacitus consulted Servilius Nonianus (on Tiberius), Cluvius Rufus and Fabius Rusticus (on Nero), and Vipstanus Messalla (on the year 69), who are only names to us. He also turned, as far as he felt necessary, to the Senate's records, the official journal, and such firsthand information as a speech of Claudius, the personal memoirs of the younger Agrippina, and the military memoirs of the general Corbulo. For Vespasian's later years and the reigns of Titus and Domitian, he must have worked more closely from official records and reports, applying the impressions of his own and his friends' knowledge.

In the light of his administrative and political experience, Tacitus in the *Histories* was able to interpret the historical evidence for the Flavian period more or less directly. Yet contemporary writing may lack perspective. He recognized this problem when, in the *Annals*, he revived the study of the Julio-Claudian dynasty. But to go back a century raises additional problems of historical method. Tacitus first had to determine the factual reliability and political attitude of his authorities and then to adjust his own general conception of the empire, in case it was anachronistic, to the earlier conditions. The strengh of his conviction limited his judgment at both points. He underplayed the effect of immediate circumstances and overplayed the personal factor, a tendency that influenced his use of the historical sources. In particular Tiberius, who in spite of his political ineptness struggled with real difficulties, suffered in reputation from this treatment. But Tacitus did not spare any man in power. He controls the performance of his characters; it is magnificent writing, but it is not necessarily strict history.

Literary style. Since he was a conscious literary stylist, both his thought and his manner of expression gave life to his work. Greek historiography had earlier defined ways of depicting history: one could analyze events in plain terms, set the scene with personalities, or heighten the dramatic appeal of human action. Each method had its technique, and the greater writer could combine elements from all three. The Roman "annalistic" form, after years of development, allowed this varied play of style in significant episodes. Tacitus knew the techniques and controlled them for his political interpretations; as a model he had studied the early Roman historiographer Sallust.

It is finally his masterly handling of literary Latin that impresses the reader. He wrote in the grand style, helped by the solemn and poetic usage of the Roman tradition, and he exploits the Latin qualities of strength, rhythm, and colour. His style, like his thought, avoids artificial

smoothness. His writing is concise, breaking any easy balance of sentences, depending for emphasis on word order and syntactical variation and striking hard where the subject matter calls for a formidable impact. He is most pointed on the theme of Tiberius, but his technique here is only a concentrated form of the stylistic force that can be found throughout his narrative.

Tacitus' work did not provide an easy source for summaries of early imperial history, nor (one may guess) was his political attitude popular in the ruling circles; but he was read and his text copied until in the 4th century Ammianus Marcellinus continued his work and followed his style. A thousand years after his own day it was the Renaissance that welcomed him for his illustration of statecraft, as did the political thinkers of the French Revolution, who enjoyed his condemnation of dynastic tyranny. More soberly modern scholarship has probed his evidence and appreciated his Latin, and, in light of contemporary epigraphic and archaeological study, one may set Tacitus' political pattern within the wider perspective of the Roman Empire.

Tadzhik Soviet Socialist Republic

The Tadzhik (or Tajik) Soviet Socialist Republic (Tadzhik S.S.R., or Tadzhikistan, in the Russian spelling; as transliterated from the Tadzhik language in its own modified Cyrillic script, the name is Tojikiston), lying in the mountainous heart of Asia, is one of the 15 constituent union republics of the Soviet Union. It is in the extreme south, bounded by China to the east, Afghanistan to the south, and the Uzbek and Kirgiz S.S.R.'s to the west and north. Covering 55,250 square miles (143,100 square kilometres), it was the home by 1975 of almost 3,400,000 people. The capital is Dushanbe, known from 1929 till 1961 as Stalinabad. The republic includes the Gorno-Badakhshan Autonomous Oblast, with its capital at Khorog. Tadzhikistan was first constituted as an autonomous republic within the Uzbek S.S.R. in 1924; it became a union republic in 1929.

As in the other Central Asian republics, an economic and social transformation has taken place during the Soviet period: industry now provides a large share of the republic's income, although cotton growing is still a mainstay of the economy. This change has been accompanied by considerable immigration and a high birth rate. Much of the old way of life nevertheless survives, and the republic's ancient cultural traditions are preserved.

For related information see also PAMIR MOUNTAIN AREA; TIEN SHAN (MOUNTAINS); INNER ASIA, HISTORY OF; CENTRAL ASIAN PEOPLES, ARTS OF; INDO-IRANIAN LANGUAGES: *Iranian languages*; SOVIET UNION; RUSSIA AND THE SOVIET UNION, HISTORY OF.

THE LAND

Relief and drainage patterns. The Tadzhik S.S.R. is a mountainous country, more than half its territory lying above 10,000 feet (3,000 metres). The western Tien Shan reaches into the north, with the Kuramin and Mogoltau ranges. In the central portion of the republic are found the massive ranges of the southern Tien Shan: the Turkistan Range and the slightly lower Zeravshan, Gissar (Hissar), and, in part, Alay ranges. The southeast contains the ice-clad peaks of the Pamir–Alay mountain system, which is made up of the Pamir Upland and, extending westward, the Peter I and Darvaz ranges. The Soviet Union's highest peaks—Lenin Peak (23,405 feet [7,134 metres]) and Communism Peak (24,590 feet [7,495 metres])—are found in the northern portion of the Pamirs. The relief of the southwestern portion of the republic, lying between the Gissar range and the Pyandzh (Panj) River (Ab-e Panj in Afghanistan), is made up of a series of transverse ranges interspersed by wide river valleys and structural depressions.

The valleys, although important on Tadzhikistan's human geography, comprise less than 10 percent of the total area of the republic; the largest are the western portion of the Fergana (Fergnana) Valley in the north and the Gissar, Vakhsh, Yavansu, Obikiik, Lower Kafirnigan (Kafirnihan), and Pyandzh valleys to the south. The whole country is in an active seismic belt, and severe earthquakes are common.

Rivers

The republic has a dense river network, the largest courses being those of the Syrdarya and the Amu Darya, together with their tributaries, notably the Vakhsh and the Kafirnigan. Upstream from the Vakhsh–Amu Darya junction, the latter river is known as the Pyandzh and forms a good portion of the southern boundary of the republic. Other rivers include the Zeravshan (Zarafshān), which runs through the central part of the republic. Most of the rivers drain into the Aral Sea Basin, although a few of the small streams running down from the Pamirs empty into Lake Kara-Kul, which has no outlet. The rivers have two high-water periods each year: in the spring, when the mountain snows melt and rainfall occurs, and in the summer, when the glaciers begin to melt. The summer flow is particularly helpful for irrigation purposes.

Most of the few lakes in Tadzhikistan are found in the Pamir region. Lake Kara-Kul, salt and devoid of life, lying at an altitude of about 13,000 feet, is the largest; Lake Sarez was formed in 1911 during an earthquake, when a colossal landslide dammed the Murgab River. The Zeravshan range contains Iskanderkul, of glacial origin like most Tadzhikistan lakes.

Climate and plant and animal life. The climate of Tadzhikistan is sharply continental and changes with altitude. In the subtropical valley areas, summer is very hot and dry; the mean July temperature is 81.3° F (27.4° C) in Leninabad and 86.5° F (30.3° C) in Kulyab, farther south. The corresponding January figures are 29.7° F (−0.9° C) and 36.1° F (2.3° C), respectively. In very severe winters, the mercury has been known to drop to −4° F (−20° C), and even lower. Annual precipitation is slight, ranging between six and 10 inches (150 and 250 millimetres), but is higher in the Gissar Valley. In the highlands the situation is different; the mean January temperature in Murgab is −3.3° F (−19.6° C), and the temperature sometimes drops to −51° F (−46° C), with the record standing at −81° F (−63° C). Precipitation is scant, barely reaching two to three inches (60 to 80 millimetres) a year, mostly falling in summer.

Precipitation

The long, wide valleys that separate the ranges of the Tien Shan and the Pamir-Alay join in the Turgay Valley in the southwest, but in the east the high mountain barriers form dead ends. As a result, moist air masses from the west move up the valleys and suddenly reach low temperature areas, with heavy precipitation (30–60 inches [800–1,500 millimetres] or more annually), falling

mostly as snow. Not all this snow melts in the summer heat, and there are large ice fields in the higher regions.

This topographic and climatic variation has given Tadzhikistan an extremely varied plant life, with more than 5,000 kinds of flowers alone. Generally, grasses, bushes, and a variety of shrubs predominate. Animal life, too, is rich and varied. The great gray lizard, jerboa, and gopher are typical inhabitants of the desert regions. In wooded areas deer and tigers are still sometimes seen, and jackals and wildcats live and hunt in reed thickets. In the mountains, the brown bear is found at the lower levels, and the goat and the golden eagle frequent higher altitudes.

The human imprint. The soils of the republic are mostly gray soils, poor in organic humus but rich in mineral nutrients. In unirrigated areas, there are dark gray steppe soils and brown mountain loess. About two-thirds of the surface is covered by sand, shingle, scree, bare rock, and permanent snow and ice. Those desert and semidesert areas suitable for irrigated farming have been turned into flourishing oases, with cotton plantations, gardens, and vineyards, by means of an extensive irrigation network. Population density is also high in the large villages strung out in clusters along the foothill regions.

The Pamir region

The landscapes of the Pamir region are quite distinctive, especially in the east, where there is sparse vegetation and the underbrush, known as *teresken*, supplies the only fuel. The high-altitude semidesert regions manage to provide year-round food for sheep. There are also narrow valleys with small villages (*qishlaq*s) surrounded by apple orchards, apricot trees, mulberry groves, and small cultivated fields.

Tadzhikistan may be divided into a number of regions: Northern Tadzhikistan, the southern boundary of which is the northern slope of the Turkistan Range; Central Tadzhikistan, or Kukhistan (*kūhistān*, "mountain country"), containing the Turkistan, Zeravshan, and Gissar ranges; low-lying Southwestern Tadzhikistan, containing two-thirds of the country's people and stretching to the south of the Gissar Range; and the Pamirs. The last may be subdivided into the East Pamirs—which, in its structure, resembles Tibet—and the deeply cleft West Pamirs.

THE PEOPLE

National origins and demographic trends. The name Tadzhik (Tajik) did not acquire its present definition till very recent times. Not unil the 1920s did an official Tadzhik administrative unit come into being under that name. The area's population is ethnically extremely mixed, as it has been for centuries. At the census of 1970, which showed a total population of 2,900,000, only 56.2 percent was Tadzhik.

On the basis of language, customs, and other traits, the Tadzhiks can be subdivided into a number of distinct groups. The Pamir Tadzhiks include minority people speaking Wakhī, Shughnī, Rōshānī, Khufī, Yāzgulāmī, Ishkashmī, and Bartang, grouped in the Gorno-Badakhshan Autonomous Oblast. Another distinct group is formed by the Yaghnābīs, direct descendants of the ancient Sogdians, who live in the Zeravshan River basin.

So closely are the Tadzhiks mixed with their Muslim coreligionists the Uzbeks that the Soviet partition of the area in 1924 failed to segregate the two nationalities with any degree of thoroughness. The 665,662 Uzbeks constituted the second largest ethnic group in Tadzhikistan in 1970, making up nearly 23 percent of the population. Russian immigrants and descendants of earlier Russian immigrants formed almost 12 percent of the population. Others, in order of size, were Tatars, Germans, Kirgiz, Ukrainians, and Jews, altogether supplying an additional 6.5 percent.

The density of population is low, but the average figure —some 61 persons per square mile (24 per square kilometre)—conceals a variation between the valleys (up to five times the average figure) and the almost empty eastern mountain regions.

Like the other Central Asian republics, Tadzhikistan has a high rate of population increase. The natural population growth rate is three times the overall Soviet figure and is even higher in the Gorno-Badakhshan region. Half the population is under 20 years of age, and children under nine constitute more than 30 percent.

The population is made up of collective farmers (54 percent), workers (31 percent), and white-collar employees (about 16 percent). Women constitute almost 40 percent of the industrial and office employees.

Urban life

Patterns of settlement. The Tadzhik S.S.R. contains almost 20 cities, together with about 50 other settlements classified as urban. The two largest cities are Dushanbe, with a population of some 436,000 in 1975—the Tadzhik portion of which had evidently grown little, if any, above the 26.2 percent it formed in 1970—and Leninabad (formerly Khojand), with more than 100,000. Russians dominate Dushanbe's ethnic mixture (1970), constituting 42 percent of the inhabitants; Uzbeks make up 10.3 percent. The more important of the smaller urban centres are Kulyab, Kurgan-Tyube, and Ura-Tyube. Kayrakkum, Ordzhonikidzeabad, Kalininabad, Nurek, and Regar are new creations. The combined urban population of the republic exceeded 1,240,000 by the mid-1970s.

The larger part of the population, however, continues to live in the rural *qishlaq*s. Such a settlement usually consists of 200 to 700 one-family houses built along the banks of a river or an irrigation ditch. Traditionally, the house is surrounded by a mud fence. Many houses have flat roofs, and every household has an orchard or vineyard. In the mountains, the *qishlaq*s, sited in narrow valleys, form smaller settlements, usually 15 to 20 households. On the steep slopes, the flat roof of one house often serves as the yard for the house above it. There are schools, clinics, shops, and cultural centres in most *qishlaq*s. Settlements in newly developed areas have a more urban aspect; they cluster together and often include two-story houses and a community service centre.

THE ECONOMY

Tadzhikistan is a major producer of long-staple cotton, accounting for more than 10 percent of the Soviet cotton output. The main industries are nonferrous metallurgy, cotton processing, oil production, fruit canning, and wine making. Capital investment in the republic's economy has grown substantially, more than doubling during the decade of the 1960s.

Resources. The republic is rich in mineral deposits, including iron, lead, zinc, antimony, mercury, gold, tin, and tungsten. Nonmetals include common salt, carbonates, fluorite, arsenic, quartz sand, asbestos, and precious and semiprecious stones. The major mineral fuel is coal. There are also considerable deposits of petroleum and natural gas. Tadzhikistan's natural wealth also includes medicinal mineral springs. Finally, there is great potential electric power in the republic's rivers, most of it concentrated in the south.

Industry. Although 62.9 percent of the republic's entire population and 74.5 percent of the Tadzhiks themselves remained in the countryside in 1970, Soviet authorities classify Tadzhikistan as an industrial-agrarian republic, with both sectors versatile.

The chief mining and ore-dressing area is in the north. Oil extraction and coal mining are among the oldest industries in the republic, the latter the more significant. Gas extraction began in the Kyzyl-Tumshuk and Komsomol fields (the latter near Dushanbe) in the mid-1960s, but, because of its small scale, local supplies have to be augmented by natural gas from Afghanistan, delivered by means of a pipeline built in 1974. The power industry has been developing rapidly. Major power stations include the Kayrakkum on the Syrdarya and the Golovnaya on the Vakhsh, with capacities of 126,000 and 210,000 kilowatts, respectively. The Nurek station on the Vakhsh, which became operational in 1972, will eventually have a capacity of 2,700,000 kilowatts. An important thermal power station operates near Dushanbe.

Electric power

Light industry includes a dozen cotton-cleaning mills and two silk factories. The Dushanbe textile mill complex is the republic's largest enterprise in the cotton industry. Other branches of light industry include manufacture of knitted goods and footwear, sewing, and tanning. The

Soviet Union's largest carpet-making factory is in Kayrakkum. The food industry concentrates on processing local agricultural products, which include fruit, grapes, various natural oils, and tobacco. The republic is the main Soviet producer of geranium oil, used in perfumery.

Engineering and metalworking experienced a 15-fold increase during the 1950s and '60s; products include looms, power transformers, cables, and agricultural and household equipment. The chemical industry includes a nitrogen fertilizer plant in Kalininabad (built in 1967), and an electrochemical complex is under development at Yavan. An aluminum plant at Regar began operations in 1975 upon delivery of the first power from the Nurek power station.

Agriculture. Cotton growing is the leading branch of Tadzhik agriculture. Other important branches are cattle raising and the growing of fruit, grain, and vegetables; sericulture is also widespread, except in the Pamirs. Wheat and barley are the predominant grains, and rice cultivation has been expanded. Horticulture has been significant in Tadzhikistan since ancient times: apricots, pears, apples, plums, quinces, cherries, pomegranates, figs, and nuts are all grown. Dried apricots, nuts (particularly almonds), and grapes are important exports. There are almost 1,000,000 long-horned cattle in the republic and nearly 3,000,000 sheep (Gissar sheep) and goats.

The role of irrigation

Agriculture in Tadzhikistan would be severely limited without extensive irrigation. Emulating the technique widely practiced in Central Asia since ancient times, two main canals, the Vakhsh and the Gissar, were built at the end of the 1930s, followed by two joint Tadzhik–Uzbek projects, the Great Fergana and North Fergana canals. After World War II the network was expanded by construction of the Dalverzin and Parkhar–Chubek irrigation systems; the Muminabad, Kattasay, and Selbur reservoirs; the Hungry Plains irrigation system; and a tunnel through which water is brought from the Vakhsh to the Yavansus Valley.

Transportation. The railway net in Tadzhikistan is not extensive, and about two-thirds of it is narrow-gauge. Standard-gauge railways cross the northern part of the republic and enter the Gissar Valley in the south. Narrow-gauge railways connect Dushanbe with the Vakhsh Valley and the Kulyab district. A standard-gauge railway line 160 miles long, completed in the early 1970s, connects the power and industrial complex at Yavan in the south of the republic with other regions. Just under half of the total freight turnover is handled by rail, the rest by motor transport. About half of the highways are surfaced. Regular air service connects Tadzhikistan with Moscow, Tashkent, and other Soviet cities, and there is much internal air traffic. Dushanbe is the air-transport centre, and there is an airport in Leninabad. A small amount of freight is carried by water, mainly between the river port of Termez (in the Uzbek S.S.R.) and Faizal-Kala (160 miles up the Amu Darya).

ADMINISTRATIVE AND SOCIAL CONDITIONS

Constitutional framework. The constitution of the Tadzhik S.S.R., adopted on March 1, 1937, states that the republic has all the rights of a sovereign state, including its national emblem and anthem. In practice, this republic, like the other 13 non-Russian union republics, does not possess and cannot exercise independence from Moscow in any vital matter, whether economic, social, cultural, political, or military. The republic has a Supreme Soviet, selected every four years, which ordinarily meets briefly twice each year to provide *pro forma* sanction to acts and decisions taken elsewhere. The Council of Ministers is the administrative organ and, though formally accountable to the republic's Supreme Soviet, takes its direction from executive bodies in Moscow. Local administration is carried out by regional, district, city, and village bodies, selected from a single list of candidates every two years. Judges are selected in a similar manner every five years; the courts include the Supreme Court of the Tadzhik S.S.R., the court of the Gorno-Badakhshan Autonomous Oblast, and district and city courts.

Supreme Soviet and Council of Ministers

The Communist Party of Tadzhikistan, with more than 94,200 members and candidates in 1975, is the true centre of power in the republic, but it, too, takes its direction in all respects from the party headquarters in the Russian S.F.S.R. Though Tadzhik membership in the union-wide party organization had grown from a mere 234 in 1925 to 57,271 by 1972, the proportion of Tadzhik party members to Tadzhik population remains lower than that of any other union republic eponymous nationality except the Moldavians. Within the Communist Party of Tadzhikistan, Tadzhiks have also remained in minority status; in 1962 Tadzhiks constituted 45.5 percent of the members, compared with 24.2 percent Russians, while their percentages in the total population (1959) were 53 and 13.3, respectively. The Young Communist League (Komsomol), another party organization, had a membership in 1975 of about 305,000. Tadzhik trade unions, representing party and state rather than workers' interests, have about 750,000 members of various nationalities.

Social conditions. The republic constitution says that all inhabitants, regardless of nationality or race, have equal right to employment, vacations, education, and social security on retirement or during disablement. In actuality, considerable inequality exists in the realization of such rights; the educational level, for example, of different ethnic groups varies greatly. Tadzhiks awarded college degrees grew from 0.8 percent in 1959 to 2.1 percent in 1970, while Russians rose from 4.4 to 6.2 percent. Tatars living in Tadzhikistan also surpassed their host Tadzhiks substantially.

Education

Nevertheless, the educational level of Tadzhiks has risen greatly in the 20th century, initially under the impetus supplied by the Jadid (New Method) schools in Bukhara, Samarkand, and elsewhere, opened or taught by intellectual leaders such as Shakuri, Behbudi, and Ayni. In the late 19th century and early 20th there were also a few tsarist schools offering secular learning to indigenous pupils. The educational establishment was dominated until the 1920s, however, by the network of Muslim *mektebs* and *medreses* for which Central Asia was well known.

Literacy for Tadzhikistan's inhabitants between the ages of nine and 49 in 1970, according to official statistics, reached 99.6 percent, though there remained many Tadzhiks over age 49 who had not finished a grade school or high school education. Progress in schooling among younger groups has been great and will no doubt in a few decades offset the limitations in the education of older adults.

There were in the mid-1970s about 3,200 schools attended by some 900,000 children; about 40 specialized secondary schools enrolling 37,400 students; and nine institutions of higher learning had a combined registration surpassing 47,000. There are about 60 research institutes, 16 of them under the auspices of the Tadzhik Academy of Sciences, founded in 1951. This emphasis on education and research keeps Tadzhikistan supplied with young specialists. The education of women lags far behind that of men (0.7 percent of Tadzhik women in the republic held college degrees in 1970). The chronic Central Asian problem of placing indigenous graduates in employment commensurate with their advanced training besets the Tadzhiks, for most urban and industrial jobs are held by outsiders such as Russians, Tatars, and Ukrainians.

There is an extensive modern medical system, with 96 hospital or clinic beds and 19 doctors per 10,000 people. Housing construction and community services are also developing. Electricity has been brought to every settlement, and the gas network is being extended. Every year about 20,000 modern flats are turned over to tenants, and living conditions generally are improving. These amenities, however, benefit principally the urban centres, with their large non-Tadzhik populations.

CULTURAL LIFE

Tadzhikistan has an ancient culture, and over the centuries it has given the world poets, philosophers, and scientists. Many of the popular traditions and customs have

Festivals

been retained, including the costumes worn by both men and women and such ancient festivals as the New Year celebration of the tillers of the land, known as Navrūz, which takes place on March 21, the period of the vernal equinox. A festival celebrated after the gathering of the cotton crop is another. These festivals are colourful affairs, incorporating horse races and horsemanship and wrestling contests. The Muslims (mostly Sunnī) continue regular mosque worship and observe religious holidays where possible, though religion is actively persecuted.

The national cuisine includes flat cakes, the equivalent of bread, made in special ovens; *manti*, a kind of large dumpling; *laghmān*, a stew of chopped meat and noodles; *kaurdak*, fried meat and potatoes; and fermented milk. Fruit is an important dietary item, as are black and green tea.

Languages

The principal language of Tadzhikistan, Tadzhik (known to its speakers as Tojikī), with distinct northern and southern dialects, belongs to the southwest group of Iranian languages, in the Indo-European family; it is very close to the language used widely in neighbouring Afghanistan, where it is known as Farsī. The language of the Pamir Tadzhiks belongs to the east Iranian group. Tadzhik was formerly written in a modified Arabic and later in the Roman alphabet but since 1940 has used a modified Cyrillic script. Writers from this region have made notable contributions to Persian literature since the 10th century AD, and a vigorous folk literature is still being collected.

A number of Tadzhik poets and novelists have achieved fame in the Soviet Union and beyond. They include Abdalrauf Fitrat, whose *Last Judgment* has been reprinted many times in Tadzhik, Russian, and Uzbek, and Sadriddin Ayni, known for his novels *Slaves* and *Dokhunda* and for his autobiography, *Bukhara*. Abū ol-Qāsem Lāhūtī's poems *We Won* and *Crown and Banner*, and Mirzo Tursunzode's poem *Hasan the Arab* respond to the changes of the Soviet period; the latter's lyric cycle *The Voice of Asia* won him the Lenin Prize in 1960, followed by a number of other major awards noting his contribution to Soviet Tadzhik poetry and his influence on younger poets.

For centuries, songs, dances, and theatrical and circus performances have been a distinctive popular tradition in the region: singers, tightrope walkers, conjurers, musicians, and other performers continue to entertain audiences. In addition, festivals are now held for amateurs working in both traditional and modern fields.

The Tadzhik National Theatre, which was established in 1929, has nine separate theatres presenting opera, ballet, musical comedy, and puppetry. The cinema is developing, with Tadzhik studios producing feature films and documentaries as well as dubbing films from elsewhere. Radio and television services are increasing, and Dushanbe has had a television centre since 1960.

PROSPECTS

The Tadzhik republic has much potential for further economic development and associated improvements in the material and cultural life of its people. Industrial development will continue, a major role being played by electrical power production. This latter trend will include the completion of the final units of the Nurek hydroelectric station complex, which will enable additional capacities in the metallurgical and electrochemical industries to come into operation.

The Tadzhik people are among the most outward-looking of Central Asia, in part because so many of them live outside the Soviet Union (mainly in Afghanistan) and also because of affinities strongly felt with the people of Iran. The Soviet Tadzhiks' intellectual rivalry with their closest neighbours, the Turkic Uzbeks, has been encouraged by the Soviet authorities in order, among other things, to maintain the separateness of the Central Asian nationalities. These factors support Tadzhik national consciousness as the group continues to modernize its economy and society. Handicaps include lack of national sovereignty, which prevents Tadzhiks from taking ultimate responsibility for important developments affecting their future. Pressing problems remain in the fields of education, women's rights, and intellectual life, among others. Book publishing (per capita) in Tadzhik declined noticeably on the average, between 1959 and 1970, gains in influential Communist Party membership and posts are coming very slowly, and unemployment of educated Tadzhiks has become evident, though most Tadzhiks remain on farms or in country villages.

Despite these difficulties, the Tadzhiks should grow in strength and confidence as their population rapidly increases and their educational standing generally improves. Where the new generations of educated Iranian Central Asians will find suitable outlets, either in the region or outside it, for their talents and skills is a question without obvious answers in the mid-1970s.

BIBLIOGRAPHY. Various aspects of Tadzhik life are dealt with in the following works: JIRI BECKA, "Tajik Literature from the 16th Century to the Present," in JAN RYPKA, *History of Iranian Literature* (1968); TERESA RAKOWSKA-HARMSTONE, *Russia and Nationalism in Central Asia: The Case of Tadzhikistan* (1970); LAWRENCE KRADER, *Peoples of Central Asia*, 3rd ed. (1971); and EDWARD ALLWORTH (ed.), *The Nationality Question in Soviet Central Asia* (1973).

(A.I.I./E.Al.)

Tagus River

The Tagus (Spanish Tajo, Portuguese Tejo) is one of the great rivers of Europe. The longest river of the harsh and arid Iberian Peninsula, it has been of vital importance to the economic and social development of two nations. Its total length is 626 miles (1,007 kilometres), made up of 488 miles across Spain, a 27-mile section as the frontier between Spain and Portugal, and a final 111-mile stretch in Portugal until it reaches the Atlantic at Lisbon. Its drainage basin of 31,505 square miles (81,600 square kilometres) covers the heart of Portugal and Spain and is only slightly smaller than that of the Ebro, to the northeast.

Geographers and naturalists have been associated with the study of the river since the time of the Greeks and Romans. During the reign of the Spanish king Philip II in the 16th century, studies were made to determine the extent of the river's navigability for use during times of war. Philip III and IV continued the studies, sending various expeditions from Toledo to Portugal. The Tagus was found unsuitable, however, for military logistic purposes.

In 1828 a court navigator, Francisco Javier Cavanas, following the work of a predecessor, Juan Bautista Antonelli, two and a half centuries earlier, investigated the possibility of making the river a trade artery between Aranjuez and Portugal. It proved too expensive and, until the present day, only the lower part of the Tagus is used for navigation of any importance. By the 1970s there was an official Spanish agency, the Confederación Hidrográfica del Tajo, specializing in scientific study of the Tagus. Several Spanish ministries had departments concerned with the river. The interest of such private bodies at the Sociedad Española de Ciencias Naturales, the Real Sociedad Geográfica, and the Instituto Celestino Mutis further testified to the importance of the river.

The course of the river

The Tagus rises in the Sierra de Albarracín, near Casas de Fuente García (Teruel province) in eastern Spain, at an altitude of 5,216 feet (1,590 metres). The young stream cuts into the limestone rocks and flows through narrow, sinuous valleys with deep canyons and abundant ravines in a generally southwestward direction. Near Trillo (Guadalajara province) it runs through more solid soil and rock, and its course becomes generally more peaceful. Just before the town of Bolarque it is held back by the important dams of Entrepeñas and Buendía, forming an artificial lake known as the Sea of Castile, which covers an area of 51 square miles. Again flowing southwestward, the river irrigates the fertile lands of Aranjuez (famous for its strawberries), the area around Toledo (the beautiful Roman, Gothic, Jewish, Arab, and Christian city), and Talavera de la Reina until it reaches the province of Cáceres. Here it again flows through narrow,

steep-edged trenches (among them, Salto del Corzo, del Gitano, and del Macho) formed by quarzites and shales. In Puente de Alcántara a dam has formed the greatest man-made lake in contemporary Europe, with a length of 57 miles and with a capacity of 112,000,000 cubic feet. Less than a mile downstream the river becomes the frontier between Spain and Portugal for 27 miles, entering into Portugal at Beira and the Sierra de Carbajo, and then crossing the fertile region of Abrantes. At Vila Franca de Xira it forms the Tagus (or Lisbon) Estuary, emptying at this point into the Atlantic Ocean.

Centuries ago, as one can read in Pliny the Elder (1st century AD), the Iberian Peninsula was covered with luxuriant woods, but the destructive effects of constant wars changed the landscape into semi-arid lands. The Tagus Valley area was further damaged as recently as 1936 by battles fought there during the Spanish Civil War. As a result, all the present efforts of the public and private bodies associated with the river are dedicated to increasing reforestation, land irrigation, and the creation of hydroelectric power.

In the highlands of the Tagus Basin, conifer trees are numerous, with a well-developed timber industry. Near the smaller streams poplars and willows also grow. About a third of the cultivated area is covered by cereal farms and everywhere olive trees and vineyards are found. In Extremadura, in the west of Spain, the country is semi-arid; only oaks, cork trees, and holm oaks break the monotony of a rolling and rocky landscape.

Plant and animal life

Animal life near the river is abundant and diverse, with both European and North African species, often the subject of special attention by naturalists and conservationists. Royal carp, luces, and black-bass fishing is possible in the artificial lakes of Entrepeñas and Buendía, and trout, barbels, and many other kinds of fish may be captured in the Tagus and its tributaries. There is very important big game hunting in Gredos, noted for its *capra hispánica*, or Spanish ibex, and in the ridges of Cuenca and Guadalajara fallow deer and chamoises are found.

The hydroelectric and irrigational utilization of the Tagus had made great strides forward by the decade of the 1970s. In the whole drainage basin there were 62 dams with a total capacity of about 2½ cubic miles. The most important are: Alcántara; Buendía; Valdecañas; Gabriel y Galán; Entrepeñas. The installed power is of the order of 1,200,000 kilowatts. (J.B.Ro.)

Tai Languages

The name Tai denotes a family of closely related languages, of which the Thai, or Siamese, language of Thailand is the most important member. Because the word Thai has been designated as the official name of the language of Thailand, it would be confusing to use it for the various other languages of the family as well. Tai is therefore used to refer to the entire group.

Geographical distribution

Spoken in Thailand, Laos, Burma, Assam in northeast India, North Vietnam, and the southwestern part of China, the Tai languages together form an important group of languages in Southeast Asia. In some countries they are known by different tribal names or by designations used by other peoples; *e.g.*, there is Shan in Burma; Pai-i in Yunnan, China; Chuang-chia in Kwangsi, China; Chung-chia, Dioi, Jui, Yoi, Yay, or Pu-yi in Kweichow, China; Tho, Nung, White Tai, Black Tai, Red Tai, etc. in North Vietnam; and Khün, Lü, etc. in Thailand and Laos. Ahom, an extinct language once spoken in Assam, has a considerable amount of literature. The Tai languages are divided into three linguistic groups—the Southwestern, the Central, and the Northern. Thai and Lao, the official languages of Thailand and Laos, respectively, are the best known of the languages.

The number of Tai speakers is estimated at 30,000,000 in *Ethnic Groups of Mainland Southeast Asia* (1964). Of these, 18,000,000 are in Thailand, 9,000,000 in China, and approximately 1,000,000 each in Laos, North Vietnam, and Burma. There are tremendous variations between several estimates, and these figures may serve as only rough indications of the Tai populations.

Relationship to other languages. The Tai languages are traditionally assumed to be related to the Sino-Tibetan family of languages with which they share similar phonological structures, tone systems, and some lexical items; the relationship, however, has never been definitely established. The Tai tongues are related to the Kam-Sui languages of Kweichow, China, and to the Bê language in Hainan; but because of the great divergences in both vocabulary and phonological development, the name Tai is used only to designate a more restricted group that excludes such languages as Kam, Sui, and Bê. It has also been suggested, chiefly on the basis of some similar vocabulary items, that the Tai languages are related to the Kadai languages of southwestern China and Hainan Island and ultimately to the Austronesian (Malayo-Polynesian) languages, rather than to the Sino-Tibetan tongues.

Classification. Classifications have been made according to the geographical location of the Tai speakers, social, political, and cultural criteria, and literacy versus nonliteracy. The classification used for this article is based on linguistic relationships proposed in 1959–60; the criteria for it are lexical (involving similarities in vocabulary) and phonological (involving similarities in sounds and systems of sounds). According to these features the Tai languages are divided into the three groups mentioned above (see map). Languages of the Southwestern group are spoken in Thailand, Laos, North Vietnam, Burma, and Yunnan, China; they include Thai, or Siamese, Lao, Shan, Khün, Lü, White Tai, Black Tai, etc. The Southwestern division, geographically the most widespread group, consists of two-thirds of the Tai-speaking population and represents an expansion in comparatively recent periods. To the Central group belong the Tho dialects spoken in North Vietnam and the various dialects spoken in Kwangsi, such as Lungchow. The Chung-chia or Pu-yi dialects in Kweichow and the Chuang-chia dialects in Kwangsi belong to the Northern group. Some of the Northern dialects are also spoken in Yunnan and Vietnam, and one, called Saek, is spoken as far south as Laos and Thailand.

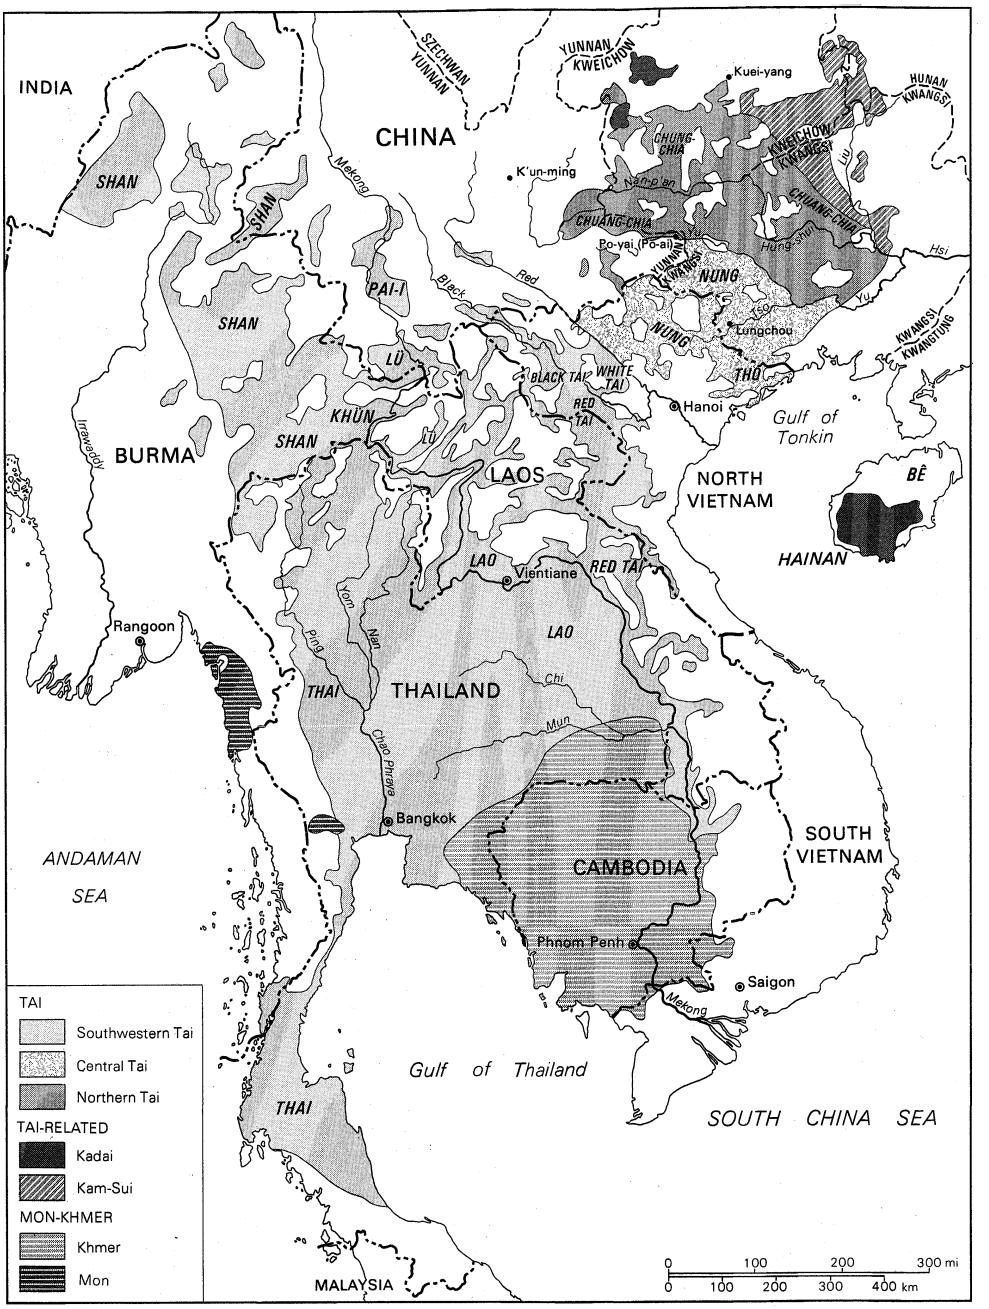
Main groups of Tai

The fairly large number of vocabulary items shared by languages of these three groups suggests their genetic relationship. There are also certain items that are shared by only two of the groups and not found in the other. For instance, the word for sky is shared by the Southwestern dialects (Siamese *fáa*) and the Central dialects (Lungchow *faa*), but another word is used in the Northern dialects (Po-ai *mïn*). Similarly, the word for beard is shared by the Central group (Lungchow *mum*) and the Northern group (Po-ai *mum*) but is replaced by another word in the Southwestern group (Siamese *nùat*); the term for knife is shared by the Southwestern (Siamese *mîit*) and the Northern groups (Po-ai *mit*) but not by the Central dialects. There are also vocabulary items that are found only in one group. In all, the evidence seems to indicate that there are three groups of dialects in the Tai family.

Dialect groups

Different phonological features may be attached to some words according to the dialect group. For instance, the Southwestern forms for the verb "to be" (Siamese *pen*) are derived from a protoform **pɛn* (with the vowel like *e* in "egg"), whereas the Central dialect forms (Lungchow *pin*) and the Northern forms (Po-ai *pan*) come from a protoform **bɛn*, as indicated by the tone. (A protoform is the presumed or reconstructed ancestral form of a word; an asterisk [*] marks those forms that are unattested and reconstructed.) Similarly, the Southwestern and the Central forms for the classifier for animals (Siamese *tua*, Lungchow *tuu*) are derived from a protoform **tua*, whereas the Northern forms (Po-ai *tuu*) are attributed to a protoform **dua*. (A classifier is a term that indicates the group to which a noun belongs, like "animate object," or designates countable objects or measurable quantities, like "yards" [of cloth] and "head" [of cattle]). Such words as the forms for "to be" and the classifier for animals are good indications of dialect boundaries.

In phonological development, the Northern dialects differ from the rest in not maintaining the distinction between aspirated and unaspirated voiceless stops. That is, the dialects have lost the feature of aspiration, which



Major divisions of the Tai languages and neighbouring languages.
Adapted from Frank M. LeBar, Gerald C. Hickey, and John K. Musgrave, *Ethnic Groups of Mainland Southeast Asia;* New Haven, Human Relations Area Files Press, 1964

sounds like a puff of breath accompanying a consonant. Aspiration may, however, be reintroduced in some dialects by later borrowing or secondary developments. The Central dialects differ from the other groups in the treatment of certain Proto-Tai consonant clusters, such as **tr-* and **thr-*. Although they have changed from the proto-forms, these are usually kept distinct in the other groups—*e.g.*, in Siamese as *taa* ("eye") and *haaŋ* ("tail"), in Po-ai as *taa* and *lïïŋ*. In the Central dialects, however, they have merged into a single sound—*e.g.*, Tho *thaa* and *thaaŋ*, Lungchow *haa* and *haaŋ*.

Phonological characteristics. The sound system of the Tai languages may best be described in terms of its syllabic structure. Each syllable consists of an initial consonant or consonant cluster followed by a vowel or vowel cluster (long vowel or diphthong), which may be further followed by a final consonant, usually a nasal sound or an unreleased stop. (An unreleased stop is a consonant in which there is complete stoppage of the airstream from the lungs, and in which the tongue or the lips maintain the position of the consonant without opening the stop-page.) In addition, each syllable has a tone. As an illustration of this type of structure, the system of the Thai, or standard Siamese, language as spoken around the Bangkok area may be given. Labials are sounds using the lips as articulators; alveolars are formed by placing the tip of the tongue at the gums behind the upper teeth; sibilants, or fricatives, involve local friction and a hissing sound resulting from incomplete closure in the mouth. Velars are sounds made with the back of the tongue touching the soft palate (velum); glottal sounds involve constriction of the vocal cords; semivowels are gliding sounds with some of the properties of both vowels and consonants; and liquids are frictionless consonants, produced with incomplete closure in the vocal tract, that sometimes function as vowels.

Five tones

There are five tones: level (*a*), low (*à*), falling (*â*), high (*á*), and rising (*ǎ*); for example, *maa* "to come," *màak* "areca nut," *mâak* "much," *máa* "horse," and *mǎa* "dog" are differentiated by the various tones.

Grammatical characteristics. The statements about morphology and syntax refer particularly to the standard language of Thailand, though they are applicable in gen-

Table 1: The Sounds of Thai (Siamese)

	initial consonants*					final consonants	
Labials	p	ph	b	m	f	p	m
Alveolars	t	th	d	n		t	n

Low	ɛ	a	ɔ	ɛɛ	aa	ɔɔ			

*Certain consonant clusters are also permitted initially, such as *kl, kr, khl, khr, tr, pl, pr, phl, phr, kw,* and *khw.*

eral to all of the Tai languages. Words or morphemes (word elements) are, for the most part, monosyllabic, but there are also many polysyllabic words, mainly compounds and loanwords from Sanskrit and from Khmer, an Austroasiatic language spoken in Cambodia. There are no inflections in Tai comparable to *-ed* in English "walked" or *-s* in "dogs," but derivations are common. Derivation is the formation of new words by the addition of endings, prefixes, or other words, often resulting in a change of the part of speech or meaning of a term—*e.g.*, English "unionize" or "unionization" from "union." Compounding is the chief Tai method of derivation—*e.g., nâa-taa* "countenance (face-eye)," *kèp-kàw* "to harvest (gather-cut with a sickle)." Reduplication, the repetition of a word or part of it, is common—*e.g., dii-dii* "very good" from *dii* "good." Partial reduplication is also found, such as *sanùk-sanăan* "to enjoy oneself" from *sanùk* "to have fun." Prefixes and infixes occur often in Indo-Aryan and Khmer loans—*e.g., pra-thêet* "country" (from Sanskrit *pradeśa*) and *d-amn-əən* "to proceed" (from Khmer *dae* "to walk") and *d-amn-aə* "process." There also developed some native prefixes that are abbreviated forms of what once were full words. For example, *ma-*, a prefix used in many names of fruits, such as *ma-phráau* "coconut," *ma-mûaŋ* "mango," is derived from *màak* "areca nut" (originally "fruit"). Similarly, in the word *sa-dïï* "navel," *sa-* is the reduced form of *săaj* "line, string," which refers to the umbilical cord. Old processes of derivation involved using the alternation of consonants or of tone or both, such as *níi* "this" and *nîi* "here," *nɔ́ɔj* "small, little" and *nɔ̂ɔj* "a little bit," *khiaw* "sickle" and *kìaw* "to cut with a sickle." Such processes are, however, no longer active.

Use of nominal predicates

A sentence is usually formed by a noun phrase (subject) followed by a verb phrase (predicate). There are, however, nominal predicates as well, in which the verb is lacking and a noun is used instead; an example is *wan-níi wan-săw* "today (is) Friday." A noun phrase consists of a noun, which may be followed by its modifiers (another noun, an adjective, or a verb phrase), which, in turn, are followed by a numeral with a classifier, and finally, by a demonstrative. For example, *tûu* "cabinet" and *náŋsïï* "book" become *tûu-náŋsïï* "bookcase"; *tûu-kèp náŋsïï* is "bookcase" ("cabinet-keep-book"); *tûu-yen* is "icebox" ("cabinet-cool"), and *tûu-náŋsïi sɔɔŋ-bai níi* is "these two bookcases" ("cabinet-book two-classifier these"). Classifiers must be used with numerals and vary according to the nouns they are to enumerate. It is not uncommon that a noun may serve as its own classifier.

A verb phrase may consist of an adjective or of a verb often followed by its object or its complements or both. A common type of complement denotes the direction of action by using such words as *paj* "to go," *maa* "to come," *khĭn* "to ascend," *loŋ* "to descend," and so on. Examples are *ʔaw náŋsïï paj* "Take the book away!"; *ʔaw náŋsïï maa* "Bring the book (here)!"; *aw náŋsïï khĭn maa* "Bring the book up!"; and *aw náŋsïï loŋ paj* "Take the book down!". A number of particles, particularly those occurring at the end of a sentence, are used to indicate a question or a command, to express emphasis or uncertainty, to show politeness and the sex of the speaker, etc. For example, *kháw maa lέεw* "He has come"; *kháw maa máj*? "Is he coming?"; *khun maa máj khráp*? "Are you coming?" (man speaking, polite); *khun maa máj khá* "Are you coming?" (woman speaking, polite).

Vocabulary. The various Tai languages have been in contact with many different languages spoken in the same area of Southeast Asia, and it is inevitable that words from different sources have been adopted by them. There is a basic core of vocabulary that is shared by most of the Tai languages and may be considered as the native vocabulary of the protolanguage (earlier form of the Tai lan-

tonal markers (used with vowel symbols)

(1) – middle tone with middle and low consonants; rising tone with high consonants
(2) ˋ low tone with middle and high consonants; falling tone with low consonants
(3) ˇ falling tone with middle and high consonants; high tone with low consonants
(4) ˊ rising tone chiefly with middle consonants

*Pronunciation key (for symbols not used in the standard Roman alphabet): ɛ = *a* as in *bad;* ɨ = the *u*-sound in some pronunciations of *just* (*e.g.*, "just a minute"); ɔ = *o* as in *law;* ə = *a* as in *sofá;* ʔ = glottal stop (the catch sound for *tt* in Cockney or Brooklynese *bottle*). †For which the long-short distinction does not apply.

guages). Nevertheless, items in this list may be found to resemble forms in other languages, such as Chinese or Indonesian, and they have given rise to different interpretations of the relationship of the Tai languages to other linguistic families. Loanwords in later periods from the Khmer and Indo-Aryan languages (Sanskrit and Pāli) are particularly common in Siamese and Lao, and loans from Chinese are abundant in the Central and the Northern dialects.

Loan words

Writing. There are two kinds of writing used among the Tai languages. One, ultimately derived from Chinese, is used by the Central and the Northern dialects; the other comes from Indo-Aryan sources and is used in many languages of the Southwestern group. The Chinese-based system, employed chiefly to write songs, consists of both Chinese characters and modified Chinese characters, very much like the early writing in Vietnam. A specimen of this type of writing dates back perhaps to the 18th century, but it may have been in use much earlier. The script adapted from Indo-Aryan sources for the Tai languages dates perhaps from the 13th century. The earliest known example of such a writing system is the inscription of Ramkhamhaeng in northern Thailand from AD 1293. The Modern Thai alphabet (see Table 2) is a modified form of the original writing. It preserves the old distinction of voiced (low) and voiceless (middle or high) consonants, a distinction that is now lost, but leaves its effects on the tone. This system also provides an unambiguous method for indicating the vowels and tones. Similar types of writing are used in Lao, Lü, White Tai, Black Tai, etc. Another type of Indo-Aryan writing, used in Shan and Ahom, lacks the difference between high and low consonants, has an insufficient number of vowel signs, and provides no tone marks. Although the shapes of the letters in Shan differ greatly from those in Ahom, the basic principle is essentially the same.

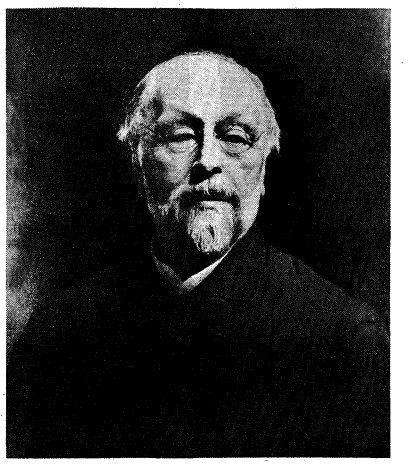
(F.K.L.)

Taine, Hippolyte

Hippolyte-Adolphe Taine achieved fame over a wide range of disciplines—as a leading French thinker, as a literary and art critic, and as a historian. His greatest influence upon his contemporaries, however, was as an intellectual leader, one of the most esteemed exponents of 19th-century French Positivism, the cult of science in its most devoted, high-minded, and rational form. His work, a reaction against spiritualist philosophy, was unified by his attempt to apply the scientific method to the study of literature and art, to psychology, to cultural history, and to the realms of metaphysics and ethics. He even aspired to base a new religion upon science, and his ideas helped to provide a theoretical basis for the literary movement of Naturalism; the novel, he argued, should be a "collection of experiments," a contribution to the scientific understanding of human nature, revealing, like the new scientific psychology he advocated, the physiological and psychological determinants of man's behaviour.



Taine, portrait by Léon Bonnat, 1889.
Hachette—J.P. Ziolo

Born on April 21, 1828, at Vouziers, in the Ardennes, Taine came from a professional middle class family; his father was a lawyer. He was educated privately at home until shortly after his father's death; thereafter, he went with his mother to live in Paris and became an outstanding pupil at the Collège Bourbon and then at the highly prestigious École Normale. He gained his *licence-ès-lettres* (preliminary degree) in 1848 and began to study for his *agrégation* (advanced degree) in philosophy, one of his dominant interests. He already held unorthodox intellectual views. He had apparently lost his Christian faith by the age of 15, and his youthful rationalist attitude led him to admire the ideas of the Idéologue philosophers who held that all knowledge must be based on sense experience, on observation and controlled experiment; this overriding conviction guided his later career. He was also already attracted by the metaphysical ideas of Hegel and Spinoza, which inspired in him a desire to find a total explanation of the causal forces of life and the universe. In contrast to these views, his new teachers of philosophy in Paris held the prevailing philosophical doctrine of eclecticism; consequently—and not without creating some scandal in academic circles—Taine's *agrégation* jury failed him in 1851. He then taught for brief periods at Nevers and Poitiers but in 1852 applied for leave of absence. Returning to Paris, he devoted himself to preparing his two dissertations for the doctorate in literature: *De Personis Platonicis* ("Concerning Plato's Characters") and, his first well-known work, a study of La Fontaine (1853; revised and published in 1861 as *La Fontaine et ses fables* ["La Fontaine and His Fables"]). He gained his doctoral degree in May 1853 and began an essay on Livy, *Essai sur Tite-Live* (1856), which, despite further criticism of his philosophical outlook, won a prize from the Académie Française. During this period he was also attending lectures in science and gathering the knowledge of physiology that he utilized later in his work on psychology. Reluctant to return to full-time teaching, he lived by private tutoring and as a man of letters. Even a holiday in 1854, necessitated by ill health, was turned to advantage: in 1855 he published a literary guide book based on his travels, *Voyage aux eaux des Pyrénées* ("Voyage to the Waters of the Pyrenees"). More important for his own development, he contributed frequent literary and historical articles to such leading journals as the *Revue des Deux Mondes*, the *Revue de l'Instruction Publique*, and the *Journal des Débats*, articles that provided the basis for three books further enhancing the reputation he had gained by his works on La Fontaine and Livy. These were *Les Philosophes français du XIX^e siècle* (1857; "The French Philosophers of the 19th Century"), a critical polemic against the prevailing eclectic philosophy of Victor Cousin and his group, which also provides in its later chapters a lucid exposition of his own Positivist theory of knowledge; a

Attack on eclecticism

first collection of *Essais de critique et d'histoire* (1858; "Essays of Criticism and History"); and his notable *Histoire de la littérature anglaise* (4 vols., 1863–64; Eng. trans., 1871, *History of English Literature*), whose celebrated "Introduction" gives a succinct statement of his approach to literary and cultural history and a basic text for the understanding of his scientific attitude to literary criticism. The same great causal factors underlie any cultural artifact of a given age and society, he claims. By studying the literary documents the psychology of their author can be understood, and this, complemented by scrutiny of the facts of his life and personality, illuminates the "*faculté maîtresse*," the predominant characteristic that determines his work; this, in turn, can then be "explained" by reference to three great conditioning facts, "*la race*," "*le milieu*," and "*le moment*"; *i.e.*, the writer's inherited personality, his social, political, and geographical background, and the historical situation in which he writes. It is evident that Taine's interest here is less in literature itself than in historical causation and psychology, and his method may well be thought to have encouraged in his admirers an excessive preoccupation with biography and literary history at the expense of critical judgment, though Taine's own abilities as a critic were considerable.

Throughout the 1860s Taine continued indefatigably his researches and his writing. Even his travels (to England, Italy, Germany, and The Netherlands) were utilized to gather notes for future work—for example, his closely observed if simplifying *Notes sur l'Angleterre* (1872; Eng. trans., *Notes on England*, 1872); and even his life in Paris led to his *Notes sur Paris: Vie et opinions de M. Frédéric-Thomas Graindorge* (1867; Eng. trans., *Notes and Opinions of Mr. Frédérick-Graindorge*, 1875), perhaps the most personal and entertaining of his books. In 1864, by a happy decision of Napoleon III, he was appointed to succeed Viollet-le-Duc, the architect, as professor of aesthetics and of the history of art at the École des Beaux-Arts in Paris, where he lectured for 20 years. The lecture courses, which he eventually published, include *Philosophie de l'art* (1865; Eng. trans., *The Philosophy of Art*, 1865), *De l'idéal dans l'art* (1867; "On the Ideal in Art"), and those concerned with the philosophy of art in Italy (1866), The Netherlands (1868), and Greece (1869). This post also gave him a security that favoured his more protracted scientific studies and helped make the later 1860s a happy and fertile period in his life. He published, in addition to the works named, his second volume of essays, *Nouveaux essais de critique et d'histoire* (1865; "New Essays of Criticism and History"), including his perceptive articles on Racine, Balzac, and Stendhal (whose psychological acuity he was one of the first to admire). In 1868 he married Mlle Denuelle, the daughter of a well-known architect and artist, by whom he had a son and a daughter. In 1870 he published the two volumes of *De l'intelligence* (Eng. trans., 1871, *On Intelligence*), a major work in the discipline of psychology, which had interested him since his youth. His devotion to science is most fully illustrated here; he opposes the speculative and introspective approach of the eclectics and outlines a scientific methodology for the study of human personality that established him, alongside thinkers such as Théodule Ribot and Pierre Janet, as a founder of empirical psychology. Though much of the work is now outdated, in its day it helped to modify methods of research by its emphasis on experiment, the search for causes, the study of pathological cases, and the physiological basis of personality. It also intensified opposition to his ideas, and he was angrily accused of holding a strictly determinist and materialist view of man—not altogether unfairly, even though he claimed to reject materialism and argued that moral responsibility was compatible with determinism as he conceived it. The work also develops his long-standing attempt to fuse Positivism and Hegelian Idealism and to provide a method for a scientific metaphysics. Through such a metaphysics, he maintained, the final causes of life itself might be discovered; its insights inspired him to an exalted pantheistic trust in nature that is movingly expressed in essays on Marcus Aurelius (in *Nouveaux essais*) and Iphigeneia (in *Derniers essais*).

Publication of *De l'intelligence*

Germany's invasion and defeat of France in 1870–71 had a profound impact upon Taine (already prepared in his mind by a visit in 1869 that had disabused him of his earlier enthusiasm for German civilization). The French defeat, in his view, sprang from a deep national sickness, and he determined to devote his final years to examining its causes. A shift of interest toward politics is illustrated by a brochure of 1872 on the problems and effects of universal suffrage, but, above all, his approach was historical: to seek the sources of the political instability that he held responsible for his country's plight. This major reorientation of concern led to his great historical work, *Les Origines de la France contemporaine* ("The Origins of Contemporary France"), a monumental analysis, claiming scientific objectivity (although its factual and interpretative reliability have been challenged). It seeks to show that France's primary fault lay in excessive centralization, originating during the *ancien régime*, and intensified by the French Revolution, about which he shares and develops Burke's hostile view. A first volume, on *L'Ancien Régime* ("The Old Regime"), appeared in 1876, followed by three volumes on the Revolution (1878–85). In 1878 he was also elected to the Académie Française. To have more time for his self-appointed task he withdrew increasingly from Paris and after 1883 even resigned his professorship to live and work, surrounded by family and friends, in his house on the lake of Annecy at Menthon-Saint-Bernard, in the peaceful natural setting he had always loved. Only one volume of *Le Régime moderne* ("The Modern Regime"), however, was published in his lifetime (1891), the second volume coming out in November 1893. The entire work was reissued in 1899. There also appeared after his death his *Derniers essais de critique et d'histoire* (1894; "Last Essays of Criticisms and History") and an unfinished autobiographical and psychological novel, written about 1861, *Étienne Mayran* (1910). He died in Paris on March 5, 1893, and was buried at Menthon-Saint-Bernard, honoured as an outstanding scientific humanist of his time.

Historical theories

BIBLIOGRAPHY. An authoritative biography and a selection of Taine's correspondence was edited by his widow under the title *H. Taine, sa vie et sa correspondance*, 4 vol. (1902–07; Eng. trans., *Life and Letters of H. Taine*, 3 vol., 1902–08). Most of Taine's works have been translated into English. Useful monographs that include a survey of his life include V. GIRAUD, *Essai sur Taine, son oeuvre et son influence*, 6th ed. (1923); A. CHEVRILLON, *Taine: formation de sa pensée* (1932); and A. CRESSON, *Hippolyte Taine, sa vie, son oeuvre* (1951). In addition, studies of his philosophy include G. BARZELLOTTI, *La Philosophie de H. Taine* (1900); D.D. ROSCA, *L'Influence de Hegel sur Taine, théoricien de la connaissance et de l'art* (1928); and M. LEROY, *Taine* (1933), in French. For a critical study of his historical work, see A. AULARD, *Taine, historien de la Révolution française* (1907). His literary criticism is fully discussed by S.J. KAHN in *Science and Aesthetic Judgment: A Study in Taine's Critical Method* (1953); and his influence in England by F.C. ROE, *Taine et l'Angleterre* (1923). Shorter studies in English are found in D.G. CHARLTON, *Positivist Thought in France During the Second Empire, 1852–1870* (1959) and *Secular Religions in France, 1815–1870* (1963); and in G.P. GOOCH, *History and Historians in the Nineteenth Century*, 2nd ed. (1952).

(D.G.Ch.)

Taipei

Taipei (Tai-bei in Pin-yin romanization) is the provisional capital of the Republic of China and a principal city of the island of Taiwan, located in the Pacific, 121 miles from the southeast coast of China. The city became the capital in exile of the Nationalist government after the victories of the Communists on the mainland in 1949.

Taipei is situated in the north of Taiwan, surrounded on all sides by mountains. About 19 miles to the northeast is Chi-lung, one of the main ports of Taiwan. Taipei was also the capital of Taiwan Province until 1957, when the capital was moved to Chung-hsing-hsin-ts'un near the west coast. The population of the city in 1972 was about 1,865,000, of whom 40 percent had migrated from the mainland after the Communist victories.

Recent growth

In the 19th century Taipei became an important centre for overseas trade. Oceangoing junks could reach it by river from the ports of Chi-lung and Tan-shui. The Japanese acquired the island in 1895 after the Sino-Japanese War and made Taipei the capital. The island reverted to China in 1945, after Japan's defeat in World War II. With the arrival of the Nationalist government from the mainland in 1949, Taipei expanded greatly. In 1967 it was declared a special municipality and given the status of a province; the total area was increased from about 26 square miles (67 square kilometres) to about 105 square miles (272 square kilometres) with the absorption of the towns and villages of Pei-t'ou, Shih-lin, Nei-hu, Nan-chiang, Mu-cha, and Ching-mei. The metropolitan area may be considered to include the whole northern part of the island, including the ports of Chi-lung and Tan-shui.

Taipei and its environs are now a major industrial area. Most of the important textile factories are located there; other industries include electronic parts, electric machinery and appliances, wires and cables, canned goods, refrigeration, shipbuilding (including yachts and other pleasure craft), motorcycles, rubber goods, and various handicrafts.

Railways and bus lines connect Taipei with all parts of the island. Within the city there are both municipal and private bus lines. While the railroad station is still the hub of the city, much new construction has occurred in the area of the Presidential Building and the Kuomintang headquarters. Broad new boulevards radiate from there to all parts of the city. The Sung-shan International Airport on the outskirts is served by a number of international airlines.

The older buildings in Taipei are mostly low, unpainted, wooden structures. In the 1960s many of these were replaced with high-rise apartment houses and office buildings. Because of the population influx and the priority given to office and industrial construction, there has been an acute shortage of housing.

The climate is subtropical and moderate. Temperatures in the summer rarely go over 95° F (35° C), and there is usually a sea breeze in the evening. Winter temperatures are seldom below 59° F (15° C). Rainy seasons are from March to June and November to January or February. The mean annual rainfall is about 83 inches 2,112 millimetres). Because of its mild climate, Taipei is a green city throughout the year.

The city and the island have excellent public-health services and are therefore free of some of the diseases endemic to most tropical and subtropical countries. The annual death rate in Taipei was reduced from 12.5 per 1,000 in 1947 to 3.2 per 1,000 in 1970. The average life expectancy is about 65 years for males and 69 for females.

In 1968 a nine-year course of education became compulsory. Taipei had almost 100 primary schools in 1971, as well as about 40 high schools and a dozen trade schools. Taiwan had over 90 institutions of higher learning, of which about 20 were located in Taipei.

The National Palace Museum

While Taipei is not a place of antiquity, it is a good place to view antiquities. The National Palace Museum, named after its original in Peking, houses one of the world's largest collections of ancient Chinese artifacts, calligraphy, paintings, and porcelain, brought over from the mainland after 1949.

One of the most popular recreation areas is Yang-min Shan, only ten miles from the centre of the city. Both the mountain and the town of Pei-t'ou at its base are known for their hot springs. Pi-t'an (Green Lake), seven miles from the city, has boating and water sports. There are ocean beaches not far away, and Tan-shui has two excellent golf courses.

There is a remarkable number of Christian churches and denominations in Taipei, which came there after being driven from the mainland. They range from the American Southern Baptist Mission to the Watch Tower Bible and Tract Society. There are also a mosque and many Buddhist and Taoist temples and nunneries.

BIBLIOGRAPHY. Information on Taipei may be found in the *China Yearbook* and various statistical publications on Taiwan. See also DAN CHEN, "City in a Hurry," *Free China Review*, 17:21–27 (1967), a review of its political, social, and economic conditions; and TAIPEI, FU-MIN GEOGRAPHICAL INSTITUTE OF ECONOMIC DEVELOPMENT, *Research Report* (1948–).

(H.-p.T.)

Taira Family

One of the houses that most influenced Japanese history, the Taira family, also known by the Sinicized pronunciation as Heike ("the house of Taira"), were essentially samurai, warriors whose climb to power was accelerated by their function of providing troops for the Imperial guards or military and police supervision of outlying districts under Imperial rule.

Origins and first period of power. The clan had its origins in 825, at a time when government finances were at a low ebb and members of the Imperial line were numerous. In an attempt to eliminate some of the drain on the finances, collateral Imperial branches were given surnames (the Imperial family had none) and sent out into the provinces. The name of "Taira" was given to Prince Takamune, the son of Prince Kuzuhara and grandson of Kammu, the 50th emperor. His descendants were accordingly called Taira of Kammu. Takamochi, a nephew of Takamune, arrived in the Hitachi district (about 40 miles [60 kilometres] northwest of present-day Tokyo) as a local official and settled there. His descendants succeeded him in the post, and the family became powerful samurai in the district.

Taira Masakado

A great-grandson, Taira Masakado, acquired great power and soon governed the whole Kantō district. In 939, he established a government in the southern part of Kantō,

styling himself *shinnō* ("new emperor") in opposition to the Emperor in the capital at Kyōto, but was subdued in 940. In 1028, when Taira Tadatsune attempted to re-establish Taira domination over the Kantō, the court dispatched another warrior, Minamoto Yorinobu, to quell the rebellion, and three years later, Tadatsune surrendered. As a result the Taira family began to decline, and the Minamoto family, descendants of Seiwa, the 56th emperor, organized a big samurai group in Kantō, with the Tairas under them.

Second era of power. In later years the Fujiwara family, who, sharing power with the emperor, had monopolized the highest posts in the court from the mid-10th to the mid-11th century, began to decline. In the latter half of the 11th century, the emperor Shirakawa abdicated the throne in favour of his son and then introduced a new political system called *insei,* by which the former emperor, who was now freed from the ceremonial requirements of the Imperial office (but could count on the loyalty of his son the real emperor), was finally able to wrest the power of the throne away from the Fujiwaras. So as to retain absolute power, the former emperor Shirakawa summoned Taira Masamori, a descendant of the Taira of Kantō with considerable local power in the Ise (present-day Mie Prefecture) district, to suppress the Minamoto family, whose military strength had been helping to ensure the dominance of the Fujiwaras at court. Masamori's success was so absolute that he stood high in the former emperor Shirakawa's favour and won speedy promotion as a court official.

Masamori's son Tadamori continued his father's successes. By eliminating the pirates along the Inland Sea in western Japan, he curried Imperial favour.

Taira Kiyomori

Taira Kiyomori, the son of Tadamori and grandson of Masamori, continued to enlarge the family's holdings and to increase its influence at court, making a conflict between the Tairas and Minamotos inevitable. Finally in 1156 a dispute over control of the court between two brothers, the former emperor Sutoku and the reigning emperor Shirakawa II, resulted in the Hogen War between Kiyomori and the head of the Minamotos. Aided by the defection of a group of Minamoto warriors, Kiyomori emerged victorious. Three years later in the Heiji War of 1159, Kiyomori brutally eliminated those Minamotos who had sided with him in the Hogen War. After that Kiyomori became the most powerful figure in Japan. To complete his career he was in 1167 finally given the highest position of any court official, *dajo-daijin* ("prime minister"). Kiyomori also managed to marry his wife's younger sister to the former emperor Shirakawa II, whose son became the prince. Kiyomori thus became even more powerful than the former emperor.

The Taira family monopolized high positions as court officials, governing almost half of all the provinces and owning more than 500 manors. Kiyomori also made huge profits from trade with China. In 1179, the court nobles led by the former emperor Shirakawa II rebelled against him but were subdued, and Shirakawa II was imprisoned. As a result, Kiyomori's grip became positively dictatorial, the period being known as the "Rokuhara regime" since he lived at Rokuhara in Kyōto. In spite of his great powers, however, he failed to make any basic changes in the Imperial system. As a result, the Taira hold over the countryside weakened as the family became accustomed to the rich court life and lost touch with the provincial warrior groups.

Rise of the Minamoto family

In 1181, when Kiyomori died after an illness, movements were started against the tyrannical Taira clan all over the country. The strongest opposition was that of the Minamoto family, whose scion, Minamoto Yoritomo, living in Kantō, had been spared in the great conflicts of 1159 because of his extreme youth at the time. With the assistance of other samurai hostile to the Tairas, he rose in arms. When the Minamoto army advanced on the capital, the Tairas escaped from Kyōto and, taking the young emperor Antoku with them, attempted to establish themselves in their stronghold in western Japan. But they were defeated in two successive battles, one at Ichinotani, west of the city of Kōbe in Settsu Province, and the other at Yashima Island, along the Inland Sea in Sanuki Province (present Kagawa Prefecture). Forced to flee further west, the Taira family was finally completely destroyed in 1185 in the great sea battle of Dannoura, which occurred off the eastern end of the strait that separates Kyushu from Honshu. In this battle the emperor Antoku drowned, taking with him the great sword that was one of the Three Imperial Regalia, the symbols of divine authority that had supposedly been brought to Japan when the first emperor descended from heaven.

BIBLIOGRAPHY. For more information on the Taira family, see *The Heike Monogatari,* trans. by A.L. SADLER, *Transactions of the Asiatic Society of Japan,* vol. 46, pt. 2, and vol. 49, pt. 1 (1918–21); and CARL SPOHR, *Gempei: The Civil Wars of Old Japan* (1967).

(K.Ho.)

Taiwan

Taiwan (T'ai-wan in Pin-yin romanization) is an island off the southeast coast of the China mainland. Since 1949 it has been the seat of the government of the Republic of China (Nationalist China), which is located in the island's capital city of Taipei. In addition to the main island of Taiwan, Taiwan comprises 15 islands in the Taiwan group and 64 islands in the Pescadores Archipelago. The total area of Taiwan, including the islands, is 13,892 square miles (35,981 square kilometres). Of the total, the Taiwan island group accounts for 13,843 square miles, while the Pescadores Archipelago, located to the west of Taiwan, has an area of 49 square miles.

Taiwan is bounded to the north by the East China Sea, to the east by the Pacific Ocean, to the south by the Bashi Channel, which separates it from the Philippines, and to the west by Formosa (Taiwan) Strait, which separates it from the China mainland. Taiwan forms part of the great island system rimming the western Pacific Ocean. The origin of its Chinese name T'ai-wan (conventionally Taiwan) is not known; it is also often known as Formosa—meaning beautiful—a name given it by Portuguese explorers.

Since 1949 the Nationalist government on Taiwan has continued to claim jurisdiction over the China mainland, whereas the government of the People's Republic of China on the mainland has claimed jurisdiction over Taiwan; both governments are in agreement that the island is a part of China. (See the city article TAIPEI; for associated physical features, see CHINA SEA; PACIFIC ISLANDS; and PACIFIC OCEAN; for historical aspects, see CHINA, HISTORY OF.)

THE LANDSCAPE

The natural environment. *Relief features.* The island is formed by a great fault block trending north-northeast to south-southwest, which is tilted toward the west. Its eastern margin, facing the Pacific Ocean and often lined with cliffs, marks the edge of the continental shelf. Its western section is on the slope of the shelf as is the Formosa Strait, the shallower parts of which are only 320 feet below sea level. The coastline on the west is simple and straight, bordered with low sand dunes and lagoons. Deep-water ports are situated at Chi-lung (Kee-lung), at the northern tip of the island, and at Kao-hsiung, on the southwest coast.

The crest of the Chung-yang Shan-mo (Central Range) lies east of and parallels the island's axis. Scores of peaks rise above 10,000 feet, the highest being Hsin-kao Shan (Yushan) (13,113 feet [3,997 metres]). Around the mountainous area are numerous independent hills, with an average height of 5,000 feet.

The relief on the east is very steep and that on the west quite gradual. The terrace tablelands and alluvial coastal plains in western Taiwan form the principal area of dense population; most of the major cities are located there.

The rivers

Drainage and soils. The rivers, all of which rise in the Chung-yang Shan-mo, are short and subject to extreme variations in flow. They are mostly shallow or dried up in the dry season, while there are floods in the monsoon (rain-bearing wind) season. Lacking steady currents, most rivers are not navigable but are liable to cause

floods, especially in the plains, necessitating extensive drainage systems. The principal rivers are the Tan-shui Ch'i, which flows northward, and the Cho-shui Ch'i, which flows westward.

Soil of alluvial origin on the plains and in the valleys covers about one-fourth of the island and is its chief resource. The upland soils, subject to drastic erosion, are leached, acid, and infertile.

Climate. Taiwan straddles the tropical and subtropical zones and has warm summers and mild winters. The climate is moderated by the warm waters of the Kuroshio (Japan) Current. The summer is long, lasting from April until November (200 days or more). In cold months the mean monthly temperature is about 59° F (about 15° C). Beginning with April, the mean monthly temperature is above 68° F (20° C). The highest mean monthly temperature reaches 86° F (30° C) from June to September. Lowland Taiwan is frost free. The temperatures fall with altitude, and in winter the central mountains are covered with snow.

Mean annual precipitation is 102 inches, although in some years the precipitation in summer alone may exceed 200 inches. The upland area receives more rain than the lowlands, and the eastern part receives more than the western part. Rainfall is more even in the north. The precipitation in summer is about 80 percent of the annual total. There are more typhoons in July, August, and September than at other times; about 78 percent of the total occurs in these three months.

Vegetation and animal life. There are green plants on the plains all the year round. As the climate varies with altitude, so does the natural vegetation. Stands of mixed bamboo, palm, and tropical evergreen grow in the lowlands; subtropical evergreen forests including camphor

Total Taiwan	13,892†	35,981†	13,161,000†	15,130,000†

*Area and population figures include Yang-ming-shan special administrative district, which has been reported statistically with T'ai-pei municipality since 1967. †Figures do not add to total given because of rounding.
Source: Official government figures.

laurel are found from 2,000 to 6,000 feet; broadleaved evergreen forests of the temperate zone are represented by cedars, cypress, junipers, rhododendrons, maples, and cryptomeria (Japanese cedar) from 6,000 to 8,000 feet; and coniferous forests are found above 7,500 feet.

Animal life, similar to that of the southern Chinese mainland, includes deer, wild boars, bears, monkeys, goats, wildcats, and panthers. Birds include pheasant, geese, flycatchers, kingfishers, larks, and many other species. Fish abound in the coastal areas.

The landscape under human settlement. *Traditional regions.* Except for the aborigines, the inhabitants of Taiwan are the descendants of immigrants from the Chinese mainland. Settlement proceeded from the area around T'ai-nan, in the south, northward and from the coast inland. From the latter part of the Ming dynasty (early 17th century) until it was occupied by the Japanese in 1895, T'ai-nan was both the largest city and the capital of Taiwan. From T'ai-nan, development spread northward and southward. In the south, development spread from Kao-hsiung to P'ing-tung, 14 miles to the northeast, then to T'ai-tung, on the southeast coast, and Hua-lien, on the east central coast. In the north, it went up from Chang-hua, on the west central plain, to T'ao-yüan, on the northwest coast, Taipei, and I-lan, on the northeast coast. The principal regions are the Chianan plain, the earliest developed region; the Kao-ping plain, on the west coast; the Hengch'un peninsula, in the south; the Hua-tung valley, in the east; the Chang-hua plain; the Hsin-chu-T'ao-yüan terrace; the Taipei basin, the fertile northern portion of

the west-coastal alluvial plain; and the I-lan plain, an isolated alluvial lowland on the northeastern coast.

Rural settlement. The patterns of rural settlement are determined by two major factors—water sources and the availability of arable land. In the northern part where water sources are abundant and the terrain is hilly, there are scattered villages. In the southern part, where the plains are flat and water is scarce, the villages are compact. Where rice paddies are located on the plain, the villages are compact and densely populated as a result of the concentration of cultivation. Upland villages are usually less compact and more widely dispersed. Villages on coastal land also are less compact and more widely scattered than those where rice is grown.

Urban settlements. Because of the straight, unbroken coastline, the only ports are Kao-hsiung, in the south; Chi-lung (the port of Taipei), in the north; and Hua-lien, in the east. In former days there were ports along the west coast at Anp'ing, Lu-chiang, and Pei-chiang, but, because of the extension of the seashore, their harbours have been filled in, and they are no longer on the sea. Because of the constant changes in water level, most rivers are not navigable, and there are few towns along the riverbanks.

Railways and highways are the principal means of inland transportation, and many towns are established along the transportation lines. In the north, the municipality of Taipei is the centre of a well-developed urban region, including Chi-lung and T'ao-yüan. In the south Kao-hsiung is the centre of an urban region that includes T'ai-nan and P'ing-tung. Other urban areas are centred on Hsin-chu and T'ai-chung.

PEOPLE AND POPULATION

The population, as already mentioned, is predominantly Chinese, most of whom are the descendants of immigrants from the southeastern Chinese provinces of Fukien and Kwantung; in addition, after the transfer of the Nationalist government to the island in 1949, there was a sizable immigration from other parts of China. The aborigines, of Indonesian origin, number about 150,000, or about 1 percent of the total population, and live in the foothills and highlands, where many practice shifting (temporary) cultivation. All have undergone partial assimilation with the Chinese.

Principal dialects

Linguistic and other groups. The post-1949 immigrants were predominantly Mandarin speaking and, because of their prominence in the Nationalist government and of the prevalence of education under the Nationalists, Mandarin has become a principal language. Several other Chinese dialects are still spoken, however, including the southern Fukien dialect and the Hakka dialect of Fukien Province. There are also several aboriginal dialects. The so-called Taiwanese dialect comprises the spoken languages of the southern Fukien areas, such as Lung-ch'i Ch'üan-chou, and Hsia-men. The aboriginal dialects include Atayal, Seepeg, Saisiat, Bunun, Tsou, Kanabu, Saroa, I-Rutkai, II-Rutkai, Paiwan, Puyuma, Ami, and Yami.

Ethnic groups. The Chinese population of Taiwan is almost entirely composed of Hans. The aborigines are divided into nine families: the Atayal, Saisiat, Paiwan, Rutkai, Bunun, Tsou, Yami, Ami, and Puyuma. Among them the Atayals predominate, with about 40 percent of the total aboriginal population; next are the Paiwans, with about 30 percent; and the Bununs, with about 20 percent.

Religious groups. In addition to the forms of worship of the aborigines, many kinds of religion have been introduced into Taiwan from many parts of the world over the past 300 years. The many Chinese immigrants brought their religions, principally Buddhism and Taoism, with them. In 1622 the Dutch introduced Protestant Christianity; in 1624 the Spanish brought Roman Catholicism to the island; and later Japan introduced Shintoism there. In addition, Confucianism has immensely influenced the Chinese people of Taiwan in ethics, morality, and academic thinking.

The principal religions in Taiwan today, in addition to the form of worship of the aborigines, are Taoism and Buddhism. There are about 2,000 Taoist temples. The Buddhist Association of the Republic of China is located in Taipei, and Buddhist associations are to be found throughout the island; there are more than 3,000 Buddhist temples and about 5,750,000 devotees. Protestant Christians number about 320,000; they have about 1,000 churches. The Roman Catholics, for their part, number about 310,000 and have more than 660 churches. There are about 40,000 Muslims, who have about 12 mosques.

Demography. *Birth and mortality rates.* The total population of Taiwan in 1972 was 15,130,000. The population of Taipei was 1,865,000—about 12 percent of the total—but it included many rural people living within the official municipality. Taiwan has had a rapid rate of population growth. Its population density in 1972—1,089 persons per square mile—was one of the highest in the world. Since the government adopted a new population policy, the birth rate has dropped from 38 per 1,000 in 1947 to 26 per 1,000 in 1971. Due to improvements in medical treatment and public sanitation, the death rate has dropped markedly, to 4.8 per 1,000 (1971).

Growth and density of population

Immigration. The Chinese mainlanders who migrated to the island after 1949 numbered over 1,800,000 by 1970. There has been a noticeable population movement from rural areas to the towns. The most rapidly growing urban areas are Taipei, Kao-hsiung, T'ai-nan, Tai-chung, Taipei County, and T'ao-yüan County.

Population distribution. The distribution of Taiwan's population is influenced by the island's terrain. The coastal plains and basins in the west are agricultural areas in which the population is dense because of the development of transportation and irrigation. The population density in the western plains reaches about 2,560 persons per square mile. In the craggy terrain of the central and eastern mountains, the density of population is fairly low.

Demographic trends. The population of Taiwan is comparatively young, with 38.7 percent under 15 years of age. The annual rate of population increase dropped from 28 per 1,000 in 1964 to 21 per 1,000 in 1971 after the government advocated birth control and family planning in 1964. Deaths from disease and calamity had also declined by the early 1970s. Rate of increase is expected to decline to 18 per 1,000 in the 1980s, when the population is thought to increase at the rate of 326,000 a year.

THE NATIONAL ECONOMY

Agriculture, long the leading element in the national economy, is developed mainly on the western plains, while industry is concentrated largely in the areas surrounding the harbours of Chi-lung and Kao-hsiung. Marked industrial development, especially in the 1960s, resulted by the 1970s in a notable change—*i.e.*, from a predominantly agricultural to a predominantly industrial economy. Export trade, which, because of Taiwan's rapid economic growth, has gained an important position, had gradually centred about industrial products; among these the proportion of textile goods had increased sharply, while the proportion represented by machinery and electrical appliances had also increased.

Resources. Although more than 50 kinds of minerals have been found in Taiwan, total mineral resources are modest. Coal is the most important, reserves occurring near Taipei and in several other areas of the north amounting to about 254,000,000 tons. Deposits of copper and gold are found in the Taipei area. Iron and sand reserves are small. Sulfur and sulfur-pyrite reserves amount to about 2,500,000 tons, with deposits in Pei-t'ou, Chu-tzu-hu, Ten-shan, and Ho-shan-chun all located north of Taipei. Marble and limestone are abundant in Hua-lien on the east coast, which has reserves of 330,000,000 tons. Dolomite (limestone or marble rich in magnesium carbonate) is mostly deposited near Hua-lien. Petroleum, phosphorus, and natural gas exist in small quantities and occurrences of manganese, asbestos, talc, glass sand, and other minerals have been found. Salt is produced by the evaporation of sea water.

Mineral resources

Forests are most abundant in the high mountains. One of the natural resources of Taiwan is camphor laurel, from which a great deal of camphor is produced.

The total output capacity of the power stations in the early 1970s was 15,171,000,000 kilowatt-hours, 20 percent of which was produced by hydroelectric stations and 80 percent by thermal stations. A nuclear power plant was under construction early in the 1970s.

Sources of income. *Agriculture.* One-quarter of the total area in Taiwan is arable and fully cultivated. Sloping areas and dry riverbeds are also under cultivation, as also are the tidal lands in the west.

Rice cultivation

The single most important crop is rice, with a total planted area of about 1,000,000 acres, about 50 percent of the total cultivated area and including most of the irrigated portion. More than 60 percent of the paddy fields are double cropped and nearly two-thirds of the rice produced is higher-grade *pon-lai* rice, introduced by the Japanese. With improved farming techniques, including increased and more effective use of fertilizer, the production of rice per acre had increased more than 50 percent between the early 1950s and the early 1970s.

Sugarcane is another important agricultural product, with a total planted area of 235,000 acres. Tea plantations are mostly in the north. Hemp and jute are grown in the middle and eastern part, while a different variety of hemp is grown in the south. Increased production and consumption of wheat reflects the presence of more northern Chinese than in earlier days. Pineapple is one of the principal export products. The total volume of pineapple production was about 359,000 tons in the early 1970s. Fruits and vegetables, such as bananas, litchis, longans, peaches, watermelons, and oranges abound; all these fruits are canned for export. Most vegetables are produced in the central and southern regions and are sufficient to meet the consumption needs of the island.

Forests and fisheries. With many mountains, Taiwan has abundant timber. The Taiwan Forest Bureau, in charge of the national forest land, is responsible for the planting, protection, and logging of forests. The annual production of forest products, including plywood, reaches an average of about 1,200,000 cubic yards, exclusive of firewood. Inaccessibility, low quality, and high costs limit production and have made import of lumber necessary. Overcutting and lack of reforestation have resulted in erosion and destructive floods.

Fishery production has increased to over 650,000 tons annually. About 12 percent of this is produced by fish farming. The balance is caught in rivers and in coastal waters. The warm currents in the Pacific Ocean off the east coast provide good deep-sea fishing grounds, especially for tuna. The Taiwan Fishery Bureau was established to help develop the fishing industry, and the number of fishing vessels is increasing in the early 1970s.

Mining and quarrying. Annual coal production averages between 4,000,000 and 4,500,000 tons. Copper production is about 3,900 tons. Quarrying of marble exceeds 1,100,000 tons and of dolomite 55,000 tons. The Chinese Petroleum Corporation not only prospects for and produces crude petroleum but also refines crude petroleum imported from abroad. Annual production of crude petroleum is about 88,000 tons and that of natural gas about 1,200,000 cubic yards. Salt production is located mainly on the southwestern coast. Production varies considerably, mainly because of weather factors, but averages about 440,000 tons.

Government-owned enterprises

Manufacturing. Industrialization was begun by the Japanese, and its growth has been accelerated under the Nationalist regime. Government-owned manufacturing enterprises include aluminum, cement, coal, fertilizer, machinery, paper, and sugar. Textile manufacture, the leading industry, is largely privately owned. Food processing, chemicals, and chemical products, electrical appliances and equipment, and tobacco processing are also important, as are the production of glass, cement, leather goods, and rubber goods. Printing and publishing, especially the reprinting, without authorization, of trade books and textbooks and sets of reference works copyrighted in other countries, has flourished, although in the early 1970s the signing by the government of international copyright agreements was being mooted, and some publishers were adhering to them.

Foreign trade. Trade balances after World War II were generally unfavourable until the mid-1960s. As before the war, exports were principally agricultural products—for example, sugar and rice—accounting for 78 percent of total value in 1952. With the growth of industry, the relative importance of agricultural exports had declined. By the 1970s, although agricultural exports—especially fruits and vegetables, including bananas—were still important, manufactured goods accounted for more than 50 percent of foreign trade, led by textile yarns and fabrics, clothing, telecommunications equipment, and plywood. Imports were highly diversified, consisting of a variety of consumer goods and raw materials, including bauxite, lumber, rubber, chemicals, cotton, wool, and synthetic fibres and resins. The government has encouraged multilateral trade, and trade patterns are diverse, especially when compared with the prewar period when they were virtually limited to Japan. In the 1970s trade has been conducted with Japan, the United States, Hong Kong, South Vietnam, West Germany, and other countries.

Management of the economy. *The private sector.* The government has established an advisory committee that is responsible for overseeing production; its main purpose is to promote foreign sales. There is only one organ of cooperative financing—the Cooperative Bank of Taiwan, jointly owned by the government and cooperatives. In addition there are four private commercial banks. Most of the public enterprises are being gradually opened to private operation, except for certain government monopoly businesses.

The public sector. Since 1953 the government has promulgated successive four-year economic development plans to spur industrial expansion and economic growth. Ten enterprises, in the fields of sugar, electricity, petroleum and natural gas, fertilizer, caustic soda, aluminum, copper, shipbuilding and repairs, and railways, are government monopolies under the Ministry of Economic Affairs.

In order to promote economic development, the government controls and helps private enterprises to employ new techniques and locate foreign investment. Most manufacturing industries receive technical cooperation from foreign companies.

Taxation. Taxes in Taiwan include income, legacy, commodity, stamp, stock, farm, land, increment on land value, and business taxes. Taxes are levied according to a progressive rate; people with small incomes pay little tax.

Trade unions. The Chinese Federation of Labor (CFL) is a nationwide organization of industrial and craft unions. Five other national labour organizations include those for seamen, railway workers, postal workers, miners, and salt workers. There are local unions in all factories, transportation and public utility units, and occupational and vocational groups.

Problems and prospects. Because Taiwan is an island and thus limited in resources and in domestic market, it must exchange goods with other countries and exploit overseas markets in order to support mass production and cut down its production costs. Although labour costs are low, shortages of labour in the future could result from success in achieving rapid economic growth. If Taiwanese society remains stable and production quality is improved, prospects for economic growth are promising.

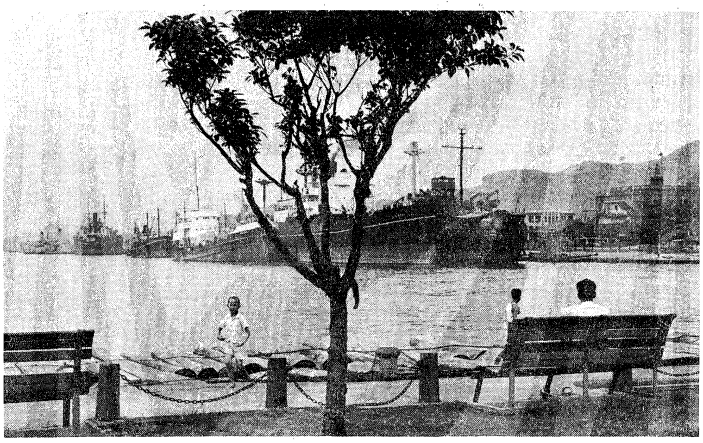
Transportation. External transport links are by air and sea. Railways and highways for internal communications are well developed.

Road networks

The well-built road networks have a total length of about 10,000 miles. The principal roads consist of a highway running around the island and three east–west highways crossing the island in the northern, middle, and southern regions of Taiwan. A north–south expressway was under construction in the 1970s. Passenger-bus transportation connecting large cities and small towns throughout the island is provided by the Taiwan Highway Bureau and private transportation companies provide both passenger and freight service. In large cities there are public buses as well as private buses and taxis. Few people own cars, but many have motorcycles.

Railways, operated by the Taiwan Railway Administration, have a total track length of about 1,000 miles, including 140 miles of double track. The main lines include those from Chi-lung, in the north, to Kao-hsiung, in the southwest; from Chi-lung to Su-ao, in the northeast; from Kao-hsiung to Fang-liao, in the south; and from Hua-lien, in the east, to T'ai-tung, in the southeast. Private railroads, including those belonging to sugar, forestry, and salt enterprises, total about 2,000 miles; they also carry a small number of passengers.

Quentell Violett—Black Star



Chi-lung harbour, the port of Taipei, with facilities to accommodate ships up to 20,000 gross tons.

The international seaports are Chi-lung, in the north; Kao-hsiung, in the south; and Hua-lien, in the east. Chi-lung is the port for Taipei city, while Kao-hsiung is an industrial port. Both cities have good facilities for anchoring large ships. Hua-lien, with facilities that are considerably more limited, has been open as an international port since 1963.

Civilian airports include Taipei International Airport, in the north; Kao-hsiung Airport, in the south; and Hua-lien Airport, in the east. Civilian air transports to T'ai-nan, T'ai-chung, T'ai-tung, and P'eng-hu are permitted to use the military air bases in those areas. From Taipei International Airport service is available to the United States and many Asian cities. Two Airlines provide several round-trip flights daily between Taipei and Hua-lien Kao-hsiung, P'eng-hu, Tai-nan, and Tai-chung.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. *Constitutional framework.* The central government of the Republic of China combines the Cabinet and presidential systems of government. The president is the supreme leader of the nation. Under him there are five independent *yüans* (councils)—executive, legislative, judicial, examination (fulfilling civil service commission functions), and control (an investigative agency).

Regional, state, and local government. According to the constitution of the Republic of China, all levels of local government below the provincial level have self-government—Taiwan having the status of a province of the republic. The provincial government is headed by a governor and has a secretariat, with a secretary general, consisting of departments, bureaus, and offices in charge of various governmental functions. The provincial government council consists of 21 members selected by the national executive *yüan* and appointed by order of the president.

The provincial government

Under the control of the provincial government, there are 16 counties (*hsien*) and five municipalities (*shih*). Eight municipalities are under the control of county governments. County governments are headed by magistrates and cities by mayors, both elected for four-year terms, as are the county and city councils.

Taipei (*q.v.*) became a special municipality under control of the executive *yüan* in 1967; it has a position equal to that of the Taiwan provincial government.

The political process. The president is elected by the National Assembly, which is composed of delegates elected from each county (or the equivalent) throughout the country. The president of the executive *yüan* is nominated by the national president with the consent of the legislative *yüan*, which is composed of the members elected by the people. The presidents of the judicial *yüan* and the examination *yüan* are also nominated by the national president with the consent of the control *yüan*. The president of the control *yüan* is elected by the provincial and municipal councils. According to the constitution, suffrage in all local elections is universal, equal, direct, and secret.

There are three parties: the Kuomingtang (Nationalist), the Young China Party, and the Democratic Socialist Party. The Kuomingtang, the oldest among the three parties, has been the ruling party since the establishment of the Republic of China; it was founded in 1894. According to the constitution of the Republic of China, citizens have the powers of election, recall, initiative, and referendum. The rights of initiative and recall have, however, been suspended, and the National Assembly exercises these rights on behalf of the people.

Justice. The judicial *yüan* is the highest organization of the nation. Under its control are the three principal judicial organizations—the Supreme Court, the Administrative Court, and the Committee on Discipline of Public Functionaries. In addition, there are district courts in the districts and autonomous regions and high courts in provinces, or special areas.

The armed forces. The armed forces include the air force, army, navy, combined service force, military police, and garrison force. The army has a strength of 390,000 men, equipped and trained by the United States; the navy has a strength of 35,000 naval personnel and 35,000 marines; and the air force has a personnel of 80,000. All of the military units are said to be well trained and fully equipped. The armed forces are under the administration of the Ministry of National Defense. The president is the supreme commander of the national armed forces.

The social milieu. *Education.* The educational system is divided into three stages: national education, middle education, and higher education. There is also preschool education (kindergarten) and social education, including adult education and special education.

National education is compulsory for nine years (six years in primary school and three years in junior middle school); middle education includes middle schools, normal schools, and vocational schools; higher education includes graduate schools, universities, colleges, and junior colleges. There are over 90 institutions of higher education, more than half of them private. The two largest are the National Taiwan University (founded 1928) at Taipei and National Chung Hsing University (founded 1961) at T'ai-chung.

Health and welfare. In the early 1970s there were more than 100 private hospitals, as well as a considerable number of public hospitals, including four general hospitals and five specialist hospitals in Taipei. There are also about 350 county sanitariums. Government sources state that all the hospitals and sanitariums are well equipped.

Housing. To meet the needs of population growth and urban development, the government has built apartments that are sold to the public by means of long-term, low-interest loans. The government provides houses for the poor without charge.

Police. Under the control of the provincial police department, every municipality or county has its own police unit for traffic regulation, maintaining order, dealing with emergencies, such as fires, handling criminal cases, preventing smuggling and larceny, and protecting alien residents.

Living conditions. Taiwan has a stable, prosperous society. Individual income has increased every year. Wages in Taiwan are comparatively low, however, and food expense accounts for a large percentage of the cost of living. National savings have increased rapidly.

The national constitution provides that "cooperative enterprises shall receive encouragement and assistance from the State," and there are agencies at all government levels to assist such enterprises. Regional cooperatives are organized to serve rural districts, villages, or townships. Specialized cooperatives include those for agricultural and industrial production, marketing, rental service (*e.g.*, agricultural machinery), labour, transportation, public utilities, procurement and consumption, credit, and insurance. In addition, there are over 200 cooperative farms, and the number of cooperatives grew from fewer than 500 in 1947 to almost 3,000 early in the 1970s.

Cooperatives

After years of effort, Taiwan has greatly improved public health conditions. As of 1970, the average life span was 69 years for females and 65 years for males. There have been no international quarantines of outbreaks of contagious diseases in Taiwan in recent years. Malaria was eliminated by 1965.

Cultural life and institutions. Chinese culture is predominant. Fine arts, surviving national folk traditions, and popular culture include Chinese painting, and Chinese music. Popular musical instruments include the fiddle, lute, flute, and zither. Dances include court dances, aboriginal dances, and Chinese folk dances. Theatre includes traditional Chinese opera, Taiwanese operas, which are mostly copied from the Chinese opera and use the Fukien dialect instead of Mandarin, and modern drama presented on the stage as well as over radio and television. Puppet shows are popular. Taiwan rivals Hong Kong in the making of Chinese motion pictures. Taiwanese handicrafts are prized for their beauty.

The cultural bureau of the Ministry of Education is in charge of the administration of cultural affairs. The National Palace Museum collection includes ancient Chinese paintings and books, pottery, porcelain, curios, and sculptures. The Art House in Taiwan holds art exhibitions and has a stage for drama and dance performances.

The media

There are about 30 daily newspapers, two of which are English language publications; 16 daily papers are published in Taipai and the rest in other major cities. There are about 1,000 periodicals, most of them house organs of various organizations. There are about 30 radio broadcasting stations; the three television stations include the Taiwan Television Enterprise, the China Television Company, and the Chunghua Television Service. Many of their programs are in colour. The Chunghua Television Service also features educational programs.

Prospects for the future. Taiwan is one of the most strategically important islands in the western Pacific; its future political role is certain to be of significance.

The government of Taiwan has proclaimed the recovery of the Peoples' Republic of China to be a matter of national policy. It thus devotes a large part of the national budget to military expenditures. Nevertheless, the growth rate of the economy in the early 1970s was keeping pace with the growth of the population. Grain crops were sufficient to supply the needs of the population, and, in addition, the government is continuing to take effective measures to improve fertilization and irrigation techniques and to develop new strains of seeds. Industry has continued to develop, both with domestic capital and foreign investment. In consequence, Taiwan has become a self-supporting country that is no longer dependent on foreign aid and that is an exporter of technical skills, particularly to developing countries in Asia and Africa.

BIBLIOGRAPHY. CHENG-SIANG CHEN, *A Geography of Taiwan*, 2 vol. (1960), fully illustrated, is a valuable reference. CHIAO-MIN HSIEH, *Taiwan-Ilha Formosa* (1964), deals with the land and people of the island. The *National Atlas of China*, vol. 1, *Taiwan*, ed. by CHI-YUN CHANG, (1963), has detailed statistical maps. The *China Yearbook* (annual), ed. by the INFORMATION BUREAU OF CHINA, treats Taiwan from various aspects, especially administration. The *Taiwan Statistical Data Book* (annual), published by the TAIWAN PROVINCIAL GOVERNMENT, is an authoritative official source. Of special interest are MEI-LING HSU, *Taiwan Population Distribution, 1965* (1969); and *Industry of Free China* (monthly), which reports economic developments.

(Y.-c.K.)

Takla Makan Desert

A desert of Central Asia and one of the largest sandy deserts in the world, the Takla Makan (Ta-ko-la-ma-gan in Chinese Pin-yin romanization) occupies the central part of the Tarim Basin in China. The desert area extends about 600 miles from west to east, and it has a maximum width of 260 miles and a total area of about 105,000 square miles (270,000 square kilometres). The desert reaches altitudes of 3,900 to 4,900 feet in the west and south and from 2,600 to 3,300 feet in the east and north.

For associated physical features, see KUNLUN MOUNTAINS; PAMIR MOUNTAIN AREA; TIEN SHAN (MOUNTAINS); and TARIM RIVER.

Physical characteristics. The Takla Makan is flanked by high mountain ranges: the Kunlun in the south, the Tien Shan in the north, and the Pamirs in the west. There is a gradual transition to the marshy Lop Nor (Lop Lake) Basin in the east, and, in the south and west, between the sandy desert and the mountains, lies a band of sloping desert lowland composed of pebble-detritus deposits.

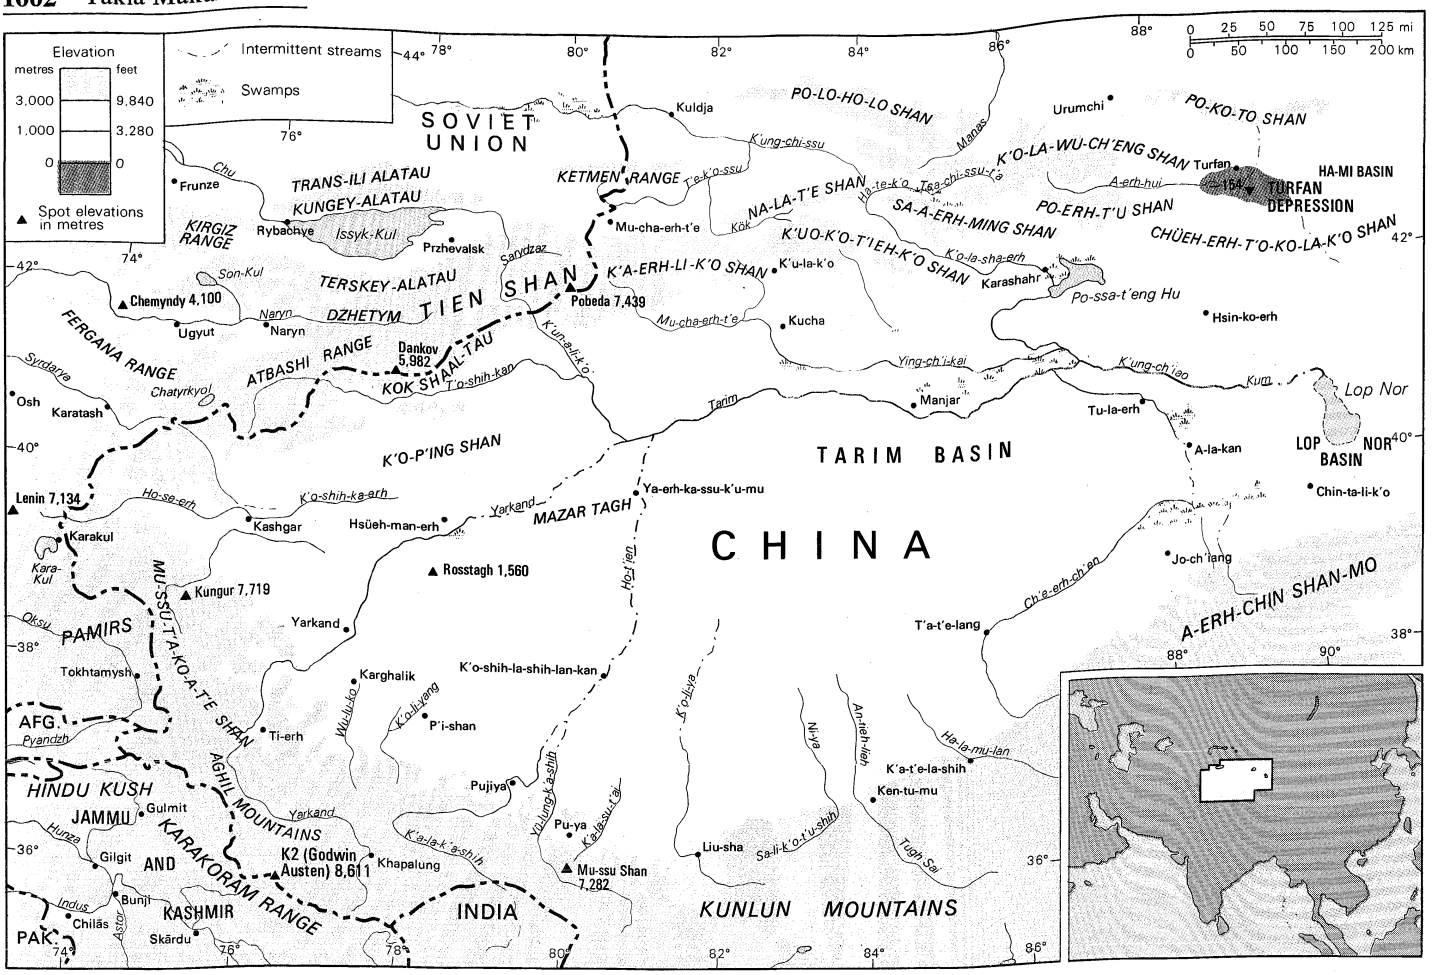
Several small mountain ranges and chains, composed of sandstones and clays from the Paleogene and Neogene periods (10,000 to 65,000,000 years ago), rise in the western part of the desert. The arc-shaped Mazar Tagh (Mazar Mountains), located between the Ho-t'ien Ho (Ho-t'ien River) or Khotan Darya (Khotan River) and the Yarkand River valleys, arch toward the southwest. Ninety miles long and from two to three miles wide, with a maximum height of 5,363 feet, they rise an average of only 1,000 to 1,150 feet above the surface of the sandy plain. The Chiao-lo Shan (Chöl Tagh) is also an insular range, surrounded on all sides by massifs of moving sands. Rosstagh, also known as Tokhtakaz Mountain, its highest peak, is 5,117 feet (1,560 metres), and the range rises from 600 to 800 feet above the plain. Both ranges are covered by a shallow mantle of eluvium and rock debris and have sparse, desert-type vegetation. In the north, the sands of the Takla Makan form a clear boundary with the vegetated Tarim River Valley.

The general slope of the plain is from south to north, and thus the rivers running off from the Kunlun Mountains flow in this direction. The Ho-t'ien and K'o-li-ya (Keriya) river valleys have survived up to the present, but a majority of the shallower rivers have been lost in the sands, after which their empty valleys fill up with windborne sand.

Wind-formed surface features

The surface of the Takla Makan is composed of friable alluvial deposits several hundred feet thick. This alluvial stratum has been affected by the wind, and its wind-borne sand cover is as much as 1,000 feet thick. There is a variety of eolian (wind-formed) topographic features, and sand dunes of various shapes and sizes are encountered. These eolian sand dunes were formed through the weathering of the alluvial and colluvial deposits of the basin and of the foothill plains of the Kunlun and eastern Tien Shan. The size of the larger sand-dune chains is considerable: they range from 100 to 500 feet high and 800 to 1,650 feet wide, with a distance between the chains of from one-half to three miles. The highest eolian topographic forms are the pyramidal dunes, rising 650 to 1,000 feet. In the eastern and central parts of the desert, networks of hollow dunes and large, complex sand-dune chains predominate. They are also common in the western portion of the desert (east of the Ho-t'ien Ho Valley), where transverse and longitudinal (with respect to the wind) topographic forms coexist. On the edge of the desert, semipermanent, clustered sand dunes with tamarisk and niter-bushes, as well as clayey regions with disconnected sand dunes, predominate. Such a diversity in wind-formed features is a result of the complex wind conditions of the basin.

Climate. The Takla Makan's climate is moderately warm and markedly continental, with a maximum annual temperature range of 70° F (21° C). Precipitation is very low, ranging from 1.5 inches in the west to 0.4 inch in the east. The air temperature in the summer is high, rising as high as 100° F (38° C) on the eastern edge of the



The Takla Makan Desert.

desert. In July the average air temperature reaches 77° F (25° C) in the eastern regions. Winters are cold: in January the average air temperature is 16° to 14° F (−9 to −10° C), and the low in winter is generally below −4° F (−20° C). Northerly and northwesterly winds predominate in the summer in the western region. These two air currents, on meeting near the desert's centre at the end of the K'o-li-ya Ho, create a complex circulation system that is clearly reflected in the topography of the sand dunes. In the spring, when the surface sand becomes warm, ascending currents develop, and northeasterly winds become particularly strong. During this period hurricane-force dust storms, filling the atmosphere with dust to altitudes of from 11,500 to 13,000 feet, often occur. Winds from other directions also raise clouds of dust into the air, covering the Takla Makan with a shroud for almost the entire year.

Hydrology. Since the Tarim depression is an internal-drainage basin, the entire runoff from the surrounding mountains collects in the basin itself, feeding the rivers and the groundwater strata. In all probability, the groundwater table under the sands has an unbroken course, flowing west to east to Lop Nor. The importance of rainfall in moistening the sands and feeding the groundwaters is slight, due to its small quantity and high rate of evaporation. The rivers draining the Kunlun Mountains penetrate from 60 to 120 miles into the desert, gradually drying up in the sands. Only the Ho-t'ien Ho crosses the desert and, in July and August, occasionally carries its waters to the Tarim River.

The groundwater table

Vegetation and animal life. Vegetation is very sparse in the Takla Makan—almost the entire territory is devoid of plant cover. In depressions among the sand dunes, where the groundwaters lie no deeper than 10 to 16 feet from the surface, thin thickets of tamarisk, niter-bushes, and reeds may be found. The thick strata of moving sands, however, prevent the wider spread of this vegetation. Along the edges of the desert, in the area where the sand dunes meet the river valleys and deltas and where the groundwaters lie comparatively close to the surface, the vegetation is richer. Here, in addition to the plants mentioned above, a number of species characteristic of river valleys are found: Turanga poplar, oleaster, camel thorn, Zygophyllaceae (caltrop family), and saltworts. Sand dunes in hummocks frequently form around the scrub.

The animal life of the Takla Makan is also very sparse. Only in peripheral regions of the desert, in ancient and modern river valleys and deltas where water and vegetation appear, are the fauna more diverse. Herds of gazelles are found in open spaces, and there are usually wild boars inhabiting thickets of bulrushes and reeds in the river valleys. Wolves and foxes are among the carnivores. As late as the beginning of the 20th century, tigers could be found, but they have since been exterminated. Rare animals include the Siberian deer, which inhabits the Tarim River Valley, and the wild camel, which at the end of the 19th century roamed over a considerable portion of the Takla Makan as far as the Ho-t'ien Ho but now appears only occasionally, in the eastern desert region.

There are a large number of rabbits, sand eels, field mice, and jerboas in the sand dunes, and, among insectivores, the long-eared hedgehog and bats are common. Small, tufted larks and the Tarim jay are the commonest birds.

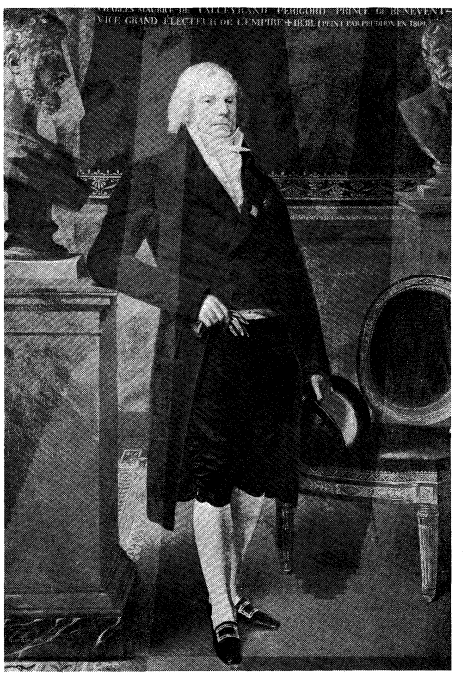
There is no fixed population in the Takla Makan. Hunters make periodic visits, but the area territory is not used by stock breeders because of the almost complete absence of vegetation.

Indications of the presence of petroleum have recently been found in the two regions—Kashgar–Khargalik at the western part of the Tarim Basin and Aksu Kucha at the northern edge of the basin. (M.P.Pe.)

Talleyrand

Charles-Maurice de Talleyrand-Périgord, a French statesman and diplomat notable for his capacity for political survival, held high office during the French Revolution, under Napoleon, at the restoration of the Bourbon monarchy, and under Louis-Philippe. As Louis XVIII's delegate to the Congress of Vienna, his skill in dividing the four allies, who had defeated Napoleon, won for France an effective voice in the settlement of Europe.

Giraudon



Talleyrand, portrait by P.P. Prud'hon, 1809. In a private collection, Paris.

EARLY LIFE

Education. Talleyrand was born in Paris on February 2, 1754, the son of Charles-Daniel, comte de Talleyrand-Périgord, and of Alexandrine de Damas d'Antigny. His parents came from old, aristocratic families but were not rich. Charles-Maurice was sent to be nursed in a Paris suburb, where, when he was four years old, he is said to have fallen off a chest of drawers, dislocating his foot. It is possible, however, that his clubfoot was congenital, linked, perhaps, to a brain disorder. At any rate, Talleyrand's clubfoot was of cardinal importance in his choice of career. As he could not follow the family tradition by going into the army, his parents intended him for the church. From the age of eight he was a pupil at the Collège d'Harcourt in Paris, and at 15 he became an assistant to his uncle Alexandre, then coadjutor to the archbishop of Reims, in the hope that the luxurious life led by the princes of the church would awaken in him a taste for an ecclesiastical career. He liked what he saw, and in 1770 he entered the seminary of Saint-Sulpice in Paris. There, he certainly learned theology; but he also read, in the seminary's large library, the works of the Philosophes, the contemporary progressive thinkers. Thus he began his political education and acquired a skepticism regarding men and affairs that was never to leave him. In addition, while still a seminarian he took his first mistress.

Clerical career. Expelled for his conduct (1775), he nevertheless received minor orders in April of that year and was, six months later, nominated by the King as abbot of Saint-Denis, at Reims. In March 1778 Talleyrand received his degree in theology from the Sorbonne, and in December 1779 he was ordained. The following day his uncle Alexandre, now archbishop of Reims, appointed him his vicar general.

At that time Talleyrand appeared to be a typical court cleric, spending more time with the most fashionable wits and beauties of the day than with churchmen. Yet he did not devote all his time to pleasure; he believed in his future and desired above all to become a bishop. The surest way to his goal was appointment to the well-paid post of agent general of the clergy, who represented the French church in its dealings with the French government in the interval between meetings of the Assembly of the Clergy, which were held regularly every five years. Talleyrand was appointed agent general in 1780. There were in fact, two agents general; but his colleague's reputation had been undermined by a notorious scandal, and Talleyrand was in practice the sole representative of the French church between 1780 and 1785. He seems to have taken his role very seriously: in any case, he showed great energy in defending the most archaic as well as the most controversial privileges of the church. He fought vigorously for the right of the church to retain all its property and did his best to smother discussion of the question (which had arisen in the Habsburg Empire) of whether the church should sell part of its property in order to relieve the state's financial distress. He also tenaciously defended ecclesiastical jurisdiction against the encroachments of royal justice, argued for the continued exemption of the clergy from ordinary taxes, and played a part in raising the standard of living of the lower clergy. His activities brought him into regular contact with various ministers of the crown. His participation in the meetings of the Assembly of the Clergy gave him an exceptional opportunity to acquire parliamentary experience. Finally, his activities won him the coveted bishopric: in November 1788 he was appointed bishop of Autun. When he took possession of his see on March 15, 1789, the Revolution was an the verge of breaking out.

Appointment as agent general of the clergy

CAREER AS STATESMAN AND DIPLOMAT

During the Revolution. His first task was to prepare the elections to the States General, the National Assembly in which the Estates (nobility, clergy, and Third Estate) were separately represented. The assembly had not met in France since 1614 and was now summoned for May 5, 1789. Talleyrand, elected by his clergy as their deputy, like all delegates had prepared a list of grievances. His list contained demands for reforms in the status of the clergy as well as for a constitution that would provide a genuine representative government guaranteeing equality for all citizens, especially fiscal equality, thus abolishing those financial privileges that he had defended four years earlier. This was the first of a long series of reversals that were to be characteristic of his career.

At the solemn opening of the States General at Versailles, Talleyrand was described by a witness as having "an angelic face animated by a diabolical spirit." The parliamentary experience he had gained at the meetings of the Assembly of the Clergy stood him in good stead: he immediately attracted attention and soon acquired great influence. During the earlier deliberations, the clergy and the nobility wanted to sit in separate chambers, as they had in 1614; Talleyrand, however, favoured uniting the three orders into one National Assembly, and this proposal was accepted on June 27.

To the great astonishment of his fellow bishops who remembered the zeal with which he had defended the church's rights in 1780 and 1785, Talleyrand, during the famous night of August 4, when the abolition of feudalism was voted, urged the repeal of the tithe. The speech created a sensation, foreshadowing his proposal, on October 10, 1789, to nationalize French church property (amounting to about 15 percent of the territory of France). The land thus appropriated was to be used to pay off the state's debts. When nationalization was voted on November 2, Talleyrand emerged as one of the most revolutionary deputies. Many other signs confirmed the revolutionary position adopted by the "limping devil." In addition to proposing the introduction of a new, uniform system of measures, the decimal system, he also drafted a plan that abolished the old system of education. When he celebrated mass at the Festival of the Federation on July 14, 1790, in commemoration of the taking of the Bastille

Advocacy of abolition of ecclesiastical privileges

the year before, he seemed the veritable "bishop of the Revolution." The same month Talleyrand succeeded in having the Civil Constitution of the Clergy adopted, which, without papal approval, completely reorganized the French church on a democratic basis. The first bishop to take the oath of loyalty to this constitution, he also consecrated the first bishops elected according to the new procedure. The resulting excommunication by the pope did not distress Talleyrand, who was already planning to leave the church. It no longer offered sufficient scope for his ambition, and, since, under the law expropriating the church he had been deprived of his property, a bishopric could no longer satisfy his monetary needs. Elected administrator of the *département* of Paris in January 1791, he resigned as bishop of Autun. On the death some weeks later of the comte de Mirabeau, the most influential deputy in the National Assembly, Talleyrand, the only member with a comparable reputation, had hoped to replace Mirabeau as secret counselor to Louis XVI. He was, however, deprived of the opportunity by the royal family's unsuccessful flight in June and the dissolution of the National Assembly in September.

Civil servant and diplomat

As deputy to the National Assembly, Talleyrand was not eligible for re-election to the assembly replacing it, the Legislative Assembly. Yet his skill as a clever negotiator had been noted, and when at the close of 1791 the French government wanted to prevent England and Prussia from joining Austria in a coalition against France, the foreign minister decided to send Talleyrand to London to persuade England to remain neutral.

Arriving in London in January 1792, Talleyrand proposed to William Pitt, the prime minister, that both countries should guarantee each other's territorial integrity: France specifically recognizing British sovereignty in Ireland and India. Returning to Paris in March without a definite answer from the British, Talleyrand persuaded Charles-François Dumouriez, the new foreign minister, to appoint the young Marquis de Chauvelin as ambassador to London, and returned there as his assistant. The two men arrived in London on April 29, just after France had declared war on Austria, with whom Prussia immediately allied itself. Although Talleyrand secured a declaration of neutrality from the British government on May 25, the storming of the Tuileries palace by the Paris mob on June 20 made his position difficult, and he left London on July 5. The overthrow of the monarchy on August 10 and the massacre of royalist prisoners in September alienated what sympathy the London government had for France and, at the same time, made it advisable for Talleyrand—suspected as a lukewarm revolutionary by the extremists—to leave Paris. After drafting—as a pledge of loyalty to the Provisional Executive Council—a circular to all European governments attributing responsibility for the events of August 10 to Louis XVI, he obtained a passport to go to London in a private capacity. Arriving on September 18, he made every effort to avert war with Great Britain, but the invasion of Belgium by the French, opening the Scheldt Estuary to international shipping (November 1792), followed by the execution of Louis XVI in January 1793, made war inevitable. Talleyrand, who had been denounced in the National Convention (the assembly elected after the overthrow of the monarchy) for conducting a secret correspondence with Louis XVI, also became undesirable in England, where the most counterrevolutionary of the French émigrés were demanding his expulsion. Expelled in January 1794, he embarked for the United States in March. He remained there for two years, engaging in profitable financial speculations that enabled him to rebuild his fortune.

Foreign residence

During the Directory. After the fall, in July 1794, of Maximilien Robespierre, the chief instigator of the Reign of Terror, Talleyrand petitioned the National Convention to remove his name from the list of émigrés, as he had left France on an official passport. His request was granted in September 1795, but he did not reach Paris until September 1796. As soon as he arrived he took his seat in the Institut National (a creation of the National Convention re-establishing, in a new form, the 18th-century academies, among them the Académie Française), to which he had been elected during his absence. The paper that he read there in July 1797, in which he concluded that France would be unable to reconquer its American colonies and should therefore attempt to establish colonies in Africa, particularly in Egypt, showed that he again hoped to enter politics. A few days later, his paper, which raised him in public esteem, and his connections with a member of the Directory governing France at the time gained him the post of foreign minister, although the four other members of the Directory did not favour him. Talleyrand's position was confirmed a few weeks later by the coup d'etat of September 4, 1797, as a result of which the two directors most hostile to him were dismissed.

As foreign minister Talleyrand confirmed Napoleon's conclusion of the Treaty of Campo Formio (October 1797) following his great victories against Austria. Talleyrand negotiated the agreements annexed to the treaty, which are said to have brought him more than a million francs in bribes. Jointly with Napoleon he urged on the Directory his idea of a military expedition to Egypt (May 1798). Led by Napoleon, the expedition, after brilliant initial successes, ended in failure. Talleyrand alone, however, was responsible for a breach between France and the United States, following the indignant withdrawal of three American envoys from whom Talleyrand had demanded enormous bribes. They had come to Paris to negotiate a treaty to replace the one of 1778, but the breakdown in negotiations led to an undeclared war between the United States and France. Moreover, the failure of the Egyptian expedition had resulted in the formation of a new coalition against France composed of England, Austria, Russia, and Turkey. Acknowledging the failure of his policies, Talleyrand resigned on June 20, 1799. After two years as foreign minister he had, by various means, amassed, as he put it, an "immense fortune" of more than three million francs, which he deposited abroad.

Partnership with Bonaparte

During the Consulate and the empire. Five months after Talleyrand's resignation, Napoleon returned from Egypt, and, following his coup d'etat of November 9–10, 1799, established the Consulate, consisting of him as the actual ruler and two other consuls. Talleyrand supported him and returned to the foreign ministry on November 22. He was to stay there until 1807. Talleyrand's principal aim was the pacification of Europe, and he immediately began negotiations with the belligerent nations. Operating from a position of strength after Napoleon's victories in Italy and in Germany, his negotiations with Austria were the first to result in a peace treaty, signed at Lunéville on February 9, 1801. Negotiations with England, in which Talleyrand played a less direct part, led to the Treaty of Amiens (March 27, 1802). For the first time in six years, Europe was at peace. Talleyrand contributed to the realization of Napoleon's ambitious plans to remodel Europe by helping him to establish French supremacy in Italy, Germany, and Switzerland. At the meeting of leading members of the Cisalpine Republic at Lyons early in 1802, he engineered various changes in the republic's new constitution (including changing its name to the more promising one of Italian Republic) and the election of Napoleon as its president. Talleyrand was also the chief author of the treaty of 1803, which extensively altered Germany's political geography. Much to his own profit, he supervised the allocation of numerous secularized church lands as compensation to those princes who had lost to France territory on the left bank of the Rhine.

Return to foreign ministry

At home Talleyrand used his influence to facilitate the return of émigrés and priests who had refused the oath of loyalty to the various constitutions since 1790 and urged the signing of the Concordat between Napoleon and Pope Pius VII (July 1801), which re-established religious peace. Then, taking advantage of the Concordat's provisions, he married his mistress, Madame Catherine Grand, the divorced French wife of an English employee of the British East India Company.

Talleyrand's policy would have been completely successful had he been able to prevent the renewal of war between France and England in May 1803. This time,

however, he did not resign. He had helped Napoleon establish himself as "consul for life" in 1802, and he continued to support him when, after the resumption of the war, Napoleon wanted to show, by means of some striking action, that he would never come to terms with the Bourbons. And so Talleyrand participated in one of the most dreadful crimes with which Napoleon has ever been charged. When Talleyrand and Joseph Fouché, the minister of police, learned that a Bourbon prince, whom they believed to be Louis-Antoine-Henri de Bourbon-Condé, duc d'Enghien, was planning the assassination of the First Consul, they advised his abduction. Although the duke was living in neutral territory, in the duchy of Baden, Talleyrand promised that he would smooth over any protests resulting from the violation of international law. And so the Duc d'Enghien was kidnapped, arrested, and transferred to Paris, where he was tried, condemned to death, and executed (March 21, 1804). Later, Talleyrand tried to remove from the archives documents proving his involvement in the death of the Duc d'Enghien. It was this crime that consolidated Napoleon's power, and when on May 18, 1804, he was proclaimed emperor, he appointed Talleyrand grand chamberlain of the empire, with an annual income of 500,000 francs. Later, Talleyrand was also appointed to the sinecure of vice elector; finally, on June 5, 1806, he became prince and duke of Benevento (a city in southern Italy that had been seized from the papacy).

Murder of the Duc d'Enghien

Nevertheless, after 1805 Talleyrand's influence diminished. He failed to persuade Napoleon to conciliate Austria after his victory at Austerlitz or to preserve the Holy Roman Empire, which was replaced by the Confederation of the Rhine and the Austrian Empire. In 1806, the negotiations he had opened with a view to restoring peace with England broke down, and a Franco-Russian peace treaty signed in Paris by Talleyrand and by the Russian ambassador was repudiated by the Tsar. When France's war with Russia and Prussia was finally ended by the Treaties of Tilsit (July 7 and 9, 1807), Talleyrand had no part in the negotiations. Alarmed by Napoleon's insatiable ambition, which, as he clearly saw, could lead only to disaster, he resigned his office in August 1807. It was not without pleasure that Napoleon accepted it. He had received innumerable complaints about Talleyrand's venality and, even was beginning to doubt his loyalty.

Between empire and restoration. Though no longer a minister, Talleyrand was still consulted by Napoleon, and it seems likely that he did not advise against the French invasion of Spain. In September 1808 Talleyrand accompanied Napoleon to a congress of European sovereigns at Erfurt. There Talleyrand had secret talks with Tsar Alexander I, urging him to oppose Napoleon, and thereafter conducted a clandestine correspondence with both Russia and Austria. This treasonable activity did not, in fact, involve Talleyrand in any great risk, since it was approved by Fouché, the minister of police, who shared Talleyrand's opposition to Napoleon's policies.

After Napoleon had divorced the empress Joséphine (1810), Talleyrand played a part in arranging the Emperor's marriage with Marie-Louise of Austria, daughter of Emperor Francis I, in the hope that this union would modify Napoleon's ambition. But nothing, apparently, could accomplish that, and when Talleyrand learned that the imperial army had invaded Russia, he declared that it was "the beginning of the end." After the disastrous retreat from Russia, Napoleon, in January 1814, asked him to return to the foreign ministry in order to negotiate with the allies, but Talleyrand, who was already planning to restore the Bourbons, refused, unmoved by the Emperor's anger. When the allies entered Paris, on March 31, 1814, the Tsar took up residence at Talleyrand's mansion and was eventually convinced by him that only the restoration of the Bourbons could guarantee peace in Europe. Talleyrand persuaded the Senate (only 63 of whose 140 members were present) to establish a provisional government of five members, including himself, and to declare Napoleon deposed. The new government immediately recalled Louis XVIII, who on May 13, 1814, appointed Talleyrand his foreign minister.

During the Restoration and the July Monarchy. As France's representative at the Congress of Vienna (1814–15), which was convened to rebuild Europe after 23 years of upheaval, Talleyrand exhibited his diplomatic skill to the full, but it is doubtful whether it benefitted France. He managed to divide the Allies, urging Austria and England to conclude secret agreements with France to prevent Russia from annexing the whole of Poland, and Prussia from annexing the whole of Saxony. This new triple alliance succeeded in reducing the territorial claims of the other great powers, and led to the agreement by which France retained the frontiers of 1792 (which were pushed back to those of 1790 after the Hundred Days, the period during which Napoleon reigned in Paris after his escape from Elba). But, in accepting the cession to Prussia of the greater part of the left bank of the Rhine, Talleyrand created a serious danger for France that became especially clear in 1870, 1914, and 1939.

Congress of Vienna

Talleyrand remained in Vienna during the Hundred Days. On Louis XVIII's return to Paris, he was appointed president of the council, while retaining the office of foreign minister. But the ultraroyalists now in power were violently opposed to a ministry dominated by two former revolutionaries, Fouché and Talleyrand. Talleyrand, moreover, had lost the Tsar's support by his tactics at Vienna, and on September 24, 1815, he was forced to resign. He then lived in retirement, writing his memoirs, until 1829, when his scheming political sense led him to ally himself with the Liberals in order to remove Charles X, the brother and successor of Louis XVIII. He established contact with Louis-Philippe, duc d'Orléans, and helped to make him king during the July Monarchy of 1830. As Louis-Philippe's ambassador in London, from 1830 to 1834, he played a vital part in the negotiations between France and Britain that resulted in the creation of a neutral kingdom of Belgium. His diplomatic career was crowned by the signing of an alliance between France, Great Britain, Spain, and Portugal in April 1834.

Talleyrand died in Paris on May 17, 1838. He received the last sacraments, having signed, a few hours before his death, a document in which he declared himself reconciled with the church and expressed regret for his former conduct. He was buried at his château of Valençay. He had separated from his wife in 1815 and left no legitimate descendants.

Assessment

Talleyrand was indisputably a man of exceptional intelligence and a skillful diplomat. During the 19th century many liberals persisted in acclaiming him as the great statesman whose political realism restored peace and order to Europe at the Congress of Vienna; and during the many international crises of the 20th century, some historians have regretted the absence of a man of his extraordinary diplomatic gifts. But his total lack of principle, his treachery and venality, leave a sense of distaste that his talents, even though almost always used in the service of peace and liberalism, cannot totally dispel.

BIBLIOGRAPHY

Sources: Talleyrand's *Mémoires* were edited by the DUC DE BROGLIE, 5 vol. (1891–92; Eng. trans. of vol. 3–5, 1891–92). They are unreliable and should be used with discretion. A number of Talleyrand's letters and dispatches have been published in the following works: G. PALLAIN, *La Mission de Talleyrand à Londres en 1792* (1889); *Le Ministère de Talleyrand sous le Directoire* (1891); *Correspondance inédite du prince de Talleyrand et du roi Louis XVIII pendant le Congrès de Vienne* (1881); and *L'ambassade de Talleyrand à Londres, 1830–1834*, 2 vol. (1891); P. BERTRAND, *Lettres inédites de Talleyrand à Napoléon, 1800–1809* (1889); H. HUTH and W.J. PUGH, *Talleyrand in America As a Financial Promoter, 1794–1796*, 3 vol. (1942).

Biographies and monographs: The basic biography of Talleyrand is G. LACOUR-GAYET, *Talleyrand, 1754–1838*, 4 vol. (1928–34), which has not been translated into English. The author has consulted the main sources, both printed and in manuscript. This work has been superseded in certain areas but has not been surpassed. The study by E.L. DARD, *Napoléon et Talleyrand* (1935; Eng. trans., 1937), which is based on extensive work in the Austrian archives, should also be noted. The following biographies contain subjective judgments of Talleyrand: A. DUFF COOPER, *Talleyrand* (1932); the COMTE

DE SAINT-AULAIRE, *Talleyrand* (1935); CRANE BRINTON, *The Lives of Talleyrand* (1936); G. FERRERO, *Talleyrand à Vienne, 1814–1815* (1940); I. MADELIN, *Talleyrand* (1942); J. BERTAUT, *Talleyrand* (1945); and J. ORIEUX, *Talleyrand, ou la fuite au désert* (1970), all favourable accounts; R. LAFORGUE, *Talleyrand, l'homme de la France* (1947), a psychoanalytical study; M. MISSOFFE, *Le Coeur secret de Talleyrand* (1956), on the romantic life of Talleyrand; E. TARLE, *Talleyrand* (French trans. from the Russian, 1958), hostile; and L.S. GREENBAUM, *Talleyrand, Statesman-Priest* (1970), an original study of Talleyrand's ecclesiastical career before 1789.

Film: *Le Diable Boiteux* by SACHA GUITRY, the famous French actor, is a pleasant and amusing film that takes considerable liberties with historical truth.

(J.Go.)

Talmud and Midrash

Talmud and Midrash are commentative and interpretative writings that hold a place in the Jewish religious tradition second only to the Bible (Old Testament).

DEFINITION OF TERMS

The Hebrew term Talmud ("study" or "learning") commonly refers to a compilation of ancient teachings regarded as sacred and normative by Jews from the time when it was compiled until modern times and still so regarded by traditional religious Jews. In this broad sense, it is a set of books consisting of the Mishna ("repeated study"), the Gemara ("completion"), and certain auxiliary materials. The Mishna is a collection of originally oral laws supplementing scriptural laws. The Gemara is a collection of commentaries on and elaborations of the Mishna, which in "the Talmud" is reproduced in juxtaposition to the Gemara (see illustration). For present-day scholarship, however, Talmud in the precise sense refers only to the materials customarily called Gemara—an Aramaic term prevalent in medieval rabbinic literature that was used by the church censor to replace the term Talmud within the Talmudic discourse in the Basel edition of the Talmud, published 1578–81. This practice continued in all later editions.

Mishna and Gemara

The term Midrash ("exposition" or "investigation"; plural, Midrashim) is also used in two senses. On the one hand, it refers to a mode of biblical interpretation prominent in the Talmudic literature; on the other, it refers to a separate body of commentaries on Scripture using this interpretative mode.

NATURE AND FUNCTIONS

Role in Jewish religion and society. Torah in Judaism refers to the divine guidance, teaching, or law for the Jewish people (and, ultimately, for mankind). In its written form, it was considered to be especially present in the first five books of the Bible (the Pentateuch), which therefore came to be called Torah. In addition to this written Torah, or "Law," there were also unwritten laws or customs and interpretations of them, carried down in an oral tradition over many generations, which acquired the status of oral Torah.

The Talmud is the literary culmination of this oral tradition, which, according to the rabbis who created the Talmud, originated at Mt. Sinai as part of the divine revelation vouchsafed to Moses, along with the material recorded in the Pentateuch. The oral tradition interpreted the written Torah, adapted its precepts to ever-changing political and social circumstances, and supplemented it with new legislation. Thus the oral tradition added a dynamic dimension to the written code, making it a self-regenerating, endless source of guidance, a perpetual process rather than a closed system. The vitality of this tradition is fully demonstrated in the way the ancient laws were adapted after the destruction of the Temple in 70 CE (Common Era = AD) and by the role the Talmud played in the survival of the Jewish people in exile. By the 11th century, Diaspora Jews lived within a Talmudic culture that unified them and that superseded geographical boundaries and language differences. Jewish communities governed themselves according to Talmudic law, and individuals regulated the smallest details of their lives by it.

But despite the central place of the Talmud in traditional Jewish life and thought, significant Jewish groups and individuals have opposed it vigorously. The Karaite sect in Babylonia, beginning in the 8th century, refuted the oral tradition and denounced the Talmud as a rabbinic fabrication. Medieval Jewish mystics declared the Talmud a mere shell covering the concealed meaning of the written Torah, and heretical messianic sects in the 17th and 18th centuries totally rejected it. The decisive blow to Talmudic authority came in the 18th and 19th centuries when the Haskala (the Jewish Enlightenment movement) and its aftermath, Reform Judaism, secularized Jewish life and, in doing so, shattered the Talmudic wall that had surrounded the Jews. Thereafter, modernized Jews usually rejected the Talmud as a medieval anachronism, denouncing it as legalistic, casuistic, devitalized, and unspiritual.

Anti-Talmudic positions

There is also a long-standing anti-Talmudic tradition among Christians. The Talmud was frequently attacked by the church, particularly during the Middle Ages, and accused of falsifying biblical meaning, thus preventing Jews from becoming Christians. The church held that the Talmud contained blasphemous remarks against Jesus and Christianity and that it preached moral and social bias toward non-Jews. On numerous occasions the Talmud was publicly burned, and permanent Talmudic censorship was established.

On the other hand, since the Renaissance there has been a positive response and great interest in rabbinic literature by eminent non-Jewish scholars, writers, and thinkers in the West. As a result, rabbinic ideas, images, and lore, embodied in the Talmud, have permeated Western thought and culture.

Content, style, and form. The Talmud is first and foremost a legal compilation. At the same time it contains materials that encompass virtually the entire scope of subject matter explored in antiquity. Included are topics as diverse as agriculture, architecture, astrology, astronomy, dream interpretation, ethics, fables, folklore, geography, history, legend, magic, mathematics, medicine, metaphysics, natural sciences, proverbs, theology, and theosophy.

This encyclopaedic array is presented in a unique dialectic style that faithfully reflects the spirit of free give-and-take prevalent in the Talmudic academies, where study was focussed upon a Talmudic text. All present participated in an effort to exhaust the meaning and ramifications of the text, debating and arguing together. The mention of a name, situation, or idea often led to the introduction of a story or legend that lightened the mood of a complex argument and carried discussion further.

This text-centred approach profoundly affected the thinking and literary style of the rabbis. Study became synonymous with active interpretation rather than with passive absorption. Thinking was stimulated by textual examination. Even original ideas were expressed in the form of textual interpretations.

The subject matter of the oral Torah is classified according to its content into Halakha and Haggada and according to its literary form into Midrash and Mishna. Halakha ("law") deals with the legal, ritual, and doctrinal parts of Scripture, showing how the laws of the written Torah should be applied in life. Haggada ("narrative") expounds on the nonlegal parts of Scripture, illustrating biblical narrative, supplementing its stories, and exploring its ideas. The term Midrash denotes the exegetical method by which the oral tradition interprets and elaborates scriptural text. It refers also to the large collections of Halakhic and Haggadic materials that take the form of a running commentary on the Bible and that were deduced from Scripture by this exegetical method. In short, it also refers to a body of writings. Mishna is the comprehensive compendium that presents the legal content of the oral tradition independently of scriptural text.

Halakha and Haggada; Midrash and Mishna

Modes of interpretation and thought. Midrash was initially a philological method of interpreting the literal meaning of biblical texts. In time it developed into a sophisticated interpretive system that reconciled apparent

biblical contradictions, established the scriptural basis of new laws, and enriched biblical content with new meaning. Midrashic creativity reached its peak in the schools of Rabbi Ishmael and Akiba, where two different hermeneutic methods were applied. The first was primarily logically oriented, making inferences based upon similarity of content and analogy. The second rested largely upon textual scrutiny, assuming that words and letters that seem superfluous teach something not openly stated in the text.

The Talmud (*i.e.*, the Gemara) quotes abundantly from all Midrashic collections and concurrently uses all rules employed by both the logical and textual schools; moreover, the Talmud's interpretation of Mishna is itself an adaptation of the Midrashic method. The Talmud treats the Mishna in the same way that Midrash treats Scripture. Contradictions are explained through reinterpretation. New problems are solved logically by analogy or textually by careful scrutiny of verbal superfluity.

Midrashic–Talmudic thinking

The strong involvement with hermeneutic exegesis—interpretation according to systematic rules or principles—helped develop the analytic skill and inductive reasoning of the rabbis but inhibited the growth of independent abstract thinking. Bound to a text, they never attempted to formulate their ideas into the type of unified system characteristic of Greek philosophy. Unlike the philosophers, they approached the abstract only by way of the concrete. Events or texts stimulated them to form concepts. These concepts were not defined but, once brought to life, continued to grow and change meaning with usage and in different contexts. This process of conceptual development has been described by some as "organic thinking." Others use this term in a wider sense, pointing out that, although rabbinic concepts are not hierarchically ordered, they have a pattern-like organic coherence. The meaning of each concept is dependent upon the total pattern of concepts, for the idea content of each grows richer as it interweaves with the others.

ORIGINS AND DEVELOPMENT

Ezra the scribe who, according to the Book of Ezra, reestablished and reformed the Jewish religion in the 5th century BCE (Before the Common Era = BC), began the "search in the Law . . . to teach in Israel statutes and ordinances."

His work was continued by *soferim* (scribes), who preserved, taught, and interpreted the Bible. They linked the oral tradition to Scripture, transmitting it as a running commentary on the Bible. For almost 300 years they applied the Torah to changing circumstances, making it a living law. They also introduced numerous laws that were designated "words of the *soferim*" by Talmudic sources. By the end of this period, rabbinic Judaism—the religious system constructed by the scribes and rabbis—was strong enough to withstand pressure from without and mature enough to permit internal diversity of opinion.

At the beginning of the 2nd century BCE, a judicial body headed by the *zugot*—pairs of scholars—assumed Halakhic authority. There were five pairs in all, between *c.* 150 and 30 BCE. The first of the *zugot* also introduced the Mishnaic style of transmitting the oral tradition.

The *tannaim*

The making of the Mishna: 2nd–3rd centuries. Hillel and Shammai, the last of the *zugot*, ushered in the period of the *tannaim*—"teachers" of the Mishna—at the end of the 1st century BCE. This era, distinguished by a continuous attempt to consolidate the fragmentary Midrashic and Mishnaic material, culminated in the compilation of the Mishna at the beginning of the 3rd century CE. The work was carried out in the academies of Hillel and Shammai and in others founded later. Most scholars believe that Halakhic collections existed prior to the fall of Jerusalem, in CE 70. Other compilations were made at Yavne, a Palestinian town near the Mediterranean, as part of the effort to revitalize Judaism after the disaster of CE 70 (see JOHANAN BEN ZAKKAI). By the beginning of the 2nd century there were many such collections. Tradition has it that Rabbi Akiba organized much of this material into separate collections of Midrash, Mishna, and Haggada and introduced the formal divisions in tannaitic literature. His students and other scholars organized new compilations that were studied in the different academies.

After the rebellion of the Jews against Roman rule led by Simeon bar Kokhba in 132–135, when the Sanhedrin (the Jewish supreme court and highest academy) was revived, the Mishnaic compilation adopted by the Sanhedrin president became the official Mishna. The Sanhedrin reached its highest stature under the leadership of Judah ha-Nasi (Judah the Prince, or President); he was also called Rabbi, as the pre-eminent teacher.

It seems certain that the official Mishna studied during his presidency was the Mishna we know and that he was its editor. Judah aimed to include the entire content of the oral tradition. He drew heavily from the collections of Akiba's pupils but also incorporated material from other compilations, including early ones. Nevertheless, the accumulation was such that selection was necessary. Thus almost no Midrash or Haggada was included. Colleagues and pupils of Judah not only made minor additions to the Mishna but tried to preserve the excluded material, the Baraitot ("Exclusions"), in separate collections. One of these was the Tosefta ("Addition"). Midrashic material was gathered in separate compilations, and later revisions of some of these are still extant. The language of all of the tannaitic literature is the new Hebrew developed during the period of the Second Temple (*c.* 6th century BCE–1st century CE).

The *amoraim*

The making of the Talmuds: 3rd–6th centuries. The expounders of the Mishna were the *amoraim* ("interpreter"), and the two Talmuds—the Palestinian (or Jerusalem) and the Babylonian—consist of their explanations, discussions, and decisions. Both take the form of a running commentary on the Mishna.

The foundations for these two monumental works were begun by three disciples of Judah ha-Nasi: Johanan bar Nappaḥa, Rav (Abba Arika), and Samuel bar Abba, in their academies at Tiberias, in Palestine, and at Sura and Nehardea in Babylonia, respectively. Centres of learning where the Mishna was expounded existed also at Sephoris, Caesarea, and Lydda in Palestine. In time new academies were established in Babylonia, the best known being those at Pumbedita, Mahoza and Naresh, founded by Judah bar Ezekiel, Rava, and Rav Pappa, respectively. The enrollment of these centres often numbered in the thousands, and students spent many years there. Those who no longer lived on the academy grounds returned twice annually for the *kalla*, a month of study in the spring and fall.

Academies differed in their methods of study. Pumbedita, for example, stressed casuistry, while Sura emphasized breadth of knowledge. Students often moved from one academy to another and even from Palestine to Babylonia or from Babylonia to Palestine. This kept open the channels of communication between the various academies and resulted in the inclusion of much Babylonian material in the Palestinian Talmud, and vice versa.

Despite the overwhelming similarity of the two Talmuds, however, they do differ in some ways. The Palestinian Talmud is written in the Western Aramaic dialect, the Babylonian in the Eastern. The former is invariably shorter, and, not having been subject to final redaction, its discussions are often incomplete. Its explanations tend to remain closer to the literal meaning of the Mishna, preferring textual emendation to casuistic interpretation. Finally, some of the legal concepts in the Babylonian Talmud reflect the influence of Persian law, for Babylonia was under Persian rule at the time.

The main endeavour of the *amoraim* was to thoroughly explain and exhaust the meaning of the Mishna and the Baraitot. Apparent contradictions were reconciled by such means as explaining that conflicting statements referred to different situations or by asserting that they stemmed from the Mishnayot (Mishnas) of different *tannaim*. The same techniques were used when amoraic statements contradicted the Mishna. These discussions took place for hundreds of years, and their content was passed on from generation to generation, until the compilation of the Talmud.

The compilation of the Palestinian and Babylonian Talmuds

The portion of the Palestinian Talmud dealing with the three Bavot ("gates")—*i.e.*, the first three tractates of the fourth order of the Mishna (for orders and tractates, see *Talmudic and Midrashic literature*, below)—was compiled in Caesarea in the middle of the 4th century and is distinguished from the rest by its brevity and terminology. The remainder was completed in Tiberias some 50 years later. It seems likely that its compilation was a rescue operation designed to preserve as much of the Halakhic material collected in Palestinian academies as possible, for by that time the deterioration of the political situation had forced most Palestinian scholars to emigrate to Babylonia.

The Babylonian Talmud was compiled up to the 6th century. Some scholars suggest that the organization of the Talmud began early and that successive generations of *amoraim* added layer upon layer to previously arranged material. Others suggest that at the beginning a stratum called Gemara, consisting only of Halakhic decisions or short comments, was set forth. Still others theorize that no overall arrangement of Talmudic material was made until the end of the 4th century.

The statement in the tractate *Bava metzi'a* that "Rabina and Rav Ashi were the end of instruction" is most often understood as referring to the final redaction of the Talmud. Since at least two generations of scholars following Rav Ashi (died 427) are mentioned in the Talmud, most scholars suggest that "Rabina" refers to Rabina bar Huna (died 499) and that the redaction was a slow process lasting about 75 years to the end of the 5th century.

According to the tradition of the *geonim*—the heads of the academies at Sura and Pumbedita from the 6th to the 11th centuries—the Babylonian Talmud was completed by the 6th-century *savoraim* ("expositors"). But the extent of their contribution is not precisely known. Some attribute to them only short additions. Others credit them with creating the terminology linking the phases of Talmudic discussions. According to another view, they added comments and often decided between conflicting opinions. The proponents of the so-called Gemara theory noted above ascribe to them the entire dialectic portion of Talmudic discourse.

TALMUDIC AND MIDRASHIC LITERATURE

Mishna. The Mishna is divided into six orders (*sedarim*), each order into tractates (*massekhtot*), and each tractate into chapters (*peraqim*). The six orders are *Zera'im, Mo'ed, Nashim, Neziqin, Qodashim*, and *Ṭohorot*.

Zera'im, Mo'ed, and Nashim

1. *Zera'im* ("Seeds") consists of 11 tractates: *Berakhot, Pea, Demai, Kilayim, Shevi'it, Terumot, Ma'aserot, Ma'aser sheni, Ḥalla, 'Orla*, and *Bikkurim*. Except for *Berakhot* ("Blessings"), which treats of daily prayers and grace, this order deals with laws related to agriculture in Palestine. It includes prohibitions against mixtures in plants (hybridization), legislation relating to the sabbatical year (when land lies fallow and debts are remitted), and regulations concerning the portions of harvest given to the poor, the Levites, and the priests.

2. *Mo'ed* ("Season" or "Festival") consists of 12 tractates: *Shabbat, 'Eruvin, Pesaḥim, Sheqalim, Yoma, Sukka, Betza, Rosh Hashana, Ta'anit, Megilla, Mo'ed qaṭan*, and *Ḥagiga*. This order deals with ceremonies, rituals, observances, and prohibitions relating to special days of the year, including the Sabbath, holidays, and fast days. Since the half-shekel Temple contribution was collected on specified days, tractate *Sheqalim*, regarding this practice, is included.

3. *Nashim* ("Women") consists of seven tractates: *Yevamot, Ketubot, Nedarim, Nazir, Soṭa, Giṭṭin*, and *Qiddushin*. This order deals with laws concerning betrothal, marriage, sexual and financial relations between husband and wife, adultery, and divorce. Since Nazirite (ascetic) and other vows may affect marital relations, *Nedarim* ("Vows") and *Nazir* ("Nazirite") are included here.

4. *Neziqin* ("Damages") consists of 10 tractates, the first three of which were originally considered one (the *Bavot*): *Bava qamma, Bava metzi'a, Bava batra, Sanhedrin, Makkot, Shevu'ot, 'Eduyyot, 'Avoda zara, Avot*, and *Horayot*. This order deals with civil and criminal law concerning damages, theft, labour relations, usury, real estate, partnerships, tenant relations, inheritance, court composition, jurisdiction and testimony, erroneous decisions of the Sanhedrin, and capital and other physical punishments. Since idolatry, in the literal sense of worship or veneration of material images, is punishable by death, *'Avoda zara* ("Idolatry") is included. *Avot* ("Fathers"), commonly called "Ethics of the Fathers" in English, seems to have been included to teach a moral way of life that precludes the transgression of law.

Neziqin, Qodashim, and Ṭohorot

5. *Qodashim* ("Sacred Things") consists of 11 tractates: *Zevaḥim, Menaḥot, Ḥullin, Bekhorot, 'Arakhin, Temura, Keretot, Me'ila, Tamid, Middot*, and *Qinnim*. This order incorporates some of the oldest Mishnaic portions. It treats of the Temple and includes regulations concerning sacrifices, offerings, and donations. It also contains a detailed description of the Temple complex.

6. *Ṭohorot* ("Purifications") consists of 12 tractates: *Kelim, Ohalot, Nega'im, Para, Ṭohorot, Miqwaot, Nidda, Makhshirin, Zavim, Ṭevul yom, Yadayim*, and *'Uqtzin*. This order deals with laws governing the ritual impurity of vessels, dwellings, foods, and persons, and with purification processes.

Tosefta. The Tosefta ("Addition") closely resembles the Mishna in content and order. In its present form it at times supplements the Mishna, at other times comments on it, and often also opposes it. There is no Tosefta on the tractates *Avot, Tamid, Middot*, and *Qinnim*. The Talmud quotes from many other collections of Mishnaiot and Baraitot: some are attributed to *tannaim*, and predate the established Mishna; and others, to *amoraim*. The original material is lost.

Talmud (Gemara). Although the entire Mishna was studied at the Palestinian and Babylonian academies, the Palestinian Talmud (Gemara) covers only the first four orders (except chapters 21–24 of *Shabbat* and chapter 3 of *Makkot*) and the first three chapters of *Nidda* in the sixth order. Most scholars agree that the Palestinian Talmud was never completed to the fifth and sixth orders of the Mishna and that the missing parts of the other orders were lost. A manuscript of chapter 3 of *Makkot* was, in fact, found and was published in 1946.

Incompleteness of the Talmuds

The Babylonian Talmud does not cover orders *Zera'im* (except *Berakhot*) and *Ṭohorot* (except *Nidda*) and tractates *Tamid* (except chapters 1,2,4), *Sheqalim, Middot, Qinnim, Avot*, and *'Eduyyot*. Scholars concur that the Talmud for these parts was never completed, possibly because their content was not relevant in Babylonia.

Midrashim. *Halakhic.* Halakhic Midrashim are exegetic commentaries on the legal content of Exodus, Leviticus, Numbers, and Deuteronomy. The five extant collections are *Mekhilta*, on Exodus; *Mekhilta deRabbi Shim'on ben Yoḥai*, on Exodus; *Sifra*, on Leviticus; *Sifre*, on Numbers and Deuteronomy; *Sifre zuṭa*, on Numbers. (*Mekhilta* means "measure," a norm or rule; *Sifra*, plural *Sifre*, means "writing" or "book.") Critical analysis reveals that *Mekhilta* and *Sifre* on Numbers differ from the others in terminology and method. Most scholars agree that these two originated in the school of Ishmael and the others in that of Akiba. In their present form they also include later additions. Mention should also be made of *Midrash tannaim* on Deuteronomy, consisting of fragments recovered from the Yemenite anthology *Midrash ha-gadol*.

Haggadic. Haggadic Midrashim originated with the weekly synagogue readings and their accompanying explanations. Although Haggadic collections existed in tannaitic times, extant collections were compiled between the 4th and 11th centuries. Midrashic compilations were not authoritatively edited and tend to be coincidental and fragmentary.

Biblical and nonbiblical Haggadot

Most notable among biblical collections is *Midrash rabba* ("Great Midrash"), a composite of commentaries on the Pentateuch and five Megillot (Song of Songs, Ruth, Ecclesiastes, Esther, Lamentations) differing in nature and age. Its oldest portion, the 5th-century *Genesis*

rabba, is largely a verse-by-verse commentary, while the 6th-century *Leviticus rabba* consists of homilies and *Lamentations rabba* (end of 6th century) is mainly narrative. The remaining portions of *Midrash rabba* were compiled at later dates.

The *Tanḥuma* (after the late-4th-century Palestinian *amora* Tanḥuma bar Abba), of which two versions are extant, is another important Pentateuchal Midrash. Additional Midrashic compilations include those to the books of Samuel, Psalms, and Proverbs. Mention should also be made of *Pesiqta* ("Section" or "Cycles") *deRab Kahana* (after a Babylonian *amora*) and *Pesiqta rabbati* ("The Great Cycle"), consisting of homilies on the Torah (Pentateuch) readings that occur on festivals and special sabbaths.

Haggadic compilations independent of biblical text include *Avot deRabbi Natan, Tanna deve Eliyyahu, Pirqe* ("Chapters") *deRabbi Eliezer*, and tractates *Derekh eretz* ("Correct Conduct"). These primarily deal with ethics, moral teachings, and biblical narrative.

Among the medieval anthologies are the *Yalquṭ* ("Compilation") *Shimoni* (13th century), *Yalquṭ ha-makhiri* (14th century), and *ʿEn Yaʿaqov* ("Eye of Jacob," 16th century). The two most important modern Haggadic anthologies are those of Wilhelm Bacher and Louis Ginzberg.

Codes. The Talmud's dialectic style and organization are not those of a code of laws. Accordingly, codification efforts began shortly after the Talmud's completion. The first known attempt was *Halakhot pesuqot* ("Decided Laws"), ascribed to Yehudai Gaon (8th century). *Halakhot gedolot* ("Great Laws"), by Simeon Kiyyara, followed 100 years later. Both summarize Talmudic Halakhic material, omitting dialectics but preserving Talmudic order and language. The later *geonim* concentrated on particular subjects, such as divorce or vows, introducing the monographic style of codification.

Codification literature gained impetus by the beginning of the 11th century. During the next centuries many compilations appeared in Europe and North Africa. The most notable, following Talmudic order, were the *Hilkhot Harif*, by Isaac Alfasi (11th century), and *Hilkhot Harosh*, by Asher ben Jehiel (13th–14th centuries). Though modelled after *Halakhot gedolot*, the *Hilkhot Harif* encompasses only laws applicable after the destruction of the Temple but includes more particulars. The *Hilkhot Harosh* closely follows Alfasi's code but often also includes the reasoning underlying decisions.

The Mishne Torah, Sefer ha-ṭurim, and Shulḥan ʿarukh

The most important of the topically arranged codifications were: the *Mishne Torah, Sefer ha-ṭurim*, and *Shulḥan ʿarukh*. (1) The *Mishne Torah* ("The Torah Reviewed") by Maimonides (12th century), is a monumental work, original in plan, language, and order; it encompasses all religious subject matter under 14 headings and includes theosophy, theology, and religion. (2) The *Sefer ha-ṭurim* ("Book of Rows or Parts"), by Jacob ben Asher (14th century), the son of Asher ben Jehiel, introduced new groupings, dividing subject matter into four major categories (*ṭurim*) reminiscent of the Mishnaic orders; it includes only laws applicable after the destruction of the Temple. (3) The *Shulḥan ʿarukh* ("The Prepared Table") by Joseph Karo (16th century), the last of the great codifiers, is structured after the *Sefer ha-ṭurim*, but presents the Sefardic (Near Eastern and North African) rather than the Ashkenazic (Franco-German and eastern European) tradition, with decisions largely following those of Alfasi, Maimonides, and Rabbi Asher. When the 16th-century Ashkenazic codifier Moses Isserles added his notes, this became the standard Halakhic code for all Jewry.

Commentaries. The interpretive literature on the Talmud began with the rise of academies in Europe and North Africa. The earliest known European commentary, though ascribed to Gershom ben Judah (10th–11th centuries), is actually an eclectic compilation of notes recorded by students of the Mayence (Mainz) Academy. Compilations of this kind, known as *quntresim* ("notebooks"), also developed in other academies. Their content was masterfully reshaped and reformulated in the renowned 11th-century commentary of Rashi (acronym of *R*abbi *Sh*lomo *Yitz*ḥaqi), in which difficulties likely to be encountered by students are anticipated and detail after detail is clarified until a synthesized, comprehensible whole emerges.

The commentaries of Ḥananel ben Ḥushiel and Nissim ben Jacob ben Nissim, the first to appear in North Africa (11th century), are introductory in nature. They summarize the content of Talmudic discussions, assuming that details will be understood once the general idea becomes comprehensible. This style was later followed by the Spanish school, including Joseph ibn Migash and Maimonides. However, as Rashi's work became known, it displaced all other commentaries. (Note its predominant role in the sample page of Talmud.)

Tosafot, novellae, and responsa

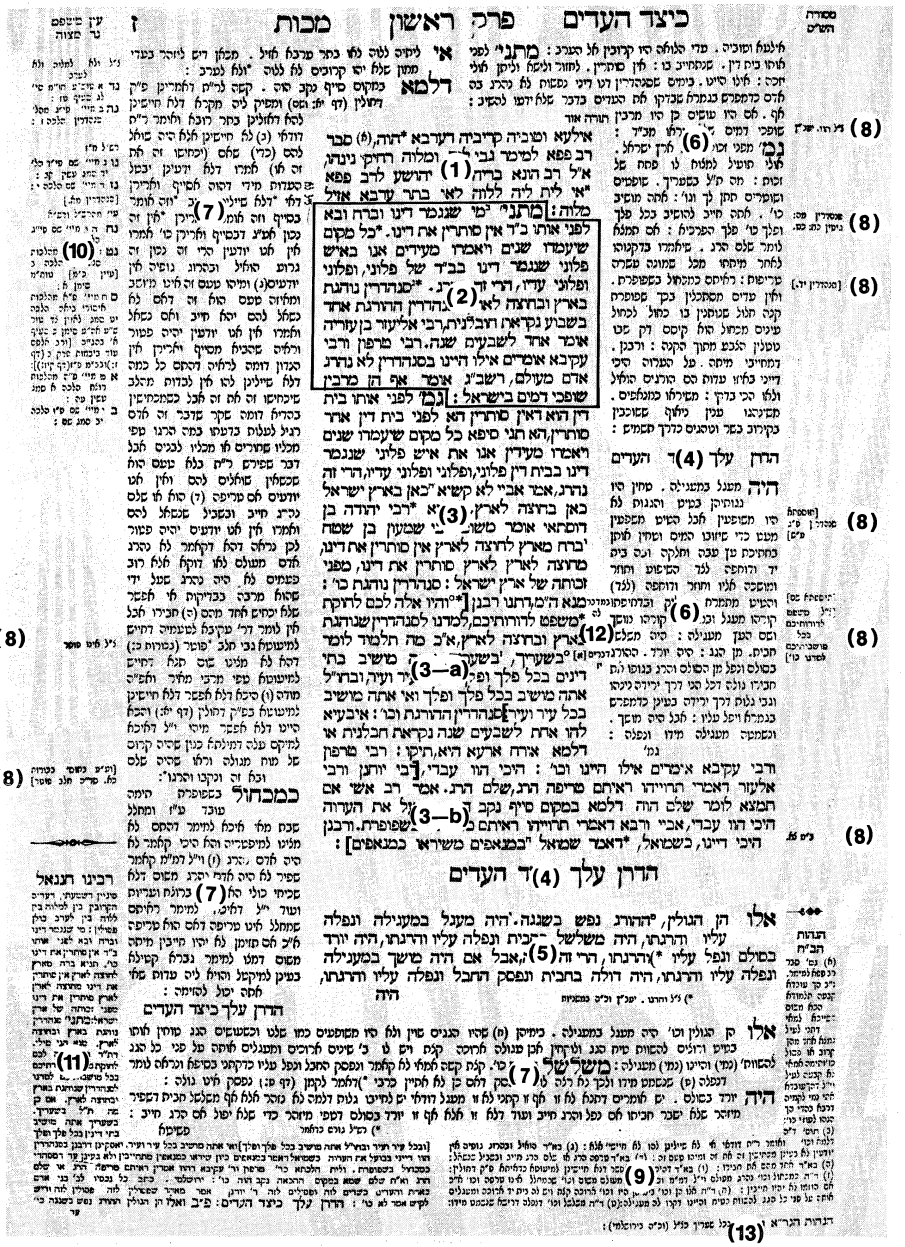
A new phase in Talmudic literature was initiated by Rashi's grandchildren, Rabbis Isaac, Samuel, and Jacob, the sons of Meir, who established the school of *tosafot*. (These medieval "additions" are not to be confused with the tannaitic Tosefta discussed above.) Reviving Talmudic dialectic, they treated the Talmud in the same way that it, in turn, had treated the Mishna. They linked apparently unrelated statements from different Talmudic discourses and pointed out the fine distinctions between seemingly interdependent statements. This dialectic style was soon adopted in all European academies. Even the writings of Ravad (Abraham ben David), Zerahiah ha-Levi, and Yeshaya deTrani, three of the most original Talmudists (12th century), reflect the strong impact of Tosafist dialectic.

The works of Meir Abulafia and Menaḥem Meiri, although of the North African genre, include a strong dialectic element. In Spain such dialectic works were known as *ḥiddushim* or *novellae* (since they sought "new insights"), the most famous being those written by four generations (13th–14th centuries) of teacher and pupil: Ramban (Naḥmanides, or Moses ben Naḥman), Rashba (Solomon ben Adret), Ritba (Yomtov ben Abraham), and Ran (Nissim ben Reuben Gerondi).

A major role in establishing Talmudic authority was also played by the *responsa* literature, which gave replies (*responsa*) to legal and religious questions. Beginning in the 7th century, when the Babylonian *geonim* responded in writing to questions concerning the Talmud, it developed into a branch of Talmudic literature that continued in virtually the same form to the present day. Then, as now, Talmudic authorities were approached for explanations and decisions. Among the *geonim* the best known respondents were Sherira (10th century) and his son Hai. In the Middle Ages the most important were Alfasi, Ibn Migash (Joseph ibn Migash), Maimonides, Ravad (Abraham ben David of Posquières), Ramban, Rashba, Rosh (Asher ben Jehiel), Ran, and Ribash (Isaac ben Sheshet Perfet).

Writing and printing of the Talmuds. Study in the academies was always oral; hence the question of when the Mishna and Talmud were first committed to writing has been the subject of much discussion. According to some scholars, the process of writing began with Judah ha-Nasi. Others attribute it to the *savoraim*.

The Palestinian Talmud was first printed in Venice (1523–24). All later editions followed this one. Printing of the Babylonian Talmud was begun in Spain about 1482, and there have been more than 100 different editions since. The oldest extant full edition appeared in Venice (1520–23). This became the prototype for later printings, setting the type of page and pagination (a total of close to 5,500 folios). The standard edition was printed in Vilna beginning in 1886. It carries many commentaries and commentaries upon commentaries. In the sample page reproduced here, the Mishna and the Gemara are placed in the centre column of the page and are printed in heavy type. The commentary of Rashi is always located in the inner column of the page and the *tosafot* in the outer column. Other commentaries and references to legal codes and to scriptural verses surround the major commentaries, in smaller type. Talmudic citations are made by tractate name, folio number, and side of the folio (a or b).



Sample page (7a) of the tractate *Makkot* (of the fourth order, *Neziqin*) of the Vilna edition of the Babylonian Talmud, first printed in 1880–86. It discusses the fate of a man who was convicted and escaped and how he is to be judged. Code numbers, a box surrounding the Mishna, and brackets indicating the extent of comments (3-a) and (3-b) have been superimposed onto the original page. (1) End of the Gemara to the previous Mishna. (2) Mishna. (3) Gemara. (3-a) Halakhic Midrash supporting the Mishna. (3-b) Three short comments from Palestine, Sura, and Pumbedita. (4) Mark indicating the end of the chapter. (5) Mishna of the next chapter. (6) Commentary of Rashi (1040–1105). (7) *Tosafot*, discussing special points in the Gemara and Rashi. (8) Cross-reference notes to other Talmudic and Rabbinic sources and textual variants. (9) Notes by Joel Sirkes (1561–1640). (10) References to the codes of Maimonides, Moses of Concy, the *Tur*, and the *Shulhan 'arukh*. (11) Commentary of Hananel of North Africa, early 11th century. (12) References to scripture. (13) Notes by Elijah Gaon of Vilna (1720–97).

NONLEGAL SUBJECT MATTER

God, Torah, and Israel

Main religious doctrines. While the Talmudic rabbis never formally systematized their beliefs, their underlying religious concepts are clearly reflected in their decisions, ideas, and attitudes. Pre-eminent in rabbinic thinking were the concepts of God, Torah, and Israel.

God. The rabbinic God was primarily the biblical God who acted in history, the creator and source of life who was experienced through the senses rather than intellect. In reaction to sectarian teachings (*i.e.*, Gnosticism and early Christianity), however, the rabbis stressed God's universality, absolute unity, and direct involvement with the world. At one and the same time his immanence and transcendence (being present in and beyond the universe) were emphasized, and biblical anthropomorphisms (ascribing human attributes to God) were explained metaphorically. The rabbis also stressed an intimacy into the relationship between God and man. God became the father to whom each individual could turn in direct prayer for his needs. To the names YHWH and Elohim, which traditionally were identified with God's mercy and judgment, respectively, the rabbis added new terms reflecting his other attributes—*e.g.*, Shekhina ("Presence"), representing his omnipresence, or immanence; and Maqom ("Place"), his transcendence.

Torah. Torah, in the Talmudic sense, refers to all religious and ethical teachings handed down by tradition. According to the rabbis, God created the Torah long

before the world. It served as his blueprint for creation and contained the eternal divine formula for the world's future workings and thus the answers to all problems for all times and all people. God himself is depicted as studying the Torah, for even he cannot make decisions concerning the world that contradict it.

Israel. The people Israel, according to the rabbis, were chosen by God to be the guardian of his Torah, and, just as God chose Israel, Israel chose God. Thus, the concept of Israel as a nation bound together by an irrevocable commitment to bring the Torah to the world, and bearing corporate responsibility for this mission, was formed. No Jew can free himself from this commitment, but anyone accepting it, regardless of race, becomes a full-fledged Jew with obligations binding him and his descendants.

With this in mind, the rabbis repeatedly emphasized the importance of studying Torah. They pointed out that the Torah is not a declaration of religious beliefs. Rather it is a statement of a discipline regulating each detail of life. Any transgression of this discipline hampers the divine plan of establishing God's way of life in this world.

Sanctification of everyday life

Worship. The intensive rabbinic religious involvement led to the growth of a new concept of worship. While in the Bible worship was usually centred in the sanctuary of the Temple in Jerusalem, the rabbis, particularly after the destruction of the Second Temple (CE 70), attempted to sanctify all of life. Thus, they said that one must bless God upon arising in the morning, before dressing, before and after meals, and in all ordinary daily actions or routines. Each move in life should be an act of worship glorifying God's name.

Messianic kingdom. In rabbinic thinking the establishment of God's kingdom was tied to the Messiah, who was to be a descendant of King David, wise, just, a great scholar, a moral leader, and courageous king. He would redeem the Jews from exile and re-establish their independence in the land of Israel. With this the world would be ushered into a new era of righteousness and universal peace. The rabbis referrred to this era as "the world to come," portraying it as an immense academy in which the righteous would study Torah without interruption. They refrained, however, from describing it further, saying that human language and fantasy are inadequate to depict its wonders.

The nature of the Messiah and the time of his arrival raised much speculation. Following the defeat of Bar Kokhba, leader of the revolt against Roman rule (CE 135), the Messiah's coming, in rabbinic thought, faded into the mysterious and distant future, and descriptions concerning his personality assumed supernatural overtones.

For a fuller discussion of major religious doctrines, see JUDAISM.

Doctrine of man. The fate of man, his achievements and failures, his being and nothingness, occupy an important place in Talmudic literature. The rabbis' concept of man was a universal one. While they assumed that Jews are bound by greater religious duties than others, they considered all men equal, all created in the image of God. "Therefore, but a single man was created . . . That none should say to his fellow, 'My father was greater than thy father' " (tractate *Sanhedrin*).

The world, according to the Talmud, was created for the sake of man, and it is incumbent upon him to keep it in order. His responsibility begins at home. Man must care for his health, marry, build a family, provide for and educate children, honour parents, friends, and elders. He also carries social responsibilities and has to be part of the community. He must learn a trade and work so that he does not become a burden to the community.

The uniqueness of man in this world, likened by the Talmud to the uniqueness of God in the universe, lies in his freedom of choice. Nature follows its laws and angels their missions, but man is his own master. In contrast to St. Paul's doctrine that the original sin of Adam made sin an integral part of human nature, the rabbis considered man a wondrous and harmonious being. The duality of his nature was explained by the existence of a good and bad impulse, personified by two angels, *yetzer ha-ṭov* (the good inclination) and *yetzer ha-raʿ* (the evil inclination), which enter each man after birth. It is the duty of man to overcome his evil inclination, and it is for this that he is rewarded. Moreover, since there is corporate responsibility, not only is the sinner punished but the community at large also suffers. Here again, however, man is his own master. He can reverse the course of sin and punishment by repentance. Although repentance may be accompanied by formal and ceremonial acts, such as fasting, its basic principle is the renunciation of the sin and the wholehearted decision not to repeat it. When a man transgresses against God, his sin is forgiven by repentance alone, but, when he transgresses against his fellow man, he must make good his wrongdoing as well as repent.

The *yetzer ha-ṭov* and *yetzer ha-raʿ*

Medicine and science. The Talmud devoted considerable attention to the maintenance of good health, regarding it a religious duty. A keen understanding of the importance of hygiene in preventing illness was reflected in an emphasis upon bodily cleanliness. The rabbis also stressed the necessity for moderation in eating and drinking and the importance of a proper diet. The Talmud prescribed remedies for illnesses and mentioned surgical techniques, such as cesarean section.

Religious concerns surrounding the calendar, prohibitions against planting seeds of different kinds together, dietary laws, and sabbath-walking limits resulted in an intense rabbinical interest in astronomy, zoology, mathematics, and geometry.

Legend and folklore. Side by side with the Midrashic Haggada, which was the outgrowth of Bible exegesis and developed in the academies, the Talmuds and Midrashic collections contain a large quantity of Haggadic material with mythological rudiments, allusions to pagan beliefs and customs, and folkloristic elements of a world strange to the rabbis. Folktales and legends, animal lore, and adventure narratives, containing pagan ideas and beliefs, that were told by their Gentile neighbours were no doubt a major attraction to the common Jews, especially those in the countryside (the *ʿam ha-aretz*, or "people of the land"). The rabbis realized the great danger involved in this situation and developed their own folk material. They adopted the dramatic and artistic parts of these stories but rejected the unwanted elements, replacing them with their own ideas. Thus the animals and birds in fables quote the Bible and discuss it in the same manner that the rabbis do.

The challenge of pagan myths, legend, and folklore

Ancient mythology seems to have been well known and liked by the Jewish masses. Again, in order to fight its influence, the rabbis reworked its content in their own spirit. They retained the mythological suspense—the sea tries to drown the earth—but there is no mythological struggle between equal powers; angels try to prevent the creation of man, but they do not possess titanic power. All are subdued by the command of God. Thus, the rabbis transformed the ancient myths into dramatic evidence against polytheism. (See also JEWISH MYTH AND LEGEND.)

Astrology, magic, and divination. Astrology was a recognized science in the ancient world. The rabbis could not reject it entirely, and some concluded that the power of the stars is confined to Gentiles. Others made it part of God's order, saying that stars influence this world in the same way that climate influences plants. The rabbis strenuously objected to omens and other forms of divination because they considered them magic. Dreams were considered by some rabbis as meaningless, while others saw in them an element of prophecy.

The rabbis believed in the efficacy of magic but strenuously objected to its practice. They permitted only magic that had been proved effective in healing. They also permitted the use of incantations for the purpose of counteracting the hold of magic. Because of their supposedly protective nature, the use of amulets was also countenanced.

Demons (evil spirits) and the evil eye

The existence of a demonic kingdom was accepted by the rabbis without question. Evil spirits are invisible and fill the nether world. They avoid sunlight and concentrate in waters and deserted places. They also mingle with people, trouble them, and help them. They have passions and are born and die like people. However, they also have some of the traits and powers of angels. The evil eye was considered as dangerous as evil spirits. It was thought that

for mysterious reason some people have the power to injure others by looking at them and that it is generally jealousy that triggers this effect. The rabbis, however, repeatedly emphasized that all of these strange powers are under the divine government and, moreover, that they cannot hurt the pious.

TALMUDIC LAW AND JURISPRUDENCE

Sacral basis of Talmudic law

Unlike the Romans, who considered ritual law (*fas*) God-given and social law (*lex*) man-made, the rabbis believed all Jewish law to be of divine origin. Thus, for example, unfairness in labour relations was considered a religious sin and caring for the sick a religious obligation. Though familiar with the concept of natural law (ethical principles inherent in the nature of things and apprehensible through human reason), the rabbis objected to making nature the basis of law. Even rabbinic ordinances were regarded as having validity only because the authority of the rabbis is sanctioned by the Torah.

Methods of arriving at legal principle and decisions. Ancient Halakha knew no controversy. The earliest controversy dates to the pre-tannaitic *zugot*. Hillel and Shammai differed on significant issues, and, with the rise of their schools, Halakhic uniformity began to crumble. Halakha became a scholastic discipline that developed in academic rather than judicial settings, more and more issues remaining unresolved. Over 300 controversies between the schools of Hillel and Shammai (called the House of Hillel and the House of Shammai, respectively) are reported in Talmudic sources. As time passed, disputes proliferated even more and were considered legitimate provided they conformed to the rule of Halakhic discipline.

No attempt was made to restore Halakhic uniformity until the beginning of the 2nd century CE. Controversies were sometimes resolved by citing old traditions, by establishing precedents, or, when the sages could convene, by vote taking.

At Yavne, Gamaliel II, the president of the revived Sanhedrin (*c.* CE 80–*c.* 115), attempted to suppress diversity of opinion, but failed. The right to differ was already established. Moreover, in the Halakhic collection compiled at Yavne (tractate *'Eduyyot*), the views of individual scholars were preserved. The sages at Yavne, however, did take a major step toward restoring Halakhic consistency by upholding the generally more lenient views of the House of Hillel over those of the House of Shammai, thus establishing the Hillelite tradition as the main trend of rabbinic Judaism.

The principle that differing opinions should be recorded was followed by Judah ha-Nasi in his Mishna. Modern scholars differ as to whether he meant to compile a code of law or merely a Halakhic collection. The *amoraim*, however, accepted his Mishna as the definitive code and introduced a set of guidelines according to which disputes were decided. Thus, for example, collective (" . . . the sages said") and individual opinions stated anonymously were taken as law; Akiba's decisions were upheld over those of his colleagues. Similar guidelines developed also with regard to amoraic controversies.

Guidelines for settling Halakhic controversies

With the completion of the Talmud, a new phase in Halakhic development began. Not only were there two different Talmuds and a large Haggadic literature but even within each of the Talmuds diversified opinions were reported. The *geonim* laid down rules governing the use of this enormous literature for lawmaking. They designated the Babylonian Talmud the highest authority, taking the Palestinian Talmud into consideration only when it did not disagree with the Babylonian or when the latter expressed no opinion on a subject. They also deprived the Haggadic literature of Halakhic authority and set guidelines for the precedence of opinion among *amoraim*. These geonic rules served as the basis of all future codifications.

After the geonic period two methods of decision making were applied. The first of these relied primarily upon the authoritative codes. The Mediterranean rabbis, for example, made the code of Maimonides the source of all of their lawmaking. The second method relied on the original Talmudic sources for decision making. This method was applied by the Tosafists and their followers, who, though they consulted the older codes, did not accept them as the final authorities. The *responsa* literature represents a synthesis of these two methods. Although it makes use of codes as the main source of law, its decisions are always accompanied by a discussion and analysis of earlier relevant literature. This approach has been used by rabbis to the present day.

In addition to the above, in particular instances throughout the ages rabbinic authorities promulgated ordinances (*taqqanot*) and edicts (*gezerot*). These were made in response to pressing needs of time and circumstance, and this form of lawmaking was most frequently used by rabbinic synods in the Middle Ages.

Administration of justice. *Courts.* A comprehensive judicial system is described in Talmudic sources. The highest court was the Great Sanhedrin. It consisted of 71 members and convened daily in one of the Temple halls. It was the highest legal and religious authority in the country and had exclusive jurisdiction over matters of a national and public nature. It also functioned as the court of appeals, dealing with cases that were not resolved by the lower courts.

The Great and Lesser Sanhedrins

Next in line of judicial authority was the Lesser Sanhedrin. Each town with a population of 120 or more had a court of this kind. These courts each consisted of 23 members and dealt with cases involving capital punishment.

The members of the Sanhedrins had to be ordained, pious, mature in age, sound in mind and body, of wide knowledge, and of pure Jewish descent. Persons who were too old or who had never had children were ineligible, for it was thought that they might not be merciful.

The lower courts dealt with all remaining cases. Each consisted of three members and convened on Mondays and Thursdays. In cases involving a penalty the three judges had to be ordained, but in those involving ordinary monetary ligitation ordination was not required. In the latter type of case, concerned parties were allowed the alternative of setting up ad hoc arbitration bodies.

Rules of evidence. Jewish law was extremely strict regarding evidence acceptable in court. In cases entailing physical punishment, no circumstantial evidence, confession, or self-incrimination was recognized. The testimony of two eyewitnesses who confronted the defendant was required. In monetary cases documentary evidence and, at times, oaths were acceptable. Any mental or moral defects or self-interest in the case disqualified witnesses. Relatives could not serve as judges or witnesses.

Trial procedure. Jewish law knows of no lawyers. After the facts were presented, the court investigated, deliberated, and made its decision by voting. Both sides had to be treated equally, even to the point of seeing to it that neither should be dressed more richly than the other. Each side could be heard only in the presence of the other.

In the trial procedure of capital cases, there was a clear tendency toward bias in favour of the defendant. Thus, only the judges could argue for conviction, but all present could argue for acquittal. The most junior judges voted first so that they would not be unduly influenced by their seniors. A majority of one was sufficient for acquittal, but a majority of two was necessary for conviction. A verdict of acquittal could be reached on the same day but one of conviction only on the following day. When the court erred, only its convictions, and not its acquittals, were reversed.

Criminal law. In Jewish law, ritual and nonritual transgressions were crimes punishable by court. Each of the 36 most severe transgressions (*e.g.*, adultery, sodomy, idolatry, sorcery, or murder) carried one of four types of death penalty (stoning, burning, beheading, and strangling). Rabbinic law, however, tended to minimize the practice of capital punishment. The rigorous cross-examination of witnesses and the warning of impending punishment that the transgressor had to receive immediately before committing his crime made it almost impossible to reach a death verdict.

Death penalties

If despite all of this a death verdict was reached, every legal effort was made to allow for a last-minute reversal. Execution was expedited and carried out in the most humane manner possible, the accused being given an opiate before dying. To show their compassion the judges fasted on the day of execution. According to tradition the death penalty was abolished 40 years before the destruction of the Temple, when the Great Sanhedrin was exiled from the Temple complex.

The punishment for 207 other transgressions (*e.g.*, perjury, some forms of incest, the eating of forbidden foods) was flagellation. Here, too, the rabbis tended to be lenient. As in capital cases, a rigorous cross-examination and a warning were required. The maximum number of stripes administered was 39. Prior to flagellation the transgressor was examined medically to determine the number of stripes he could withstand.

Side by side with the above penalties, the courts also inflicted *makkat mardut* (disciplinary stripes) and excommunication in cases where regular flagellation could not legally be applied. These two punishments were generally used in Babylonia, where ordained courts did not exist. It should be mentioned also that the Mishna includes a few obscure references to a form of imprisonment used instead of capital punishment.

Civil and social law. Although the rabbis considered both ritual and nonritual law sacred, they demonstrated great independence in supplementing the relatively brief relevant scriptural comments and regulations with a comprehensive system of civil and social law. In response to variations in social and economic circumstances, certain differences in Palestinian and Babylonian Talmudic law emerged. The Babylonian rabbis, for example, recognized the law of the state as binding in monetary matters, while the Palestinian rabbis did not. In general, however, Jewish civil law developed relatively autonomously. In instances where the rabbis did adopt alien legal concepts, they elaborated upon them until they could be fully integrated into the spirit and structure of Jewish law.

Social welfare, torts, family law, financial law

The following are some of the areas covered: (1) Social welfare: a comprehensive social welfare system was worked out, including obligations to provide for children, educate them, and train them for a profession. Regulations of charity, medical assistance, and burial of the dead were established. (2) Torts: included were all damages caused by a person directly or indirectly via his property. The main aim was to compensate for damages. Consequently, no torts were classified as criminal. Even "an eye for an eye" was interpreted to mean financial compensation. (3) Family law: included were regulations concerning marriage and divorce procedures and the innovation of the *ketubba* (marriage contract), which spells out the mutual obligations of husband and wife in the areas of finance, medical care, clothing, housework, sexual relations, and child care. According to biblical law, the right to inherit belongs to sons first. To protect the rights of wives and daughters, rabbinic law obligated the sons to maintain the widows and unmarried daughters. (4) Financial law: except for Gen. 23:9 ff., Jer. 32:10, and Ruth 4:8, Scripture makes no reference to transaction procedures. The growth of finances, industry, and land estates led the rabbis to develop laws concerning contracts, partnerships, and legal arrangements to circumvent the biblical prohibition against usury. A series of modes of transaction effecting the transfer and acquisition of property evolved. Labour relations, rents, and leases were also carefully regulated.

THE TALMUD TODAY

Role in the Jewish community. With the rebirth of a Jewish national state (since 1948) and the concomitant revival of Jewish culture, the Talmud has achieved renewed importance. Orthodox Jewry has always focussed upon its study and has believed it to be the absolute Halakhic authority. This belief has now become even further intensified. While rabbinic courts in Israel have jurisdiction only in the area of family life, it has become one of the aims of religious (Orthodox) Jewry there to establish Talmudic law as the general law of the state.

It should also be noted that, aside from the special case of Israel, the legal system described above has continued to function down to the present day in Jewish communities all over the world. The jurisdiction of rabbinic courts is voluntarily accepted by Orthodox Jews. These courts continue to exert authority, especially in the areas of family and dietary law, the synagogue, and the organization of charity and social activity.

Conservative Jewry, too, has always been committed to rabbinic tradition. It has, however, conceptualized this tradition as an evolutionary process in which Halakha changes to meet the challenge of new conditions. Professional scholarship was considered crucial for understanding the furthering of this process. More recently, however, as a result of revived nationalism, new emphasis has been put upon lay education. Thus, a network of day schools and higher institutions of learning in which rabbinic tradition occupies a major role in the curriculum has been established. Scores of young Conservative Jews now search in the Talmud for answers to crucial problems, such as abortion and civil violence.

Classical (19th-century) Reform Judaism not only disassociated itself from the Talmud but negated it. More recently, however, Reform leaders have been inclined to re-establish some measure of ritual practice and rabbinic climate. Thus, it is now not unusual to find them stating their decisions in the form of *responsa* and using the rabbinic style of argument and even the casuistic type of Talmudic dialectic (*pilpul*) to justify their religious practices.

Talmudic scholarship. Although Talmudic scholarship continues to be advanced by individuals in a number of countries, its two main centres are in Israel and the United States. The Israeli centre has tended to focus upon research of a critical nature. Like Bible criticism, this work is divided between source criticism (*i.e.*, discovering the different sources, their dates, and the methods by which Talmudic literature was formed) and textual criticism (*i.e.*, establishing the correct text and reading). Research is also being done on Haggadic concepts and thinking, Talmudic law, and Halakhic development.

Talmudic scholarship in the United States has tended to be more philosophically and historically oriented. There has been great interest in the development of Halakha and also in folklore and custom. Essential work has also been done and continues to be done in the areas of source criticism. A work unique in scope and method is S. Lieberman's commentary on the Tosefta.

BIBLIOGRAPHY. B. GERHARDSSON, *Memory and Manuscript* (1961), contains a description of the methods and techniques by which the oral tradition was transmitted. H.L. STRACK, *Introduction to the Talmud and Midrash* (1931); and M. MIELZINER, *Introduction to the Talmud*, 4th ed. (1968), are still the best introductions for the general reader. The latter is particularly helpful in explaining Talmudic dialectic terminology and debate. J. BOWKER, *The Targums and Rabbinic Literature* (1969); and E. DEUTSCH, *The Talmud* (1895), are both descriptions of the Talmud, the former concentrating upon Talmudic literary compilations and the latter upon Talmudic content. The introduction of J. GOLDIN, *The Living Talmud* (1957), contains a vivid description of Talmudic debate. C. ALBECK, *Introduction to the Talmud*, in Hebrew (1969); and Z.H. CHAJES, *The Student's Guide Through the Talmud* (Eng. trans. 1952), are more advanced introductions, the former analytical and scientific and the latter representing the traditional view. J. NEUSNER (ed.), *The Formation of the Babylonian Talmud* (1970), contains summaries of some research by modern scholars on the question of how the Talmud was formed. L. GINZBERG, "Introduction to the Talmud," in *A Commentary on the Palestinian Talmud*, vol. 1 (1941), is the only introduction to the Palestinian Talmud available in the English language. L. FINKELSTEIN, *Akiba* (1962), is a historical and sociological approach to the development of Halakha. S. LIEBERMAN, *Greek in Jewish Palestine* (1942) and *Hellenism in Jewish Palestine* (1950), deal with the interrelationship between the ancient rabbinic world and its Gentile environment. B. COHEN, *Jewish and Roman Law*, 2 vol. (1966); and I. HERZOG, *The Main Institutions of Jewish Law*, 2 vol. (1966–67), are the best English descriptions of Jewish law. J. Z. LAUTERBACH, *Rabbinic Essays* (1951); G.F. MOORE, *Judaism*, 3 vol. (1927–30); S. SCHECHTER, *Aspects of Rabbinic Theology* (1961); and E.E. URBACH,

The Sages: Their Concepts and Beliefs, in Hebrew (1969), cover the major aspects of rabbinic theology. I. HEINEMAN, *Paths of the Aggadah*, in Hebrew (1970); M. KADUSHIN, *The Rabbinic Mind*, 2nd ed. (1965); and D. BEN AMOS, *Narrative Forms of the Haggadah: Structural Analysis* (1969), discuss Haggadic methods, forms, concepts, and thinking. L. ZUNZ, *Die Gottesdienstlichen Vorträge der Juden* (1892; updated Hebrew translation, 1950), is a thorough historical survey of Haggadic literature. D. NOY, *Motif-Index of the Talmudic-Midrashic Literature* (1954); J.J. SLOTKI, *Index Volume to the Soncino Talmud* (1952); M. GASTER, *The Exempla of the Rabbis* (1924, rev. ed. 1968); and C.G. MONTEFIORE and H. LOEWE, *A Rabbinic Anthology* (1938), are very helpful as reference guides; while W.O.E. OESTERLEY, H. LOEWE, and E.I.J. ROSENTHAL, *Judaism and Christianity*, rev. ed. (1969); and C. MERCHAVIA, *The Church Versus Talmudic and Midrashic Literature*, in Hebrew (1970), describe the relationship between the church and rabbinic Judaism. L. FINKELSTEIN (ed.), *The Jews*, 3rd ed., 2 vol. (1960); and E.R. BEVAN and C. SINGER (eds.), *The Legacy of Israel* (1927), deal with the influence of Judaism on world culture. Extensive bibliographies may be found in the works of Gerhardsson, Mielziner, Bowker, and Ben Amos.

(H.Z.D.)

Tamil Nadu

One of the southern states of India, Tamil Nadu (Land of Tamil) is located in the extreme southeast of the Indian peninsula. Representing the Tamil-speaking area of what was formerly Madras Presidency, it has an area of 50,180 square miles (129,966 square kilometres) and a population of about 41,103,000. It is bounded by the Indian Ocean to the east and south, by the states of Kerala to the west, Mysore to the northwest, and Andhra Pradesh to the north. Its capital is Madras.

While it has an industrial core in Madras, the state is essentially agricultural. Proud of their Dravidian language and culture, the Tamils have resisted attempts to make Hindi the national language. (For information on the state capital, see the city article MADRAS.)

The three Tamil kingdoms

History. *Early history.* The history of Tamil Nadu begins with the establishment of a trinity of Tamil powers in the region—the Cēra, Cōḷa, and Pāṇḍya kingdoms. By about AD 200 the influence of northern Aryan powers had progressed, and the Aryan saint Agastya had established himself as a cultural hero. The use of Roman gold and lamps and the consumption of Italian wine attest to the extensive foreign trade of the period. From the mid-6th century until the 9th century, the Cālukyas of Bādāmi, the Pallavas of Kāñcī, and the Pāṇḍyas of Madurai fought a long series of wars in the region. The period, nonetheless, was marked by a revival of Hinduism and the advance of the fine arts. From about AD 850, Tamil Nadu was dominated by the Cōḷas, of whom Rājendra I (reigned 1014–44) was the most distinguished ruler. In the mid-14th century the Hindu kingdom of Vijayanagar, including Tamil Nadu, came into prominence. During the 300 years of Vijayanagar administration, Telugu-speaking governors and officials were established.

The British period and independence. In 1639 the British East Indian Company opened a trading post at the fishing village of Madraspatnam (now Madras) with the permission of the declining Vijayanagar Empire. The history of Tamil Nadu from the mid-17th century to 1946 is the story of the Madras Presidency in relationship to the rise and fall of British power in India. After 1946 the Madras Presidency was able to make steady progress, as it had a stable government. In 1953 the Telugu-speaking state of Andhra Pradesh was formed, and in 1956 the presidency was further divided into the states of Kerala, Mysore, and Tamil Nadu.

The landscape. *Relief, drainage, and soils.* The state is divided naturally between the flat country along the eastern coast and the hilly regions in the north and west. The broadest part of the eastern plains is the fertile Cauvery Delta; farther south are the arid plains of Rāmanāthapuram and Madurai. The high Western Ghāts range runs all along the state's western border. The lower hills of the Eastern Ghāts and its outliers—locally called the Javādis, Kalrāyans, and Shevaroys—run through the centre of the region.

The important rivers include the Cauvery, the Ponnaiyār, the Pālār, the Vaigai, and the Tambraparni, all of which flow eastward from the inland hills. The Cauvery and its tributaries are Tamil Nadu's most important sources of water and power. The rivers

Apart from the rich alluvial soil of the river deltas, the predominant soils are clays, loams, sands, and red laterites (soils with a high content of iron oxides and aluminum hydroxide). Black cotton soil is found in parts of Salem and Coimbatore in the west, Rāmanāthapuram and Tirunelveli in the south, and Tiruchchirāppalli in the central region of Tamil Nadu.

Climate. The climate is essentially tropical. The temperature in summer seldom exceeds 109° F (43° C) and in winter seldom falls below 64° F (18° C). The lowest temperatures are recorded during December and January, and the highest in April to June. The average annual rainfall, falling mainly between October and December, depends on the southwest and northeast monsoons and ranges between 25 and 75 inches a year. The most precipitation falls in the Nīlgiris and other hill areas, the lowest in the Rāmanāthapuram and Tirunelveli districts.

Vegetation and animal life. Forests cover about 15 percent of the state. At the highest altitudes of the Western Ghāts—the Nīlgiri, Anamalai, and Palni Hills—the mountains support subalpine vegetation. Along the eastern side of the Western Ghāts and in the hills of the northern and central districts, the plant life is a mixture of evergreen and deciduous plants, some of which are markedly adapted to arid conditions. The state's aquatic birds are represented in the bird sanctuary at Vedantangal; other forms of wildlife may be seen in the game sanctuary at Mudumalai.

Population. *Ethnic groups.* The present population has changed little over the centuries. Population characteristics include short to medium stature, dark to brown skin colour, and wavy hair. Dark pigmentation is more general in the southern districts and among the lower castes and tribes. Most of the hill tribes are of Veddoid origin. Caste is still strong, though untouchability has been banned by law. Former untouchables, now officially termed "scheduled castes," number about 6,000,000; and hill tribes number about 250,000.

Linguistic patterns. Tamil, the official state language, is spoken by over 83 percent of the people. For a considerable number of the population long resident in the state, Tamil has almost become a mother tongue. Telugu is spoken by almost 10 percent of the population, Kannada by almost 3 percent, Urdu by less than 2 percent, and Malayalam by more than 1 percent. In the Nīlgiris district in the west, Kannada (and its dialect Badaga) and Malayalam are stronger. English is spoken as a subsidiary language.

Religious affiliations. The main religions are Hinduism, Christianity, Islām, and Jainism. Followers of the first three are found in all districts, but Jains are confined to North and South Arcot and Madras city. Hindus form almost 90 percent of the population, Christians 5 percent. The largest concentration of Christians is in the Tirunelveli and Kanyakumari districts. The growth of atheism is a recent development; in 1961 about 34,000 persons declared themselves atheists, possibly as a protest against Brahmin ritualism.

Patterns of settlement. Though Tamil Nadu is one of the two most urbanized states of India (27 percent of the population is urban), it is still a rural land. Almost 25,000,000 people live in more than 14,000 nucleated villages. The poorest low-caste villagers live in segregated areas called *cēri*. The urban population lives in almost 443 towns, 17 of which have more than 100,000 inhabitants. The Madras metropolitan conurbation, covering the industrial areas, townships, and villages, has a population of about 2,500,000. There are 16 other conurbations, of which those around Madurai, Coimbatore, and Tiruchchirāppalli are the most important.

Administration. *State government.* The governor, the Legislative Assembly (235 members), Legislative Council (63 members), and the chief minister and his cabinet together constitute the legislative and executive wings of

the state government. The ministries are housed in Ft. St. George in Madras, though the offices of several heads of departments are in multistoried buildings outside the fort.

Local government. The state has 14 administrative districts, each administered by a district collector. Lower administrative units are divisions called *taluka, firka,* and villages. All of these units are responsible to the Revenue Department and the Board of Revenue. After independence, new units—*pañcāyat*s (village councils)—were established for purposes of local self-government and rural development. Above the *pañcāyat* there are *pañcāyat* unions and development councils. Villagers get their first lessons in democracy and administration in the *pañcāyat*s.

Justice. The judiciary is controlled by the High Court at Madras; there are district judges and magistrates at the lower levels.

Social conditions. *Health and the cost of living.* In the early 1970s, the annual per capita income in Tamil Nadu was Rs. 564, or about U.S. $79. Distribution of wealth is uneven. Though the death rate of the same period, eight per 1,000 persons, was low, and the birth rate of 24 per 1,000 moderate, infant mortality was as high as 60 per 1,000 live births. Smallpox seemed to be under control, but cholera, malaria, and filariasis (disease caused by infestation of the blood and tissues by parasitic worms) were not. Urban sanitation and drainage were substandard. There were more than 1,500 public and private hospitals, dispensaries, and primary health centres in the state.

Education. The literacy rate was almost 40 percent in 1971. About 92 percent of the children between the ages of six and 14 were at school in 1968–69. There were over 31,500 primary and middle schools, more than 2,500 high schools, and almost 150 arts and science colleges, as well as medical colleges, engineering colleges, polytechnic institutes, and industrial training institutes. The three state universities are at Madras, Anamalai, and Madurai. A vigorous effort is being made to make Tamil instead of English the medium of instruction at the university level.

Welfare. In the early 1970s the lowest castes, called Harijan (Children of God), continued to be the most miserable section of the Hindu population. The Department of Harijan Welfare was in charge of programs to improve their housing, education, and economy. Government positions were reserved for them, and there were also reserved constituencies for them for elections to the state legislature and Parliament. The State Social Welfare Board and Department of Women's Welfare are concerned with the problems of the handicapped, widows, and children. The state government provides free lunches for poor children at the elementary schools.

The economy. *Agriculture.* Agriculture is the mainstay of life for about three-quarters of the rural population. From very early times Tamil farmers have skillfully conserved scarce rainwater in small and large irrigation reservoirs, or "tanks." Government canals, tube wells, and ordinary wells also form part of the irrigation system. There are 17 river valley irrigation schemes, with 21 reservoirs and about 14,000 miles of distribution canals. As several of the river valley projects depend for water on the erratic northeast monsoon, the government is trying to tap subsoil water sources.

The irrigation system

Agricultural practices have undergone radical improvement since 1950. Multiple cropping, the use of new and better strains of rice, cotton, sugar, and millet, and the use of chemical fertilizers have been widely adopted. By 1967 the state was self-sufficient in the production of food grains. Tamil Nadu accounts for about 11 percent of India's rice production and 15 percent of its peanuts. Cotton and sugarcane are other important cash crops.

Industry. Improved port facilities and the effective use of electric power resources have helped industrial development. The state is the third most industrialized of the Indian states. In 1971 there were four thermal and 15 hydroelectric power stations with a capacity of almost 2,000,000 kilowatts. These were to be further augmented upon completion of an atomic power plant at Kalpakkam (scheduled for 1974). Cotton ginning, spinning, and weaving continued to be the major industries, followed by the manufacturing of cars, motorcycles, electric motors, and transformers. Other major undertakings include refineries and fertilizer plants and tire, aluminum, cement, chemical, and paper factories.

Transport and communications. The transport system of the southern Indian states converges on Madras. About 235 miles of broad-gauge or metre-gauge railways run through Tamil Nadu. The artificial harbour of Madras handles seaborne traffic. Apart from the international airport at Meenambakkam near Madras, there are three other airports at Tiruchchirāppalli, Madurai, and Coimbatore. There are 2,209 miles of motorable roads. Passenger bus transport is being nationalized; express buses take passengers to all important towns and places of interest. Post and telegraph offices are widely distributed and telephone services are available. The two radiobroadcasting stations are at Madras and Tiruchchirāppalli.

Cultural life. *The cultural milieu.* Despite attempts to break the religious and poltical power of the priestly Brahmin caste, Hinduism remains at the core of the culture. The more than 9,300 larger temples come under the administrative control of the Hindu Religious and Charitable Endowments Department. In most towns—and particularly in Chidambaram, Kānchipuram, Thanjāvūr (Tanjore), and Madurai—the *gopuram*s, or gateway towers, of the temples are dominant. The cycle of temple festivals attracts large congregations of devotees. Noteworthy are the car festivals during which large chariots decorated with icons are dragged around the temple. Hindu families owe allegiance to a number of sectarian monastic institutions, or *mutt*s, of which the most important is the Sankara Mutt at Kumbakonam.

The cultural role of Hinduism

The arts. Classical *bhārata-nātya* dancing and Carnatic music are widely practiced. Painting and sculpture, however, are less developed although there are schools for stone and bronze sculptors. Tamil literature rapidly adapted to the Western literary forms of the novel and the short story. The poet Subrahmanya Bharati (who died in 1922) was one of the first to modify traditional Tamil poetry. Since the 1940s, the motion picture has become the most popular form of mass entertainment. There are both touring and permanent cinema theatres; and sentimental and spectacular films, often featuring light music and dancing, are produced by the state's film studios.

The press. In 1968 there were over 400 periodicals published in Tamil, of which 41 were daily newspapers. The *Dinathanthi* is the leading paper. Among English newspapers, *The Hindu* of Madras maintains excellent journalistic standards.

BIBLIOGRAPHY. K.A. NILAKANTA SASTRI, *The Culture and History of the Tamils* (1964) and *A History of South India from Prehistoric Times to the Fall of Vijayanagar,* 3rd ed. (1966), are eminently readable and factual texts. Important data and an excellent atlas of the state may be found in the *Census of India 1961,* vol. 9, *Madras,* pt. 1–8 (1965–67). The proceedings of the 21st International Geographical Congress, Madras, *This Is Tamil Nadu* (1968), contains a collection of papers on a wide range of topics.

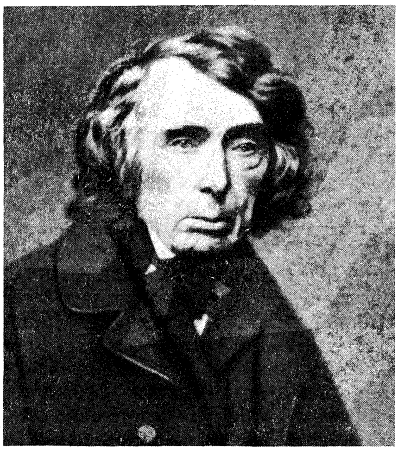
(A.Ai.)

Taney, Roger Brooke

Roger Brooke Taney, fifth chief justice of the Supreme Court of the United States, is principally remembered for the decision in the Dred Scott case, with which the court's majority opinion set back the cause of the antislavery forces by many years. Yet Taney was more than merely a rigid supporter of states' rights; in many important cases he advanced, in strict accordance with the Constitution, the power of the federal government.

He was born March 17, 1777, the son of Michael and Monica (Brooke) Taney. Of English ancestry, Michael Taney had been educated in France and was a prosperous tobacco grower in Calvert County, Maryland.

After graduation from Dickinson College in Pennsylvania, in 1795, Taney studied law with Judge Jeremiah Chase, of the Maryland General Court. He was admitted



Taney, photograph by Mathew Brady (c. 1823–96)
By courtesy of the Library of Congress, Washington, D.C.

to the bar in 1799 at Annapolis and served one year in the Maryland House of Delegates before settling down in Frederick, Maryland, to practice law. In 1806 he married Anne Key, whose brother, Francis Scott Key, later wrote "The Star-Spangled Banner."

Taney was a member of the conservative, property-conscious Federalist Party until 1812, when the party opposed the war against England. He returned to the Maryland House of Delegates in 1816, when, as a political maverick, he was elected to the state senate. Two years after his term expired in 1821, he moved his family to Baltimore, where he was soon recognized as an excellent lawyer. Juries were impressed with his sense of fair play and his courtesy toward opposing attorneys. In 1827 he was appointed attorney general of Maryland. By this time he had aligned himself with Andrew Jackson, the leader of the Democratic Party, and when Jackson, elected president in 1828, reorganized his cabinet in 1831, he appointed Taney attorney general of the United States.

Fight against the Bank of the United States

Throughout his tenure in Washington, Taney had been an outspoken leader in the Democrats' fight against the central bank, the Bank of the United States, which was widely regarded as a tool of Eastern financial interests. Taney believed it had abused its powers, and he strongly advised the president to veto the congressional bill that would renew the bank's charter and wrote much of the veto message; he also recommended that government funds be withdrawn from the bank and be deposited in a number of state banks.

As a result of his role in the fight over the Bank of the United States, Taney had become a national figure and in 1833 President Jackson appointed him secretary of the treasury. But opposition to Taney and his financial program was so strong that the Senate rejected him in June 1834, marking the first time that Congress had refused to confirm a presidential nominee for a cabinet post.

Taney returned to Baltimore to rebuild his law practice. A year later, Jackson nominated him to the Supreme Court of the United States as an associate justice. Taney's enemies stalled the nomination indefinitely. Then, on July 6, 1835, Chief Justice John Marshall died, and Taney was nominated to fill his place on the bench.

Despite powerful resistance, led by such prominent politicians as Henry Clay, John C. Calhoun, and Daniel Webster, Taney was sworn in as chief justice in March 1836. Although he had inherited the conservative tradition of the Southern aristocracy and had supported states' rights, the Taney court did not discard John Marshall's ideas of federal supremacy. Taney believed firmly in divided sovereignty, but he also believed it was the Supreme Court's role to decide which powers should be shared. Eventually, many of those who had opposed Taney's appointment came to respect him.

One of the most important decisions for which the Taney court is noted concerned rights granted by charters. The majority opinion in *Charles River Bridge* v. *Warren Bridge* (1837) declared that rights not specifically conferred could not be inferred from the language of a document. In this decision Taney rejected the claim of a bridge company that the subsequent grant by the state legislature of a charter to another bridge company impaired the legislature's charter to the first company.

The Dred Scott case

But the majority opinion that Taney delivered 20 years later, on March 6, 1857, in *Dred Scott* v. *Sanford* is the one for which he became famous. In essence, the decision argued that Scott was a slave and as such was not a citizen and could not sue in a federal court. Taney's further opinion that Congress had no power to exclude slavery from the territories and that Negroes could not become citizens was bitterly attacked in the Northern press. The Dred Scott decision probably created more disagreement than any other legal opinion in U.S. history; it became a violently divisive issue in national politics and dangerously undermined the prestige of the Supreme Court.

Whenever state authorities threatened or interfered with the execution of federal power, however, Taney upheld federal supremacy. His opinion in *Ableman* v. *Booth* (1858), denying state power (in this case the courts of the state of Wisconsin) to obstruct the processes of the federal courts, remains a magnificent statement of constitutional federalism. Under Taney's leadership federal judicial power was expanded over corporations, the federal government was held to have paramount and exclusive authority over foreign relations, and congressional authority over U.S. property and territory was vigorously upheld. His conflict with President Lincoln over the president's suspension of a citizen's petition for a writ of habeas corpus in time of war made him an object of bitter criticism, although in time many jurists came to agree with Taney's defense of an individual's constitutional rights.

Taney, a deeply religious Roman Catholic, considered slavery an evil. He had freed the slaves he had inherited before he came to the Supreme Court. It was his belief, however, that slavery was a problem to be resolved gradually and chiefly by the states in which it existed. As an adherent of the South, he could do nothing but watch the defeat of his cause. He died in Washington on October 12, 1864. Even though his thinking ran counter to the dominant historical trends of his time, he had an enduring influence on the substance and evolution of American constitutional law.

T'ang Hsüan Tsung

Under Hsüan Tsung (in Pin-yin romanization Tang Xüan Zung), the sixth emperor of the T'ang dynasty, the T'ang reached the zenith of their power and the peak of their culture. Hsüan Tsung ascended the throne in 712 under the nominal regency of his father, Jui Tsung; he achieved full power in 713 and abdicated in 756.

Early life and career

Hsüan Tsung, whose personal name was Li Lung-chi, was the third son of Jui Tsung by his empress *née* Tou. He was born in Lo-yang in 685, during a period when actual power was entirely in the hands of Empress Wu, although his father was nominal emperor. Hsüan Tsung survived purges in the 680s and early 690s, living with his father in strict seclusion, while many of the T'ang Imperial family were killed. Enfeoffed as prince of Ch'u in 687, he was re-enfeoffed as prince of Lin-tz'u in 693 after Empress Wu's usurpation of the throne. Toward the end

of her reign he was appointed an officer in the Imperial Guard of the Right and to an office in the Imperial Household department. On the restoration to the throne in 705 of his uncle Chung Tsung, he became vice president of the Court of Imperial Insignia, which controlled the arsenals of the capital. Although these posts were probably ceremonial, they gave him influence over the Imperial guards and palace armies.

In 710 Chung Tsung was poisoned by his domineering empress Wei, who appointed a 15-year-old puppet to the throne, intending to rule herself. This plan was thwarted by a coup led by the princess T'ai-p'ing, daughter of Empress Wu and sister of Jui Tsung. The empress Wei was killed, the puppet emperor deposed, and Jui Tsung restored to the throne. As a result of Hsüan Tsung's key role in this coup, he was appointed heir apparent.

Gradually, the court divided into factions around the princess T'ai-p'ing, who wished to continue a system of corrupt patronage, and Hsüan Tsung, who had instituted various administrative reforms. In 712 Jui Tsung abdicated in favour of Hsüan Tsung but, at T'ai-p'ing's urging, remained "Supreme Emperor," a sort of regent with control over appointments to high offices, which were filled with the Princess' supporters. The struggle between Hsüan Tsung and his aunt was intensified. In 713 she planned yet another coup, but this was forestalled by Hsüan Tsung, and she committed suicide. Hsüan Tsung then assumed full authority as emperor, and his father retired into seclusion.

Assumption of full imperial authority

Hsüan Tsung's reign began well. He carried out a sweeping reform of the bureaucracy, which had become vastly inflated by great numbers of nominal and supernumerary officials, many of whom had been appointed by patronage and many more by the open purchase of their posts. Some stability was regained, and the normal channels of authority, which had fallen into disorder under Empress Wu, were restored. The purchase of office was restricted. The numbers of Buddhist clergy and monasteries were reduced, and irregular ordinations, carried out to evade tax and civil responsibility, were severely restricted. Some financial reforms were effected, and the canal system, upon which the capital at Ch'ang-an relied and which had fallen into decay while Empress Wu resided in Lo-yang, was restored to action. Successful campaigns were waged against the Tibetans, the Turks, and the Khitan. During this early stage of Hsüan Tsung's reign, which lasted until about 721, the court continued to be dominated by the examination-recruited ministers who had served the empress Wu, Chung Tsung, and Jui Tsung. The authority of the throne, the efficient functioning of the regular bureaucracy, and the finances of the state were largely restored. Moreover, the members of the Imperial clan were gradually excluded from any effective political role, while the power of the palace officials and members of consort families was strictly limited to avoid any further palace coups.

A period of wide-ranging reforms in administration began in 720. The whole structure of central government was changed in such a way as to concentrate more and more authority in the hands of the chief ministers. At the same time there was a marked resurgence of the influence of the old aristocracy at court, and the period 721–737 was one of continuous political tension between the aristocrats and the examination-recruited professional bureaucrats. The aristocratic faction had its chief centres of power in the censorate, which was in general control of the functioning of the bureaucracy, and in the various new irregularly established commissions that implemented a series of sweeping financial reforms. The population was effectively reregistered, bringing vast numbers of taxpayers onto the rolls and a sharp increase in revenue; the coinage was improved, and the transportation system was reformed so effectively that the Emperor no longer had to move the court between Ch'ang-an and Lo-yang periodically to avoid famine. The empire's revenues increased, enabling the Emperor to establish along the northern frontiers an ever-growing permanent military establishment (by the end of his reign numbering 600,000 men), without overburdening the population.

The political influence of these financial experts grew even greater in the latter part of Hsüan Tsung's reign, and after 737, Li Lin-fu, chief representative of the aristocratic interest, became virtual dictator and the aristocratic party was firmly entrenched in power. From about 740 onward the Emperor's actual control of affairs began to decline. The reforms, which theretofore had mostly been necessary for greater administrative efficiency, now tended more and more to destroy the balance of political power. The chief ministers formally acquired unprecedented power and prestige as heads of the government. At the same time the Emperor began to erect around him a complex palace administration, including two private secretariats (used to bypass the normal channels for drafting legislation) and palace treasuries handling the Emperor's private purse. The financial experts, too, devoted more and more of their attention to purely exploitative measures designed to pay for court extravagance and the Emperor's personal needs.

Decline of Hsüan Tsung's control

Moreover, after 737, the vast regional commands established earlier in the reign to control the northern border and to provide a necessary network of strategic command now began to develop widespread powers in other fields and to acquire territorial authority. By the late 740s some of these generals had grown immensely powerful and began to intervene in court politics. Most important of them was Li Lin-fu's protégé An Lu-shan, who controlled the northeast and had an army of 180,000 troops. The central government had no standing armies under its own command to rival the forces of these military governors.

Meanwhile Hsüan Tsung had withdrawn more and more. Always a great patron of the arts—he had founded Imperial music academies to provide court musicians and had patronized poets, painters, and writers—he now became deeply involved in the study of Taoism, from whose founder the T'ang royal house claimed to be descended.

He also began to suffer from family problems. Hsüan Tsung had produced 59 children, of whom 48 survived to maturity. Many of these had been married into the great aristocratic families, thus helping to cement the authority of the latter. The Emperor kept very strict control over his children and their innumerable descendants, but he nevertheless came under the powerful influence of at least two of his many consorts. The first was Wu Hui-fei, who had great influence from the early 720s until her death in 737; she was influential in the rise of Li Lin-fu, and shortly before her death she was involved in an incident that resulted in the death of the crown prince and three other princes who stood in the way of her own eldest son's becoming heir to the throne. The eventual heir, however, was another prince (the future Su Tsung), who was opposed to Li Lin-fu. From 746 onward there were several alleged succession plots, which led to purges involving many prominent ministers and generals.

The Emperor also came under the influence of another favourite, the consort Yang Kuei-fei, who was originally the wife of his own son Li Mao but who had been taken into the Imperial harem. During the later years of his reign, Hsüan Tsung was completely infatuated with her and heaped honours on members of her family. One of these relatives, her cousin Yang Kuo-chung, rose rapidly to rival even Li Lin-fu in power and, on the latter's death in 752, replaced him as the dominant chief minister. There had already been some tensions between Yang Kuo-chung and An Lu-shan. With the removal of his patron at court, and the increasing hostility of Yang Kuo-chung, An Lu-shan began building up his provincial power base in readiness for an armed confrontation. This began at the end of 755. An Lu-shan's forces swiftly struck into the northeastern provinces, and, by the summer of 756, they were approaching Ch'ang-an. Hsüan Tsung, accompanied only by a small group of intimate courtiers, Yang Kuei-fei, and a few troops, fled to take refuge in Szechwan, the power base of the Yang clan. They had reached Ma-wei when the soldiers mutinied, killed Yang Kuo-chung, and forced Hsüan Tsung to have Yang Kuei-fei killed.

Shortly afterward, the heir apparent, who had fled separately to Ling-wu, west of the capital, proclaimed himself

Abdication

emperor. Hsüan Tsung, who heard of this only some time after it had occurred, acquiesced and abdicated formally in his favour. He lived in retirement until his death in 762.

Although Hsüan Tsung's reign ended in political disaster and personal tragedy, it was a period of internal stability, good government, and prosperity, an era of confidence during which real progress was made in every field. The sudden end of this period not only changed the political system completely but it was also a dramatic, traumatic experience for the men of the time. In the next decades the confident pride of Hsüan Tsung's age was replaced by self-questioning, by withdrawal from public affairs, and by a new spirit of social and political criticism.

BIBLIOGRAPHY. The only satisfactory account of this period in a Western language is E.G. PULLEYBLANK, *The Background of the Rebellion of An Lu-shan* (1955), which deals primarily with the political events of the latter part of the reign. There is no standard biography in any language. OTTO FRANKE, *Geschichte des chinesischen Reiches*, vol. 2 (1936), gives an account based upon the standard Chinese official histories. HOWARD S. LEVY has discussed Hsüan Tsung's succession to the throne in "How a Prince Became Emperor: The Accession of Hsüan-tsung," *Sinologica*, 6:101–121 (1961). The financial and administrative reforms of the period are dealt with in D.C. TWITCHETT, *Financial Administration Under the T'ang Dynasty* (1963).

(D.C.T.)

T'ang T'ai Tsung

The second emperor and real founder of the T'ang dynasty, which ruled China from AD 618 to 907, was Li Shih-min, whose posthumous title was T'ang T'ai Tsung (Pinyin romanization Tang Tai Zong). The new dynasty proved long and enduring and became the model for its successors down to modern times. This continuity was largely the work of T'ai Tsung, who was as competent as an administrator and ruler as he was triumphant as a general. His achievement was to re-found the united Chinese Empire on a basis that endured under successive dynasties for more than 1,000 years.

The second son of Li Yüan, a military governor under the Sui dynasty, T'ai Tsung was born in 600 a member of an aristocratic family of Chinese and Tatar descent. As early as 618 he instigated the revolt of his father against the failing Sui dynasty and then led the armies of the new T'ang regime to complete victory over 11 rivals. In 626 he succeeded his father as emperor and reigned until his death in 649. China had been divided into two rival empires, north and south, Tatar and Chinese, for 272 years until reunited in 590 by the short-lived Sui dynasty. The new unity collapsed under the second Sui emperor, Yang Ti; and it was in the ensuing anarchy that the future T'ai Tsung, in a series of brilliant campaigns, established the T'ang dynasty and restored the unity of the Chinese empire.

Establishment of the T'ang dynasty

The restoration of unity was a considerable feat of arms. At the fall of the Sui dynasty almost all the provinces set up separate regimes that were in conflict with each other and that aimed, individually, to win supreme mastery of the empire. The south seceded under a claimant of a former southern dynasty. The Turks, meanwhile, then the dominant tribe among the nomads beyond the Great Wall (extending from the Yellow Sea roughly west to Central Asia), raided China, set up their own puppet emperors in border regions, and planned more massive invasions.

In the six years between 618 and 624, T'ai Tsung defeated all rivals and repelled the Turks. The south was reconquered; many of the contesting leaders fought to the death, though some joined the T'ang and obtained rank and title. The unity of the empire was popular with the mass of the people, for it alone ensured peace and absence of internal strife. But T'ai Tsung was less skillful at court intrigue. He provoked the jealousy of his less distinguished elder brother, the crown prince Chien-ch'eng, who intrigued to have T'ai Tsung dismissed from his command and plotted to assassinate him. T'ai Tsung, supported by his generals and advisers, forestalled

T'ang T'ai Tsung, portrait by an unknown artist. In the National Palace Museum, Taipei.
By courtesy of the National Palace Museum, Taipei

the attempt and ambushed his brother and followers at the palace gate, shooting them down with arrows. His father abdicated, but this violent solution to a political problem was copied in later generations, proving detrimental to governmental stability. T'ai Tsung also failed to find a suitable son as successor, being bound by custom and political pressure to choose one born to the senior empress, not to any concubine. His first choice, the crown prince Ch'eng-ch'ien, proved to have an unstable character; he plotted against his father and had to be demoted. The second choice, Prince Chih, was docile, weak, and incapable, becoming after T'ai Tsung's death, as Emperor Kao Tsung, the instrument of his ambitious and capable empress, Wu Tse T'ien.

Domestic policies

As a ruler T'ai Tsung was eminently successful. His authority was never disputed, and his reforms reinvigorated and transformed old institutions. The system of public examinations for the civil service was among the most important of his innovations; in time, it transformed the Chinese governing class from a dominant aristocracy to a bureaucracy recruited from a much wider field of literate gentry. This was indeed T'ai Tsung's purpose; to end the contests of aristocratic families, such as his own, which had made the period of division between north and south one of incessant dynastic instability. The army was converted from levies raised by great aristocrats into a professional army, stationed on the frontiers and commanded by officers who had no eminent social background. Hence it was a stabilizing influence in the earlier T'ang period and remained the model system for later ages. T'ai Tsung also promoted education, setting up a state college, which might almost be called a university, to train future scholars for the civil service. His thorough administration included reorganization of provincial government, finance, taxation, and land tenure. The government of the T'ang empire was then the most developed and most sophisticated system anywhere in the world.

Posterity, with the exception of Communist historians, has hailed T'ai Tsung as the greatest emperor to occupy the Chinese throne. His career was certainly a most formative influence on later Chinese history and civilization. An accomplished patron of learning, he personally edited

the history of the division between north and south, and his calligraphy, an art much esteemed in China, has been recorded on stone inscriptions and used as a model in schools for more than 1,000 years. The middle T'ang period, the 8th century, is regarded as one of the ages of highest cultural achievement in Chinese history, and the conditions for this development were created by the political stability and reforms established under T'ang T'ai Tsung.

(C.P.F.)

Tanks and Armoured Vehicles

Tanks are the principal type of tracked military armoured vehicle. Essentially mobile platforms for direct-fire weapons, they make the weapons mounted in them more effective by virtue of their cross-country mobility and the protection that they provide for their crews. Tank weapons have ranged from a single machine gun of small calibre to present-day combinations of one or more machine guns with a large gun of 75- to 152-millimetre calibre. A few experimental tanks have been armed with even larger guns and some tanks are now supplied with guided missiles.

Other major tracked armoured vehicles include: personnel carriers, originally conceived only for transporting infantrymen into battle, but since also used for fighting, although they are less powerfully armed than tanks; self-propelled guns, which are sometimes unarmoured and wheeled; armoured cars, which often resemble the lighter reconnaissance types of tanks but run on wheels; and other specialized vehicles, including armoured recovery vehicles, bridgelayers, and armoured bulldozers, all of which are principally intended to assist tanks, and amphibious armoured vehicles that are used for assault landing operations.

HISTORY OF ARMOURED VEHICLES IN WARFARE

Earliest developments. Ideas for armoured fighting vehicles may be traced as far back as the 2nd millennium BC, when horse-drawn war chariots were used in the Middle East by the Egyptians, Hittites, and others as mobile platforms for fighting with bows and arrows. Other concepts, including protection of armoured vehicles, can be traced back through wheeled siege towers and battering rams in the Middle Ages to similar devices used by the Assyrians in the 9th century BC. More recent forms of the protected vehicle idea may be found in battle cars proposed in 1335 by Guido da Vigevano, by Leonardo da Vinci in 1484, and by others down to J. Cowan, who secured a patent in England in 1855 for a wheeled, armoured vehicle based on the steam tractor.

It was only at the beginning of this century, however, that armoured vehicles began to take practical form. By then, the essential mechanical elements had been developed. In particular, the traction engine and the motor car became available for military application. The first self-propelled armoured vehicle was produced in 1900 in England when John Fowler & Company armoured one of their steam traction engines for hauling supplies in the South African War of 1899–1902. The first use of the motor car as a gun carrier was in 1899, in England, when a Maxim machine gun was mounted on a powered four-wheeled vehicle with a bicycle seat and handle bar steering (quadricycle). The inevitable next step was a vehicle that was both armed and armoured. Such a vehicle was constructed and exhibited in London in 1902. In the latter part of 1899 a machine-gun-armed motor car was built in the United States and in 1902 a partially armoured machine-gun car was exhibited in Paris by the Société Charron, Girardot et Voigt, which two years later developed a fully armoured car with a turret. By 1904 a turreted armoured car was also built in Austria by the Austro-Daimler Company.

First self-propelled armoured vehicle

To complete the evolution of the basic elements of the modern armoured vehicle, it remained only to adopt tracks as an alternative to wheels and this became inevitable with the appearance of the tracked agricultural tractor. There was no incentive for this development, however, until after the outbreak of World War I.

Proposals for tracked armoured vehicles failed to arouse the interest of military authorities. Suggestions for an armoured tracked gun made in 1903 in France and five years later in Britain were both denied consideration. Similarly, a design for a tracked armoured vehicle put forward in 1911 was rejected, in turn, by both the Austro-Hungarian and German general staffs, and in 1912 the British War Office turned down still another design.

World War I. The outbreak of World War I in 1914 radically changed the situation. Its opening stages of mobile warfare accelerated the development of armoured cars, numbers of which were quickly improvised in Belgium, France, and Britain. Trench warfare, which ended the usefulness of armoured cars, brought forth new proposals for tracked armoured vehicles. Most of these resulted from attempts to make armoured cars capable of moving off the roads, over broken ground, and through barbed wire. The first tracked armoured vehicle was improvised in July 1915, in Britain, by mounting an armoured car body on a Killen-Strait tractor. The vehicle was constructed by the Armoured Car Division of the Royal Naval Air Service, whose ideas, backed by the First Lord of the Admiralty, Winston S. Churchill, resulted in the formation of an Admiralty Landships Committee. A series of experiments by this committee led in September 1915 to the construction of the first tank, called "Little Willie." A second model, or "Big Willie," quickly followed; it was designed to cross wide trenches. "Big Willie" was accepted by the British Army, which ordered 100 tanks of this type in February 1916.

First tracked armoured vehicle

Simultaneously but independently, tanks were also being developed in France. Like the very first British tank, the first French tank (the Schneider) amounted to an armoured box on a tractor chassis; 400 were ordered in February 1916. But French tanks were not used until April 1917, whereas British tanks were first sent into action on September 15, 1916. Only 49 were available and their success was limited. On November 20, 1917, however, 474 British tanks were concentrated at Cambrai and achieved a spectacular breakthrough. These tanks, however, were too slow (four miles per hour) and had too short a range (20–40 miles) to exploit the breakthrough. In consequence, demand grew for a lighter, faster type of tank and in 1918 the 14-ton Medium A appeared with a speed of eight miles per hour and a range of 80 miles. After 1918, however, the most widely used tank was the French Renault F.T., a light and slow 6-ton vehicle designed for close infantry support (see Figure 1, right).

When World War I ended in 1918, France had produced 3,870 tanks, and Britain 2,636. Most French tanks survived into the postwar period; these were the Renault F.T., much more serviceable than their heavier British counterparts. Moreover, the Renault F.T. fitted well with traditional ideas about the primacy of the infantry; the French Army adopted the doctrine that tanks are a mere auxiliary to infantry. France's lead was followed in most other countries; the U.S. and Italy both assigned tanks to infantry support and copied the Renault F.T. The U.S. copy was the M1917 light tank, and the Italian the Fiat 3000. The only other country to produce tanks by the end of the war was Germany, which built about 20.

Interwar developments. The Renault F.T. remained the most numerous tank in the world into the early '30s. Aware of the need for more powerful vehicles, if only for leading infantry assaults, the French Army took the lead in developing well-armed tanks. The original 1918 French Schneider and St. Chamond tanks already had 75-millimetre guns while the heavier British tanks were at best armed with 57-mm guns. After the war the French built ten 68-ton 2C tanks with the first turret-mounted 75-mm guns and continued to develop 75-mm-gun tanks, notably the 30-ton Char *B* of 1936.

In the meantime, Britain took the lead, technically and tactically, in developing the mobility of tanks. Even before World War I had ended, work had started on the Medium D with a maximum speed of 20 mph. The

British Army ordered 160 of the new Vickers Medium tanks between 1923 and 1928. They were virtually the only tanks the British Army had until the early '30s and the only tanks to be produced in quantity anywhere in the world during the mid-'20s. Capable of 20 mph, the Vickers Mediums stimulated the Royal Tank Corps to develop mobile tactics. Various experiments during the '20s and early '30s resulted in general adoption of two separate categories of tanks. Mobile tanks were intended for the role performed earlier by horse cavalry. Slower but more heavily armoured tanks provided infantry support.

Tankettes

Before this division into mobile and slow tanks had crystallized, several different designs were tried. The British Independent tank of 1925 with five turrets started a trend toward many turrets among heavy tanks. Another trend setter was a small turretless tankette originated in Britain by Maj. G. le Q. Martel and J. Carden in the mid-'20s, and a slightly heavier, turreted two-man light tank. The number of light tanks and tankettes grew rapidly after 1929, as several countries started to produce armoured vehicles. The Soviet Union was by far the most important producer; on a much smaller scale Poland, Czechoslovakia, and Japan entered the field in 1930–31. Concurrently, tank production started up again in France and Italy. As tank production grew and spread among nations, the value of tankettes and light tanks armed only with machine guns decreased and heavier models armed with 37- to 47-mm guns for fighting other tanks began to displace them. An early example was the Vickers-Armstrongs 6-ton model of 1930, copied on a large scale in the Soviet Union (as the T-26). The most successful example was the BT, also built in large numbers in the Soviet Union. Fastest tank of its day, the BT was based on the designs evolved in the U.S. by J.W. Christie, who in 1928 built an experimental model capable of 42.5 mph. Christie's vehicles could run on wheels after the removal of tracks, and, far more significant, had road wheels independently suspended. This feature enabled them to move over broken ground faster than tanks with the usual arrangement of wheels.

Although they were relatively well armed and mobile, tanks of the T-26 and BT type were underarmoured (plates 10 to 15 millimetres thick) and were not, therefore, suitable for close infantry support. This was clearly demonstrated in 1937 during the Civil War in Spain where T-26 and BT tanks were used by the Communist forces. Even before this time, it had become clear that tanks that moved at the slow pace of the infantry and were therefore exposed to the full effect of anti-tank guns had to be thickly armoured. This realization led, in the mid-'30s, to such infantry tanks as the French R-35 with 40-mm and the British A.11 with up to 60-mm armour.

Apart from being lightly armoured, the Soviet BT, the equivalent British cruiser tanks, and the German Pz. III also required support from more heavily armed tanks if they were to engage in fighting of any intensity. The need for more powerful 75-mm gun tanks was clearly recognized in Germany, leading to 1934 design of the Pz. IV. The problem was realized less clearly in the Soviet Union, even though the T-28 and T-35 multiturret tanks with 76-mm guns were first built there in 1932–33. But the Russians recognized more quickly than others the need for the next step, which was to replace all the light–medium tanks armed with 37- to 47-mm guns by medium tanks armed with 75- or 76-mm guns. Thus, in 1939, while the Germans were still developing the Pz. III from a 37-mm to a 50-mm gun version, the Russians were already concentrating on the T-34 medium tank with a 76-mm gun.

In Britain even 40-mm gun tanks were scarce on the eve of World War II, and all but 80 of the 1,148 British tanks produced between 1930 and 1939 were still armed only with machine guns. Italy was even worse off, with only 70 M/11 tanks with 37-mm guns while the rest of its total of 1,500 were L/3 tankettes. Except for a few experimental models, the U.S. had only about 300 machine-gun-armed light tanks. Most of the 2,000 tanks produced in Japan were equally lightly armed. By comparison, France had a more powerful tank force—2,677 modern tanks, of which, however, only 172 were the Char *B*, armed with 75-mm guns. The largest force was the U.S.S.R.'s, which, as a result of a massive production program started 1930–31, had about 20,000 tanks by 1939, considerably more than the rest of the world put together.

World War II. The most effective tank force proved to be the German, composed in 1939 of 3,195 vehicles, including 211 Pz. IV's. What made the German tanks so formidable was that instead of being divided between various infantry and cavalry tank units they were all concentrated in the panzer divisions. The successes of the panzer divisions during the first two years of World War II led the major armies to reorganize most of their tanks into similar formations; this resulted in a dramatic increase in production, as shown in the following table:

German panzer divisions

Tank Production During World War II

year	country				
	Germany	Britain	U.S.	U.S.S.R.	Japan
1939	249	969	...	...	462
1940	1,460	1,399	331	2,794	1,023
1941	3,256	4,841	4,052	6,590	1,024
1942	4,278	8,611	24,997	24,668	1,165
1943	5,966	7,476	29,497	20,000	776
1944	9,161	...	17,565	17,000	342

The campaigns of 1940 and 1941 in which armoured forces played such an important role also intensified development of tanks and other armoured vehicles. The German Pz. IV and Soviet T-34 were rearmed in 1942 with longer barrelled, higher velocity guns; soon afterward, these began to be displaced by more powerfully armed tanks. In 1943 the Germans introduced the Panther medium tank with a long 75-mm gun having a muzzle velocity of 3,070 feet per second (ft/sec) compared with 1,260 ft/sec for the original Pz. IV and 2,460 ft/sec for its 1942 version (see Figure 2, left). The 43-ton Panther weighed almost twice as much as its predecessor and was correspondingly better armoured. The Germany also introduced the still more powerful Tiger tank, armed with an 88-mm gun. Its final version (Tiger II), at 68 tons, was to be the heaviest tank used during World War II. To oppose it, the Russians brought out the JS, or Stalin, heavy tank that appeared in 1944 armed with a 122-mm gun. Its muzzle velocity was lower than that of the German 88-mm guns, however, and it weighed only 46 tons. At about the same time the T-34 was rearmed with an 85-mm gun.

In contrast to the breakthrough role of the earlier heavy tanks, the Tiger and JS tanks functioned chiefly to support basic medium tanks by destroying enemy tanks at long range. German and Soviet armies also developed other heavy vehicles for this purpose, such as the 128-mm-gun Jagdtiger and the 122-mm-gun ISU, which, in effect, were turretless tanks. In addition, all armies developed lightly armoured self-propelled antitank guns and the U.S. Army developed a specialized category of tank destroyers, which resembled self-propelled guns in being relatively lightly armoured but, like tanks, had rotating turrets.

Turretless tank

The turretless tank type of vehicle originated with the Sturmgeschutz or assault gun introduced in 1940 by the German Army for infantry support but subsequently transformed into more versatile vehicles particularly suited for destroying enemy tanks. No such vehicles were produced in Britain or the U.S. To the end of World War II, however, the British Army retained a specialized category of infantry tanks, such as the Churchill, and of cruiser tanks, such as the Crusader and Cromwell. The former were well armoured, and the latter were fast, but none was well armed compared to German and Soviet tanks. As a result, during 1943 and 1944, British armoured divisions were mostly equipped with U.S.-built M4 Sherman medium tanks (see Figure 2, right). The M4 was preceded by the mechanically similar M3 medium, also armed with a medium-velocity 75-mm gun, but mounted in the hull instead of the turret, because this could be put into production more quickly when tanks were urgently required in 1940 and 1941. Production of the M4 began in 1942 (it replaced the stop-gap M3); eventually 49,234 were built, making it the principal tank of U.S. and other allied armoured forces. Successful when first introduced, it was, by 1944, no longer adequately armed and should have been replaced by a new medium tank. Several factors kept it in production, including a contemporary obsession with numbers inspired by the usual overestimates of enemy strength. Furthermore, the U.S. Army, like the British, believed the fallacious doctrine that armoured divisions should confine themselves to exploitation of infantry breakthroughs and did not, therefore, need powerfully armed tanks. Only toward the end of the war did the U.S. Army introduce a few M26 Pershing heavy tanks with a 90-mm gun comparable to that of the original German Tiger. Similarly, the British Army introduced the prototypes of the Centurion tank with a 76-mm gun comparable to that of the German Panther. Otherwise, U.S. and British tanks were well behind the German and Soviet tanks in their gun power.

POSTWAR TANK DESIGN

Tanks in the nuclear age

After World War II it was generally recognized that all tanks must be well-armed to fight enemy tanks. This finally ended the division of tanks into undergunned categories of specialized infantry and cavalry tanks, which the British Army retained longer than any other. Still not fully recognized were the advantages of concentrating tanks in fully mechanized formations; the British and U.S. armies continued to divide tanks between the armoured divisions and the less mobile infantry divisions. After World War II, tanks also suffered from one of the periodic waves of pessimism about their future. New antitank weapons, such as rocket launchers and recoilless rifles, and the mistaken belief that the value of tanks lay primarily in their armour protection caused this attitude. The Soviet Army, however, maintained large armoured forces; the threat they posed to western Europe as the Cold War became more intense, together with the havoc created by Soviet-built T34/85 tanks during the invasion of South Korea in 1950, provided a new impetus to development.

Development of tactical nuclear weapons in the mid-'50s changed the situation again. These new weapons dictated employment of mobile forces capable of dispersed operation in small self-contained units that could make up for the low troop density on the battlefield by their mobility and weapon power and that could better evade destruction by keeping the situation fluid. Nuclear weapons consequently encouraged the use of armoured forces because of their cross-country mobility and relatively high ratio of weapon to manpower. Moreover, tanks and other armoured vehicles, by virtue of the protection that they provide against blast and radioactivity, can operate fairly close to nuclear explosions and can cross areas that have been subjected to nuclear strikes without undue risk to their crews. Armoured units survive enemy nuclear weapons better and can better exploit the devastating effects of nuclear strikes. Thus tanks and other armoured vehicles have become even more important with the advent of tactical nuclear weapons.

The British Centurion. The most significant feature of tank development since World War II has been the emphasis placed on armament. Progress in this field is best illustrated by the British Centurion, which started in 1945

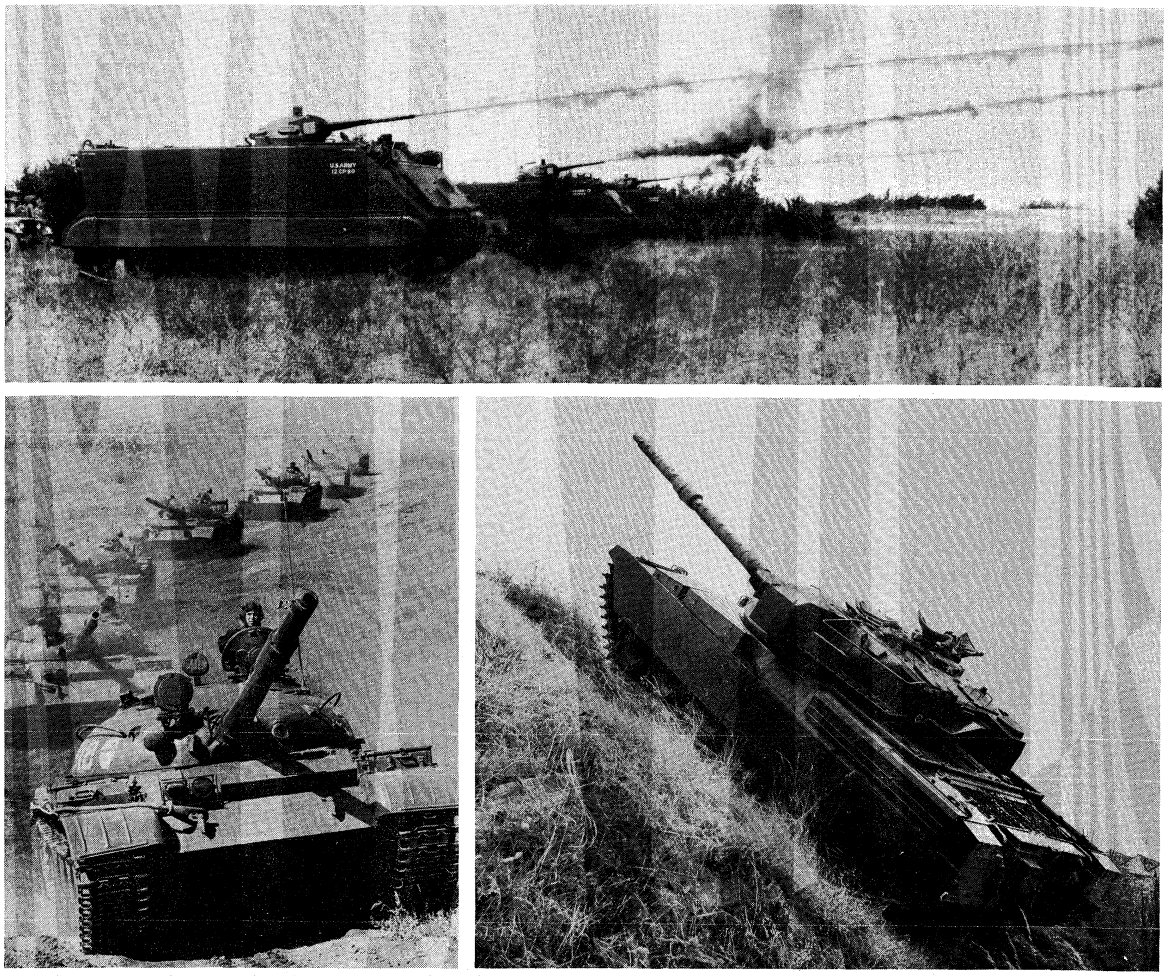

Figure 3: *Tanks and armoured vehicles since World War II.*
(Top) U.S. Army M132 armoured personnel carriers, mounted with flame throwers. (Left) Soviet T-62 tanks armed with 115-millimetre guns. (Right) British Chieftain tank with 120-millimetre gun.

with a 76-mm gun but in 1948 was rearmed with an 83.4-mm, 20-pounder gun firing newly developed, tungsten-carbide-cored, armour-piercing ammunition with a muzzle velocity of 4,800 ft/sec. As a result, the 83.4-mm gun could penetrate armour almost twice as thick as that which the most powerful 88-mm gun of the German Tiger penetrated. In 1959 the Centurion was again upgunned, this time with a 105-mm weapon.

As a result of its outstanding performance the Centurion was adopted not only by Britain and major Commonwealth countries but also by Sweden, Switzerland, and later Israel; it was also delivered under the U.S. military aid program during the 1950s to The Netherlands and Denmark, the total exported from Britain amounting to more than 2,500. In the meantime the British Army had developed an even more powerful tank, the Conqueror, which was armed with a 120-mm gun firing armour-piercing ammunition, introduced in 1954 as a heavy gun tank to support the Centurions. Unfortunately its thick armour gave the Conqueror a weight of 65 tons in contrast to the Centurion's 50 tons; when the Centurions were rearmed with the longer ranged 105-mm guns, the Conqueror was withdrawn from service (1958).

Soviet tanks. At about the same time the Soviet Army also began to withdraw some of its heavy tanks, the JS-3, and later the T-10, both armed with 122-mm guns. The basic Soviet tank for many years after World War II was the T-34/85, of which 11,778 had been produced in 1944. It was finally replaced by the T-54, which evolved from the T-34/85 through the T-44 but had a 100-mm gun in a much better profiled turret, a crew of four instead of five, a transversely mounted engine, and other improvements. Introduced around 1953, the T-54 became during the late '50s the standard tank of the Communist bloc, manufactured not only in the U.S.S.R. but also in Poland and Czechoslovakia. A copy of the T-54 was also produced in China, which exported some to Pakistan in 1966 while the U.S.S.R. supplied more than 2,000 to Egypt, Syria, Iraq, and Algeria after 1955 and exported some to Finland, Afghanistan, and Cuba. In 1963, however, the T-54 and its improved version, the T-55, began to be replaced in the Soviet Army by the current T-62 (see Figure 3, left). The T-62, externally similar to the T-54, has a much more powerful, high-velocity 115-mm gun; it represents concentration on a single type of battle tank as well-armed as contemporary technology will allow.

U.S. tanks. At first the U.S. Army also subscribed to a policy of developing heavy as well as medium tanks. Formulated in 1946 this policy led to the design of the 90-mm-gun T42 medium and the 120-mm-gun T43 heavy tanks. Designated as the M103, a few T43s were built, between 1951 and 1954, mainly for the U.S. Marine Corps. Meanwhile the T42 was supplanted in 1948 by the M46 medium tank. This was basically the earlier M26 heavy tank with a new 810 horsepower air-cooled engine and cross-drive transmission. After the conflict in Korea in 1950, the turret of the T42, which for the first time incorporated a stereoscopic range finder, was mounted on the hull of the M46 to produce the M47 medium. This, in turn, was succeeded in 1952 by the M48, which was similar to the M47 except for a ballistically superior turret and hull and a four-man instead of five-man crew.

The M48 became virtually the only battle tank of the U.S. Army during the late '50s, while the M46 and M47

tanks were transferred to the French and Italian armies. More M47 tanks were later supplied to Belgium, West Germany, Greece, Spain, Turkey, and several other countries, followed still later by deliveries of the M48, which was being replaced in the U.S. Army by the 47-ton M60. The M60 was essentially the M48 with an air-cooled diesel in place of the gasoline engine and a British-designed 105-mm gun instead of the 90-mm gun of the earlier American tanks.

The 105-mm British tank gun was also adopted for the Swiss Pz. 61, the first tank ever produced in Switzerland. One of its characteristics is its relatively light weight of 36.5 tons. However, an even lighter tank, the 34.5-ton Type 61 was produced in Japan, the first after the demilitarization of 1945; it was armed with the same 90-mm gun as the U.S. M48.

France and Germany. After World War II the French Army started developing a single battle tank, the AMX-50, armed at first with a 100-mm gun and then a 120-mm gun. After building a number of prototypes, however, the French concluded that the disadvantages of such heavy, 50-ton tanks outweighed their advantages and developed instead a lighter battle tank, the AMX-30. This 36-ton tank is armed with a French-designed 105-mm gun, which fires an unusual type of armour-piercing projectile with a shaped charge mounted in ball bearings to prevent spinning and thereby retain its performance. The AMX-30, first produced in 1966, was originally designed to a specification agreed to in 1957 by France, Germany, and Italy. Italy subsequently withdrew from the agreement, however, and adopted the U.S. M60, some of which have since been built in Italy. France and Germany, on the other hand, adopted their own alternative designs, the German being the Leopard. The first prototypes of the Leopard were built in 1961, the first tanks built in Germany since 1945. The first of 1,845 Leopards ordered by the German Army were built in 1965; subsequently Leopards were ordered by the Belgian, Norwegian, and Dutch armies to replace their earlier U.S. or British tanks. The Leopard is armed with a British 105-mm tank gun and in spite of being four tons heavier than the AMX-30 it has the same high power-to-weight ratio of 20 horsepower per ton due to its 830-hp diesel.

The German Leopard

Chieftain. A tank having the same main armament and general characteristics as the Leopard was developed at about the same time in Britain by the Vickers Company but for the Indian and not the British Army. Called the Vijayanta, production began in 1966 in India where no tank had been built before. But in contrast to the Leopard, as well as the AMX-30, Pz. 61, and the U.S. M47, M48, and M60, the Vickers Vijayanta does not have an optical range finder. Instead it has a 0.5-inch ranging machine gun, in addition to the usual rifle-calibre coaxial machine gun. The ranging-machine-gun system was originally introduced on the upgunned 105-mm Centurions and adopted in the later British Chieftain. The Chieftain (Figure 3, right), which first came into service in 1966, is armed with a high-velocity 120-mm gun and weighs 51 tons. In the early '70s it was the most heavily armed and armoured battle tank in service anywhere in the world. It also embodies several novel features, including a supine position for the driver to lower the height of the hull, a two-stroke, opposed-piston diesel engine and, recently, a laser range finder.

Sweden's S-tank. The most original design is, however, the Swedish S-tank, developed since 1956 and adopted by the Swedish Army in 1964. This turretless vehicle has its 105-mm gun fixed to the hull so that the gun can only be elevated by altering the pitch of the hull. This is accomplished by means of an adjustable hydropneumatic suspension. To turn the gun in a different direction, the crew must turn the entire tank. Elimination of the turret and the fixed gun mounting considerably reduced the silhouette of the S-tank and facilitated installation of a loading mechanism, which made it possible to reduce the size of the crew from four to three. The consequent reduction in tank size has kept the weight down to 36.5 tons without sacrificing armour.

The S-tank also has an original engine installation consisting of a diesel and a gas turbine coupled to a common output shaft. All other battle tanks since the U.S. M48 and the British Centurion and an increasing number of lighter armoured vehicles are powered by diesel, rather than gasoline engines, because of their greater overall efficiency and range.

MBT-70. Another significant departure from general practice is represented by the U.S. M60A1E1 and M60A1E2 tanks, which have a 152-mm gun-launcher. The gun-launcher fires Shillelagh guided missiles as well as conventional projectiles but its barrel is too short to fire high-velocity armour-piercing shots; this reduces its flexibility in attacking enemy tanks. This shortcoming has been corrected in a more recent version of the 152-mm gun-launcher, which can fire armour-piercing ammunition as well as high explosive shells and missiles and which was mounted in the MBT-70. Development of the MBT-70 was started by the U.S. and Germany in 1963; in addition to the 152-mm gun-launcher it incorporated several advanced features, including a 1,475 hp diesel, which gave a power-to-weight ratio of almost 30 hp per ton, and an adjustable hydropneumatic suspension instead of the customary torsion-bar suspension. The MBT-70 was also provided with an automatic loader, which reduced its crew to three men. For the first time the crew was concentrated in the turret, which became an environmental control capsule protecting from radiological, chemical, and biological effects. Location of the driver in the turret alongside instead of below other crew members reduced the height of the MBT-70. This necessitated, however, a counter-rotating cupola for the driver to keep him pointed forward irrespective of the rotation of the turret, thus complicating the driving controls. All the sophistication incorporated in the MBT-70 made it very expensive. Production cost per tank was estimated in 1969 at $750,000 to $850,000, compared with $200,000 to $250,000 for the M60, Leopard, and Chieftain. As a result, Germany withdrew from its joint development in 1970 and the U.S. Army in 1972 abandoned its more austere XM803 version.

The U.S. gun-launcher

The most controversial feature of the MBT-70/XM803 was its gun-launcher. Its Shillelagh missiles gave it an advantage over enemy tanks at long ranges where tank guns are rather inaccurate, but they were highly questionable on cost-effectiveness grounds at the usual tank combat ranges of less than 2,000 metres, since one missile costs about $3,000, or the equivalent of 20 armour-piercing rounds. The gun-launcher is also a compromise between the requirements of gun and missile systems; it necessitates an overlarge gun to accommodate the large diameter missile and at the same time it prevents the missiles being launched without the vehicle exposing itself. Consequently, at an early stage the Germans wanted to rearm the MBT-70 with a 120-mm gun and favoured the development of special vehicles to fire missiles only. These are exemplified by the Jagdpanzer Rakete, a tank destroyer armed with SS-11 or Hot missiles.

OTHER ARMOURED VEHICLES

Airborne and amphibious vehicles. In 1941, the U.S. Army commenced development of the T9, the first air-transportable light tank. The first tanks actually flown into battle, however, were British Tetrarchs, a few of which were landed by glider in Normandy on D-Day in 1944. After 1946, the French Army built the AMX-13, a 14.3-ton air-transportable vehicle (75-mm gun), used chiefly as a tank destroyer and reconnaissance vehicle. Less successful was the M41 76-mm-gun light tank, constructed in 1950 by the U.S. Army. At 22.8 tons, this vehicle proved too heavy for contemporary transport aircraft. The latest U.S. light tank is the M551 Sheridan, equipped with a 152-mm gun-launcher.

The Sheridan was designed to meet two military needs, that of reconnaissance for a highly mobile vehicle, and that of airborne operations for a light but effective self-propelled weapon. Usually these two requirements have been met by separate vehicles. Thus the Soviet Army has the ASU-85, an 85-mm turretless assault gun, for its airborne forces, and the PT-76 amphibious light tank for

its reconnaissance units. The development of amphibious tanks dates back to the Medium D of 1919. Though all amphibious tanks have sacrificed armament for light weight and have been bulky to achieve sufficient buoyancy, the overall mobility of tanks such as the PT-76 made them effective reconnaissance vehicles.

Since the middle of World War II many other tanks have been made amphibious by collapsible flotation screens, which, when erected, allow even relatively heavy tanks to float. This method was first used with M4 medium tanks during the D-Day landings in Normandy in 1944. More recently, flotation screens have been permanently installed on the S-tank, the Vickers Vijayanta, the M551 Sheridan, and the Scorpion light reconnaissance tank introduced in 1969 by the British Army.

An alternative method to crossing rivers is "submerged fording," first tried in 1940 with the British A.9 cruiser and the German Pz. III and IV. Since World War II, provision for submerged fording has been built into several tanks including the Soviet T-54 and T-62 and the Leopard and the AMX-30.

Landing Vehicle Tracked

An entirely different problem is posed by amphibious landings from the open seas; to solve it the U.S. Marine Corps developed the Landing Vehicle Tracked, or LVT. Originally built in 1941 as an unarmoured cargo carrier, the LVT quickly acquired armour. Two types evolved: an armoured amphibious personnel and cargo carrier, and a turreted amphibious gun-vehicle for close fire support during landing operations. Altogether 18,620 LVTs were built during World War II; these played a prominent role in the Pacific campaigns from Guadalcanal onward. After World War II, LVTs were successfully used in Korea, notably for the 1950 Inchon landing. Two new models were built between 1951 and 1957: a 39-ton LVTP5 amphibious carrier, capable of carrying as many as 37 men, and an LVTH6 armed with a turret-mounted 105-mm howitzer. Both are still in service but a new LVTPX12 was developed during the late '60s to replace them. It incorporates several improvements, the most important being a boatlike hull with a stern instead of bow loading ramp and two water-jet propulsion units that greatly improve its performance in comparison with that of the earlier LVTs (propelled in water as well as on land by means of their tracks). At the same time the LVTPX12 has retained the seagoing qualities of the earlier LVTs, which could negotiate rough seas and Pacific surf in contrast to other amphibious vehicles intended primarily for crossing inland water obstacles. The use of water jet propulsion units in the LVTPX12, however, has been preceded by their use in several amphibious reconnaissance vehicles, including the Soviet PT-76.

Self-propelled guns. Development of self-propelled guns has also continued since World War II, except for self-propelled antitank guns. These became largely superfluous when it was recognized that all tanks needed to be sufficiently well armed to fight enemy tanks. Turretless assault guns, much favoured during World War II by the German and Soviet armies, have also largely disappeared except for a few specialized models such as the Soviet ASU-85 and the 90-mm-gun Jagdpanzer Kanone of the German Army. The general trend among the remaining self-propelled guns has been either toward lightly but completely armoured models with guns mounted in turrets with all-round traverse, like most tanks, or toward partially armoured models that are essentially tracked chassis with guns mounted on top. Examples of completely armoured guns are the 155-mm M109 self-propelled howitzer used by the U.S. and several west European armies, and the British 105-mm Abbot self-propelled gun. Partially armoured models include the U.S.-built M107 175-mm gun, the M110 8-inch howitzer, and the French 155-mm howitzer on the AMX-13 chassis. Though the Soviet Army has not produced either type of self-propelled gun, continuing to rely on tractor-towed guns, it has developed several armoured self-propelled launchers for its tactical missiles that make use of PT-76 and IS tank chassis.

Armoured personnel carriers. Since World War II armoured personnel carriers have become the next most important armoured vehicle after battle tanks. Though a few experimental models were built in Britain at the end of World War I, development of armoured carriers did not really begin until they were adopted for the panzer division infantry at the beginning of World War II. Germany's example was quickly followed by the U.S. which, by the end of the war, had produced 41,000 carriers. Both the German and U.S. carriers of World War II were of the half-track type and provided only light protection; nevertheless, they represented a major advance on the earlier method of transporting infantry into battle in unarmoured trucks. Moreover, the panzer grenadiers used them effectively as combat vehicles and fought from them on the move, thus greatly increasing the mobility of the infantry on the battlefield.

After World War II the U.S. Army led in developing fully tracked carriers with all-round protection (see Figure 3, top). The first postwar carrier was the M44 armoured utility vehicle of 1945. Though unduly large, this vehicle demonstrated the advantages of its type. Next came the M75, first built in 1948. Essentially a scaled-down M44 with a similar box body, it carried 12 instead of 27 men. Adopted in 1953, the M75 became the first tracked armoured personnel carrier used in quantity. The war in Korea, in which a few M75s successfully carried infantry under fire, added impetus to armoured personnel carrier development. When the 1955 tactical nuclear weapons tests in Nevada demonstrated that armoured carriers permitted infantry to operate relatively close to nuclear explosions, armoured carriers were demanded for infantry as well as armoured divisions.

The M75 in Korea

By 1955 the M59 began to replace the M75. Though similar, the newer M59 was less expensive and able to swim across calm inland waters. In 1960 the M59 was supplanted by the current M113, lower and considerably lighter due partly to the contemporary development of aluminum armour. The M113 was in fact the first aluminum-armoured vehicle to be put into large-scale production. Since its appearance an increasing number of the lighter vehicles have been built using aluminum armour, including the M109 155-mm self-propelled howitzer, M551 Sheridan, LVTPX12, Scorpion, and the Fox armoured car. Battle tanks, however, have continued to use steel armour, which is more effective against large-calibre armour-piercing projectiles and does not have to be as thick as equivalent aluminum armour.

As well as being lighter, the M113 was also less expensive than its predecessors, costing only $22,000, a significant factor in its large-scale adoption, first by the U.S. Army and then by several other armies. By 1970 about 40,000 M113 carriers had been produced, making the type the most numerous armoured vehicle outside the Soviet bloc. M113 carriers have been used on a large scale in the war in Vietnam, often as combat vehicles, though they were not designed for the role and are at a disadvantage in spite of the addition of roof-mounted machine guns with shields. The shortcomings of the M113 stem from the original U.S. Army doctrine that infantry must dismount from carriers to close with the enemy. As a result the M113 and the earlier U.S. carriers were designed as transport rather than fighting vehicles.

The first attempt to produce a tracked armoured carrier from which the infantry could fight on the move was made by the French Army. The AMX-VTT production began in 1958; from within, its occupants could fire their own hand weapons and a machine gun mounted in a turret. A further step forward was taken when the German Army ordered the HS-30 carrier for its panzer grenadiers. This offered better protection and had a turret with a 20-mm automatic cannon, which enabled it to fight other light armoured vehicles.

By the mid-'60s the need to replace the original type of carrier by what came to be known as the mechanized infantry combat vehicle, or MICV, was generally recognized and the U.S. Army developed its first vehicle of this type. The experimental XM701 had a 20-mm gun turret and provision for its occupants to fire their own weapons from within. A basically similar vehicle, the Marder, was adopted by the German Army.

Like the British, the Soviet Army originally relied mainly on wheeled armoured carriers. The early BTR-152s were little more than armoured six-wheeled trucks but the more recent BTR-60P is a much more advanced amphibious vehicle with eight-wheel drive and a water jet-propulsion unit. The first Soviet tracked carrier, the BTR-50P, introduced around 1955, was little more than the PT-76 tank without its turret; but in 1967 the Soviet Army revealed a much more advanced tracked amphibious armoured personnel carrier or mechanized infantry combat vehicle. This has a turret with a medium-calibre gun and a machine gun and is also fitted with antitank guided missiles. In consequence it represents a versatile fighting unit, which, in some circumstances, could rival tanks as the basic armoured vehicle.

WHITE, *British Tanks and Fighting Vehicles 1914–1945* (1970), photographs and descriptions of British armoured vehicles, and *Tanks and Other Armoured Fighting Vehicles 1900–1918* (1970), descriptions of the earliest armoured vehicles.

(R.M.O.)

Tanzania

The United Republic of Tanzania is a sovereign state located in eastern Africa. It was formed in 1964 by the union of the Republic of Tanganyika on the East African mainland with the offshore state of Zanzibar, comprising the islands of Zanzibar and Pemba. The total area of the republic is 364,945 square miles (945,203 square kilometres). The area on the mainland is 363,728 square miles, of which nearly 22,805 square miles consists of water. The island of Zanzibar has an area of 640 square miles and the island of Pemba an area of 380 square miles. The two islands are separated from the mainland by a channel, which, at its narrowest, is about 22 miles wide. Farther south lies the island of Mafia, with an area of 200 square miles; it is administered from the mainland. The United Republic has a total population of over 14,000,000, of whom about 13,600,000 live in the mainland and about 400,000 on Zanzibar. The capital is the port city of Dar es Salaam.

To the north, Tanzania is bounded by Kenya and Uganda, which converge on Lake Victoria; about half of the lake lies within Tanzania; to the northwest lie the republics of Rwanda and Burundi. To the west, the waters of Lake Tanganyika (of which about half belongs to Tanzania) separate the republic from Zaire. To the southwest Tanzania is bordered by Zambia and Malawi. Since the 1960s part of the Malawi–Tanzania boundary has been in dispute, with Malawi claiming the eastern shore of Lake Nyasa and Tanzania claiming a border through the lake to join the Tanzania–Malawi–Mozambique tripoint in the southeast end. To the south the Ruvuma River is the land boundary between Tanzania and Mozambique.

In the 20th century the mainland territory has been, successively, a German colony, a British-administered League of Nations mandate, a United Nations trust territory under British administration, and, finally—since 1961—an independent state within the Commonwealth of Nations. Tanzania is one of the larger African countries and has a primarily agricultural economy. During the period of British colonial administration, the limited development funds available for East African territories were often devoted to Kenya or to Uganda rather than to Tanzania, so that today the country has more to do to catch up with these two neighbours, with which it is now linked through membership in the East African Community. Cash crops grown for export include sisal, cotton, and coffee; diamonds also are exported. Under the leadership of President Julius Nyerere a program of African socialism has been launched, of which an important feature is the establishment of *ujamaa vijijini* (cooperative village communities). The Tanzam railway, 1,100 miles long, scheduled to be completed in the mid-1970s, was being constructed (with aid from the People's Republic of China) to transport Zambian copper to the port of Dar es Salaam, thereby lessening land-locked Zambia's dependence upon white-administered southern African states, while opening up parts of Tanzania for development. For associated physical features, see EAST AFRICAN LAKES; EAST AFRICAN MOUNTAINS; for historical aspects, see EAST AFRICA, HISTORY OF.

Developmental efforts

THE LANDSCAPE

Relief features. Although most of Tanzania consists of plain and plateau, it has some spectacular relief features, including Africa's highest mountain, Kilimanjaro (19,340 feet, or 5,895 metres high), and Lake Tanganyika (1,174 feet, or 358 metres, below sea level) which forms part of the world's greatest rift-valley system. The coastal area is low-lying and is narrow, except where rivers flow into it from the west.

The mountain system is sprawled in a twisting pattern, extending north to southwest. In the southwest, the tail of the pattern is formed by the Ufipa Plateau, the Mbeya Range, and Rungwe Mountain. Running northward in elongated form are the Southern Highlands, and the Ukaguru and Nguru mountains. Near the coast and aligned from southeast to northwest are the Usambara and Pare mountains; the highland complex culminates in the snowclad peak of Kilimanjaro, west of which lies Meru (14,979 feet, or 4,565 metres) and the perfect rim of the Ngorongoro Crater (volcanic). The Mbulu-Kondoa ranges and the Kiboriani Mountains complete the pattern where they meet the Ukaguru Range. The Uluguru Mountains stand 120 miles west of Dar es Salaam and east of the Rubehorn Mountains; overlooking Lake Nyasa in the south are the Kipengere and Livingstone mountains.

Northward from Lake Nyasa the rift system bifurcates. The Western Rift is well defined, especially by the deep, linear form of Lake Tanganyika. The Eastern Rift is well defined only in the north and central parts, where faulting is complex. Ol Doinyo Lengai, west of Kilimanjaro and south of the small Lake Natron, is the only active volcano. Directly or indirectly, the rifts have produced depressions such as the Pangani Valley (which extends southeastward from Kilimanjaro to the Indian Ocean) and the Malagarasi Swamp (in the northwestern part of the Central Plateau), formed numerous volcanic features, altered the pattern of drainage, and caused shallow lakes. Lake Victoria, however, which ranks as the third largest lake in the world, is not part of the Rift System.

The rivers

The largest river, the Rufiji, together with its tributaries, drains most of southern Tanzania. Like the snowfed Pangani, the Wami, the Ruvu, and the Ruvuma rivers, it also empties into the Indian Ocean. The Kagera and several small rivers drain into Lake Victoria, while the Bubu, the Wembere, and some other rivers flow into interior basins.

Soils. Tanzania possesses a greater variety of soils than any other African country. On a regional basis, eluvials (soils formed from the decomposition of rock and found in their place of origin) and illuvials (soil material that has been leached out or washed away from

its place of origin) both exist. Soils in a repetitive sequence that is determined by relief and drainage are known as catenas (connected series). In the humid and highland areas, brown volcanic soils and ferrisols (iron-bearing soils) located on crystalline rocks are the most productive soils. Areas receiving annual rainfall in excess of 53 inches (such as Bukoba and Tukuyu) have productive yellow-brown and yellow-red soils of low fertility. In the north and northeast plateau country, soils are fertile but lose much moisture because of a high rate of evaporation and transpiration from plants. Over the Central Plateau and in the south podsolic soils (infertile, acidic forest soils) occur on sandstone and crystalline rock. The fertile soils of the river basins require management, such as drainage. Scattered over many parts are rocky outcrops, debris, and stony shallow soils.

Climate. Tanzania experiences an equatorial type of climate, generally modified by altitude. Seasonal changes are more marked in rainfall than in temperature.

A low-pressure zone, apparently accompanying the sun's annual movement, draws two major airstreams into the region. Between March and September, moisture-laden southeast airstreams sweep across the Indian Ocean before moving over the mainland. At other seasons northeast airstreams, originating in Asia, are drier.

The variation in the mean monthly temperature is small, amounting to 4° F (2° C) at Mwanza on the southern shore of Lake Victoria, to 7° F (4° C) at Dar es Salaam on the coast and to 9° F (5° C) at Dodoma in central Tanzania; diurnal variations can be great. Temperatures vary considerably with altitude. Daily maximums near the coast exceed 90° F (32° C); on the highlands, minimum temperatures may fall below 68° F (20° C).

The seasonal rainfall pattern also varies considerably in different regions. The two rainy seasons in the north (March to May and October to December) contrast with the one in the south (December to April). Rainfall totals depend on aspect and altitude. Places on the western side of Lake Victoria receive more rainfall than those on the eastern side. The windward and leeward sides of the Uluguru Mountains receive rainfall of about 101 inches and between 23 and 31 inches, respectively. Areas bordering the lakes and the coast receive more rainfall than the Central Plateau.

Vegetation. Woodland, called miombo, extends over nearly 30 percent of Tanzania. Typically, the ground is covered with grass, from which rise trees of the *acacia*, *Brachystegia* (a genus of trees of the pea family having 30 tropical African species), and *Isoberlinia* (a genus of trees of the pea family having six tropical African species) groups. Similarly, wooded grassland, of which less than 50 percent has tree cover, presents a parklike appearance. Several types of forest are found in small, discontinuous stretches. Above the forest line are intermontane grasslands, and even alpine deserts. Semidesert vegetation is found on the leeward side of the Pare, Usambara, and Kilimanjaro mountains. In other areas, reed and grass swamps contrast with the thick mangrove forests of the coastal creeks. The salt pans around Lake Natron are barren.

Animal life. The animal life of Tanzania is unique in abundance and variety; it includes the five big game animals—elephant, rhinoceros, buffalo, lion, and leopard. The plains teem with hoofed animals such as the zebra, the giraffe, and various species of antelope—the gazelle, the eland, the kudu, the dik-dik, and the wildebeeste. Less common are the chimpanzee and such species of antelope as the topi, the oryx, the puku, and the oribi. The carnivores include the leopard, various cats, the hyena, and the wild dog. Hippopotamuses and crocodiles inhabit riverbanks and lakeshores. Nearly 1,500 varieties of birds, including the ostrich, are common, as are many species of snakes, lizards, and insects. Big game animals

Traditional regions. Tanzania can be divided into four general regions—the coastal area, the highlands, the lake region, and the Central Plateau.

The coastal area is climatically hot and humid, and, as already mentioned, is low-lying and narrow, except where rivers enter it from the west. The cultural and economic mode of life is distinctive due to overseas contacts, Islāmic influence, and the Swahili language.

The highlands, which are cooler and which receive adequate rainfall, are generally densely populated and can be subdivided into northern and southern regions. In the north, the Chagga, Arusha, Pare, and related peoples have been exposed to external influences; producing both cash and subsistence crops, they have progressed economically and socially. In contrast, in the south, the Nyakyusa and Ngoni peoples have suffered from the inaccessibility of their area; their economy remains traditional.

The Lake Victoria region is a zone of contrasts and is generally thickly peopled. In the west-northwest, the Haya people now have to migrate because the production of coffee and bananas has fallen. The Sukuma and Nyamwezi peoples, however, are well established, raising cattle, and growing cotton and food crops.

In the dry, monotonous Central Plateau, independent pastoralists, best exemplified by the Masai and related groups, contrast with the Gogo, who eke out a harsh existence based on cattle and grains.

The landscape under human settlement. *Rural settlement.* The majority of people live in dispersed farmsteads. In the fishing and farming economy of the coastal area, villages with irregular streets consisting of mud and pole houses and their compounds are set amidst coconut palms and fields planted with cashews, cassavas, and other crops. Individual homesteads are densely scattered in the Kilimanjaro and Meru area. The lush vegetation of banana and coffee trees shelters a lower tier of food crops. Maize is grown in the plains, and cattle are stall fed. Cylindrically shaped huts, surmounted with cone-shaped roofs, are being replaced by modern houses. The Sukuma have a village area within which houses may be dispersed, each homestead having at its disposal a range of different soils. The homestead compound has concentric encircling hedges around the garden, the houses (built for the head of the homestead and his wives), the grain stores, and the cattle pen. In the central and drier parts of the north, the houses are thinly distributed and are semi-permanent. The Gogo have squat, rectangular, flat-roofed houses, grouped to form a courtyard in which cattle are kept. Most traditional forms of settlements are rapidly undergoing change; the house form is becoming uniformly rectangular.

Urban settlement. Tribal and traditional constraints are eased in the towns. Dar es Salaam (which in 1970 had Dar es Salaam

a population of 350,000) is the largest, most picturesque, and most cosmopolitan of the towns of Tanzania. The business section is dominated by Asians. Disparity between the rich and the poor is still apparent but is less along racial lines than in the past. Suburbs for the low-income group are characterized by overcrowded six-room "Swahili" houses. The bungalows of the rich are dispersed in scenic locations. The port of Tanga, with a population of 61,000, is located opposite the island of Pemba. It is similar to Dar es Salaam but retains many more buildings of the German period; its fortunes are tied to sisal. The old towns of Bagamoyo, Pangani, and Kilwa, with ancient buildings and narrow lanes, are falling into decay. Arusha, with a population of 32,000, is a new town; it is the capital of the East African Community and the centre of some of the most famous game parks in East Africa. Mwanza (population 35,000), Kigoma (21,000), Musoma (15,000), and Bukoba (8,000) are all lake ports. Other important towns are Moshi (27,000), Morogoro (25,000), Dodoma (24,000), Iringa (22,000), Tabora (21,000), and Mtwara (20,000).

Zanzibar and Pemba. *Relief.* Low-lying Pemba, whose highest point reaches an altitude of 311 feet, and Zanzibar, which reaches 390 feet, are islands whose structure consists of coralline rocks. The west and northwest of Zanzibar consist of several ridges rising above 200 feet, but nearly two-thirds of the south and east are low-lying. Pemba appears hilly because the level central ridge has been gullied and eroded by streams draining into numerous creeks. On Zanzibar Island short streams drain mostly to the north and west. The few streams in the east disappear into the porous coralline rock.

Soils. Among the ten types of soils recognized in Zanzibar are fertile sandy loams and deep-red earths, which occur on high ground; on valley bottoms, less fertile gray and yellow sandy soils are found. The eight soil types in Pemba include brown loams; pockets of infertile sands are found on the plains.

Climate. Zanzibar and Pemba have rainfall of 60 inches and 80 inches, respectively. The rainfall is highest in April and May, lowest in November and December. Humidity is high. The average temperature is 81° F (27° C) in Zanzibar and 79° F (26° C) in Pemba; the annual temperature ranges are small.

Vegetation. Long human occupation has resulted in the clearance of most of the forests, which have been replaced with coconuts, cloves, bananas, citrus, and other crops. On the eastern side of the islands, especially on Zanzibar, there is bush (scrub).

Animal life. Although there is some difference between the animal life of the two islands, it is generally similar to that on the mainland. Animal life common to both islands includes monkeys, civet cats, and mongooses. More than 100 species of birds have been recorded in Zanzibar.

Rural settlements. The rural settlements—and the life in them—changed drastically after the nationalization of land, which was followed by agricultural reforms. By 1970 large plantations of cloves and coconuts, once almost exclusively the property of fewer than 50 Arab families, had been redistributed in three-acre units to about 24,000 peasant families. The production of food crops, especially rice, is being encouraged. Fishing villages are still important in the east.

Urban settlements. The city of Zanzibar, with a population of 68,000, is still primarily a Muslim town, although the distinctive mode of life and culture, reminiscent of an Eastern commercial centre, has almost disappeared since the downfall of the Arab oligarchy in 1964. The hub of civic life is moving from Stone Town with its narrow lanes to a new town with modern buildings and amenities that is being built at Ngambo, the former African quarter. Kilimani, Bambi, and Chaani are being developed into new rural towns; a similar change is taking place in Pemba at Mkoani, Chake Chake, and Wete.

Zanzibar city

PEOPLE AND POPULATION

Linguistic groups. For official purposes both Swahili and English are commonly used. Swahili originated between Kilwa, on what is now the southern coast of Tanzania, and Lamu, on what is now the northern coast of Kenya. During the early 19th century it gradually spread westward as a language of trade to become the lingua franca of Tanzania. The language has a Bantu base, and its vocabulary has been enlarged with additions from Arabic, English, Hindi, and Portuguese.

Four of the main language groups in Africa are represented in Tanzania. More than 95 percent of the people speak Bantu languages, of which about 100 are distinguishable. The chief Bantu languages are Kisukuma, Kinyamwezi, Kimakonde, Kihaya, Kichagga, Kigogo, Kiha, Kihehe, Kinyakyusa, and Kiluguru. In north and north central Tanzania are three other main language families. Nilotic languages are spoken by the Masai, Tatoga, and Luo peoples. The languages spoken by Iraqw, Gorowa, Alawa, Ngomvia, and Mbugu (in the Usambaras) belong to the Cushitic grouping. Only the Sandawe and the Hadza speak the Khoisan, or Click language, common among the Bushmen and Hottentots of southern Africa. Arabic is widespread on the coast. The main languages spoken by the Asians are Gujarati, Hindi, Punjabi, and Urdu, whereas the Goanese speak Konkani.

Ethnic groups. Tanzania is a multitribal state in which historically, culturally, and politically no single group has dominated. During the Stone Age, bands of hunter-gatherers of the Bushmen type inhabited parts of the country. The Sandawe are vestiges of this early group. About 1,000 BC southern Cushites, represented by the Burungi, Gorowa, Iraqw, and Mbugu peoples, began to expand from Ethiopia into the highlands and Rift Valley of what is now Tanzania. Early in the first and second millennium, Bantu speakers from the west or southwest penetrated into the country. As they were more numerous and were also agriculturalists familiar with iron tools, they gradually absorbed the hunters and gatherers or forced them to retreat to less desirable areas. As each group settled, customs, social organization, and languages became distinct. Today only the Sukuma number over 1,000,000. The Nyamwezi, Hehet Nyakyusa, Haya Chaga (Chagga), Gogo, and Ha each number over 300,000. The Ngoni, Nyakyusa, and Yao groups represent the Bantu groups from the south that have retreated northward. The Nilotics, chiefly consisting of the Luo, Tatoga, and the Massai, form a distinctive group.

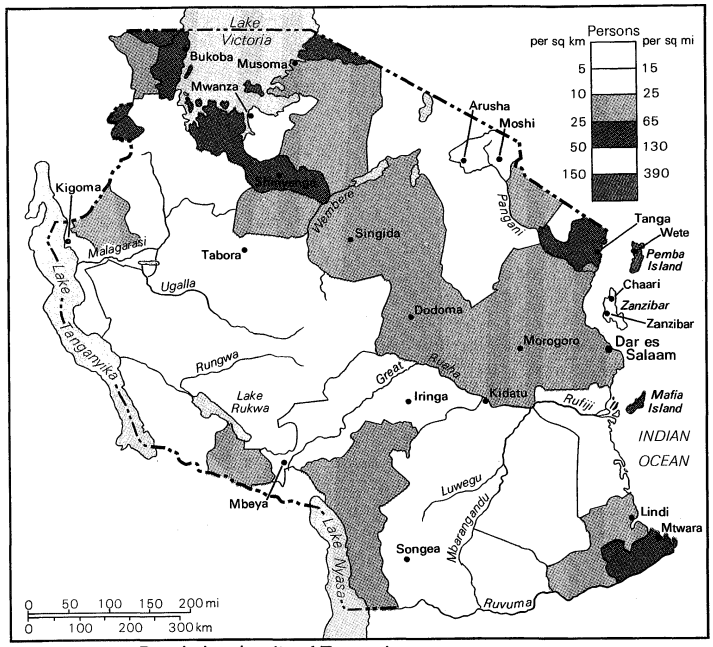
There are also Asian and European minorities. The Asians are a very diverse group, consisting of Ismāʿīlīs, Bohrās, Sikhs, Punjabis, Jains, and Goanese. The largest group of Europeans are English speaking. Others include Germans, Scandinavians, Italians, and Greeks. The Arabs also form a distinct minority group.

Religious groups. The number of people professing traditional (mostly animistic) beliefs is gradually declining. During the last population census, 31 percent claimed to be Christians of various denominations. Muslims (31 percent) are most widespread in the coastal areas, where they form 63 percent of the urban population. Among adherents of Islām, both the Sunnī and Shīʿah sects are represented. Among Asian communities, the majority of Muslims are Ismāʿīlī Khōjās, who recognize the Aga Khan as their leader. Other Asians adhere to Hinduism, Jainism, and Buddhism, while the Goanese are Roman Catholic, and the small Parsi community practices Zoroastrianism.

Demography. *Birth rates and death rates.* At the 1967 census the population of mainland Tanzania was about 11,960,000, representing an increase of 3,000,000, or 35 percent, since 1957. Between 1957 and 1967 mortality dropped from an estimated 24 to 25 per thousand to 22, while the birth rate increased from 45 to 46 to 47 per thousand. Life expectancy, which was estimated to be between 35 and 40 years, is currently between 40 and 41 years. The population growth is close to 3 percent a year.

Population growth

Population characteristics. One of the main demographic characteristics of Tanzania is the youthfulness of its population; 44 percent are less than 15 years old, and only 3 percent are more than 75 years old. Another characteristic is the sex ratio of 95 males to 100 females. Regional variations however, are striking. In the Tanga,



Population density of Tanzania.

Pangani, and Mzizima districts the ratios are about 120 males to 100 females, but in the Kibondo, Kasulu, and Njombe districts they are about 80 males to 100 females.

Emigration and immigration. Temporary emigration from southern Tanzania to Central Africa and the mines in the Republic of South Africa has now ceased. Internal migration is, however, still widespread because of inequalities in economic opportunities. Most of the southern regions of the country experience a relatively high degree of emigration.

The immigration of large numbers of Asians, including Arabs, and of Europeans, which was a feature of the colonial period has, in the case of the Asians, been reversed. International immigrants are mainly refugees from southern Africa, of whom 75 percent come from Mozambique alone. According to the 1967 census, during the preceding decade the Coast Region—especially the city of Dar es Salaam—attracted the most people (about 114,000), followed by Tabora (70,000), Arusha (59,000) and Tanga (49,000), while Kigoma, Iringa, Singida, and Zanzibar had the least number of immigrants.

Population distribution. Most of the well-populated areas of Tanzania are located on the periphery of the country—around the shores of Lake Victoria, in the highlands, and in other well-watered areas. The population is very sparse in the central and western parts, partly because of infestation by the deadly tsetse fly and—in the north and central parts—because of very dry conditions. Only about 6 percent of the people live in urban areas.

In 1967 the population density on the mainland was 34.7 per square mile, compared with 25.6 in 1957. Two of the most densely peopled regions are Mwanza and Kilimanjaro, which have densities of 140 and 127 per square mile, respectively. At the other extreme, the Ruvuma and Tabora regions have less than 18 persons per square mile. Local variations in densities are considerable. In the Masai, Monduli, Nachingwea, and Mpanda districts, densities are as low as 5 persons per square mile, in contrast with 442.1 in the Ukerewe District.

Demographic trends. With better child care and improvements in health facilities, mortality is expected to continue to decline, life expectancy to increase, and the rate of population increase to accelerate. Sex ratios are likely to normalize. With the emphasis on *ujamaa* (commune) villages, and with the establishment of better links with the south, population is expected to become more clustered and the pattern of its distribution to alter.

Zanzibar: people and population. *Languages.* Swahili is the principal language in Zanzibar and Pemba. The classical dialect is Kiunguja. Arabic is also important because of long-established Islāmic tradition, past Arab overlordship, and the presence of a large Arab-speaking minority. Three Bantu languages are spoken on the islands—Kipemba on Pemba, Kitumbatu in southern Pemba and northeastern Zanzibar, and Kihadimu mostly in southern and eastern Zanzibar. There are several dialects surviving in local areas. Among the Asian communities, the chief languages are Gujarati, Kutchi, and Hindustani. English, taught in schools, is widely used.

Source: Official government figures.

Ethnic groups. There are several groups of Africans, nearly a third of whom are recent arrivals from the mainland. Indigenous Bantu groups, consisting of the Pemba in Pemba and the Hadimu and Tumbatu in Zanzibar, have absorbed the settlers who came from Persia in the 10th century. These groups, and some of the descendants of slaves, call themselves Shirazi. The Afro-Shirazi group comprises the majority of people on the islands. There are also small enclaves of Comorians and Somalis. Arab settlements were also established early, and intermarriage with the local people took place. Later Arab arrivals came from Oman and constituted an elite. The poorer recent immigrants from Oman are known as Manga. The genealogy of the Afro-Arab groups is blurred. The Asians, now forming a very small minority, may be divided into Muslim and non-Muslim groups.

The Afro-Shirazi group

Religion. Almost the whole of the Arab and the African peoples of Zanzibar—about 96 percent—profess the Islāmic faith. Traditional African beliefs are also found existing in conjunction with Islām. Among Muslims, the Sunnī sect is preferred by the indigenous people. The

small Ibāḍī sect was once important because it was adhered to by members of the Arab elite. Other Islāmic groups are confined to the Asians, and include the Ismāʿīlīs, Ithnā ʿAsharīs, Sunnīs, and Bohrās. The non-Muslims, who are in a minority, are mainly Hindus, although the few Goanese are all Catholic. African converts to Christianity are few.

Demography. The population of Zanzibar and Pemba in 1967 was about 354,000. The total growth during the decade 1957 to 1967 was 18 percent. Zanzibar Island, with 190,000 inhabitants, was the more populous, while Pemba, with 427 persons per square mile was more densely peopled. With an average of 347 persons per square mile, the overall density of population is high.

The ratio of males per 100 females has declined from 111 in 1957 to 102 in 1967. In the Magharib rural area of Zanzibar, however, it continues to remain high, at 124. Also, in contrast to the mainland, a comparatively high proportion—23 percent—of the population is urbanized. It is estimated that between 1957 and 1967 the crude death rate of from 20 to 21 per thousand changed little; life expectancy increased from between 42 and 43 to between 43 and 44 years, and infant mortality declined from 160 to 140 per thousand.

THE NATIONAL ECONOMY

If international comparisons are made, Tanzania is a poor country. Per capita gross domestic product was $65 U.S. in the 1960s. (The monetary unit is the Tanzanian shilling [TSh.] with TShs. 7.14 equalling $1 U.S., and TShs. 18.615 equalling £1 sterling as of December 1970).

Importance of agriculture to the economy

The country is noted for its primary agricultural products, being one of the world's foremost suppliers of sisal, cashew nuts, and cloves, and—to a lesser extent—cotton, pyrethrum, and tobacco. The country is large and its resource base is wide. Regional cooperation through a common market with Kenya and Uganda has aided commerce. Trade and communication links have been established with other African countries.

Resources. *Mineral resources.* Diamonds and salt are important. Prospecting for other minerals is continuing. The Nyanzian rocks south and east of Lake Victoria are gold bearing; to the west, tin and tungsten deposits have been located. Mica is found in central and eastern Tanzania. In the south, deposits of lead, copper, silver, and gold have been found. In the southwest, large quantities of coal and iron have been proved. In several of the volcanic pipes (eruptive passages of volcanoes) diamonds are to be found. Deposits of limestone, gypsum, salt, kaolin (china clay), and rock phosphate occur in the coastal and lake regions.

Biological resources. Tanzania has substantial biological resources. There are a great variety of grasslands that are not fully utilized because of infestation by the tsetse fly, which is deadly to cattle. The forests contain tropical hardwoods, such as mahogany and teak; softwoods are found in mountain areas. Great concentrations of animal life still survive in several parts of the country, especially in the north. The exploitation of coastal fisheries has barely begun. Several lakes—including Lake Victoria—and the rivers are important sources of fish.

Power resources. The ample energy resources of Tanzania include quantities of charcoal and firewood, large resources of coal in the south (amounting to more than 304,000,000 tons), and adequate waterpower.

Sources of national income. *Agriculture, forestry, and fishing.* Tanzania is primarily an agricultural country, with nearly 90 percent of the people gaining a living from the land. In 1970 the contribution of agriculture, hunting, forestry, and fishing to the gross domestic product was over 39 percent. The major crops produced in 1969 were sisal, cashew nuts, sugar, lint cotton, coffee, wheat, and tea. Tobacco and pyrethrum are also produced. Substantial quantities of staple grains, fruits, and vegetables are produced for local consumption.

Annual fish production was estimated to be 140,000 tons; the fish were mainly caught in lakes and rivers, especially Lake Victoria.

Only a fraction of the forest production is recorded. Forests with indigenous trees, mostly hardwoods, cover 37,000,000 acres, but softwood production is increasing. Among the main timbers being exploited are *Podocarpus* (a genus of evergreen trees with a soft, pulpy fruit), camphorwood, mahogany, and mangrove. Forestry

There are close to 11,000,000 head of cattle, and there is an export trade in meat and meat products, hides, and skins. Many goats, sheep, and poultry are raised.

Mining and quarrying. Mineral exports include diamonds, of which those from Mwadui have proved the most valuable since the 1940s. Gold production is declining, whereas the production of salt from Uvinza near Lake Tanganyika and the coastal area is increasing. Gemstones, including the rare Tanzanite, are important. Around Dar es Salaam quarrying is undertaken on a large scale. With the development of transport and industry, it is anticipated that the large quantities of coal (284,000,000 tons at Ruhuhu and 20,000,000 tons at Songwe), iron (78,000,000 tons at Liganga), phosphate, kaolin (2,000,000 tons), and salt will be utilized.

Manufacturing. The contribution of the manufacturing sector to the gross domestic product in 1970 was 8 percent. While textile production is increasing, food processing still remains the largest manufacturing industry. Ninety-five percent of the manufactured goods were produced for local consumption. The main manufacturing centres are Dar es Salaam (food, brewing, textiles, shoes, petroleum refining, rubber cement, and motor assembly), Tanga (twine, furniture, food processing, and fertilizers) Arusha and Moshi (food and drink, textiles and furniture) and Mwanza (food and drink and textiles).

Hydroelectric plants

Energy. The largest installed hydroelectric complex is on the Pangani River. The Hale and Pangani Falls generating stations and two thermal stations at Dar es Salaam provide power for the coastal grid supplying Dar es Salaam, Tanga, and Morogoro. A new station at Kidatu, which will ultimately have a capacity of 200 megawatts, is to be completed by 1975. One of the forerunners of multi-purpose dams is the Nyumba ya Mungu on the Pangani River. Thirty towns have electricity for domestic and industrial use.

The capacity of the petroleum refinery at Dar es Salaam is 750,000 tons. Large quantities of petroleum products are exported to Zambia through the Tanzama Pipeline, which is 1,080 miles long.

Financial services. The Bank of Tanzania replaced the East African Currency Board in 1966. Its main functions are the control of banking and credit, issuance of currency, management of foreign exchange, and those of a government bank and fiscal agency. The National Bank of Commerce replaced the 12 nationalized banks in 1967. It maintains numerous branches and rural agencies.

Other financial services are provided by the National Insurance Company, the Permanent Housing and Finance Company, the Tanganyika Development Finance Company the National Provident Fund, the Tanzania Post Office Savings Bank, the National Co-operative Bank, the National Development Credit Agency, and the National Lotteries.

Foreign trade. In recent years the pattern of trade has altered. Between 1962 and 1970 the value of sisal, coffee, and cotton exports dropped from 58 percent to 39 percent, and the value of imports of consumer goods dropped from 48 percent to 33 percent, while imports of capital goods increased from 26 percent to 40 percent. Total trade more than doubled. There is a growing trade with socialistic countries. Trade with Kenya and Uganda, while relatively large, is commonly marked by a deficit.

Tourism. Tanzania's eight national parks are among the finest in Africa. The Serengeti and Ruaha parks have a combined area of over 10,000 square miles. Gombe is noted for chimpanzees, and the Ngorongoro Park occupies the immense crater already mentioned. Hotel accommodations have increased greatly in the north and on the coast near Dar es Salaam. About 40,000 visitors came to Tanzania in 1968, and it is anticipated that this figure will soon double.

Management of the economy. *The private sector.* The private sector has diminished in importance, although

the bulk of the retail trade is still in private hands. African retailers, since the early 1960s, have outnumbered the previously predominant Asian traders by three to one. Other important businesses in private hands include the importation of motor vehicles, transportation, farming, construction, and numerous small industries. Private industrial companies continue to participate in joint ventures with the government.

Nationalization

The public sector and the role of the government. At the time of independence, in 1961, there was a modest public participation in the economy; the proportion has dramatically increased since 1967. The main targets of nationalization were the banks, large importing and exporting firms, and eight large milling firms with associated food-manufacturing industries. The National Insurance Company was brought under public ownership and given the monopoly of insurance, and the government received majority shares in the sisal industry and the wholesale trade. Major governmental capital expenditure for the financial year 1970 to 1971 was in the National Development Corporation of Tanzania, the Tanzania Tourist Corporation, the National Agriculture and Food Corporation, the Tanzania Tea Authority, the Tanzania Electric Supply Company, and the State Trading Corporation.

Taxation. Direct and indirect taxes are collected by three separate bodies. The East African Community is responsible for collecting income and surtaxes, import tax, excise duty, and a transfer tax levied on some manufactured goods from the partner states. The central government collects personal tax, corporation tax, export tax on crops, indirect sales tax, and estate and other taxes. Local government is responsible for taxes collected for vehicle registration, liquor licenses, and market dues.

Trade unions and employer associations. In 1964 the National Union of Tanganyika Workers (NUTA) was established as the sole body authorized to represent workers. Membership is not mandatory, although where more than 50 percent of an establishment are members, the minister responsible for labour can be requested to order the rest to join the union. Official strikes were declared illegal in 1962. There is also a Federation of Tanganyika Employers.

Ujamaa vijijini. Tanzania's policy of *ujamaa vijijini* was adopted in 1967, and official backing given to ideology and strategy for development at a grass-roots level for the diffusion of economic and political power after other cooperative efforts had failed. By 1970, more than 1,200 villages had been established. The main features of life in the villages include collective production, equality of opportunity, and self-reliance. The government is committed to support these collective peasant enterprises by supplying productive and social amenities.

Contemporary economic policies. The major means of production and exchange are intended to be under the control of the government, so that all resources of the country may be utilized to eliminate poverty, ignorance, and disease. Much emphasis has been placed on rural development and agriculture, which the government plans to revolutionize through *ujamaa* (the Tanzanian version of socialism). Toward this end, massive investments in development are projected in the second five-year development plan (1969 to 1974).

The second five-year plan

Problems and prospects. To offset dependence on primary commodities, which are subject to fluctuation in world prices as well as to fluctuations in output, production is being diversified.

The future direction that the economy will take depends to a great extent upon the success of the *ujamaa* program.

Transportation. Tanzania maintains regional transport links with Kenya and Uganda within the framework of a common authority over rail, shipping, and harbour development. Since 1965 similar links with Zambia have helped to end the isolation of southern Tanzania. Parts of a major road running from Dar es Salaam to Lusaka in Zambia, via Iringa and Mbeya, have been completed.

The general program for road construction aims at providing seven first class roads—four running east to west and three running north to south; parts of these roads have been completed. The number of feeder roads is also to be increased. Between 1961 and 1971 the length of paved roads increased from about 250 miles to about 1,400 miles, and the number of vehicles increased from 40,000 to 80,000.

The railways

The core of the railway system consists of the 218-mile German-built railway from Tanga to Moshi, and the 830-mile east-to-west Central Line from Dar es Salaam to Kigoma. The two lines were not linked until 1963. During the British administration the Tanga Railway was joined to the Kenya railway system and was also extended to Arusha, while the Central Line was linked with the lake port of Mwanza. Construction of the 1,100-mile Tanzam Railway from Dar es Salaam to Zambia, due to completion by 1977, began in 1970.

Dar es Salaam, the facilities of which include six deepwater berths, is the main port; its hinterland stretches to Burundi, Zaire, and Zambia. Tanga to the north and Mtwara to the south are smaller but are significant for the export of sisal and cashew nuts, respectively. Regular shipping services operate on Lake Victoria and Lake Tanganyika; Lake Victoria has a train–ferry operating between the lake ports.

The national airline, which operates both domestic and international services, is owned jointly with Kenya and Uganda. Dar es Salaam was the only international airport until, to promote the tourist trade, another international airport was completed at Kilimanjaro in 1970. Most international airlines call at Dar des Salaam. Scheduled domestic flights connect about 20 smaller airports. Nearly 200 small landing strips dot the country.

ADMINISTRATION AND SOCIAL CONDITIONS

The structure of government. *The constitutional framework.* The Interim Constitution, established in 1965, gives Tanzania two authorities—the United Republic and Zanzibar. The former has rights over the mainland as well as over a number of union matters, which include the constitution, external affairs, defense, police, emergency powers, citizenship, immigration, external trade and borrowing, most taxes and communications, currency, and the public services of the United Republic. The Zanzibar authority deals with nonunion affairs and with internal matters pertaining to the former People's Republic of Zanzibar. The Zanzibar government has its own executive and legislature consisting of a Revolutionary Council. The government is headed by the president of Zanzibar.

The presidency

The executive power of the United Republic is vested in the president, who is head of state and commander in chief of the armed forces. He is advised by a cabinet of ministers, including the two vice presidents. One of the vice presidents must be from Zanzibar; the second is the leader of the National Assembly and the president's principal assistant.

The National Assembly and the president constitute Parliament. A large majority of members of Parliament, who represent constituencies and institutions, are elected, but the 32 members of the Zanzibar Revolutionary Council and up to 20 others from Zanzibar are nominated by the president. Regional commissioners are ex officio members. Other provisions of the constitution concern the maintenance of an independent judiciary, the establishment of a Permanent Commission of Enquiry, union financial matters, and armed forces.

Regional, state, and local government. In organization for the administration of mainland Tanzania there are 17 regions and the city of Dar es Salaam. Each region is administered by a regional commissioner responsible to the central government and appointed by the president. Regions are divided into districts under an area commissioner. The commissioners, being political appointees, help to link the administration with the party.

There are both urban and rural local governments. The former Native Authority Councils under chiefs (who have had no official power since 1961) have been replaced by nearly 60 district councils that are elected and dominated by Tanzania's single party (see below). Only the large towns have municipal or town councils.

Elections. Tanzania has universal suffrage. Elections are held at all levels, from the ten-household cells (see below) to the National Assembly. For the National Assembly, the National Executive Council of the national party presents two names from each constituency from which the electorate makes its choice. General elections are held every five years. Constituencies are homogenous areas grouping about 100,000 people within each district. There were 120 constituencies in 1970.

The Tanganyika African National Union

The party. Tanzania became a one-party state in 1965, with the Tanganyika African National Union (TANU) at its helm. In Zanzibar, the sister organization is the Afro-Shirazi Party. TANU is a mass party with membership open to all adults older than 18 years. The party has a number of sections (such as a women's organization and a parents' association) and institutional affiliates. The basic organ of the TANU is a cell, which consists of ten households under an elected leader who represents the cell at the annual conference of the party's local branch. Each such conference has an executive body. TANU also has organs at the district and regional level. The national organs consist of committees and conferences, including the National Executive Committee.

De facto political developments. Tanzania has chosen a socialistic form of government. To prevent elites, members of Parliament and high-income civil servants, under the leadership code, may not receive two or more salaries or own shares in companies. More than 70 percent of the eligible voters registered for the 1970 elections. The presidential incumbent, Julius Nyerere, received over 98 percent of the votes in Zanzibar and 94 percent on the mainland.

Justice. Under the constitution, the judiciary is granted complete independence from political and executive influences. Judges are appointed by the president in consultation with the chief justice. A unified judiciary system was initiated in 1962 when the former native and local courts dealing with customary laws became primary courts. There are more than 800 primary courts, where magistrates, each assisted by two local assessors, and using Swahili, have jurisdiction over customary and Islāmic law and certain sections of the penal code. Qualified lawyers, acting as resident magistrates in district courts, hear appeals from primary courts and also have regional jurisdiction in most criminal and civil cases. The High Court, consisting of eight puisne (junior) judges and the chief justice, have original jurisdiction over constitutional matters, serious crimes including murder, and civil claims for large sums, and they also hear appeals from lower courts. The final court of appeal is the Court of Appeal for East Africa. The tenets of law are made up of English, Islāmic, and customary laws. Customary laws, often unwritten, are being restated.

In Zanzibar and Pemba, Muslim courts deal with such personal matters as marriage, divorce, and inheritance. The Revolutionary Council assesses justice after the decision of the courts.

Armed forces. The main defense force consists of an army of 10,000 men. Four infantry battalions are supported by 12 light tanks, other armed vehicles, and a few artillery units. Elementary military instruction is given during national service. The navy has four small patrol boats and about 100 men. The air force, which is unarmed, consists of ten transport planes and seven trainers.

Administration. *Education.* The education system has three levels—primary school (seven years), secondary school (four to six years), and university. There are also professional, vocational, and religious schools. Secondary school education has been greatly expanded in recent years, and primary school education has also increased. There are about 4,500 primary schools and more than 100 secondary schools. In 1970 the constituent part of the University of East Africa located at Dar es Salaam was established as a national institution, the University of Dar es Salaam.

Educational orientation

Following the views expressed in *Education for Self-Reliance,* written by President Nyerere in 1967, the education system was reoriented away from preparation for university education and toward the goal of community service. The entrance age to primary schools was raised to seven years, and practical instruction was emphasized.

Health services. There is a countrywide network of medical services operated by the government, by local authorities, and by missions. There are more than 120 hospitals run jointly by the government and missions, but for the majority of the people the 1,600 dispensaries are the only source of medical assistance. Public medical services are socialized, but there are also private practitioners. There is one doctor for every 22,000 people. The national expenditure on health has been greatly increased. Emphasis is placed mainly on preventive medicine, which stresses nutrition, environmental sanitation, maternal and child health, control of communicable diseases, and the establishment of rural health centres.

Housing. There is a program for the construction of low-income housing. The major expenditure of the National Housing Corporation established in 1962, has been on slum clearance in Dar es Salaam, where about 4,000 low-cost and about 400 medium-cost housing units had been constructed by 1971.

Police services. Tanzania has a police force of 8,000 men and women under the control of an inspector general. In addition to the regular police force, there are railway, mine, and marine police units. The police are generally unarmed and are assisted by a special constabulary and, on occasions, by civilian volunteers. In addition, there are four special paramilitary units.

Social conditions. *Wages.* Only 9 percent of the economically active labour force is in the wage economy. The highest average wages are gained in commerce, the lowest in agriculture. Minimum wages are set by law.

Environmental diseases

Health conditions. The main environmental diseases are malaria, sleeping sickness, schistosomiasis (a parasitic disease), and onchocerciasis (a parasitic disease that may cause blindness). Communicable diseases include smallpox, poliomyelitis, leprosy, tuberculosis, dysenteries, and enteric fevers. Defective nutrition is also a major problem. Significant improvements in health have resulted from implementation of control measures.

CULTURAL LIFE AND INSTITUTIONS

Tanzania has a remarkable cultural milieu. One of the earliest evidences of human ancestry, dating back 1,250,000 years, was discovered at Olduvai Gorge, just north of the tip of Lake Eyasi in the Eastern Rift area. Rock paintings, mounds, and other evidence of prehistoric human settlement continue to be found. Transoceanic contacts with Arabia, India, and China, and later with Europe, have left their mark. Of even greater significance in the heritage of the country are the variety of traditions, languages, and customs that exist. The national language, Swahili, is perhaps one of the most versatile languages in black Africa as well as one of the most widely distributed.

The arts. Among the plastic arts practiced are traditional abstract Makonde wood carving, the more common Zaramo carving of animals and people, and the fabrication of weaponry by the Masai. Zanzibar is renowned for its Arab chests and elaborately carved and studded doors. Elsewhere, crafts include the making of baskets, mats, pots, skin work, drums, and musical instruments. Every tribe has its dances and folklore. Swahili poetry and prose writing, once neglected, now flourish. The prose and poetry of Shaaban Robert (who died in 1962) merit attention, as do President Julius Nyerere's translations of Shakespearean plays into Swahili.

Press and broadcasting. Much has been done to give the press a national identity and to widen its circulation. The important Swahili dailies are *Uhuru* and *Ngurumo.* Several other smaller Swahili and vernacular newspapers are published throughout the country. The English language newspaper *The Standard-Tanzania* has the second largest circulation. Although nationalized, it operates independently and commercially. It also publishes a weekly, the *Sunday News.* The *Nationalist,* another English language daily, is the party newspaper. East African dailies printed in Nairobi also have a wide circulation.

The Tanzania Information Service is responsible for the

Radio broadcasting

reception of news from abroad, through agreement with Reuters and other agencies, and for the dissemination of local news. Because of the size of the country, radio broadcasting is very important. Radio Tanzania broadcasts in Swahili and English, with special programs for schools and farmers. Public listening posts and private sets assure widespread reception. Programs in English, Ambo (Ovambo), Zulu, Herero, and Portuguese are broadcast to southern Africa to assist African liberation movements there.

PROSPECTS FOR THE FUTURE

The development of Tanzania as an agricultural country suffers as a result of falling prices for primary products and rising prices for manufactured goods. To remedy the situation, efforts are being made to diversify export crops and markets.

In the decade since independence, stock has been taken of national resources, and priorities and strategies for change have been redefined. There has been a shift away from massive investment in a few settlement schemes to the establishment of numerous socialistic villages (*ujamaa vijijini*); from industrial development to emphasis on rural development; from dependence on foreign aid to a greater degree of self-reliance. Since 1967, the major means of production have been nationalized, and the emphasis is now on socialist planning.

During the first five-year plan (1964–69), it was intended that economic growth take place at the rate of 6.7 percent a year, but growth took place at 5 percent. The proposed investment for the second plan (1969–74) aims to achieve an annual growth rate of 6.5 percent as a result of applying the five principles of social equality: *Ujamaa*, self-reliance, economic transformation, social transformation, and economic links with African countries.

Politically, public participation in the affairs of the country has been made possible through popular elections. Tanzania's foreign policy is based on defending basic human rights, and this defense is typified by the fight against apartheid (the policy of racial segregation of South Africa) and colonialism. Tanzania's other interests include maintaining unity and cooperation among African states, and they have also found expression in the East African Community as well as in the establishment of a practical and mutually beneficial relationship with Zambia.

BIBLIOGRAPHY. R. OLIVER *et al.* (eds.), *History of East Africa*, 3 vol. (1963–68), gives an authoritative historical account of Tanzania during the colonial era, in an East African context. Resources are regionally covered in E.W. RUSSELL (ed.), *The Natural Resources of East Africa* (1962). The two companion volumes, *Tanganyika: A Review of Its Resources and Their Development* (1955) and *A Handbook of Tanganyika*, 2nd ed. (1958), both ed. by J.P. MOFFETT, mostly cover developments during the British period. A contemporary semi-official handbook with a comprehensive though not detailed coverage of the United Republic is *Tanzania Today* (1968). Spatial aspects of resources and development are found in the official *Atlas of Tanzania* (1967); and the more comprehensive *Tanzania in Maps*, ed. by LEONARD BERRY (1972). Various government ministries publish annual reports. For post-independent economic development, the volumes for the two *Five-Year Plan(s) for Economic and Social Development* (1964–69) and (1969–74), issued by the Government Printer, are important documents. The *Economic Survey and Annual Plan* annually supplements the current plan. President JULIUS NYERERE, *Freedom and Unity* (1967), *Freedom and Socialism* (1968), and *Education for Self Reliance* (1967), contain important policy statements. For Zanzibar, M.F. LOFCHIE, *Zanzibar: Background to Revolution* (1965), is important. A useful summary of society and politics is found in J. MIDDLETON and J. CAMPBELL, *Zanzibar: Its Society and Its Politics* (1965). The official account of development is contained in *The Fruits of the Revolution in the Islands: The Story of the Progress Made in Zanzibar and Pemba During the Three Years Following the Revolution of January 12th, 1964*, published by the Government Printer (1967). General statistical information may be found in the *Statistical Abstracts* (1964–), issued by the CENTRAL STATISTICAL BUREAU.

(A.C.M.)

Taoism

Taoism, along with Confucianism, is one of the two major indigenous religio-philosophical traditions that have shaped Chinese life for more than 2,000 years.

In the broadest sense, a Taoist attitude toward life can be seen in the accepting and yielding, the joyful and carefree sides of the Chinese character, an attitude that offsets and complements the moral and duty-conscious, austere and purposeful character ascribed to Confucianism. Taoism is also characterized by a positive, active attitude toward the occult and the metaphysical (theories on the nature of reality), whereas the agnostic, pragmatic Confucian tradition considers these issues of only marginal importance, although the reality of such issues is, by most Confucians, not denied.

More strictly defined, Taoism includes: the ideas and attitudes peculiar to the *Lao-tzu* (or *Tao-te Ching;* "Classic of the Way of Power"), the *Chuang-tzu*, the *Lieh-tzu*, and related writings; the Taoist religion, which is concerned with the ritual worship of the Tao; and those who identify themselves as Taoists. (See also TAOISM, HISTORY OF; TAOIST LITERATURE; and CONFUCIANISM.)

NATURE AND SIGNIFICANCE

Taoist thought permeates Chinese culture, including many aspects not usually considered Taoist. In Chinese religion, the Taoist tradition—often serving as a link between the Confucian tradition and folk tradition—has generally been more popular and spontaneous than the official (Confucian) state cult and less diffuse and shapeless than folk religion.

Taoist philosophy and religion have found their way into all Asian cultures influenced by China, especially those of Vietnam, Japan, and Korea. Various religious practices reminiscent of Taoism in such areas of Chinese cultural influence indicate early contacts with Chinese travellers and immigrants that have yet to be elucidated.

Distinctions between Taoist philosophy and religion

Both Western Sinologists and Chinese scholars themselves have distinguished—since Han times (206 BC–AD 220)—between a Taoist philosophy of the great mystics and their commentators (*Tao-chia*) and a later Taoist religion (*Tao-chiao*). This theory—no longer considered valid—was based on the view that the "ancient Taoism" of the mystics antedated the "later Neo-Taoist superstitions" that were misinterpretations of the mystics' metaphorical images. The mystics, however, should be viewed against the background of the religious practices existing in their own times. Their ecstasies, for example, were closely related to the trances and spirit journeys of the early magicians and shamans (religious personages with healing and psychic transformation powers). Not only are the authors of the *Tao-te Ching*, the *Chuang-tzu* (book of "Master Chuang"), and the *Lieh-tzu* (book of "Master Lieh") not the actual and central founders of an earlier "pure" Taoism later degraded into superstitious practices but they can even be considered somewhat on the margin of older Taoist traditions. Therefore, because there has been a nearly continuous mutual influence between Taoists of different social classes—philosophers, ascetics, alchemists, and the priests of popular cults—the distinction between philosophical and religious Taoism in this article is made simply for the sake of descriptive convenience.

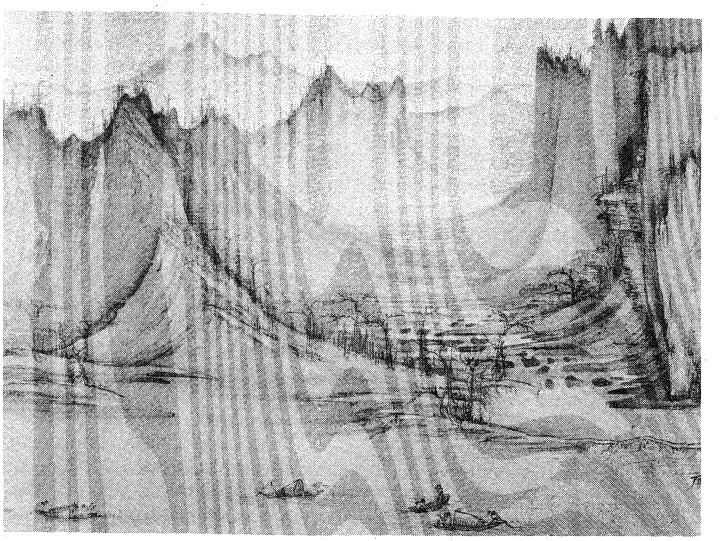
There is also a tendency among scholars today to draw a less rigid line between what is called Taoist and what is called Confucian. The two traditions share many of the same ideas about man, society, the ruler, Heaven, and the universe—ideas that were not created by either school but that stem from a tradition prior to either Confucius or Lao-tzu.

Viewed from this common tradition, orthodox Confucianism limited its field of interest to the creation of a moral and political system that fashioned society and the Chinese empire; whereas Taoism, inside the same world view, represented more personal and metaphysical preoccupations.

In the case of Buddhism—a third tradition that influenced China—fundamental concepts such as the nonexistence of the individual ego and the illusory nature of the

physical world are diametrically opposed to Taoism. In terms of overt individual and collective practices, however, competition between these two religions for influence among the people—a competition in which Confucianism had no need to participate because it had state patronage—resulted in mutual borrowings, numerous superficial similarities, and essentially Chinese developments inside Buddhism, such as the Ch'an (Zen) sect. In folk religion, since Sung times (960–1279), Taoist and Buddhist elements have coexisted without clear distinctions in the minds of the worshippers.

Certain concepts of ancient agrarian religion have dominated Chinese thought uninterruptedly from before the formation of the philosophic schools until the first radical break with tradition and the overthrow of dynastic rule at the beginning of the 20th century, and they are thus not specifically Taoist. The most important of these concepts are: the solidarity of nature and man; that is, the interaction between the universe and human society; the cyclical character of time and the universal rhythm and the law of return; and the worship of ancestors, the cult of Heaven, and the divine nature of the sovereign.



"Fishing in a Mountain Stream," detail of an ink drawing on silk by Hsü Tao-ning, 11th century. The drawing suggests the Taoist concept of harmony of the universe and man's relative role in the universal order. BASIC CONCEPTS OF TAOISM

The meaning of Tao

Man and the universe. Tao is a key term in all Chinese thought, including the Confucian. In common usage it means "way," also *the* Way to be followed and, by extension, a code of behaviour and a doctrine. The philosophical notion of Tao expressed the religious sympathy and complete solidarity that unites nature and man. In the magical arts that influenced Taoism, Tao designated the magical feat of bringing Heaven and Earth, the sacred powers and man, into communication with each other. In this sense, Tao was an art and a power, specifically the power of the magician and the king. Tao also was the universal force in the cosmos, expressed, in the human realm, in the power of the exemplary ruler. The "Way of the King" (*wang tao*) consisted in periodical ritual actions intended to restore order in nature by imitating the "Way of Heaven" (*t'ien tao*).

This is what Lao-tzu called the Tao that can be named. He used the name Tao also, however, for the ineffable reality, experienced in ecstasy, that lies at the origin of the universe and behind or within appearances. This permanent Tao (*ch'ang tao*) comes nearest to what other religions and mysticisms call the Absolute.

The microcosm–macrocosm concept. The conception of the universe common to all Chinese philosophy is neither materialistic nor animistic (a belief system centring on soul substances); it can be called magical or even alchemical. The universe is viewed as a hierarchically organized mechanism in which every part reproduces the whole. Man is a microcosm (small universe) corresponding rigorously to this macrocosm (large universe); his body reproduces the plan of the cosmos. Between man and universe there exists a system of correspondences and participations that the ritualists, philosophers, alchemists, and physicians have described but certainly not invented. This originally magical feeling of the integral unity of mankind and the natural order has always characterized the Chinese mentality, and the Taoists especially have elaborated upon it. The five organs of the body and its orifices and the dispositions, features, and passions of man correspond to the five directions, the five holy mountains, the sections of the sky, the seasons, and the elements (*wu-hsing*), which in China are not material but more like five fundamental phases of any process in space-time. Whoever understands man thus understands the structure of the universe. The physiologist knows that blood circulates because rivers carry water and that the body has 360 articulations because the ritual year has 360 days. In religious Taoism the interior of the body is inhabited by the same gods as those of the macrocosm. An adept often searches for his divine teacher in all the holy mountains of China until he finally discovers him in one of the "palaces" inside his head.

Return to the Tao. The law of the Tao as natural order refers to the continuous reversion of everything to its starting point. Anything that develops extreme qualities will invariably revert to the opposite qualities: "Reversion is the movement of the Tao" (*Lao-tzu*). All being issues from the Tao and ineluctably returns to it; Undifferentiated Unity becomes multiplicity in the movement of the Tao. Life and death are contained in this eternal transformation from Non-Being into Being and back to Non-Being, but the underlying primordial unity is never lost.

The eternal transformation from Non-Being to Being to Non-Being

For society, any reform means a type of return to the remote past; civilization is considered a degradation of the natural order, and the ideal is the return to an original purity. For the individual, wisdom is to conform to the rhythm of the universe. The Taoist mystic, however, not only adapts himself ritually and physiologically to the alternations of nature but creates a void inside himself that permits him to return to nature's origin. Lao-tzu, in trance, "wandered freely in the origin of all beings." Thus, in ecstasy he escaped the rhythm of life and death by contemplating the universal return. "Having attained perfect emptiness, holding fast to stillness, I can watch the return of the ever active Ten Thousand Beings." The number 10,000 symbolizes totality.

Change and transformation. All parts of the universe are attuned in a rhythmical pulsation. Nothing is static; all beings are subjected to periodical mutations and transformations that represent the Chinese view of creation. Instead of being opposed with a static ideal, change itself is systematized and made intelligible, as in the theory of the five phases (*wu-hsing*) and in the 64 hexagrams of the *I Ching* (*Book of Changes*), which are basic recurrent constellations in the general flux. An unchanging unity (the permanent Tao) was seen as underlying the kaleidoscopic plurality.

Chuang-tzu's image for creation was that of the activity of the potter and the bronze caster: "to shape and to transform" (*tsao hua*). These are two phases of the same process: the imperceptible Tao shapes the universe continuously out of primordial chaos; the perpetual transformation of the universe by the alternations of Yin and Yang, or complementary energies (seen as night and day or as winter and summer), is nothing but the external aspect of the same Tao. The shaping of the Ten Thousand Beings by the Supreme Unity and their transformation by Yin and Yang are both simultaneous and perpetual. Thus, the saint's ecstatic union is a "moving together with the Tao; dispersing and concentrating, his appearance has no consistency." United with the permanent Tao, the saint's outer aspect becomes one of

ungraspable change. Because the gods can become perceptible only by adapting to the mode of this changing world, their apparitions are "transformations" (*pien-hua*); and the magician (*hua-jen*) is believed to be one who transforms rather than one who conjures out of nothing.

The social ideal of primitivism. Any willful human intervention is believed to be able to ruin the harmony of the natural transformation process. The spontaneous rhythm of the primitive agrarian community and its unself-conscious symbiosis with nature's cycles is thus the Taoist ideal of society.

The ideal society

In the ideal society there are no books; the *Lao-tzu* (*Tao-te Ching*) itself would not have been written but for the entreaty of the guardian of the pass Yin Hsi, who asked the "Old Master" to write down his thoughts. In the Golden Age, past or future, knotted cords are the only form of records. The people of this age are "dull and unwitting, they have no desire; this is called uncarved simplicity. In uncarved simplicity the people attain their true nature."

Chuang-tzu liked to oppose the Heaven-made and the man-made; that is, nature and society. He wanted man to renounce all artificial "cunning contrivances" that facilitate his work but lead to "cunning hearts" and agitated souls in which the Tao will not dwell. Man should equally renounce all concepts of measure, law, and virtue. "Fashion pecks and bushels for people to measure by and they will steal by peck and bushel." He blamed not only the culture heroes and inventors praised by the Confucians but also the sages who shaped the rites and rules of society.

> That the unwrought substance was blighted in order to fashion implements—this was the crime of the artisan. That the Way (Tao) and its Virtue (*te*) were destroyed in order to create benevolence and righteousness—this was the fault of the sage.

Even "coveting knowledge" is condemned because it engenders competition and "fight to the death over profit."

Religious goals of the individual. The Confucian saint (*sheng*) is viewed as a ruler of antiquity or a great sage who taught men how to return to the rites of antiquity. The Taoist sainthood, however, is internal (*nei sheng*), although it can become manifest in an external royalty (*wai wang*) that brings the world back to the Way by means of quietism: variously called "non-intervention" (*wu-wei*), "inner cultivation" (*nei yeh*), or "art of the heart and mind" (*hsin-shu*).

Whereas worldly ambitions, riches, and (especially) discursive knowledge scatter the person and drain his energies, the saint "embraces Unity" or "holds fast to the One" (*pao i*); that is, he inspires to union with the Tao in a primordial undivided state underlying consciousness. "Embracing Unity" also means that he maintains the balance of Yin and Yang within himself and the union of his spiritual (*hun*) and vegetative (*p'o*) souls, the dispersion of which spells death; Taoists usually believed there were three *hun* and seven *p'o*. The spiritual soul tends to wander (in dreams), and any passion or desire can result in loss of soul. To retain and harmonize one's souls is important for physical life as well as for the unification of the whole human entity. Cleansed of every distraction, the saint creates inside himself a void that in reality is plenitude. Empty of all impurity, he is full of the original energy (*yüan ch'i*), which is the principle of life that in the ordinary man decays from the moment of birth on.

Proof of sainthood

Because vital energy and spirituality are not clearly distinguished, old age in itself becomes a proof of sainthood. The aged Taoist sage became a saint because he had been able to cultivate himself throughout a long existence; his longevity in itself was the proof of his saintliness and union with the Tao. Externally he had a healthy, flourishing appearance and inside he contained an ever-flowing source of energy that manifested itself in radiance and in a powerful, beneficial influence on his surroundings, which is the charismatic efficacy (*te*) of the Tao.

The mystic insight of Chuang-tzu made him scorn those who strove for longevity and immortality through physiological practices. Nevertheless, physical immortality was a Taoist goal probably long before and alongside the unfolding of Taoist mysticism. The adept of immortality had a choice among many methods that were all intended to restore the pure energies possessed at birth by the infant whose perfect vital force Lao-tzu admired. Through these methods, the adept became an immortal (*hsien*) who lived 1,000 years in this world if he so chose and, once satiated with life, "ascended to heaven in broad daylight." This was the final apotheosis of the Taoist who had transformed his body into pure Yang energy.

Symbolism and mythology. Taoists prefer to convey their ecstatic insights in images and parables. The Tao is low and receiving as a valley, soft and life-giving as water, and it is the "mysterious female," the source of all life, the Mother of the Ten Thousand Beings. Man should become weak and yielding as water that overcomes the hard and the strong and always takes the low ground; he should develop his male and female sides but "prefer femininity," "feed on the mother," and find within himself the well that never runs dry. Tao is also the axis, the ridgepole, the pivot, and the empty centre of the hub. The sage is the "useless tree" or the huge gourd too large to be fashioned into implements. A frequent metaphor for the working of the Tao is the incommunicable ability to be skillful at a craft. The skilled artisan does not ponder on his action, but, in union with the Tao of his subject, he does his work reflexively and without conscious intent.

Preservation and transformation of ancient Chinese myths

Much ancient Chinese mythology has been preserved by the Taoists, who drew on it to illustrate their views. A chaos (*hun-tun*) myth is recorded as a metaphor for the undifferentiated primal unity; the mythical emperors (Huang Ti and others) are extolled for wise Taoist rule or blamed for introducing harmful civilization. Dreams of mythical paradises and journeys on clouds and flying dragons are metaphors for the wanderings of the soul, the attainment of the Tao, and the identity of dream and reality.

Taoists have transformed and adapted some ancient myths to their beliefs. Thus, the Queen Mother of the West (Hsi Wang Mu), who was a mountain spirit, pestilence goddess, and tigress, became a high deity—the Fairy Queen of all immortals.

PHILOSOPHICAL TAOISM

Philosophical Taoism is developed mainly in the book *Lao-tzu* (or *Tao-te Ching*) and in the apparently later work of Chuang-tzu (late-4th century–*c.* 300 BC).

Discursive knowledge, for Lao-tzu and Chuang-tzu, had only the negative role of demonstrating the relativity of all knowledge that is not gained in ecstatic vision. Solitary meditation, "sitting in forgetfulness" (*tso wang*), is viewed as the sole way to true knowledge and power. For Chuang-tzu, "the Tao cannot be affirmed to exist or not to exist. The name Tao is merely an artifice for practical purposes . . . neither speech nor silence can convey it. Let us banish both speech and silence." Nevertheless, these problems were discussed unendingly. Tao was used intellectually as a "principle of universal intelligibility." Chuang-tzu's injunction "vomit your intelligence" expressed only the Taoist ridicule for dialectical argumentation and any kind of abstract realism.

The Tao cannot be grasped, but it can be received. Under a master "teaching without words," the adept goes through a cathartic process of emptying his mind of all passions, notions, and distinctions ("the cleansing of the heart," *hsin chai*) until it becomes a "mirror of Heaven and Earth reflecting the multiplicity of things." He becomes inhabited by the Tao and finally reaches an ecstatic trance in which "his body has the appearance of dead wood and his soul the insensibility of dead ashes," while he floats, not knowing "whether he carries the wind or whether the wind carries him," in time and space—or, rather, in an eternal now: "strolling at the origin of all things."

The teachings of Lao-tzu. The *Tao-te Ching* is a short anthology of paradoxical statements circumscribing the nature of the Tao and of maxims for the ruler who governs through the power (*te*) of the Tao.

Variations on the meaning of Tao

Cosmology. What Lao-tzu calls the "permanent Tao" in reality is nameless. The name (*ming*) in ancient Chinese thought implied an evaluation assigning an object its place in a hierarchical universe. The Tao is outside these categories.

> It is something formlessly fashioned, that existed before Heaven and Earth; . . . Its name (*ming*) we do not know; Tao is the byname that we give it. Were I forced to say to what class of things it belongs I should call it Immense.

Tao is the "imperceptible, indiscernible," about which nothing can be predicated but that latently contains the forms, entities, and forces of all particular phenomena: "It was from the Nameless that Heaven and Earth sprang; the Named is the mother that rears the Ten Thousand Beings, each after its kind." The Nameless (*wu-ming*) and the Named (*yu-ming*), Not-Being (*wu*) and Being (*yu*), are interdependent and "grow out of one another."

Not-Being (*wu*) and Tao are not identical; *wu* and *yu* are two aspects of the permanent Tao: "in its mode of being Unseen, we will see its mysteries; in the mode of the Seen, we will see its boundaries."

Not-Being does not mean Nothingness but rather the absence of perceptible qualities; in Lao-tzu's view it is superior to Being. It is the Void (that is, empty incipience) that harbours in itself all potentialities and without which even Being lacks its efficacy.

Emptiness realized in the mind of the Taoist who has freed himself from all obstructing notions and distracting passions makes the Tao act through him without obstacle. An essential characteristic that governs the Tao is spontaneity (*tzu-jan*), the what-is-so-of-itself, the self-so, the unconditioned. The Tao, in turn, governs the universe: "The ways of Heaven are conditioned by those of the Tao, and the ways of Tao by the Self-so."

This is the way of the saint who does not intervene but possesses the total power of spontaneous realization that is at work in the universe; of his accomplishments "everyone, throughout the country, says 'It happened of its own accord' (*tzu-jan*)."

Man and society. The power acquired by the Taoist is *te*, the efficacy of the Tao in the realm of Being, which is translated as "virtue." Lao-tzu viewed it, however, as different from Confucian virtue:

> The man of superior virtue is not virtuous, and that is why he has virtue. The man of inferior [Confucian] virtue never strays from virtue, and that is why he has no virtue.

The "superior virtue" of Taoism is a latent power that never lays claim to its achievements; it is the "mysterious power" (*hsüan te*) of Tao present in the heart of the sage—"the man of superior virtue never acts (*wu-wei*), and yet there is nothing he leaves undone."

Wu-wei is not an ideal of absolute inaction nor a mere "not-overdoing." It is an action so well in accordance with things that its author leaves no trace of himself in his work: "Perfect activity leaves no track behind it; perfect speech is like a jade worker whose tool leaves no mark." It is the Tao that "never acts, yet there is nothing it does not do." There is no true achievement without *wu-wei* because every deliberate intervention in the natural course of things will sooner or later turn into the opposite of what was intended and will result in failure.

The sage who practices *wu-wei* lives out of his original nature before it was tampered with by knowledge and restricted by morality; he has reverted to infancy (that is, the undiminished vitality of the newborn state); he has "returned to the state of the Uncarved Block (*p'u*)." *P'u* is uncut, unpainted wood, simplicity. Society carves this wood into specific shapes for its own use and thus robs the individual piece of its original totality. "Once the uncarved block is carved, it forms utensils (that is, instruments of government); but when the Sage uses it, he would be fit to become Chief of all Ministers. This is why the great craftsman (ruler) does not carve (rule)."

The *Tao-te Ching* as a handbook for rulers

The *Tao-te Ching* was meant as a handbook for the ruler. He should be a sage whose actions pass so unnoticed that his very existence remains unknown. He imposes no restrictions or prohibitions on his subjects; "so long as I love quietude, the people will of themselves go straight. So long as I act only by inactivity, the people will of themselves become prosperous." His simplicity makes the Ten Thousand Beings passionless and still and peace follows naturally. He does not teach them discrimination, virtue, or ambition because "when intellect emerges, the great artifices begin. When discord is rife in families, 'dutiful sons' appear. When the State falls into anarchy, 'loyal subjects' appear." Thus, it is better to banish wisdom, righteousness, and ingenuity, and the people will benefit a hundredfold.

> Therefore the Holy Man rules by emptying their hearts (minds) and filling their bellies, weakening their wills and strengthening their bones, ever striving to make the people knowledgeless and desireless.

The word people in this passage more likely refers not to the common people but to those nobles and intellectuals who incite the ruler's ambition and aggressiveness.

War is condemned but not entirely excluded: "Arms are ill-omened instruments," and the sage uses them only when he cannot do otherwise. He does not glory in victory; "he that has conquered in battle is received with rites of mourning."

The teachings of Chuang-tzu. Whereas the *Lao-tzu* is addressed to the sage-king, the *Chuang-tzu* is the earliest surviving Chinese text to present a philosophy for private life, a wisdom for the individual. Chuang-tzu is said to have preferred the doctrine of Lao-tzu over all others; many of his writings strike the reader as metaphorical illustrations of the terse sayings of the "Old Master."

Whereas Lao-tzu in his book as well as in his life (in legend) was concerned with Taoist rule, Chuang-tzu, some generations later, rejected all participation in society. He compared the servant of state to the well-fed decorated ox being led to sacrifice in the temple and himself to the untended piglet blissfully frolicking in the mire.

No Chinese philosopher, however, has been able to divert his interest completely from political problems. Chuang-tzu's answers are those of the mystic. The ruler should seek the Tao and do nothing else. The mere presence of a holy man makes a country prosper: "By concentrating his spirit, he can protect creatures from sickness and plague and make the harvest plentiful."

Ideas of knowledge and language. Characteristic of Chuang-tzu are his ideas of knowledge and language developed under the stimulus of his friend and opponent, the philosopher Hui Shih.

Because, in the Taoist view, all beings and everything are fundamentally one, opposing opinions can arise only when people lose sight of the Whole and regard their partial truths as absolute. They are then like the frog at the bottom of the well who takes the bit of brightness he sees for the whole sky. The closed systems—*i.e.*, the passions and prejudices into which petty minds shut themselves—hide the Tao, the "Supreme Master" who resides inside themselves and is superior to all distinctions.

The relativity of moral and epistemological notions

Thus, Chuang-tzu's holy man fully recognizes the relativity of notions like good and evil and true and false. He is neutral and open to the extent that he offers no active resistance to any would-be opponent, whether it be a person or an idea. "When you argue, there are some things you are failing to see. In the greatest Tao nothing is named; in the greatest disputation, nothing is said."

The person who wants to know the Tao is told: "Don't meditate, don't cogitate. . . . Follow no school, follow no way, and then you will attain the Tao"; discard knowledge, forget distinctions, reach no-knowledge. "Forget" indicates that distinctions had to be known first. The original ignorance of the child is distinguished from the no-knowledge of the sage who can "sit in forgetfulness."

The mystic does not speak because declaring unity, by creating the duality of the speaker and the affirmation, destroys it. Those who speak about the Tao (like Chuang-tzu himself) are "wholly wrong. For he who knows does not speak; he who speaks does not know." Chuang-tzu was aware of the fact that, in speaking about it, he could do no more than hint at the way toward the all-embracing and intuitive knowledge.

Identity of life and death. Mystic realization does away with the distinction between the self and the world.

This idea also governs Chuang-tzu's attitude toward death. Life and death are but one of the pairs of cyclical phases, such as day and night or summer and winter. "Since life and death are each other's companions, why worry about them? All beings are one." Life and death are not in opposition but merely two aspects of the same reality, arrested moments out of the flux of the universal mutations of everything into everything. Man is no exception; "he goes back into the great weaving machine: thus all beings issue from the Loom and return to the Loom."

Viewed from the single reality experienced in ecstasy, it is just as difficult to distinguish life from death as it is to distinguish the waking Chuang-tzu from the dreaming butterfly. Death is natural, and men ought neither to fear nor to desire it. Chuang-tzu's attitude thus is one of serene acceptance.

The perfect man as pure spirit

The perfect man. Chuang-tzu's descriptions of the indescribable Tao, as well as of those who have attained union with the Tao, are invariably poetic. The perfect man has identified his life rhythm so completely with the rhythm of the forces of nature that he has become indistinguishable from them and shares their immortality and infinity, which is above the cycle of ordinary life and death. He is "pure spirit. He feels neither the heat of the brushlands afire nor the cold of the waters in flood"; nothing can startle or frighten him. Not that he is magically invulnerable (as the adepts of physical immortality would have it), but he is "so cautious in shunning and approaching, that nothing can do him injury."

"A man like this rides the clouds as his carriages and the sun and moon as his steeds." The theme of the spiritual wandering (*yüan yu*), which can be traced back to the shamanistic soul journey, crops up wherever Chuang-tzu speaks of the perfect man.

> Those who let themselves be borne away by the unadulterated energies of Heaven and Earth and can harness the six composite energies to roam through the limitless, whatever need they henceforth depend on?

These wanderings are journeys within oneself; they are roamings through the Infinite in ecstasy. Transcending the ordinary distinctions of things and one with the Tao, "the Perfect Man has no self, the Holy Man has no merit, the Sage has no fame." He lives inconspicuously among men, and whatever applies to the Tao applies to him.

Contributions of the "I Ching" and the school of Natural Change. *The idea of Yin and Yang.* Yin and Yang literally mean "dark side" and "sunny side" of a hill. They are mentioned for the first time in the *Hsi tz'u*, or "Appended Explanations" (*c.* 4th century BC), an appendix to the *I Ching (Book of Changes)*: "One [time] Yin, one [time] Yang, this is the Tao." Yin and Yang are two complementary, interdependent principles or phases alternating in space and time; they are emblems evoking the harmonious interplay of all pairs of opposites in the universe.

First conceived by musicians, astronomers, or diviners and then propagated by a school that came to be named after them, Yin and Yang became the common stock of all Chinese philosophy. The Taoist treatise *Huai-nan-tzu* (book of "The Master Huai-nan") describes how the one "Primordial Breath" (*yüan ch'i*) split into the light ethereal Yang breath, which formed Heaven; and the heavier, cruder Yin breath, which formed Earth. The diversifications and interactions of Yin and Yang produced the Ten Thousand Beings.

> The warm breath of Yang accumulated to produce fire, the essence of which formed the sun. The cold breath of Yin accumulated to produce water, the essence of which became the moon.

Cosmic and active energies

The idea of ch'i. Yin and Yang are often referred to as two "breaths" (*ch'i*). *Ch'i* means air, breath, or vapour —originally the vapour arising from cooking cereals. It also came to mean a cosmic energy. The Primordial Breath is a name of the chaos (state of Unity) in which the original life force is not yet diversified into the phases that the concepts Yin and Yang describe.

Every man has a portion of this primordial life-force allotted to him at birth, and his task is not to dissipate it through the activity of his senses but to strengthen, control, and increase it in order to live out his full span of life.

The idea of wu-hsing. Another important set of notions associated with the same school of Yin-Yang are the "five agents" or "phases" (*wu-hsing*) or "powers" (*wu-te*): water, fire, wood, metal, earth. They are also "breaths" (*i.e.*, active energies), the idea of which enabled the philosophers to construct a coherent system of correspondences and participations linking all phenomena of the macrocosm and the microcosm. Associated with spatial directions, seasons of the year, colours, musical notes, animals, and other aspects of nature, they also correspond, in the human body, to the five inner organs. The Taoist techniques of longevity are grounded in these correspondences. The idea behind such techniques was that of nourishing the inner organs with the essences corresponding to their respective phases and during the season dominated by the latter.

Eclectic philosophical thought. *Yang Chu and the Lieh-tzu.* Yang Chu (*c.* 400 BC) is representative of the early pre-Taoist recluses, "those who hid themselves" (*yin-shih*), who, in the *Analects* of Confucius, ridiculed Confucius' zeal to improve society. Yang Chu held that each individual should value his own life above all else, despise wealth and power, and not agree to sacrifice even a single hair of his head to benefit the whole world. The scattered sayings of Yang Chu in pre-Han texts are much less hedonistic than his doctrine as it is presented in the *Lieh-tzu* (book of "Master Lieh").

Lieh-tzu was a legendary Taoist master whom Chuang-tzu described as being able to "ride the wind and go soaring around with cool and breezy skill." In many old legends Lieh-tzu is the paragon of the spiritual traveller. The text named after him (of uncertain date) presents a philosophy that views natural changes and human activities as wholly mechanistic in their operation; neither human effort nor divine destiny can change the course of things.

Kuan-tzu and Huai-nan-tzu. In the several Taoist chapters of the *Kuan-tzu* (book of "Master Kuan"), another text of uncertain date, emphasis is placed on "the art of the heart (mind)"; the heart governs the body as the chief governs the state. If the organs and senses submit to it, the heart can achieve a desirelessness and emptiness that make it a pure receptacle of the "heart inside the heart," a new soul that is the indwelling Tao.

The *Huai-nan-tzu* is a compilation of essays written by different learned magicians (*fang-shih*) at the court of their patron, the Prince of Huai-nan. Although lacking in unity, it is a compendium of the knowledge of the time that had been neglected by the less speculative scholars of the new state Confucianism. The *Huai-nan-tzu* discusses the most elaborate cosmology up to that time, the position of man in the macrocosm, the ordering of society, and the ideal of personal sainthood.

Neo-Taoism. During the 3rd and 4th centuries AD, in the political and social chaos that followed the collapse of the Han dynasty, a new philosophy took shape. Termed "obscure learning" (*hsüan hsüeh*), it oscillated between "nihilistic revolt" and "mystical escapism." The word *hsüan*, meaning "dark," "abstruse," "mysterious," alludes to the first chapter of the *Tao-te Ching*, in which the Tao is described as "*hsüan* of the *hsüan*," "mystery of mysteries."

Nihilistic revolt and mystical escapism

Ho Yen (died AD 249) and Wang Pi (flourished 3rd century AD) wrote commentaries to the *Tao-te Ching* and the *I Ching* but honoured Confucius (who "embodied Not-Being" and dealt with Being) above Lao-tzu and Chuang-tzu (who constantly spoke of Not-Being because they were still entangled in Being). The commentators Hsiang Hsiu (flourished AD 250) and Kuo Hsiang (died AD 312) also criticized Chuang-tzu in their commentary (the *Chuang-tzu chu*, also called the Kuo-Hsiang commentary), but they saw no basic difference between the doctrine of the "great Sage" Confucius and the Taoist philosophers, and they used Taoist thought to reinterpret the sayings of Confucius. Their real problem was to reconcile the opposing claims of a life of public ser-

vice and the hermit's quietism. Their type of sage lived in the world and out of it at the same time; "although he moves up and down through ten thousand critical decisions, he remains tranquil and self-possessed" (Kuo Hsiang). Others compared the rhythm of office holding and retirement to the "naturalness" (*tzu-jan*) of the coming and going of the seasons.

"Naturalness" was the foremost law and ideal of the Neo-Taoists. The "thusness-in-itself" combined for them the ideas of unspoiled nature, spontaneity, and the Tao. The so-called Seven Sages of the Bamboo Grove, among them Hsi K'ang (flourished 3rd century) and Yüan Chi (flourished 3rd century), tried to avoid the dangers of the political scene and worshipped "naturalness" with wine, poetry, and music.

RELIGIOUS TAOISM

Long life and the vital force were common concerns of all Taoist traditions and inseparable from saintliness. The original state of the infant or even the embryonic state in which the vital force is still perfectly concentrated and undiminished was the ideal of the mystics, who sought it in trance, as well as of the religious Taoists, who developed countless formulas and practices to restore the infant's complete Yang energy to the physical body. This effort, however, made them shift away from the classical ideal of adaptation to the course of nature and attempt a reversal of the natural flow toward death. Thus, the ideal of Yin and Yang as complementary, which implied the alternation of life and death, changed into a desire for the victory of life-giving Yang over Yin.

Spirit and matter as a continuum of vital energies

Longevity and immortality. For the ancient Chinese in general, spirit and matter formed a continuum of more or less rarefied or crude vital energies, deriving from Heaven and Earth. Man was believed to be composed of several kinds of vital energies, to which the Western dichotomy of spiritual and material is not particularly relevant. The techniques of longevity were intended to prevent the scattering of these energies, which would result in death. They also sought to refine the coarse, perishable energies and transform the heavy mortal body into a light immortal one.

The Chinese ideogram for "immortal" (*hsien*) depicts a man and a mountain, suggesting a hermit; the older form of *hsien*, however, shows a man dancing around, flapping his sleeves like wings. To become immortal is to be "transformed into a feathered being." This image comes from the mythology of eastern Chinese tribes who claimed bird ancestors, worshipped bird deities, and held religious rites with bird dances performed on stilts. The affinity of the Taoist immortals to birds (crane, phoenix, magpie, stork, or raven) is a persistent theme in iconography and legend.

There are many categories of immortals. The highest are those who "ascend to heaven in broad daylight." There are also those who live in terrestrial paradises (on holy mountains or islands) for centuries without growing old and later appear disguised in this world to transmit their immortality formulas and magical powers to worthy adepts. Lower immortals do not reach paradise before dying an apparent death (*shih chieh*), leaving their sandals or their canes in the coffins to take on the appearance of their corpses.

Techniques of longevity. *Hygiene techniques.* The detailed correspondence between the human microcosm and the macrocosm are at the basis of all techniques to "nourish the vital force" (*yang-hsing*). The communication between the five inner organs (lungs corresponding to metal, heart to fire, spleen to the earth, liver to wood, and kidneys to water), all other body organs, and the outer world proceeds through the orifices (nose for the lungs, ears for the heart, mouth for the spleen, eyes for the liver, and the lower orifices for the kidneys). All these orifices are passageways for entry and exit of vital forces and have to be closely guarded. Because the orifices are sense organs and desires result in loss of vital force, the senses have to be carefully kept in balance lest disease be caused through overindulgence in any one of the corresponding desires.

All dietary regimens are intended to nourish the respective organs in right proportions with foods and medicinal herbs containing the energy (*ch'i*) corresponding in quality to their respective elements. A preliminary step in diet is complete abstinence from all cereals in order to starve and kill the "three worms," or the "three corpses," which are maleficent demons inside the body that work to hasten its decomposition.

Abstinence from certain foods and practice of gymnastics

In order to make all energies in the body reach their proper place and to maintain a continuous circulatory process, the adept practices gymnastics called "to conduct (the breath) and to stretch" (or to attract it to its proper place, *tao yin*). Chuang-tzu mentions (and ridicules) the *tao yin* adepts who practice "bear hangings and bird stretchings" in order to render their bodies flexible and make the energy circulate everywhere. Gymnastics as well as massage assist the circulation of breaths; they eliminate any internal obstructions, which can cause disease. They untie internal knots so that everything inside the organism can communicate freely.

Respiratory techniques and meditation. Chuang-tzu stated that ordinary people breathe through the throat but the saint breathes through the whole body, starting from the heels. The Taoist breathes not only atmospheric air but solar, lunar, and stellar emanations. He absorbs the characteristic energies of the five directions, guiding the green emanation of the east to the liver, the red emanation of the south to the heart, and so on. The *Ling pao wu fu Ching*, or "Classic of the Five Sacred Talismans" (a revealed sacred text of the 3rd or 4th century AD), gives a formula for absorbing the emanations of the sun at noon (the peak moment of Yang) and of the moon at midnight (the peak of Yin). Others inhale the emanations of dawn in spring, of noon in summer, of dusk in autumn, and so on. Others warn against the practice of this discipline in the latter part of the day, because the universe exhales dead air from noon to midnight. Another method taught how to "feed on air" by retaining breath and conducting it throughout the body. One who could hold his breath for the time of 1,000 respirations would become immortal.

About the time of the T'ang period (618–907) ordinary respiration (*wai ch'i*) was replaced by the respiration of inner breath (*nei ch'i*), or "embryonic breathing" (*t'ai hsi*). This inner breath was viewed as man's share of the primordial life breath contained in the lower of the three "cinnabar [mercuric sulfide] fields" of the body (centres located in the head, chest, and abdomen). This life breath is conducted, in a closed circuit like that of the embryo, through the body and directed by means of the "inner sight" (*nei-kuan*), an inward-turned vision of the eyes (considered a source of light). In case of sickness, the inner breath is conducted to the diseased organ and heals it.

The *T'ai-p'ing Ching*, or "Classic of the Great Peace," the first sacred text of religious Taoism (3rd century AD), mentions the ability of the interior vision to discern the gods residing in the five organs. Books like the two *Huang-t'ing Ching* ("Classic of the Yellow Court"), from the 3rd century AD, owe their popularity to the enumeration of thousands of gods in all parts of the body, the same gods as those residing in the macrocosm. Meditation establishes communication with these gods, either by making the external gods descend and visit their organs in the body and fortify it or by externalizing the inner gods and disposing them in a mandala (a symbol of the universe) around oneself. The latter practice is a preparation of religious ceremonies and recitation of sacred texts.

In many Taoist physiological practices an influence of Indian Yoga (a system of psychological and physiological meditation) is perceptible. Borrowings from Tantrism can be found in Taoist texts as early as the 7th century.

Sexual techniques. The techniques of the "inner chamber" (*fang chung*) go back to antiquity. Their aim was to secure vitality, longevity, and male progeny. Specifically Taoist practices were the "Way of the Yin" of the immortal Yung-ch'eng (1st century AD), a technique "to make the semen return and repair the brain" (*huan ching pu*

The "Way of the Yin"

nao). This technique consisted in the prevention of ejaculation during the sexual act and was thought to make the semen (*ching*, a potent mixture of all physical energies) circulate—mixed with breath—through the body from the lower to the upper "cinnabar field," there to vitalize the brain. Immortals are often depicted with a huge skull that is the storeroom of their Yang energy. Another idea was to blend seminal essence with breath in the "lower cinnabar field" and there to form the "mysterious embryo" (*hsüan t'ai*) of the new immortal body.

For the "repairing of the brain," the male adept also needed to absorb as much as possible of female Yin essence (and vice versa). It was therefore desirable to have intercourse with a succession of partners. This led to the much-decried communal "union of breaths" (*ho ch'i*), a highly ritualized ceremony that might have resembled more a group ordeal than an orgy.

The abstention from ejaculation exists equally in Tantric practices, which were known to the Taoists since T'ang times or earlier. As in Tantrism, the sexual terminology refers also to mental operations because only thought processes can make semen and breath circulate and "marry" to thus create the immortal man.

Alchemical techniques. Dietary and breathing techniques only prolong life so as to give time for the preparation of the elixir of immortality, which was composed of cinnabar (*tan*, for its red, or Yang, colour and its transmutability) and gold (*chin*, for its incorruptibility).

Alchemy evolved early in connection with metallurgy. The patron of alchemy was the Yellow Emperor (Huang Ti), who ascended to Heaven after the casting of a sacred metal crucible. This legend is alluded to in the alchemical recommendations given by Li Shao-chün, a 2nd-century-BC alchemist, to the emperor Han Wu Ti (*c.* 133 BC), in the *Shih-chi* (composed *c.* 85 BC), the earliest known reference to alchemy in any literature of East or West.

The "elixir of immortality"

Later, Taoist alchemists sought to produce liquid gold and pure (nine times transmuted) cinnabar, or a combination of both in an "elixir of immortality." "If these two substances are eaten," stated the alchemist Ko Hung (flourished 4th century AD), "they bring about a sublimation in the human body." Ko Hung's *Pao-p'u-tzu*, or "He Who Holds to Simplicity," distinguishes the art of "gold and cinnabar," that is, the compounding of the elixir, from the art of the "yellow and white," that is, the transmutation of baser metals into silver and gold. All of these practices were supposed to take place in the solitude of sacred mountains and were to be accompanied by preliminary fasting, purifications, and sacrifices to the patron gods. Also important was the right time for the operation and the notion of accelerating natural processes in time. Although Ko Hung, the most sober, inquisitive, and well-informed Taoist writer on alchemy at that time, was himself too poor to afford the ingredients of his formulas, he wrote of operative alchemy and laboratory work (*wai tan*, external alchemy).

This is not mentioned in the probably earlier and most popular alchemical treatise, the *Chou-i ts'an t'ung ch'i* by Wei Po-yang (of uncertain date, possibly 2nd century AD), which reads like the application of the doctrines of the *I Ching* to the procedures and principles of alchemy. Written in a highly abstract language, it has later been interpreted in terms of internal alchemy (*nei tan*).

The term internal alchemy refers to physiological or mental techniques of immortality that employ the language of the laboratory but in actuality refer to the human body. The human body becomes the alchemical crucible, the microcosm in which breath and semen, the "true" lead and the "true" mercury, circulate and fuse. The Yin and Yang energies rise and descend in the two main energy conduits *jen* and *tu* (already mentioned by Chuang-tzu), the two passageways between the upper and lower parts of the body. Embryonic respiration is often described in alchemical language, and the frequently sexual images of the "marriage" of Yin and Yang have led to interpretations (denied by some commentators) of *nei tan* treatises in terms of sexual practices.

The aim of *nei tan* was to reverse the normal vital processes leading to old age and death. Instead of externalizing vital energies, especially sexual energies, the Yin and Yang forces of the body are made to unite in a hierogamy (holy marriage) and to create the "elixir of life," the "golden flower," the "mysterious embryo," the "infant"; *i.e.*, the new immortal being that eventually leaves the mortal body through the occiput (the top of the skull) and ascends to Heaven.

Use of charms and talismans

Magical techniques. Charms and talismans were used in all sects. Magical diagrams written on paper were burned and swallowed for healing. In order to penetrate into the mountains in search of medicinal herbs and divine revelations, magic formulas and gestures as well as talismans and mirrors were needed for protection against demons and for communication with immortals. The *fu* ("talisman") was written on bamboo, metal, or paper and broken into halves for each partner of a contract between the adept and his human or divine master.

Communal religious Taoism. Practice of the above techniques of immortality was restricted to the affluent and educated few. In the rural communities of the two Han dynasties (206 BC–AD 220) emerged the popular Taoist religion.

The beliefs and institutions of the popular Taoist sects took form when Buddhism was beginning to spread in China, but scholars now tend to minimize any causal connection. The pantheon, ritual, and moral codes, as well as the theocratic organization of the early Taoist Church, bear much closer similarity to the Imperial and Confucian ideologies than to Buddhism. The new foreign religion, however, was at first mistaken for another form of Taoism because Lao-tzu was supposed to have preached to the "barbarians" after his legendary departure from China to the West. On this theory of the "conversion of the barbarians" (*hua hu*) focussed most of the subsequent polemics between the two religions. Buddhism soon became a formidable rival, conscious of its originality; and the Taoists endeavoured to limit its influence by polemics and by extensive (though more formal than essential) borrowings, imitating its institutions (*e.g.*, monasticism and celibacy) and the style of its scriptures. Folk Taoism came to be deeply influenced by the Buddhist beliefs in reincarnation and punishment in hells.

The rise and influence of Taoist sects

Religious communities. Popular Taoist communities can be traced back to the T'ai-p'ing ("Great Peace") movement and the "Way of the Celestial Masters" (*Tien shih Tao*, or "Way of the Five Pecks of Rice," *Wu-tou-mi Tao*), which propagated popular Taoist cults and formed village communities in the 2nd century AD. The legendary first celestial master, Chang Tao-ling, was a magician and faith healer. His descendants evolved into a hierarchy of priests ("libationers," *chi-chiu*) who assumed temporal as well as religious authority in their parishes. They were exorcists who treated the sick by ritual and prayer, using charmed water and talismans. Because disease was believed to be caused by sin, the sick were sent to "pure [or calm] houses" in order to repent and to recite the *Tao-te Ching*, which was explained to them in simple terms of physiology and moral conduct. They also were supposed to make amends by doing public works, such as road building. Taoist temples played an important social role in the villages throughout Chinese history as focuses of community organization.

Morality and the system of merits. Insistence on moral teachings and on seasonal collective ceremonies was a new accent. The moral code was based on the *Tao-te Ching*, of which the T'ai Shang Lao-chün (that is, Lao-tzu deified) became the divine revealer. Moral conduct was rewarded with health and long life; immorality caused sickness, premature death, and, according to later texts, suffering in hell. Numerous deities came to be the "directors of destiny" (*ssu ming*), record keepers of man's virtues and vices. A complex heavenly bureaucracy received annual reports on the deeds of the family or the individual from the god of the hearth (Tsao Chün) at New Year or from the malevolent "three worms" residing in the human body. A proliferating literature of merits and demerits, including schedules of points for good and bad deeds (the most famous being the *T'ai shang kan-ying p'ien*, or "Tract on the Most Exalted One on

Actions and Retributions," probably from the 11th century), probably shaped the minds of the masses more than any other religious texts in China.

Incipient messianic and millenarian ideals

Theocracy and messianism. The sect of the Celestial Masters developed into a lasting Taoist church. Other, dissident, movements shaped the idea of the Taoist saint as ruler into an alternative to the Imperial heavenly mandate. "The Way of the Great Peace" (T'ai-p'ing Tao) was the first known Chinese movement to attempt to fuse a religious organization with an Imperial type of administration into one messianic empire. Nostalgia for this ideal was a recurrent feature of Chinese peasant rebellions. Political distress or, more often, economic distress again and again sparked a latent messianism and millennialism. Charms played an important role in these movements: as badges of office, as protection against demons, and as the sign by which the expected divine ruler (the deified Lao-tzu or his emissaries) would distinguish the virtuous "chosen people" (*chung min*) from the villains and reward them with official appointments in the heavenly bureaucracy that would come down to Earth. The founders of the T'ang (618–907) and Ming (1368–1644) dynasties apparently utilized Taoist prophecies and magic to secure popular support. Dissident movements continued to be animated by the Taoist vision of a perfect government; some of their ideas live on in syncretistic religions and secret societies.

Sacred texts and revelation. All sects had an esoteric character; the Taoist priesthood could be entered only through an initiation that culminated in the transmission of the sect's sacred scriptures. Sacred texts served to procure communication with the gods and to ward off demons. There were manuals for immortality practices (arts that had to be learned orally from a master), lists of names of deities used in meditation and liturgy, and divine revelations. The mere perusal of a text without initiation into its esoteric meaning was worthless if not sacrilegious or fatal. The more important a text, the more carefully it was hidden from the profane and the more rarely revealed and transmitted.

Preparatory conditions for the reception of revelations

Divine revelations were transmissions of a teaching the gods themselves had received from higher deities. Only the highest, the Yüan Shih T'ien Tsun ("Celestial Worthy of the Original Beginning"), could face the power and understand the meaning of the primordial revelation, the first and purest emanation of undifferentiated unity. In diminished and adapted form he passed it on until it reached the lower gods, who can reveal some of it to worthy adepts. In all ages adepts have gone to the mountains in search of texts hidden by the immortals in grottoes accessible only to the initiated. Many of the most important scriptures were revealed in trance. The Mao Shan sect is famous for its mediumistic seances, to which is owed the *Shang-ch'ing* (another name for the Mao Shan sect) writings, such as the *Huang-t'ing Ching* ("Classic of the Yellow Court"). The Mao Shan revelations were written with a brush by mediums versed in calligraphy. The immortals appearing at such seances used to identify themselves, relate their biographies, and specify their heavenly rank. Their hagiographies (biographies of saints) compiled from the records of medium cults at different periods became a prolific and confused lore that gradually constituted a pantheon. Thus, mediumism is one of the reasons for the unsystematic and contradictory character of the Taoist pantheon.

The pantheon and the Taoist canon. The Chinese gods do not reign over the world. They act as administrators and control the harmonious functioning of the universe of which they themselves are a part. The Taoist pantheon is thus constructed as a vast other-worldly bureaucratic administration. Many names of gods are really titles of functions (*e.g.*, "Director of Destiny"), the holders of which are deified human beings who change their functions as they advance in grade. Another category of gods, introduced by the Ling Pao, or "Sacred Treasure," sect (5th century), are the celestial worthies (T'sien Tsun), personifications of aspects of the Tao. The foremost of these highest and remotest gods are the Taoist triad Yüan Shih T'ien Tsun, his disciple T'ai Shang Tao-chün ("Most Exalted Lord of the Tao"), and T'ai Shang Lao-chün ("Most Exalted Lord Lao"), who is identified with Lao-tzu. There are as many celestial worthies as there are aspects of the Tao that can become manifest to the believer; some texts enumerate hundreds. The Taoist master T'ao Hung-ching (flourished 5th–6th centuries), among others, attempted to codify the sprawling multiplicity in his *Chart of the Ranks and Functions of the Gods* (*Shen ling wei yeh t'u*).

The concept of a canon (accepted texts) of all Taoist scriptures goes back to the Taoist ritualist and reformer Lu Hsiu-ching (AD 406–477), and it bears witness to a cohesiveness existing among different schools of Taoism. Lu Hsiu-ching mentioned 1,228 scriptures—of which 1,090 were known in the world and 138 were "still in heaven," that is, not yet revealed—and divided them into three *tung*, in imitation of the early Buddhist canon. The root meaning of the word *tung* is "cave," but it also means "to communicate, to understand the mysteries." The term thus evokes the mysterious mountain grottoes, real or imaginary, harbouring hidden revelations and the dealings with the sacred powers that can initiate one into their meaning.

Priesthood and monasticism. The "libationers" of the sect of the Celestial Masters were a married, hereditary priesthood. They lived in the community they served and performed exorcisms and increasingly complex rituals. The present Chang family of the Celestial Masters claims descent from Chang Tao-ling, founder of the sect during Han times (since Sung times, it has been called "Way of Orthodox Unity," Cheng-i Tao). The libationers' title (*chi-chiu*) is still used in the Cheng-i sect of Fukien and Taiwan, pointing to an unbroken tradition. Organized religious Taoism never had a permanent central authority. There was no institutional cohesion among the sects.

Taoist monasticism as a reaction to Buddhism

Taoist monasticism is a later element but no less important than the priesthood. The Mao Shan sect formed religious communities of families in phalanstery-like, communal establishments called *kuan*. This way of life was created essentially in order to facilitate everyday observance of Taoist meditation, liturgy, hygiene, and other matters. It was also a reaction to the Buddhists' establishment of monasteries, with which the Mao Shan sect seems to have had close relations. The monk Sung Wen-ming (flourished 6th century) may have been the first to advocate celibacy. This was encouraged by two imperial edicts (972 and 1009) forbidding married monks to live in the tax-exempt monasteries. Since the Yüan dynasty (1279–1368), the monasticism of the Ch'üan Chen ("Perfect Realization") sect has been a conspicuous feature of the Taoist tradition. The founder of this sect, Wang Che (flourished 12th century), advocated the syncretism of the three religions and placed emphasis on meditation as a means to return to one's original nature and thus to prolong life. Monasteries were not subject to any higher jurisdiction except for their recognition by the government. The Ch'üan Chen sect is usually called the Northern School of Taoism.

Liturgical practices and ceremonies. The most important, as well as one of the oldest, liturgies is the *chiao*, a "pure" ritual (in contrast to rites for the dead) that renews the community through communication with the gods. A *chiao* of three, five, or seven days is still celebrated in Taiwanese villages, usually once every three years, with a more extensive ritual that is celebrated once in a generation and is combined with a restoration of the village temple. There are other *chiao* rites for the ordination of priests, for the birthdays of gods, for warding off calamities, and for other occasions. All are celebrated on two levels: a village feast outside the temple and an esoteric liturgy (in Classical Chinese) inside the closed temple. The inner *chiao* ritual's communication with the highest gods (the T'ien Tsun triad) is modelled on the ritual of Imperial court audiences with the Son of Heaven.

Ceremonial objects

An incense burner, the central object in the temple, is essential to every Taoist rite. A mystical incense burner is "lighted" inside the body of the main priest, whose meditation transforms him into a mediator with the divine

Taoist priest burning incense in honour of two minor deities.
Dmitri Kessel, *The World's Great Religions* © Time Inc.

who makes possible the efficacy of the *chiao* rite. Incense also plays a role in the ecstatic visit to Heaven performed inside a microcosmic sacred area marked by five buckets of rice. Several written documents are used, among them a "memorial to the throne" (*chang*), which is burnt ("sent off to Heaven") to announce the purpose and report the performance of the liturgy. Other important ritual objects are swords, lamps, flags, masts, charmed water, musical instruments, masks, vestments, statues, picture scrolls, and sacred texts.

In medieval China, among the collective rites called *chai*, was the "Mud and Soot [T'u T'an] *chai*," a frenzied public rite for the atonement of sins. In modern times, the term *chai* is reserved for funeral rites for individuals. Aside from the *chiao* and the *chai*, which belong simultaneously to both religions, it is difficult to distinguish between the festivals of folk religion and Taoism.

Communal folk Taoism (shen chiao). Popular, or folk, religion is not a separate religious tradition but the wholly unorganized undercurrent of Chinese religious culture from the earliest times, shared by all strata of society. The Chinese have no single name for it; it may be called the religion of the gods, or spirits (*shen chiao*). The deities of the popular pantheon come from all traditions. What the deities have in common is that in *shen chiao* they are all gods intimately involved in everyday life as givers of blessings or bringers of calamities. Every object or activity of daily life has its presiding spirit that has to be consulted and feasted or appeased and driven off, especially at all special occasions in the life of the family or the community. The person primarily involved in the practice of *shen chiao* in modern times is the *fa shih* (magician). For the orthodox Taoist priests the *shen chiao* rites are the "little rites"; the *chiao* rituals, the exclusive function of the Taoist priests, are the "great rites." Both kinds of priests—the orthodox and the magicians—operate on different occasions in the same temples and are consulted for the family rites of burial, birth, marriage, house construction, and business affairs.

Major exorcism rites (*e.g.*, purification of haunted houses and treatment of the sick or mentally deranged) are performed by the orthodox Taoist priests, who, being ordained into the ranks of the *shen*, have power over the demons with whom they are on an equal footing. The *fa shih* priest's specific function is the manipulation of possessed mediums (specially gifted lay persons). The medium puts himself into a trance in which he becomes the mouthpiece of a deity (or a deceased relative) giving medical, personal, or business advice that is interpreted by the *fa shih*. Professional mediums attached to a temple or a private cult lacerate themselves in trances. This is considered to be a vicarious atonement for the community during the great feasts. A different form of mediumistic communication among lay people is automatic writing, either with a brush on paper or with a stick on sand.

The functions of the folk priest (or magician)

Contemporary religious Taoism. Religious Taoism lives on wherever its basis, traditional Chinese culture, survives. The best example is in present-day Taiwan, where the religion has had, since about 1960, a veritable renaissance—manifested in the restoration and construction of costly temples and in the frequency of lavish festivals. The Taiwanese orthodox Taoist priests preserve a vast liturgical heritage and still receive their rank in the Taoist church from the Celestial Master. The 63rd Celestial Master, Chang En-pu, fled to Taiwan in 1949. After his death in 1970 he was succeeded by the 64th Celestial Master, Chang Yüan-hsien. On a smaller scale, similar active Taoist communities exist in the Chinese quarters of Pinang (Malaysia; Penang), Singapore, and Bangkok (Thailand).

Almost nothing is known about the fate of Taoism on the Chinese mainland. The Po Yün Kuan ("White Cloud Monastery") in Peking and some other temples elsewhere were open and inhabited by monks until the mid-1960s. In 1958 it was officially claimed that 30,000 Taoist priests were still active in different parts of the country. At the end of 1971, soldiers were seen at the Po Yün Kuan, apparently quartered there.

Not only on the mainland but throughout the Chinese culture area, the surviving Taoist traditions can be expected to lose their traditional place in society as their gods and practices are increasingly challenged by the advance of Western education and ways of life.

Other forms of Taoist thought and influence. *Secret societies.* Politically dissident messianic movements have existed and developed separately from the established Taoist church from the very beginning (2nd century AD). Their leaders were priest-shamans, similar to the modern *fa shih* priests of folk Taoism. Their followers were the semiliterate or illiterate classes socially below the tradition of orthodox Taoism, and their organization was similar to that of the syncretistic religions and of modern secret societies. Although the secret societies have had no organizational contact with the Taoist tradition for centuries, their religious beliefs, practices, and symbols contain some Taoist elements, such as initiation rites, worship of Taoist deities, mediumism, and the use of charms and amulets for invulnerability. These influences reached them either directly or through popular religion.

Relationship of secret societies to Taoism

The syncretistic religions (*hui-men tao*), such as the I Kuan Tao, or "Way of Pervading Unity," and at least 40 other named organizations that have no organizational ties with religious Taoism, have to be distinguished from the secret societies. In their practice of mediumism and in many of their beliefs they participate in a popular tradition nourished from Taoist sources.

Taoist aspects of traditional Chinese medicine. Taoist physiological techniques have, in themselves, no devotional character. They have the same preoccupations as physicians: to preserve health and to prolong physical life. Medicine developed independently from about the 1st century AD, but many Taoist faith healers and hygienists added to medical knowledge.

The earliest surviving medical book, the *Huang Ti nei Ching*, or "The Yellow Emperor's Esoteric Classic" (3rd century BC?), presents itself as the teachings of a legendary Celestial Master addressed to the Yellow Emperor.

Experiments with minerals, plants, and animal substances, inspired to some extent by Taoist dietetics and by the search for the elixir of life, resulted in the 52 chapters of pharmacopoeia called *Pen-ts'ao kang-mu*, or "Great Pharmacopoeia" (16th century).

Taoism in Japan. There was never an attempt to implant a Taoist religion officially in Japan, but a random choice of Taoist beliefs and customs have, at various ages, been adopted and transformed at the Japanese

court, in the temples, and among the people. Records from the early 7th century contain traces of Taoism, which was appreciated chiefly for its magical claims. The "masters of Yin and Yang" (*ommyō-ji*), a caste of diviners learned in the *I Ching*, Chinese astrology, and occult sciences who assumed importance at court in the Heian period (8th–12th centuries), probably were responsible for the introduction of Taoist practices, such as the Keng-shen (Japanese Kōshin) vigil and the observance of directional taboos (*katatagae*). In the 8th century, disputations were held at court over Buddhism and the philosophy of Lao-tzu and Chuang-tzu. The *Pao-p'u-tzu* was known, and Kōbō Daishi, the founder of Shingon Buddhism, reported (in 797) on Taoist physiological practices and beliefs in immortals. Buddhist (Shingon and Tendai) ascetics, wandering healers, and mountain hermits known as *yamabushi* probably came closest to Taoism in their techniques for prolonging life (abstinence from grains, etc.) and their magical arts (exorcisms, sword dance) and objects (mirrors, charms), which must have reached them through the Tantric elements in Shingon. Taoist mysticism lives on in that it has influenced the two Chinese Zen schools of Lin-chi (Rinzai) and Ts'ao-tung (Sōtō), introduced in the 12th and 13th centuries and still active in Japan. Popular Taoist moral tracts were printed and widely diffused in the Tokugawa period. Modern Japanese scholarship on Taoism (Dōkyō) ranks very high in the world.

Introduction of Taoist practices to Japan

TAOISM AND OTHER RELIGIONS

Confucianism and Buddhism. Confucianism is concerned with human society and the social responsibilities of its members; Taoism emphasizes nature and what is natural and spontaneous in man. The two traditions, "within society" and "beyond society," balance and complement each other. This classic definition is generally correct concerning orthodox Han Confucianism; it neglects some aspects of Confucian thought, such as the speculations on the *I Ching*, that is considered to be among the Confucian Classics and the prophetic occult (*ch'an-wei*) commentaries to the classics. As far as Taoism is concerned, this definition neglects the social thought of the Taoist philosophers and the political aspects of Taoist religion. Chinese Buddhism has been viewed not as a Sinified Indian religion but as flowers on the tree of Chinese religions that blossomed under Indian stimulus and that basically maintained their Chinese character. Indian Buddhist thought was understood in China, but the more accurate and the less Sinified the translations became in the T'ang dynasty, the less appeal they had for the Chinese mind and the less stimulus they provided for spiritual creativity.

Relationship of Taoist and Buddhist concepts

The idea of Buddhist Mādhyamika (Middle View) philosophy that there is no difference between worldly existence and otherworldly salvation; *i.e.*, that *saṃsara* (the round of mortality) and Nirvāṇa (the state of salvation) coincide, led to the concept of the inborn Buddha-nature and of salvation not as an effort to become a Buddha after many lives but as an illuminating realization—here and now—of the Buddha-nature ever-present within. At this point Chinese Buddhism met with the Taoist ideal of "non-activity" and of the union with the Tao. The result of this process of assimilation was Chinese Ch'an (Zen) Buddhism, a revival of Taoist mysticism in new form.

Ch'an Buddhism deeply influenced Neo-Confucianism, the renaissance of Confucian philosophy in Sung times (960–1279), which in Chinese is called "Learning of the Tao" (Tao Hsüeh). In this movement Confucianism acquired a universal dimension beyond a concern for society. Neo-Confucian thought often seems as Taoist as Neo-Taoist philosophy and literature seem Confucian. What is called Neo-Taoism was a world view accepted by disillusioned officials who had to cope with political chaos, whereas Neo-Confucianism was the attempt by state-supported intellectuals to make the official ideology more attractive by incorporating Taoist (and Buddhist) thought. Viewed from their share in both traditions, it appears almost an historical accident that the one movement was named Taoism, the other Confucianism.

As early as the T'ang dynasty, there are traces of the syncretism of the "Three Religions" (San Chiao), which became a popular movement in Sung and Ming China. A mixture of Confucian ethics, the Taoist system of merits, and the Buddhist concept of reincarnation produced such "books on goodness" (*shan-shu*) as the *Kan ying p'ien* ("Tract on Actions and Retributions"). The school of the "three Religions" was rejected by most Confucians and Buddhists but received wide support in Taoist circles. Many Taoist masters of those periods transmitted *nei tan* and other techniques of inner cultivation to their disciples while at the same time preaching the moralism of the "Three Religions" to outsiders.

Other Asian religions. The affinities of Taoism with other Asian religions are numerous. If one distinguishes between universal religions of salvation, such as Buddhism and Islām, and the older, more culture-bound, such as Japanese Shintō and Hinduism, Taoism undoubtedly belongs to the second category.

The fact that no record of Shintō antedates the introduction of Chinese script makes it difficult to distinguish between Taoist affinities and influences on Shintō features, such as the cult of holy mountains, the representation of the human soul as a bird, bird dances, the representation of the world of the dead as a paradisiac country of immortality, and the concept of the vital force (*tama*, in objects as well as in man). Like Taoism, Shintō is the religion of the village community.

Western mysticism and religions. The similarity of mysticism in all religions points to the fact that there is only one Inner Way, the experience of which is expressed differently in the respective cultural and religious environments. Lao-tzu's notion of "the One," which is not only primordial unity but the oneness underlying all phenomena, the point in which all contraries are reconciled, was spoken of by such Western mystics as Plotinus, a 3rd-century-AD Greek philosopher, and Nicholas of Cusa, a 15th-century French philosopher.

Similarities between Taoism and Western mystical thought

Taoism, as all other forms of Eastern mysticism, distinguishes itself from Western mysticism by its conscious techniques of mind and body designed to induce trance and to give access to mystical experience. These disciplines of learning to "sit in forgetfulness" are akin to Plotinus' concern to "be deaf to the sounds of the senses and keep the soul's faculty of apprehension one-pointed" and to the 16th-century Spanish mystic Teresa of Avila's state where "the soul is fully awake as regards God, but wholly asleep as regards things of this world and in respect of herself." Lao-tzu's strangely sober and abstract descriptions of ecstatic union with the Tao have been compared to the medieval German mystic Meister Eckeharts' "still desert of the Godhead" and his pupil Heinrich Suso's union of the essence of the soul with "the essence of Nothingness." One instance of Western physiological techniques is the Hesychasts, a sect of Greek Orthodox mystics on Mt. Athos in the 14th century who used respiratory practices and concentration on internal organs to prepare for the mental "Jesus prayer."

TAOISM AND CHINESE CULTURE

Taoist contribution to Chinese science. Scholars have stated that the Taoists initiated the sciences of chemistry, mineralogy, botany, zoology, and pharmaceutics in East Asia. This interest in science is considered a reflection of the Taoist emphasis on direct observation and experience of the nature of things, as opposed to Confucian reliance on the authority of tradition. Chuang-tzu declared that tradition tells what was good for a bygone age but not what is good for the present.

The Taoist secret of efficacy is to follow the nature of things; this does not imply scientific experimentation but rather a sensitivity and skill obtained by "minute concentration on the Tao running through natural objects of all kinds." This knowledge and skill cannot be handed down but is that which the men of old took with them when they died (*Chuang-tzu*). The image for it is the skill of the artisan admired by the Taoists in their numerous parables on wheelwrights, meatcutters, sword makers, carvers, animal tamers, and musicians.

Though extolling the intuitive comprehension and skillful handling of matter, the Taoists did not observe nature in the Western sense and rejected technology out of their aversion to the artificial. Any new idea or discovery in China was phrased as "what the old masters really meant." This ideology of rediscovery makes it hard to study the evolution of scientific thought. Some progress over the ages (for example, in alchemy) can be seen, but the Taoist contribution to Chinese science might be smaller than it has been assumed.

Taoist influence on literature and art. The Taoist conception of the craftsman's skill is already on the threshold of art. Like the meatcutter and the woodworker in *Chuang-tzu*, the artist has to feel his subject from the inside and see it with the eyes of the spirit in order to grasp the vital breath of what he is painting or putting into tunes, words, or calligraphy. As the first of the six principles presiding over painting, the painter and critic Hsieh Ho (*c.* AD 500) names "consonance with the vital breath" (*ch'i-yün*), which means that the artist should attune himself to the vital rhythm of his subject in order to be able to express the life and movement manifest in nature. If the *ch'i* in the subject is missed, the spark of Tao is absent from the work of art. A similar concept applies to Chinese poetry, one of the most characteristic themes of which is harmony with nature. Creative art in China is less compartmentalized than in the West. One man was often a painter, calligrapher, and poet. Underlying all artistic creation, even by Confucian artists, is the concept of "spontaneity" that was cherished especially by the Neo-Taoists (among them the greatest Chinese calligrapher, Wang Hsi-chih, flourished 4th century, who was a member of the Celestial Masters sect). Chinese art criticism and art philosophy are animated by Taoist views of the artist and of the world he expresses.

The Taoist view that the artist must see his subject with the eyes of the spirit

Both Confucianism and Buddhism have a limited understanding of art and value it only as an expression of basically nonartistic—ethical or religious—concerns. The Taoist pervasion of the great tradition dominated by Confucianism grew stronger the more the Confucian gentleman embraced all human endeavours, including the arts, for ends that were not purely moral. Through the practice of poetry, calligraphy, and painting, the Taoist understanding of nature and creativity became a necessary part of Confucian individual cultivation, especially with the rise of Neo-Confucianism in Sung times.

Distinctive religious elements of Taoism. The essential quest of Taoism is how to gain, preserve, and increase the vital force through a realization of harmony. On the basis of the Chinese concept of a concentric, well-ordered, and single universe, Confucianism built its wisdom of the order and functioning of human society in accordance with the Whole; and Taoism expressed the individual's as well as the group's need of harmony with the perceptible and the imperceptible Great Order (Tao) in all variations of magic, religion, and mysticism. To live in harmony with the universal mechanism without intervening (*wu-wei*) anywhere is to preserve one's energy.

The essential quest of Taoism

This preoccupation with the vital force is one reason for that lack of speculative thought distinctive of Taoism. Taoist mystics are poets, priests are technicians of the occult, and thinkers are specialists in alchemy, ritual, or pharmacognosy. There are no theologians in the Western sense and few philosophers in the Buddhist sense. This accounts for the Taoist weakness in competing with Confucians and Buddhists in debate. This also accounts for the fact that among the highly developed religions, Taoism is the one with the least rationalization, in which the communication of man with the sacred appears in its most immediate and unreflective form.

BIBLIOGRAPHY

General works: MAX KALTENMARK, *Lao tseu et le taoïsme* (1965; Eng. trans., 1969), a good general introduction to Taoist philosophy and religion; HOLMES WELCH, *The Parting of the Way: Lao Tzu and the Taoist Movement* (1957), a most readable interpretation of the *Tao-te Ching* and first coherent account of the Taoist movement; HENRI MASPERO, *Le Taoïsme et les religions chinoises,* rev. ed. (1971), a classic pioneer work on religious Taoism.

Philosophy: ARTHUR WALEY, *The Way and Its Power* (1934), a classic translation of the *Tao-te Ching* preceded by a good introduction on its place in Chinese thought; BURTON WATSON, *The Complete Works of Chuang Tzu* (1968), a very readable translation of the most important and most difficult text of Taoist mysticism; A.C. GRAHAM, *The Book of Lieh-tzu* (1961), a good translation and introduction to Taoist mysticism; MARCEL GRANET, *La Pensée chinoise* (1934), the classic work on the basic systems of classification in Chinese thought—difficult but highly enlightening; FUNG YU-LAN, *A History of Chinese Philosophy,* 2nd ed., 2 vol. (Eng. trans. 1952–53), a classic work with sections on Taoist thought; JOSEPH NEEDHAM, *Science and Civilization in China,* vol. 2, *History of Scientific Thought* (1956), a section on Taoist contribution to scientific thought (most thorough documentation and bibliography).

Religion: MAX KALTENMARK, *Le Lie-sien tchouan* (1953), a translation of the earliest extant Taoist hagiography with much information on mythology hidden in long notes; *History of Religions,* vol. 9, no. 2 and 3 (1969–70), issues devoted to the reports from the First International Conference on Taoist Studies, papers on the conference discussions, on Chuang-tzu, on Neo-Taoism, on Taoist antecedents in Buddhist thought, and on Taoist messianism; ANNA K. SEIDEL, *La Divinisation de Lao tseu dans le Taoïsme des Han* (1969), a study of the beginnings of the popular Taoist religion; KRISTOFER SCHIPPER, *L'Empereur Wou des Han dans la légende taoïste* (1965), a translation of a Taoist hagiographic novel and study of its ritual background in the Mao Shan sect; JAMES R. WARE, *Alchemy, Medicine and Religion in the China of A.D. 320: The Nei P'ien of Ko Hung* (1966), an imperfect but only complete translation of probably the most important text of religious Taoism; ARTHUR WALEY, *The Travels of an Alchemist* (1931), a translation of the contemporary account of the journey of the Taoist priest Ch'ang-ch'un from China to the Hindu Kush at the summons of Genghis Khan, with a good historical introduction; NATHAN SIVIN, *Chinese Alchemy: Preliminary Studies* (1968), an annotated translation of a treatise by a 6th-century alchemist—a most scholarly introduction on the study of Chinese alchemy; MICHEL SOYMIE, "Bibliographie du Taoïsme—études dans les langues occidentales," in *Études Taoïstes (Dôkyô kenkyû),* vol. 3–4 (1968–71), the first and only comprehensive bibliography of Western-language studies on Taoism and Chinese folk religion.

(A.K.Se.)

Taoism, History of

Taoism, with Buddhism and Confucianism one of the major spiritual "ways" of China, is said to be founded, according to tradition, by the sage Lao-tzu in the 6th century BC, and for more than 2,000 years it has influenced Chinese thought in every sphere—in religion, politics, the social system, and the arts and sciences. Further, it has provided the impetus for various changes in the historical development of China.

TAOISM IN CHINESE HISTORY

"Taoism" is commonly used to designate two distinct aspects of Chinese thought and belief. First, Taoism is viewed as a philosophy or form of mysticism, of which the first evidence is contained in texts of the 4th and 3rd centuries BC. In this regard it has continued throughout Chinese history to be a spiritual goal or diversion of the leisured and the learned class. Secondly, it is viewed as a religion that is highly organized, with a hereditary priesthood (of which the earliest original documents date from the 2nd century AD). As such, it began as a popular movement and soon extended its influence to all ranks and classes of the Chinese population. Though these two views of Taoism appear to be quite distinct, they in fact have many points of interconnection; the same person might participate in the communal ceremonial aspects of organized religious Taoism (Tao-chiao) as well as involve himself in solitary mystical abstraction. Many conceptual and linguistic links also exist between the classics of Taoist speculation and the liturgies and contemplative tracts of the organized religion.

The two common views about Taoism

Although philosophical Taoism (Tao-chia) has attracted much attention among scholars, investigation of the Taoist religion (Tao-chiao) is only just beginning. Western scholars generally have placed emphasis on certain practices or crafts that they suppose have been par-

ticularly "Taoist," notably the quest for physical immortality, breath control, techniques of sexual union, herbalism, dietetics, and alchemy. In such a view, though, as in the question of doctrine in general, there is some ambiguity as to what is specifically Taoist and what is simply Chinese. An adequate investigation and description of Taoism, for more than 2,000 years a crucial component of Chinese spiritual and cultural history, cannot be undertaken on a purely intellectual or doctrinal or, especially, technological basis.

Taoism has at all times been a social phenomenon, and this is reflected throughout Taoist literature. Religious Taoism has from the beginning had a distinctive organization—a hierarchy of priesthood and believers, linked by sworn bonds in spiritual and economic union. Developing and changing over the centuries, certain residues of this organizational structure still survive in Taoism in the 20th century, especially in Taiwan and Southeast Asia. It is precisely these institutional and economic aspects of the religion that are in most need of profound and detailed study by modern scholars.

Religious Taoism was quite distinct from Buddhism, traditionally supposed to have been its constant opponent and competitor for official patronage. Far more fundamental and historically important, however, has been Taoism's basic opposition to those beliefs and practices comprising the worship of what Taoists termed the "gods of the profane" (*su shen*); *i.e.*, the whole body of popular religious tradition and folklore. The Taoist master, with his hereditary lineage, his institutional affiliations, and his complex rituals with their liturgies in the Chinese literary language, considered himself to be far apart from both the exorcist of the folk religion, whose task was to cast out demons, and the medium, who was chosen for his visionary or hypnotic aptitude and who performed his operations in the colloquial language, expressing his spiritual and therapeutic efficacy through ecstatic and frenzied performances. The activities of the exorcists and mediums seemed to Taoist adepts to partake more of the demonic than of the pure and impersonal Tao (the "Way"); indeed, for the Taoists, the whole proliferating pantheon of Chinese popular gods were, at best, auxiliary spirits, or, at worst, dangerous demons, leading their deluded worshippers to insanity and perdition. At this point, Taoism converged with both Buddhism and the secular ("Confucian") state administration in their desires to rechannel or suppress unauthorized worship (*yin-ssu*, "abusive cults"). Unregulated religious expression among the populace was considered as dangerous to the commonwealth as it was to the individual worshipper who had become addicted to unrestrained spiritual enthusiasm.

Differences between Taoist masters and the priesthood of folk religion

Religious Taoism, then, may be considered as China's own indigenous higher religion; and its history thus requires close critical study in its dynamic interaction with the other elements constituting the spiritual life of China (*e.g.*, Buddhism, Confucianism, and folk religion). Despite the fundamental distinctiveness of Taoism's special character, it has both influenced and been influenced by other traditions with which it has so long been in contact.

Future studies of Chinese religion should therefore take adequate account of the Taoists' own view of their beliefs and practices, instead of considering Taoism exclusively from outside views, especially as Taoism appears in generally hostile Buddhist or Confucian documents. The basic textual source materials for such study are available in the great collection of Taoist texts, the Taoist canon (*Tao tsang*). Scholarly work on the canon has dealt primarily with texts of Taoism's formative period (*c.* 2nd to 6th centuries AD), and historical accounts must as a result devote a disproportionate amount of space to the first five centuries of the movement. Documentary sources, however, can give but a partial picture of the religion. Traditional Taoist practices may still be observed in Taiwan and the Chinese communities of Southeast Asia; and in these areas more recording and study must be carried out before this tradition accommodates itself to the pressures of modernization (see also TAOISM; CHINESE RELIGION; TAOIST LITERATURE; and ALCHEMY).

A Confucian (left), a Buddhist (centre), and a Taoist, a painting of a tranquil discussion that exemplifies the peaceful coexistence of the "three ways" in China. The figures show ideal types, each representative of his faith; the Confucian is dressed as a scholar, the Buddhist as a monk, and the Taoist, in his garment of leaves, as a forest ascetic.

THE ORIGIN AND EARLY DEVELOPMENT OF TAOISM

Philosophers and mystics. *The interpretation of the role of Lao-tzu.* Behind all forms of Taoism stands the figure of Lao-tzu, who has been viewed as a supposedly historical sage, an often reincarnated personage of legendary history, or a god—*i.e.*, the personification of the primal creative life breath of the universe. Lao-tzu as an historical figure is the reputed author of the book that bears his name, the *Lao-tzu*, or *Tao-te Ching* ("Classic of the Way of Power"). At once a manual of the art of government by inaction (*wu-wei*) and a unique spiritual testament, this brief work has long exercised a dominant influence on all Chinese thought.

The first mention of Lao-tzu is found in another early classic of Taoist speculation, the *Chuang-tzu* (4th–3rd centuries BC). In this work Lao-tzu is described as being one of Chuang-tzu's own teachers, and the same book contains many of the Master's (Lao-tzu's) discourses, generally introduced by the questions of a disciple. The *Chuang-tzu* also presents seven versions of a meeting of Lao-tzu and Confucius. Lao-tzu is portrayed as the elder and his Taoist teachings confound his celebrated interlocutor. The *Chuang-tzu* also gives the only account of Lao-tzu's death. Thus in this early source, Lao-tzu appears as a senior contemporary of Confucius (6th–5th centuries BC) and a renowned Taoist master, a curator of the archives at the court of the Chou dynasty (*c.* 1122–221 BC) and, finally, a mere mortal.

The teachings of Lao-tzu and Chuang-tzu

The first consistent biographical account of Lao-tzu is found in the "Historical Records" (*Shih-chi*)—China's first universal history (2nd century BC)—of Ssu-ma Ch'ien. This concise résumé has served as the classical source on the philosopher's life. Lao-tzu's family name was Li, his given name Erh; and he occupied the post of archivist at the Chou court. He is said to have instructed Confucius on points of ceremony. Observing the decline of the Chou dynasty, Lao-tzu left the court and headed west. At the request of Yin Hsi, the guardian of the frontier pass, he wrote his treatise on the Tao, some 5,000 characters, in two scrolls. He then left China behind, and what became of him is not known. The historian quotes variant accounts, including one that attributed to Lao-tzu an exceptional longevity; the narrative terminates with the genealogy of eight generations of Lao-tzu's supposed descendants. With passing references in other early texts, this constitutes the body of information on the life of the sage as of the 2nd century BC; it is presumably legendary. Modern scholarship has little to add, and the book, the *Tao-te Ching*, doubtfully credited to Lao-tzu, stands

alone, with all its attractions and enigmas, as the fundamental text of both philosophical and religious Taoism (see also LAO-TZU).

The interpretation and role of Chuang-tzu. Pseudo-historical knowledge of the sage Chuang-tzu is even less well defined. Most of Ssu-ma Ch'ien's brief portrait of the man is transparently drawn from anecdotes in the *Chuang-tzu* itself and as such has no necessary basis in fact. The book that bears his name, the *Chuang-tzu,* however, is valuable as a monument of Chinese literature and because it contains considerable documentary material, describing numerous speculative trends and spiritual practices of the Warring States period (481–221 BC). Breath control, meditation, gymnastics, and dietetics are all mentioned, as are spiritual beings ("perfected ones," *chen-jen*), who have transcended the human condition. The work describes spirit journeys that seem to adapt and refine the concrete practices of ecstatic religion, and it gives accounts of masters and disciples that prefigure the spiritual relationships current within the later Taoist religion. The earliest Taoist thinkers were the most articulate members of a much larger class of philosophers and mystics. The "Taoist school" (Tao-chia) only dates from the early Imperial period, at which time it first becomes possible to discuss in factual detail the history of a Taoist movement (see also CHUANG-TZU).

Taoism in the Ch'in and Han periods (221 BC–AD 220) of the Chinese empire. *Esoteric traditions of eastern China.* The textual remains of Taoism during the Warring States period were all presumably produced in connection with official patronage; similarly, developments in Taoist thought and practice during the early Imperial age principally have to be studied from the vantage point of the court. At the Imperial court, representatives of different local traditions met as competitors for official favour, and the court consequently served as the principal meeting place for the exchange of ideas. The historians who recorded the progress of these varying intellectual and religious currents were themselves court officials and often were active participants in the movements they describe. The emperors, anxious to consolidate and expand their power, were a natural focus for wonder-workers and specialists in esoteric arts.

Taoism's influence at the Imperial court

A series of such wonder-workers from the eastern seaboard visited the courts of the Ch'in and early Han. They told of islands in the ocean, peopled by immortal beings —which the *Chuang-tzu* had described—and so convincing were their accounts that sizable expeditions were fitted out and sent in search of them. The easterners brought the cults of their own region to the capital, recommending and supervising the worship of astral divinities who would assure the emperor's health and longevity. One of their number, Li Shao-chün, bestowed on the Han emperor Wu Ti counsels that are a résumé of the spiritual preoccupations of the time. The emperor was to perform sacrifices to the furnace (*tsao*), which would enable him to summon spiritual beings. They in turn would permit him to change cinnabar powder (mercuric sulfide) into gold, from which vessels were to be made, out of which he would eat and drink. This would increase his span of life and permit him to behold the immortals *(hsien)* who dwell on the Isles of P'eng-lai, in the midst of the sea. Here, for the first time, alchemy joins the complex of activities that were supposed to contribute to the prolongation of life.

The Huang-Lao tradition. Also originating in the eastern coastal region (Shantung), alongside these same thaumaturgic (wonder-working) tendencies, was the learned tradition of the Huang–Lao masters, devotees of the legendary "Yellow Emperor" (Huang Ti) and Lao-tzu. The information on the life of Lao-tzu transmitted by Ssu-ma Ch'ien probably derives directly from their teaching. They venerated Lao-tzu as a sage whose instructions, contained in his cryptic book, describe the perfect art of government. The Yellow Emperor, with whose reign Ssu-ma Ch'ien's universal history opens, was depicted as a ruler of the Golden Age who achieved his success because he applied his teachers' precepts to government. The Yellow Emperor also was celebrated as the patron of technology; and the classic works of many arcane arts, including alchemy, medicine, sexual techniques, cooking, and dietetics, were all placed under his aegis. Unlike Lao-tzu, the Yellow Emperor is always the disciple, an unremitting seeker of knowledge, and the Huang–Lao masters' ideal of the perfect ruler who values good teachers.

From the court of the King of Ch'i (in present-day Shantung Province) where they were already expounding the *Lao-tzu* in the 3rd century BC, the teachings of the Huang–Lao masters soon spread throughout learned and official circles in the capital. Many early Han statesmen became their disciples and attempted to practice government by inaction *(wu-wei);* among them were also scholars who cultivated esoteric arts. Although their doctrine lost its direct political relevance during the reign of the emperor Hsiao Wu Ti (reigned 141–87 BC), their ensemble of teachings concerning both ideal government and practices for prolonging life continued to evoke considerable interest and is perhaps the earliest truly Taoist movement of which there is clear historical evidence.

Revolutionary messianism. Among the less welcome visitors at the Han court had been a certain Kan Chung-k'o. At the end of the 1st century BC he presented to the emperor a "Classic of the Great Peace" (*T'ai-p'ing Ching*) that he claimed had been revealed to him by a spirit, who had come to him with the order to renew the Han dynasty. His temerity cost him his life, but the prophetic note of dynastic renewal became stronger during the interregnum of Wang Mang (AD 8–23); and other works—bearing the same title—continued to appear. At this time, promotors of a primitivistic and utopian T'ai-p'ing (Great Peace) ideology continued to support the Imperial Liu (Han) family, claiming that they would be restored to power through the aid of the Li clan. A century and a half later, however, as the power of the Later Han dynasty (AD 23–220) declined, the populace no longer hoped for a renewal of Han rule.

T'ai-p'ing messianism

The great Yellow Turban Rebellion broke out in the east in AD 184. Its leader, Chang Chüeh, declared that the "blue heaven" was to be replaced by a "yellow heaven"; and his followers wore yellow turbans in token of this expectation. Worshipping a "Huang-lao Chün," the movement gained a vast number of adherents throughout eastern China. Though they were eventually defeated by the Imperial forces, the tendency towards messianic revolt continued to manifest itself at frequent intervals. A great many charismatic leaders came from the Li family, and certain of them claimed to be the god Lao-tzu returned to earth; a sage of western China, Li Hung, who had actually lived during the 1st century BC, became the favourite recurrent figure of later would-be messiahs. Such revolutionary religious movements, which included Taoist ideological elements remained a persistent feature of medieval Chinese history. The last recorded Li Hung was executed in 1112. These sporadic popular manifestations of revolutionary messianism, though, did not represent the activities of the formal Taoist organization and must be distinguished from the organized religious Taoism that also appeared at the end of the Later Han period.

DEVELOPMENT OF THE TAOIST RELIGION FROM THE 2ND TO THE 6TH CENTURIES

The Way of the Celestial Masters. *The development of organized Taoism.* The Taoist organization that was to endure first developed in the mountains of the province of Szechwan. There, a certain Chang Tao-ling, in AD 142, is said to have received a revelation from T'ai-shang Lao-chün ("Lord Lao the Most High"). The deified Lao-tzu bestowed on Chang his "orthodox and sole doctrine of the authority of the covenant" (*cheng-i meng-wei fa*), meant as a definitive replacement for the religious practices of the people, which are described as having lapsed into demonism and degeneracy.

The new dispensation at first was probably intended as a substitute for the effete rule of the Han central administration. Chang is said in time to have ascended on high and to have received the title of *t'ien-shih* ("celestial master") and by the latter part of the 2nd century, under the leadership of his descendants, the T'ien-shih Tao

(Way of the Celestial Masters) constituted an independent religio-political organization with authority throughout the region, a "Taocracy" (rule of Tao), in which temporal and spiritual powers converged. For ceremonial and administrative purposes, the realm was divided into 24 (later 28 and 36) units, or parishes (*chih*). The focal point of each was the oratory, or "chamber of purity" (*ching-shih*), which served as the centre for communication with the powers on high. Here the *chi-chiu* ("libationer"), the priestly functionary of the nuclear community, officiated. Each household contributed a tax of five pecks of rice to the administration, whence came the other common name of the movement, the Way of the Five Pecks of Rice (Wu-tou-mi Tao).

Ritual activities of the libationer

The ritual activities of the libationer seem principally to have been directed towards the cure of disease by prescribed ceremonial means. Believed to be a punishment for evil deeds, whether committed by the sufferer himself or by an ancestor, illness was in fact a sentence pronounced by the San Kuan (Three Officials), judges and custodians of the dead. The sentence was carried out by the spectral hordes of the Six Heavens (Liu T'ien), a posthumous dwelling place of all unhallowed mortals. Against such judicial severity, only formal appeal to higher authority might avail. Using the rising flame and smoke of the incense burner in the centre of the oratory to transmit the message borne by spirits exteriorized from within his own body, the libationer submitted petitions (*chang*) to the appropriate bureau of the three Taoist heavens (*san t'ien*). The Taoist canon contains long lists of the "officials and generals" (*kuan chiang*), each specializing in a different sort of complaint, who would respectively pronounce on the appeal and marshal the celestial forces against the offending demons.

The officiant came to dispose of a large selection of bureaucratic stock drafts: memorials, plaints, and appeals, all of which were modelled on secular administrative usage. Also effective were written talismans (*fu*); drawn by the libationer, these would be burned and the ashes, mixed with water, swallowed by the demons' victim. The libationer also functioned as a moral preceptor, instructing the faithful in the sect's own highly allegorical interpretation of the *Lao-tzu*, which they considered to be the revealed work of Lord Lao the Most High. Their fundamental concern with right actions and good works as being most in the spirit of the Tao and consequently ensuring immunity from disease is also shown by their construction of way stations in which provisions and shelter were placed for the convenience and use of travellers, as well as in the numerous injunctions to charity and forebearance recorded in the written codes of the movement.

Communal ceremonies. Both the nuclear communities and the "Taocratic" realm as a whole were bound together by a ritual cycle, of which only fragmentary indications remain. Among the most important ceremonial occasions were the communal feasts (*ch'u*) offered at certain specific times throughout the year (during the first, seventh, and 10th months) as well as on other important occasions, such as initiation into the hierarchy, advancement in rank or function, or the consecration of an oratory. These feasts were of varying degrees of elaborateness, depending on the circumstances. The common essential element, however, was the sharing of certain foods, in prescribed quantities, among masters and disciples. This was envisaged as a communion with the Tao, at once attesting the close compact with the celestial powers enjoyed by the members of the parish and reinforcing their own sense of cohesion as a group.

The Union of Breaths rite

Much more notorious was the rite known as the Union of Breaths (Ho Ch'i), a communal sexual ritual said to have been celebrated at each new moon. Later Buddhist sources described this as a riotous orgy of outrageous and disgusting license. Several cryptic manuals of instruction for the priest in charge of these proceedings are preserved in the canon; and they depict, however, scenarios of a highly stylized erotic choreography of cosmic significance. Like the communal feasts, these rites might be interpreted as a concentrated and idealized adaptation of older, more diffuse agrarian religious customs. This suggests a pattern of the integration of local practices that has remained characteristic of Taoism throughout its history.

Official recognition of the Taoist organization. In AD 215, the celestial master Chang Lu, grandson of Chang Tao-ling, submitted to the authority of the Han general Ts'ao Ts'ao, who six years later founded the Wei dynasty in the north. This resulted in official recognition of the sect by the dynasty; the celestial masters in turn expressed their spiritual approbation of the Wei's mandate to replace the Han. Under these conditions a formal definition of the relations of organized Taoism to the secular powers developed. In contrast to the popular messianic movements, Lao-tzu's manifestation to Chang Tao-ling was considered to be definitive; the god was not incarnate in them but rather designated Chang and his successors as his representatives on earth. Under a worthy dynasty, which governed by virtue of the Tao, the role of the celestial masters was that of acting as intermediaries for celestial confirmation and support. Only when a responsible ruler was lacking were the celestial masters to take over the temporal guidance of the people and hold the supreme power in trust for a new incumbent. Abetted by this flexible ideology of compromise, the sect made constant progress at the courts of the Wei and Western Chin dynasties until, by the end of the 3rd century, it counted among its adherents many of the most powerful families in North China.

Buddhist and Taoist interaction. The first mention of Buddhism in China (AD 65) occurs in a Taoist context, at the court of a member of the Imperial family known for his devotion to the doctrines of Huang-Lao. The Indian religion was at first regarded as a foreign variety of Taoism; the particular Buddhist texts chosen to be translated during the Han period reveal the Taoist preoccupation of the earliest converts with rules of conduct and techniques of meditation. Early translators employed Taoist expressions as equivalents for Buddhist technical terms. Thus, the Buddha, in achieving enlightenment (*bodhi*) was described as having "obtained the Tao"; the Buddhist saints (*arhat*) become perfected immortals (*chen-jen*); and "non-action" (*wu-wei*) was used to render Nirvāṇa (the Buddhist state of bliss). A joint sacrifice to Lao-tzu and the Buddha was performed by the Han emperor in AD 166. During this period occurred the first reference to the notion that Lao-tzu, after vanishing into the west, became the Buddha. This theory enjoyed a long and varied history. It claimed that Buddhism was a debased form of Taoism, designed by Lao-tzu as a curb on the violent natures and vicious habits of the "western barbarians," and as such was entirely unsuitable for Chinese consumption. A variant theory even suggested that, by imposing celibacy on Buddhist monks, Lao-tzu intended the foreigners' extinction. In approximately AD 300, the Taoist scholar Wang Fou composed a "Classic of the Conversion of the Barbarians" (*Hua hu Ching*), which was altered and expanded in subsequent centuries to encompass new developments in the continuing debate. Although there is no evidence that the earliest Taoist organization, literature, or ceremonies were in any way indebted to Buddhism, by the 4th century there was a distinct Buddhist influence upon the literary form of Taoist scriptures and the philosophical expression of the most eminent Taoist masters.

Taoist interpretations of Buddhism

The process of interaction, however, was a mutual one, Taoism participating in the widening of thought because of the influence of a foreign religion and Buddhism undergoing a partial "Taoicization" as part of its adaptation to Chinese conditions. The Buddhist contribution is particularly noticeable in the developing conceptions of the afterlife; Buddhist ideas of purgatory had a most striking effect not only upon Taoism but especially on Chinese popular religion. On a more profound level the ultimate synthesis of Taoism and Buddhism was realized in the Ch'an (Japanese Zen) tradition (from the 7th century on), into which the paradoxes of the ancient Taoist mystics were integrated. Likewise, the goal of illumination in a single lifetime, rather than at the end of an indefinite

succession of future existences, was analogous to the religious Taoist's objective of immortality as the culmination of his present life.

The Southern tradition. The political partition of China into three parts following the collapse of the Han dynasty in AD 220, the so-called period of the Three Kingdoms, had its spiritual counterpart in certain well-defined regional religious differences. Against the independent dynasties in the north and west stood the empire of Wu, south of the Yangtze River.

Developments in alchemical and other traditions. A region exposed comparatively lately to Chinese influence, this southeastern area had long been famous for its aboriginal sorcerers and dancing mediums. In the course of Chinese colonization, separate learned spiritual traditions developed alongside the ecstatic practices of the populace. To the court of the emperors of Wu came savants and wonder-workers representing a variety of traditions that were to acquire lasting influence.

Among these personages was a certain Ko Hsüan (3rd century AD), who was said to have been initiated into an ancient alchemical tradition. His great-nephew Ko Hung in the next century became one of the most celebrated writers on the various technical means for attaining immortality. In his major work, the *Pao-p'u-tzu* ("He Who Holds to Simplicity"), Ko Hung expounded the alchemical formulas received and transmitted by Ko Hsüan. In so doing, he took care to distinguish the divinely inspired "gold elixir" (*chin-tan*), or "liquefied gold" (*chin-i*)—*i.e.*, preparations of true edible, or potable, gold, the consumption of which leads to immortality (aurifaction)—from the mere counterfeiting of the precious substance, with intention to deceive (aurifiction). These alchemical methods have been designated as belonging to the T'ai-ch'ing (Great Purity) tradition, from the name of the heaven of the Immortals to which the elixirs were said to elevate their consumer. The chapters of alchemy in the *Pao-p'u-tzu* are among the earliest documents to describe the art in detail.

The goals and methods of alchemy

Ko Hung enumerated an extensive selection of material substances and practical operations to which he attributed varying degrees of relative efficacy in the prolongation of life. Dietetics (grain and alcohol avoidance), ingestion of solar, lunar, and astral exhalations and their cycling within the body, gymnastics, and conservation of vital fluids through proper sexual techniques were all necessary and fundamental. The usefulness of written talismans and the performance of good works were also not denied. Above all, it was essential that all disease be eliminated from the body before undertaking more positive, specialized practices for achieving immortality. Herbs and plants were useful not only against disease, but in many cases (particularly in that of mushrooms) their use resulted in definite lengthening of life. For a definitive transformation into an immortal (*hsien*), with all the powers and prerogatives that implied, however, an alchemical elixir must be compounded and consumed. Ko Hung admitted, however, that he himself had never succeeded in making one. After a strenuous life in civil and military service, in the course of which he managed to write voluminously on many subjects, this great eclectic scholar is said to have undertaken a long journey to China's colonial dominions in Vietnam in quest of the pure cinnabar found there. He stopped at Lo-fou Shan, near Canton, however, where he died.

The *Pao-p'u-tzu* was nearly finished in 317, when Lo-yang, capital of the Western Chin dynasty, fell to the Hsiung-nu. This event set off a considerable emigration to the unsubdued region south of the Yangtze River. The Imperial household was followed in its flight by numerous high-ranking dependents and their spiritual ministers. During this period the Way of the Celestial Masters, established at the court of Lo-yang since the early 3rd century, apparently first penetrated in force to the Southeast. While the secular, military menace remained in the North, and factional struggles raged among the emigrants, the Way of the Celestial Masters waged unremitting war against the indigenous sects and cults of demons of the Southeast. Many of the old established families, settled in the region since the end of the Han dynasty, turned away from local traditions to become members of the Taoist faith of their new political superiors. At first these converts were content to entrust the direction of their spiritual lives to the libationers of the movement, though these religious specialists were generally men of lower social standing than themselves. Among the second and third generation of converts from the old aristocracy of Wu, however, new and original impulses, which were to have most profound effects upon the development of Taoism as a whole, began to occur.

The Mao Shan Revelations. The most brilliant synthesis of the Way of the Celestial Masters with the indigenous traditions of the Southeast occurred in the 4th century AD in a family closely related to Ko Hung. Hsü Mi, an official at the Imperial court, and his youngest son, Hsü Hui, were the principal beneficiaries of an extensive new Taoist revelation. A visionary in the Hsüs' service, Yang Hsi, was honoured with the visits of a group of perfected immortals (*chen-jen*) from the heaven of Shang-ch'ing (Supreme Purity), an improvement on the T'ai-ch'ing heaven and the ordinary immortals (*hsien*) that peopled it. In the course of his visions, which lasted from AD 364 to 370, Yang received a whole new scriptural and hagiographic literature, in addition to much practical information from the "perfected" (*chen*) on how it was to be understood and employed. Like the Ko family, the Hsüs belonged to the old aristocracy of Wu, who had been displaced from prominence by the arrival of the great families of the North, to whose Taoist beliefs they had been converted. The perfected assured them that the present unjust order was soon to end and that the rule of men on Earth was to be replaced by a universal Taoist imperium. The present (*i.e.*, the 4th century) was a time of trials, given over to the reign of the demonic Six Heavens, and marked by war, disease, and the worship of false gods. The sole mission of the demonic forces, however, was to cleanse the earth of evildoers, a task that would be completed by an overwhelming cataclysm of fire and flood. At that time the Good would take refuge deep in the earth, in the luminous caverns of the perfected beneath such sacred mountains as Mao Shan (in Kiang-su Province), which was the immediate focus of spiritual interest for the Hsüs. There they would complete the study of immortality already begun in their lifetimes, so as to be ready for the descent from heaven of the new universal ruler, Lord Li Hung, the "sage who is to come" (*hou-sheng*). This was prophesied for the year 392. Yang and the Hsüs would get high office in the heaven of Shang-ch'ing and rule over a newly constituted earth below, peopled by the elect (*chung-min*).

Synthesis of the Way of Celestial Masters with the Southeast traditions

Yang Hsi's prodigious genius gave great consistency and consummate literary form to his comprehensive synthesis of many spiritual traditions. Popular messianism was adapted to provide an encompassing framework and temporal cogency. Yang and his patrons, however, were also thoroughly familiar with Buddhist thought. In addition to integrating Buddhist concepts into their Taoist system, the perfected also dictated a "Taoicized" version of large portions of an early Buddhist compilation, the *Sūtra in Forty-two Sections* (*Ssu-shih-erh chang Ching*). Buddhist notions of predestination and reincarnation were subtly blended with native Chinese beliefs in hereditary character traits and the clan as a single unit involving mutual responsibility on the part of all its members, living and dead. Furthermore, building upon the Way of the Celestial Masters, the Mao Shan revelations envisaged some reform of the practices of the parent sect. Its sexual rites in particular were stigmatized as inferior practices, more conducive to perdition than to salvation. In place of this, a spiritualized union with a celestial partner was apparently realized by Yang Hsi and promised to his patrons. Other rituals of the Celestial Masters were allowed to continue in use among the Mao Shan adepts but were relegated to a subordinate position. Thus, the movement did not reject but rather incorporated and transcended the older tradition.

Though the perfected inveighed against the popular cults, even elements of these were absorbed and trans-

formed. There is some evidence that, before Yang's inspired writings, Lord Mao himself, the august perfected immortal who gave his name to the mountain, was no more than a local minor god worshipped by an exorcistic priestess in the shadow of Mao Shan. Among the more learned traditions, alchemy received particular attention, being adopted for the first time into the context of organized religious Taoism. The perfected revealed the highly elaborate formulas of several of the elixirs that served them as food and drink. For all their extravagance, they were intended as real chemical preparations and described as being deadly poisonous to mortals. By preparing and ingesting one of them, the younger Hsü probably willingly ended his earthly existence in order to take up the post that had been offered him in the unseen world and to make ready for the coming of the new era.

Absorption of elements from local popular cults

The Ling Pao scriptures and liturgies. Another member of the Ko family was responsible for the second great Taoist scriptural tradition. Ko Ch'ao-fu began composing the *Ling pao Ching* ("Classic of the Sacred Jewel") *c.* AD 397. He claimed that they had been first revealed to his own ancestor, the famous Ko Hsüan, early in the 3rd century. In these works the Tao is personified in a series of "celestial worthies" (*t'ien-tsun*), its primordial and uncreated manifestations. These in turn were worshipped by means of a group of liturgies, which, during the 5th century, became supreme in Taoist practice, completely absorbing the older, simpler rites of the Way of the Celestial Masters. As each celestial worthy represented a different aspect of the Tao, so each ceremony of worship had a particular purpose, which it attempted to realize by distinct means. The rites as a whole were called *chai* ("retreat"), from the preliminary abstinence obligatory on all participants. They lasted a day and a night or for a fixed period of three, five, or seven days; the number of persons taking part was also specified, centring on a sacerdotal unit of six officiants. One's own salvation was inseparable from that of his ancestors; the Huang-lu chai (Retreat of the Yellow Register) was directed towards the salvation of the dead. Chin-lu chai (Retreat of the Golden Register), on the other hand, was intended to promote auspicious influences on the living. The T'u-t'an chai (Mud and Soot Retreat, or Retreat of Misery) was a ceremony of collective contrition, with the purpose of fending off disease, the punishment of sin, by prior confession; in Chinese civil law, confession resulted in an automatic reduction or suspension of sentence. These and other rituals were accomplished for the most part in the open, within a specially delimited sacred area, or altar (*t'an*), the outdoor complement of the oratory. The chanted liturgy, innumerable lamps, and clouds of billowing incense combined to produce in the participants a cathartic experience that assured these ceremonies a central place in all subsequent Taoist practices.

The great Southern masters. Though Taoism never became the exclusive state religion in the South, its most eminent representatives founded powerful organizations that received considerable official support. Lu Hsiu-ching in the 5th century epitomized the Ling Pao tradition, the liturgies of which he codified. His establishment at the great Buddho-Taoist centre, Lu Shan (in Kiangsi Province), carried out ceremonies and provided auspicious portents in favour of the Liu-Sung dynasty (420–479), in whose rulers Taoists complacently agreed to recognize the fulfillment of the old messianic prophesies and the legitimate continuation of the Han dynasty. Lu was frequently invited to the capital (present-day Nanking), where the Ch'ung-hsü Kuan (Abbey) was founded for him and served as the focal point of the Ling Pao movement.

The influence of Lu Hsiu-ching and T'ao Hung-ching

Like Lu, who was a member of the old aristocracy of Wu, T'ao Hung-ching of the 5th and 6th century enjoyed even greater renown as the most eminent Taoist master of his time. He spent years in searching out the manuscript legacy of Yang Hsi and the Hsüs, and in 492 retired to Mao Shan, where he edited and annotated the revealed texts and attempted to re-create their practices in their original setting. T'ao's fame as a poet, calligrapher, and natural philosopher has persisted throughout Chinese history; he is perhaps best known as the founder of critical pharmacology. T'ao was an intimate friend of the great Liang emperor Wu Ti (of the 6th century), and his Mao Shan establishment was able to survive the proscription of all other Taoist sects in 504. Though whole Taoist families lived under T'ao's spiritual rule at Mao Shan, he himself stressed the need for celibacy and full-time commitment to the work of the Tao. In his state-sponsored Chu-yang Kuan, T'ao appears to have effected a working synthesis of the public rites of the Ling Pao liturgies with the private and individual practices enjoined in the Mao Shan revelations. This dual practice was to remain a feature of all subsequent Taoist sects. T'ao's primary interest, however, was in the scriptures of the perfected of Shang-ch'ing; and this is reflected in the revelations vouchsafed by these same spiritual agents to a 19-year-old disciple of T'ao's, Chou Tzu-liang, in 515–516. These revelations show a pronounced Buddhist influence, and T'ao was himself reputed to be a master of Buddhist as well as Taoist doctrine. His writings evidence a complete familiarity with Buddhist literature, and it is reported that both Buddhist monks and Taoist priests officiated at his burial rites.

State Taoism in the North. Under the foreign rulers of North China, independent developments likewise were in progress. In 415, one K'ou Ch'ien-chih received a revelation from Lao-chün himself. According to this new dispensation, K'ou was designated celestial master and ordered to undertake a total reformation of Taoism. Not only were all popular messianic movements claiming to represent Lao-chün unsparingly condemned but K'ou's mission was particularly aimed at the elimination of abuses from the Way of the Celestial Masters itself. Sexual rites and the taxes contributed to the support of the priesthood were the principal targets of the god's denunciations; "What have such matters to do with the pure Tao?" he irately demanded. The proposed reform was far more radical than that forseen in the Mao Shan revelations of the Southeast, and K'ou was given concrete temporal power of a sort that the Hsüs had not envisaged. Political and economic factors favoured the acceptance of his message at court; Emperor T'ai Wu Ti (5th century) of the Northern Wei dynasty put K'ou in charge of religious affairs within his dominions and proclaimed Taoism the official religion of the empire. The Emperor considered himself to reign as the terrestrial deputy of the deified Lao-tzu, as is indicated by the name of one of the periods of his reign: T'ai-p'ing Chen-chün (Perfect Lord of the Great Peace). The dominant position of Taoism under the Northern Wei, however, apparently did not long survive K'ou Ch'ien-chih's death in 448.

New revelations in the North

TAOISM UNDER THE T'ANG, SUNG, AND LATER DYNASTIES

Taoism under the T'ang dynasty (618–907). China's reunification under the T'ang marked the beginning of Taoism's most spectacular success. The dynasty's founder, Li Yüan, claimed to be descended from the Lao-tzu; as his power increased, even the influential Mao Shan Taoists came to accept him as the long-deferred fulfillment of messianic prophecy. This notion was built into the dynasty's state ideology, and the emperor was commonly referred to as the "sage" (*sheng*). Prospective candidates for the civil service were examined in either the Ling Pao "Classic of Salvation" (*Tu-jen Ching*) or the Mao Shan "Classic of the Yellow Court" (*Huang-t'ing Ching*). Under a series of celebrated patriarchs, the Mao Shan organization dominated the religious life of the age. One of the greatest of the line, Ssu-ma Ch'eng-chen, initiated innumerable government officials and eminent men of letters and served as spiritual master to emperors. The personnel of the Mao Shan revelations even entered into the formal framework of state religion. When Ssu-ma Ch'eng-chen pointed out that the sacred peaks of the Imperial cult were in reality under the superintendence of the perfected of Shang-ch'ing, officially sponsored shrines were erected to them there; and their propitiation was incorporated into the traditional rites.

The period of Taoism's greatest success

The wide diffusion of Taoism throughout the vast T'ang

empire is reflected by the sizable proportion of Taoist texts discovered in the walled-up caves at Tun-huang (in Kansu Province). This town in the far west of China was the gateway to Central Asia; and here Taoists came into contact not only with Buddhists of many different doctrinal persuasions but also with Nestorian Christians (members of a church independent of the patriarch of Constantinople) and Manichaeans (Iranian religious dualists). Copies of the *Lao-tzu* were sent to the King of Tibet, and the book was translated into Sanskrit at the request of the ruler of Kashmir. It also reached Japan in the 7th century, as did texts of religious Taoism; reports of Taoism's dominance on the continent may still be read in the diaries of Japanese Buddhist pilgrims. The geographic extension of the religion at this time was also represented, in the legendary sphere, by the systematic elaboration of its sacred mountains and the traditions attaching to each of them. They are described by the great hagiographer, Tu Kuang-t'ing, at the end of the T'ang dynasty. In addition to the great "cavern-heavens" (*tung-t'ien*), 10 holy mountains known to the original Mao Shan revelations, he lists 36 lesser cavern heavens and 72 sanctuaries (*fu-ti*). Situated throughout the length and breadth of the empire, they are fitting spiritual guideposts across the dominions of the T'ang, which saw itself as an essentially Taocratic realm.

Taoism under the Sung and Yüan dynasties. *Internal developments.* The Sung (960–1279) and Yüan (1279–1368) periods witnessed a great religious effervescence, stimulated in part, under the Sung, by the menace of foreign invasion and, during the Yüan, by Tantric (esoteric, or occultic) Buddhism that was in vogue among the new Mongol rulers of China. During the preceding centuries the Way of the Celestial Masters, centred at Lung-hu Shan (Dragon-Tiger Mountain, Kiangsi), had been eclipsed by the prestige of Mao Shan. At the end of the Northern Sung period, the 30th celestial master, Chang Chi-hsien, was four times summoned to court by the Sung emperor Hui Tsung, who hoped for spiritual support for his threatened reign. Chang Chi-hsien was credited with a renovation of the ancient sect, thereafter called the "New Orthodox Unity" (Hsin Cheng-i), and with the introduction of the influential rites of the "five thunders" (*wu-lei*) into Taoist liturgy.

The founding of new Taoist sects

After the retreat of the Sung government south of the Yangtze River (1126), a number of new Taoist sects were founded in the occupied North and soon attained impressive dimensions. Among them were: the T'ai-i (Supreme Unity) sect, founded *c.* 1140 by Hsiao Pao-chen; the Chen-ta Tao (Perfect and Great Tao) sect of Liu Te-jen (1142); and the Ch'üan-chen (Perfect Realization) sect, founded in 1163 by Wang Ch'ung-yang (Wang Che). This last sect came to the favourable attention of the Mongols, who had taken over in the North, and its second patriarch, Ch'iu Ch'ang-ch'un, was invited into Central Asia to preach to Genghis Khan. The sect enjoyed great popularity, and its establishments of celibate monks continued to be active into the 20th century, with the famous White Cloud Monastery (Po-yün Kuan) at Peking as headquarters. In the South, Mao Shan continued to prosper, while the Ko-tsao sect flourished at the mountain of that name, in Kiangsi Province. This was said to be the spot where the 3rd century immortal, Ko Hsüan, had ascended to heaven; the sect looked to him as its founder, and it transmitted the Ling Pao scriptures, which he was believed to have been the first to receive.

Alchemical developments. While learned specialists continued to refine alchemical theory, the period witnessed increasing interest in internal alchemy (*nei tan*), in which the language of the laboratory was used to describe operations realized within the body. This, in a sense, was nothing new. Alchemical metaphors had very early been applied to physiology; Ko Hung, for example, called semen the "Yin elixir." By Sung times, however, the systematic interiorization and sublimation of alchemy had become so widespread that all earlier texts of operative, external alchemy (*wai tan*) were henceforth supposed to have really been written about *nei tan*, and the attempt to compound a tangible chemical elixir was thought to have been no more than a hoax. Liturgy also provided its own sublimation of the older art: the *lien-tu* ("salvation by smelting") funeral service was developed at this time, in which an "elixir of immortality" was compounded of written talismans and offered to the deceased.

Syncretism. With such prestigious examples as Ch'an Buddhism (emphasizing intuitive meditation) and Neo-Confucianism (emphasizing knowledge and reason) before them, Taoists did not long delay in constructing interesting syntheses of their own and other beliefs. Confucianism now joined Buddhism as a fertile source of inspiration. The revelations of Hsü Sun, supposed to have lived in the 4th century AD, to one Ho Chen-kung in 1131 inspired the "Pure and Luminous Way of Loyalty and Filial Obedience" (Ching-ming Chung-hsiao Tao). This sect preached the Confucian cardinal virtues as being essential for salvation, and consequently won a considerable following in conservative intellectual and official circles. Another highly popular syncretistic movement of Taoist origin was that of the Three Religions (San Chiao). Its composite moral teachings are represented by popular tracts, the so-called "books on goodness" (*shan-shu*), which have been in extremely wide circulation since the Ming dynasty (1368–1644).

TAOISM IN MODERN TIMES

Taoism on Taiwan

The principal refuge of Taoism in the 20th century is on Taiwan. Its establishment on the island is doubtless contemporary with the great emigration from the opposite mainland province of Fukien in the 17th and 18th centuries. The religion, however, has received new impetus since the 63rd celestial master, Chang En-pu, took refuge there in 1949. On Taiwan, Taoism may still be observed in its traditional setting, distinct from the manifestations of popular religion that surround it. Hereditary Taoist priests (Taiwanese *sai-kong*), called "blackheads" (*wu t'ou*) from their headgear, are clearly set off from the exorcists (*fa-shih*) or "redheads" (*hung-t'ou*) of the ecstatic cults. Their lengthy rites are still held, now known under the term *chiao* ("offering"), rather than the medieval *chai* ("retreat"). The liturgy chanted, in expanded Sung form, still embodies elements that can be traced back to Chang Tao-ling's sect. The religion has enjoyed a renaissance since the 1960s, with great activity being carried on in temple building and restoration. The most significant event in the past several centuries of Taoist history, however, probably is the ordination (in 1964) in Taiwan of a Dutch scholar, K.M. Schipper, as a Taoist priest. His systematic, first-hand researches into Taoist practices may very well revolutionize scholarly knowledge of the religion, which will thus acquire an unforeseen historical extension, in the West and into the future.

BIBLIOGRAPHY

Taoist speculation and mysticism: ARTHUR WALEY, *The Way and Its Power: A Study of the Tao tê ching and Its Place in Chinese Thought* (1934), a classic translation and study of the *Lao-Tzu*; *Three Ways of Thought in Ancient China* (1939), the *Chuang-tzu* studied in relation to the thought of its time; JOSEPH NEEDHAM, *Science and Civilisation in China*, vol. 2, *History of Scientific Ideas* (1956), a highly lucid exposé of early Taoist speculation and later Taoist technology; FUNG YU-LAN, *A History of Chinese Philosophy*, 2nd ed., 2 vol. (Eng. trans. 1952), a standard reference work on the classical period of Chinese thought.

The Taoist religion: HENRI MASPERO, *Le Taoïsme et les religions chinoises*, rev. ed. (1971), contains all his writings on Chinese religion, including fundamental studies of Taoism and popular mythology; ANNA K. SEIDEL, *La Divinisation de Lao tseu dans le Taoïsme des Han* (1969), the best detailed study of the formation of the Taoist system in the early Imperial period; EDOUARD CHAVANNES, *Le Jet des dragons* (1919), a classic study and translation of a Taoist liturgy dating from the end of the T'ang dynasty; ARTHUR WALEY, *The Travels of an Alchemist* (1931), the account of the Central Asian journey of the second Patriarch of the Ch'üan-chen sect; J.J.M. DE GROOT, *Les Fêtes annuellement célébrées à Émoui (Amoy)* (1886) and *The Religious System of China*, vol. 6 (1910, reprinted 1964), both valuable pioneering descriptions of the Taoist priesthood and popular exorcists in Fukien at end of the 19th century.

(M.St.)

Taoist Literature

Taoist literature includes the sacred texts and speculative literature of the Chinese religion and philosophy known as Taoism.

TAOIST LITERATURE AND CHINESE SOCIETY

The two classes of Taoist texts

The literature of Taoism may conveniently be divided into two classes, which may be called philosophical (or speculative) Taoism and esoteric (or religious) Taoism; they correspond largely to two distinct historical periods. The basic texts of the first group date from the 4th to 2nd centuries BC and are speculative in tone. The Taoism of this period—the Warring States period—was one among many contending schools of thought. Like other schools of the time, its treatises were probably composed with the aim of convincing a ruler. Since all ancient Chinese philosophies were essentially theories of government, these works were probably in the public domain from the outset. But documents of the period are few, and in most cases scholars know nothing of the authors of this literature or of the milieu in which they worked.

With the political unification of China at the end of the 3rd century BC, the old schools blended into the complex fabric of thought of the early Han Empire. It is Han thought, likewise, that served as a point of departure for the second group of texts, which may properly be called Taoist—the esoteric Taoism beginning in the 2nd century AD. These writings represent the literature of a succession of organized religious movements and were originally intended for the limited circle of their members. The circumstances of their transmission were strictly regulated, an oath of secrecy being the bond that united disciple and master. The texts of the first, or philosophical, group, like other speculative treatises, had come into general circulation among men of culture and learning, and works of that period have survived in a variety of secular editions. The texts of the esoteric tradition, however, were from the first the property of restricted social groups, which included comparatively extensive missionary movements as well as narrow circles of masters and disciples. When comprehensive collection of texts began in the 5th century, sectarian considerations still played an important role. The successors to these early collections were the immense Taoist canons (*Tao Tsang*); the present-day canon, printed in the 15th century, contains nearly 1,500 titles, among which are many documents from the first centuries of esoteric Taoism. It is to this single repository that scholars must turn in order to study the literature of the Taoist religion.

Of these two distinct phenomena, the earlier, philosophical Taoism has until now received far more scholarly attention. This is not surprising because the classics of speculative Taoism include some of the masterpieces of wit and imagination in all Chinese literature, and an enticing aura of mystery shrouds the circumstances of their composition. It is paradoxical that so much less is generally known of esoteric Taoist literature, though potential sources of information are far more numerous. It has by far the longer and broader creative history, for while speculative Taoism remained an upper class phenomenon, the esoteric tradition extended to all levels of society and found expression in a much wider variety of literary genres. Not only is it represented by many more datable texts, conveniently accessible in the canon, but also the outside supporting material is both more extensive and more varied and includes the dynastic histories, inscriptions, and the collected literary works of individual authors. It is thus possible to study many key works of religious Taoism in close relation to the society that produced and employed them. It is in this almost unexplored field that the most exciting and significant research remains to be done. There is increasing evidence of the pervasive influence of esoteric Taoism on every aspect of Chinese life and thought. As the literature of China's indigenous organized religion, Taoist texts represent the expression of all that is most intrinsically Chinese. The continuing study of the Taoist Canon in its wider historical context can radically alter many established conceptions of both Chinese religion and Chinese society (see also CHINESE RELIGION; CHINESE PHILOSOPHY; and CHINA, HISTORY OF).

TEXTS OF SPECULATIVE TAOISM

The Tao-te Ching. The *Tao-te Ching* (an Eng. trans., *Book of the Way and Its Power*), or *Lao-tzu*, occupies a position of importance in Chinese thought out of all proportion to its size. Very brief, its 81 sections contain only about 5,000 characters in all, from which it derives still another of its titles, *Lao Tzu's Five Thousand Words*. The text itself appears in equal measure to express a profound quietism and determined views on government. It is consequently between the extremes of meditative introspection and political application that its many and widely divergent interpreters have veered.

The book shares certain constants of classical Chinese thought but clothes them in an imagery of its own. The sacred aura surrounding kingship is here rationalized and expressed as "inaction" (*wu-wei*), demanding of the sovereign no more than right cosmological orientation at the centre of an obedient universe. Survivals of archaic notions concerning the compelling effect of renunciation —which the Confucians sanctified as ritual "deference" (*jang*)—are echoed in the recommendation to "hold to the role of the female," with an eye to the ultimate mastery that comes of passivity.

The meaning of the Tao

It is more particularly in the function attributed to the Tao, or Way, that this little tract stands apart. The term Tao was employed by all schools of thought. The universe has its Tao; there is a Tao of the sovereign, his royal mode of being, while the Tao of man comprises continuity through procreation. Each of the schools, too, had its own Tao, its way or doctrine. But in the *Tao-te Ching*, the ultimate unity of the universal Tao itself is being proposed as a *social* ideal. It is this idealistic peculiarity that seems to justify later historians and bibliographers in their assignment of the term Taoist to the *Tao-te Ching* and its successors.

From a literary point of view, the *Tao-te Ching* is distinguished for its highly compressed style. Unlike the dialectic or anecdotal composition of other contemporary treatises, it articulates its cryptic subject matter in short, concise statements. More than half of these are in rhyme, and close parallelism recurs throughout the text. No proper name occurs anywhere. This singular work is traditionally ascribed to a contemporary of Confucius (6th–5th century BC) named Lao-tzu. Current scholarly opinion prefers to regard it as a compilation, which reached its present form only in the 3rd century BC. Rather than the work of a single author, it is now considered to be an anthology of sayings drawn from various currents of thought. Some would even deny that it reflects a distinctive point of view. Although its historical enigmas are apparently insoluble, there is abundant testimony to the vast influence exercised by the book since the earliest times and in surprisingly varied social contexts. Among the classics of speculative Taoism, it alone holds the distinction of having become a scripture of the esoteric Taoist movements, which developed their own interpretations of its ambiguities and transmitted it as a sacred text (see also LAO-TZU).

Chuang-tzu. In turning from the solemn profundities of *Tao-te Ching* to the other great classic of Taoist speculation, the *Chuang-tzu*, a different world is entered. Here there is none of the *Tao-te Ching*'s studied density. Instead, this large book opens with a sprightly fable, illustrating the incomprehension of small wildfowl of the majestic splendour of a gigantic bird. Other such parables demonstrate the relativity of all values: the sliding scales of size, utility, beauty, and perfection. There is a colloquy between the Lord of the Yellow River and the God of the Eastern Ocean, in which the complacent self-satisfaction of the lesser spirit is shaken by his unexpected meeting with inconceivable vastness. Humble artisans are depicted, who, through the perfect mastery of their craft, exemplify for their social superiors the art of mastering life. Life and death are equated, and the dying are seen to welcome their approaching transformation as a fusion

with the Tao. A succession of acquiescent cripples exclaims in rapture on the strange forms in which it has pleased heaven to shape them. Those involved in state ritual are brought onstage only to be mocked, and the propositions of contemporary logic-choppers are drawn into the unending whirl of paradox, spun out to their conclusions, and so abolished. Such are a few aspects of this wild kaleidoscope of unconventional thought, a landmark in Chinese literature. Its concluding chapter is a systematic account of the pre-eminent thinkers of the time, and the note of mock despair on which it closes typifies the *Chuang-tzu's* position regarding the more formal, straitlaced ideologies that it parodies.

The Taoist Immortals

Among the strange figures that people the pages of *Chuang-tzu* are a very special class of spiritualized being. Dwelling far apart from the turbulent world of men, dining on air and sipping the dew, they share none of the anxieties of ordinary folk and have the smooth, untroubled faces of children. These "supreme men," or "perfect men," are immune to the effects of the elements, untouched by heat and cold. They possess the power of flight and are described as mounting upward with a fluttering (*hsien*) motion. Their effortless existence was the ultimate in autonomy, the natural spontaneity that *Chuang-tzu* ceaselessly applauds. These striking portraits may have been intended to be allegorical, but whatever their original meaning, these Immortals (*hsien*), as they came to be called, were to become the centre of great interest. Purely literary descriptions of their freedom, their breathtaking mobility, and their agelessness were construed as practical objectives by later generations. By a variety of practices, men attempted to attain these qualities in their own persons, and in time *Chuang-tzu's* unfettered paragons of liberty were to see themselves classified according to kind and degree in a hierarchy of the heavenly hosts (see also CHUANG-TZU).

Taoist thought in eclectic texts. In the welter of compilations that represent the opinions of the late Warring States and early imperial times (*c.* 300–100 BC), sayings of Taoist thinkers or passages from Taoist texts are often drawn upon. Even the Confucian *Lun-yü* (*Analects*) did not escape this genial contamination; among the sober sayings of the Sage are scattered a number of Taoist tales, in which crusty recluses or inspired madmen make fun of Confucius, precisely as happens in *Chuang-tzu*. Curiously, the ontology of *Tao-te Ching* proved particularly attractive to the proponents of the cynical "realist" or "legalist" theories of authoritarian statecraft. The *Han-fei-tzu* (3rd century BC) cites long extracts from the *Tao-te Ching*, which it interprets in its own Draconian manner, while the contemporary *Kuan-tzu* quotes other, unspecified Taoist writings and turns them to like account. The pervasiveness of Taoist thought is revealed in two great encyclopaedic miscellanies: the *Ch'un Ch'iu* ("Spring and Autumn" Annals), produced at the court of the King of Ch'in (*c.* 240 BC), and still more, in the *Huai-nan-tzu*, from the circle of Liu An, the Han dynasty Prince of Huai-nan (died 122 BC). The *Lieh-tzu* (compiled 3rd century AD from older materials) is in a rather special position; it shares 18 anecdotes with the *Chuang-tzu* and takes as its title the name of a mysterious figure mentioned in that work. But the last of its eight chapters expounds the doctrine of a not noticeably Taoist figure, the arch-hedonist Yang Chu. There is no lack of later collections, inevitably ascribed to the most archaic authors, which cite and expand upon one or another of the old Taoist classics. *Wen-tzu*, *Kuei-ku-tzu*, and *Ho-kuan-tzu* are all among such repositories of secondhand wisdom (see also CONFUCIAN TEXTS, CLASSICAL).

Commentaries on the *Tao-te Ching*

The scholiasts. The most famous of the many commentaries on *Tao-te Ching* was written by Wang Pi (AD 226–249). He is regarded as a founder of the school of Dark Learning (*hsüan-hsüeh*), a highly conservative philosophical movement that enjoyed a certain vogue among the cultured elite of the 3rd and 4th centuries. The *Chuang-tzu* was not long afterward annotated by Kuo Hsiang (died 312), in whose work the fundamental Confucian bias is even more prominent. The writings of these men have in recent years sometimes been called "Neo-Taoism," but nothing could be more misleading. Their primary aim was to harmonize *Tao-te Ching* and *Chuang-tzu* with their own conception of a practical life devoted to affairs of state. As administrators confronted with the challenge of Taoist thought, they preferred not to take its message at face value. Interpretative commentaries continued to be written on the classics of speculative Taoism in which the aid of the most diverse philosophies was called upon, not excluding Buddhism. Like the work of the 3rd and 4th century scholiasts, these represent the ideas of a tiny minority, the members of the scholar-official class. Though excursions into ever more refined scholasticism continued to be a diversion for them, the real creative vitality of Taoism was to be found elsewhere.

THE LITERATURE OF TAOIST ESOTERISM

Early hagiography of the Immortals. *Lives of the Immortals.* By the Han period, the careers of those free spirits described in *Chuang-tzu* were the subject of universal interest. The earliest systematic collection of biographical notices on these legendary figures is the *Lives of the Immortals* (*Lieh-hsien chuan*) of the early 2nd century AD. Such collections were a genre of the time. Brief sketches were provided for 72 figures: the same symbolic number as was found in contemporary collections of the "Lives" of the disciples of Confucius, eminent scholar-officials, and famous women. Thus Immortals came to be classified as yet another category in the highly stylized gallery of ancient worthies. Each notice is followed by a short hymn of praise. This was the standard form of inscriptions on stone; its employment in hagiographic literature may have influenced the later development of the chantefable in alternating passages of prose and verse. The text appears to reflect a growing number of local cults dedicated to individual Immortals, while the many plants mentioned suggest the extent of the use of herbal compounds as a means to transcendence.

Inscriptions. These literary notices are supplemented by epigraphic evidence, inscriptions on stone or bronze. The simplest of these are bronze mirrors depicting the plumed figures of airborne Immortals and bearing short rhyming texts of a general nature. Longer and more explicit are the texts of inscriptions on stone: tablets dedicated to the cult of a particular Immortal. They open with their subject's vital statistics, list his latter-day manifestations, and commemorate offerings made in his honour. But all of this is only by way of preface to the core of the inscription, in which his merits are celebrated in verse. Such was the eloquent votive tablet erected in honour of Wang Tzu-ch'iao, a perennial favourite among the Immortals (AD 165). Another, dedicated to Lao-tzu in the same year, describes the supposed author of the *Tao-te Ching* as a god, to whom worship had been paid by the then reigning emperor.

Texts on the cult of Lao-tzu. One of the most complex and interesting phenomena in Chinese religious history is Lao-tzu's advancement from sage to god. A scroll found in the walled-up desert library at Tun-huang, the *Book of the Transformations of Lao Tzu* (*Lao-tzu Pien-hua Ching*), shows him in cosmic perspective, omnipresent and omnipotent, the origin of all life. His human manifestations are listed, followed by his successive roles in legendary history, as the sage counsellor of emperors. Next, five of his more recent appearances are mentioned, dated AD 132–155, and localized in west China, where a temple is said to have been dedicated to him in 185. Then the god speaks, to describe his own powers. He recommends to his votaries the recitation of "my book in 5,000 words" (the *Tao-te Ching*) and enjoins a meditation on his own divine attributes as they appear within the adept's body. Finally, he calls upon the faithful to join him, now, when he is about to strike at the tottering rule of the Han dynasty. Evidently the product of a messianic group in west China at the end of the 2nd century, this valuable fragment of only 95 lines is written in a strangely disfigured Chinese, in part a reflection of its popular milieu. But it still shows more clearly than many longer and better preserved texts the essential cohesion of the several aspects of esoteric Taoism: hagiography, recitation of

Lao-tzu as a god

scriptures, and visionary meditation, all of which are here given additional temporal unity by the messianic context.

The most ancient doctrinal literature. *The Book of the Great Peace.* Just as hagiography was conceived in terms of the thought of its time, the earliest texts of esoteric Taoism that explicitly treat of doctrinal matters also fully share the holistic view of the universe (*i.e.*, stressing the organic relations between all things), which was the heritage of all traditional Chinese thinkers. But Taoists looked to an accelerated union with the universal Tao in their own lifetime, striving inwardly for its realization within their bodies and socially for its advent in their communities of initiates. One of the earliest known of these organizations was the Way of the Great Peace (*T'ai-p'ing tao*), which attracted a huge following in northeast China during the latter half of the 2nd century AD. There is an enormous *Book of the Great Peace* (*T'ai-p'ing Ching*) that may in part represent the teachings of this sect. Its style is archaic-seeming, and the frequent difficulties of interpretation may reflect northeastern regionalisms. It seems clear, too, that the work was composed at a social level rather lower than that of the highly literate metropolitan classes. Its contents are too difficult, diverse, and prolix to be easily summarized. It is written in the form of a colloquy between a "celestial master" (*t'ien-shih*) and his disciples, called "perfected-ones" (*chen-jen*). The dialogue form provides a dramatic framework in which the more-than-mortal preceptor can make his points with great effectiveness. He interrogates his anxious pupils, expressing studied astonishment when they fail to comprehend basic issues, which he then proceeds to expound. This didactic exchange is in the best tradition of the old philosophical schools, but the subject is now the correspondence and interaction of the mortal plane with the invisible world, and the attainment of transcendence.

Texts of the Celestial Masters. The protagonist of the *Book of the Great Peace* is a celestial master. When another important religious movement began in China's far west at about the same time as the group in the northeast arose, in the second half of the 2nd century AD, the same title was given to its founder, Chang Tao-ling. It is with this "Way of the Celestial Masters" (*T'ien-shih tao*) that the history of organized religious Taoism may be said to begin, in that there has been an unbroken continuity to the present day, as the movement soon spread to all of China. A few surviving works appear to belong to the organization's early years. Its central preoccupation has always been liturgical, the formalized communication with the celestial hierarchy. Liturgical fragments are preserved in 4th-century texts and presumably derive from much older practice. Liturgy was not static; it continued to grow, and liturgical texts fill many volumes of the Taoist Canon. Its full development is represented at the present time in the rites of the Taoist masters on Taiwan. The intoned liturgy has at all times been the communal expression of faith, furnishing a rhythmical support to all personal spiritual aspirations, and a backdrop for much of Taoism's subsequent literature. Still another text discovered at Tun-huang reveals a further aspect of the sect's practice. The *Hsiang-erh Commentary on the Lao Tzu*, composed by one of the first celestial masters, shows the way in which the faithful were taught to interpret and apply the *Tao-te Ching*. Lao-tzu, as Lord Lao the Most High (*T'ai-shang Lao-chün*), is seen as the concrete manifestation of the universally diffused Tao; his book is envisaged as a revelation from which clear rules of conduct are to be derived. This sectarian interpretation, then, was a predominantly moral one, and it is known that the *Tao-te Ching* continued to be transmitted as a sacred text to beginners in the "Way of the Celestial Masters."

The Book of the Yellow Court. Very different in form is the *Book of the Yellow Court* (*Huang-t'ing Ching*), also among the earliest and most influential of Taoist scriptures. It is written in verse of seven syllables to the line, rhyming in successive lines: a rather inept prosody, reminiscent of the doggerel verse on Han mirrors, as well as certain secular didactic stanzas from the 2nd century AD. The work is imperfectly understood, but what it sets forth in often puzzling detail is a procedure of systematic communication with the internal counterpart of the celestial hierarchy. The book's patron is, once again, Lao-tzu. As indicated above, he was as much at home within the bodies of his worshippers as in the heavens. The mnemonic verses were presumably to be chanted as the adept turned his concentrated gaze within: it is in fact an inward-looking liturgy (see also TAOISM; TAOISM, HISTORY OF).

Pao-p'u-tzu. It would appear that esoteric Taoism became more significant among the cultured elite in the 4th century AD. With this upward move in society, works of conscious literary art appear. The most celebrated and elaborate treatise of the period is Ko Hung's *Pao-p'u-tzu* ("He Who Holds to Simplicity"), the author's pseudonym. This voluminous collection contains 70 extended essays, of which the first 20, the "Inner Chapters," deal with the arts of immortality. In the debate on the existence of Immortals that had been waged in literate circles sporadically since Han times, Ko Hung was the most valiant champion of the Immortals' claims. But he opposed the notion that they belonged to a radically different order of beings. Rather, he stressed that all known Immortals had themselves once been men and so their state must be attainable by men today. The essentials are a good teacher and tireless perseverance. The argument is presented in the most refined but fluent prose and, oddly enough, in the dialectic form perfected by the Han skeptics. A question is put forward or an objection proposed by an imaginary opponent; this is then decisively dealt with by "Pao-p'u-tzu," who draws upon a great store of anecdotes to illustrate his own nonskeptical beliefs. His topics cover the whole range of the macrobiotic preoccupations of his day: breath control, herbalism, dietetics, sexual techniques, and alchemy. To mineral elixirs he accorded a place above all other means of attaining everlasting life, and the two long essays on the subject in *Pao-p'u-tzu* are among the earliest and most detailed documents in the history of alchemy. The 70th chapter of this remarkably rich work is Ko Hung's own autobiography, as fascinating as the rest of his book. But *Pao-p'u-tzu* is in large part a polemic exercise, intended either as a systematic refutation of unbelief or as encouragement to the adept whose enthusiasm was on the wane. For all his charm, however, the contradictory opinions that the author in his enthusiasm lets slip raise doubts as to his real understanding of the beliefs he so lustily defended. But there was soon to be more convincing literary testimony to the truly creative response that esoteric Taoism was awakening among members of the governing class. This dates from some 40 years later, and it began among Ko Hung's own kinsmen.

Techniques for achieving immortality

The Mao Shan revelations. Between 364 and 370 a young man named Yang Hsi experienced a series of visions in which he was visited by some dozen of the Perfected (*chen*), who were now formally classified as Immortals of higher rank than mere *hsien*. They presented him with a number of celestial texts, some of which were intended as more accurate versions of scriptures already in circulation among men. Among these was a new *Book of the Yellow Court*, in rather smoother verse than the older one and a good deal more intelligible. The Perfected also bestowed on Yang the texts of several of their own biographies: long narratives containing descriptions of the stages and methods by which they had achieved perfection. Their midnight interviews with the visionary were highly dramatic occasions, and Yang transcribed with care the allusive poems and ornate prose essays they dictated to him, as well as their explanations of the revealed scriptures. Most of these communications were destined for Yang Hsi's patron, Hsü Mi, a court official, and his son, Hsü Hui, who lived in retirement at Mao Shan, a chain of hills southeast of Nanking. The Hsüs recopied the revelations and also kept clear records of their own spiritual practices and dreams. So impressive were these extensive materials, both as examples of fine literary style and as tokens of divine favour toward the Hsü family, that much was preserved. Toward the end of the 5th century, T'ao Hung-ching, the greatest Taoist

Visions of Yang Hsi

master of his day and a relative of the Hsüs, collected all the surviving original manuscripts of the scriptures, lives, and visionary *dictées* (writings from dictation). He edited these *dictées*, with a commentary of his own, as *Declarations of the Perfected* (*Chen Kao*). The technical matter from the remainder of the revealed texts was included in his *Secret Instructions for Ascent to Perfection* (*Teng-chen yin-chüeh*), with an elaborate commentary treating all aspects of spiritual practice. This immense collection of dated documents, the most complete dossier of any early Taoist movement, is invaluable for the study of the period. The Mao Shan establishment that T'ao founded became the most powerful of Taoist organizations, and its literature had tremendous influence. Though he is not yet mentioned in histories of Chinese literature, the visionary Yang Hsi may well have been the most truly inspired poet of his time. The revealed documents show that he and the Hsüs expected the imminent descent of a saviour and the universal rule of the Tao, as an end to the turbulence and sufferings of the age. In a series of texts of great expressiveness and force, the Perfected told of the approaching end of the old order; they also set forth the spiritual discipline that would assure survival through the cosmic upheavals ushering in the new era and would guarantee exalted rank in the kingdom of the elect. This revelation was the highest literary achievement of esoteric Taoism's formative period, and its impact was considerable. There were numerous imitations of the scriptures, while many ostensibly independent works in the Taoist Canon are no more than extracts from *Chen Kao*.

The Ling-pao movement. The chief influence on liturgical tradition, however, came into being slightly after the Mao Shan revelations. At the very end of the 4th century, a member of Ko Hung's own clan composed the Ling-pao ("Transcendent Jewel") scriptures, which brought upon the scene a series of Celestial Reverences (*t'ien-tsun*). The supreme and primordial character of these figures may owe something to the stately succession of Buddhas, from remotest times into the incalculable future, found in the Mahāyāna (the "Greater Vehicle," a form of Buddhism predominant in East Asia) scriptures. But these hierarchs are described as emanations of the Tao, and their liturgies came to occupy a prominent place in communal Taoist worship from the 5th century on. The question of possible Buddhist influence upon the liturgical portion of this movement, too, remains open, and the whole subject requires much more research.

Subsequent developments. The influential Mao Shan and Ling-pao movements began in south China, at a time when the north was under foreign domination. Their literature soon spread northward, where independent developments had taken place. The need for a comprehensive collection of information on all the schools resulted in the first great Taoist encyclopaedia (*c.* 570). Like other such compilations in China, it was made up of extracts from sundry books, classified by subject matter. Similar reference works continued to be compiled. The most important is the *Seven Slips from the Bookbag of the Clouds* (*Yün-chi ch'i-ch'ien*) (*c.* 1022), made just after the first printing of the Taoist Canon in about 1016. It is a canon in miniature and contains many important works in their entirety. Hagiography continued to flourish. In addition to many local and sectarian compilations, there were huge general collections, containing the lives of both legendary and historical figures, such as the immense *Comprehensive Mirror of the Immortals* (*Chen-hsien t'ung-chien;* early 12th century). Sectarian historiography also developed; of particular interest are the extensive monographs devoted to the great mountain centres of Taoism. The *Treatise on Mao Shan* (*Mao Shan Chih*) (1329) is among the most monumental. It includes lives of the saints and patriarchs, notes on topography and history, and a valuable selection from 1,000 years of literary testimony and inscriptions on the mountain and its Taoism. The new Taoist movements, which took north China by storm in the 12th and 13th centuries, also furnish their own very copious literature: biographies of their masters and collections of their sayings. Among them is the famous account of the travels (1220–24) of a patriarch of the Ch'üan-chen sect into Central Asia in response to the summons of Genghis Khan. Short moral tracts for missionary purposes were yet another popular genre, and, finally, there are innumerable inscriptions from all periods that provide important data on Taoist establishments and their patrons over the centuries.

Taoist reference works

AESTHETICS AND INFLUENCE OF TAOIST LITERATURE

Taoist imagery. Taoist literature manifests such richness and variety that scholars tend naturally to seek the symbolic modes of expression which served as points of unity within its historical diversity. No image is more fundamental to all phases of Taoism than that of the child. *Tao-te Ching* praises the infant's closeness to the Tao in its freedom from outside impressions, and *Chuang-tzu* describes the spiritual beings nurtured on primal substances, air and dew, as having the faces of children. Thus many of the spirits, both indwelling and celestial, in the esoteric system are described as resembling newborn babes, while the Immortals who appear in visions, though hundreds of years old, are at most adolescent in appearance. Other persistent images are those of mountain and cavern. Present in the older texts, they are carried over, with particular connotations, into the later works. The mountain as a meeting place of heaven and earth, gods and men, and master and disciple (as already in *Chuang-tzu*), takes on a vast downward extension. Beneath the mountains are the great "Cavern-heavens" (*tung-t'ien*) of esoteric Taoism, staffed by a numerous immortal hierarchy. Thus, for example, while Mao Shan is only some 400 metres (1,300 feet) high to the gaze of the profane, the initiate knows that its luminous grottoes plunge thousands of metres into the earth. And *light* is everywhere in Taoist revelation: spirits and paradises alike gleam with brilliance unknown in the world of men.

The image of the child

Influence on secular literature. Already during the Warring States period and the early Han, Taoism had made its appearance in the works of the other schools. Both direct quotations and patent imitations were frequent, and citations from *Tao-te Ching* and *Chuang-tzu* abound throughout later Chinese literature, as do reminiscences of both their style and their content. Esoteric Taoist writings, too, held great fascination for men of letters. Their response might vary from a mere mention of the most celebrated Immortals to whole works inspired directly by specific Taoist texts and practices. Many a poet recorded his search, real or metaphorical, for Immortals or transcendent herbs, or described his attempts at compounding an elixir. A certain number of technical terms became touchstones of poetic diction. The revealed literature of Mao Shan came to have the greatest effect on secular writings. As works of great literary refinement, the *Lives* of the Perfected directly inspired a very famous tale, the *Intimate Life of Emperor Wu of Han* (*Han Wu Ti nei-chuan*; late 6th century), which in highly polished terms describes the visit to the emperor of a goddess, the Queen Mother of the West. This work, in turn, made a decisive contribution to the development of T'ang romantic fiction. Literary accounts of fantastic marvels also drew heavily on the wonders of Mao Shan hagiography and topography. The Mao Shan influence on T'ang poetry was no less important. Precise references to the literature of the sect abound in the poems of the time, while many of the greatest poets, such as Li Po, were formally initiated into the Mao Shan organization. As awareness of these influences increases, scholars are faced with the intriguing question of the possible religious origins of whole genres of Chinese literature (see also LITERATURE, EAST ASIAN).

Influence of Mao Shan literature

Influence on the arts. A number of early Chinese books of spiritual interest claim to have been inspired by pictures seen on the walls of local temples. A similar tradition attaches to the *Lives of the Immortals*, which is said to derive from a pictorial work called *Portraits of the Immortals*. As has been noted, the Immortals were

depicted on Han mirrors. Other illustrative materials were in close relation to the earliest esoteric Taoist literature. Graphic guides existed from early times to aid in the identification of sacred minerals and plants, particularly mushrooms. A later specimen of such a work is to be found in the Taoist Canon. This practical aspect of Taoist influence resulted in the exceptionally high technical level of botanical and mineralogical drawing that China soon attained. In calligraphy, too, Taoists soon set the highest standard. One of the greatest of all calligraphers, Wang Hsi-chih (303–361), was an adherent of the Way of the Celestial Master, and one of his most renowned works was a transcription of the *Book of the Yellow Court*. The efficacity of talismans, in particular, depended on the precision of the strokes from which they were created. Figure painting was another field in which Taoists excelled. China's celebrated painter Ku K'ai-chih, a practicing Taoist, left an essay containing directions for painting a scene in the life of the first Celestial Master, Chang Tao-ling. Many works on Taoist themes, famous in their time but now lost, have been attributed to other great early masters. Of these, some may have been painted for use in ritual, and religious paintings of the Taoist pantheon are still produced today. The Taoist scriptures, with their instructions for visualization of the spiritual hierarchy, including details of apparel and accoutrements, are ready-made painter's manuals. Finally, the language of speculative Taoism was pressed into service as the basic vocabulary of Chinese aesthetics. Consequently, many secular artists attempted to express their own conceptions of the "natural spontaneity" of *Chuang-tzu*, and *Lao-tzu*'s "spirit of the valley." Here Taoism found still wider imaginative extension, and the efforts of these painters are embodied in those magnificent landscapes that have come to be thought of as most characteristically Chinese.

SCHIPPER, *L'Empereur Wou des Han dans la légende taoiste* (1965), unique as a study of esoteric Taoist imaginative literature; A. WALEY, *The Poetry and Career of Li Po, 701–762* (1950), the life of a Taoist poet; *The Travels of an Alchemist* (1931), translation of the account of a Taoist's Central Asian journey.

(M.St.)

Tapestry

Historically almost any heavy material, handwoven, machine woven, or even embroidered, used to cover furniture, walls, or floors or for the decoration of clothing, has been called tapestry in popular usage. Since the 18th and 19th centuries, however, the technical definition of tapestry has been narrowed to include only heavy, reversible, patterned or figured handwoven textiles, usually in the form of hangings or upholstery fabric.

Tapestry traditionally has been a luxury art afforded only by the wealthy, and even in the 20th century large-scale handwoven tapestries are too expensive for those with moderate incomes.

Tapestry sets

Tapestries are usually designed as single panels or sets. A tapestry set is a group of individual panels related by subject, style, and workmanship and intended to be hung together. The number of pieces in a set varies according to the dimensions of the walls to be covered. The designing of sets was especially common in Europe from the Middle Ages to the 19th century. A 17th-century set, the "Life of Louis XIV," designed by the king's painter Charles Le Brun, included 14 tapestries and two supplementary panels. The number of pieces in 20th-century sets is considerably smaller. "Polynesia," designed by the modern French painter Henri Matisse, for example, has only two pieces, and "Mont-Saint-Michel," woven from a cartoon by the contemporary engraver and sculptor Henri-Georges Adam, is a triptych (three panels). Until the 19th century, tapestries were often ordered in Europe by the "room" rather than by the single panel. A "room" order included not only wall hangings but also tapestry weavings to upholster furniture, cover cushions, and make bed canopies and other items. Most Western tapestry, however, has been used as a type of movable monumental decoration for large architectural surfaces, though in the 18th century, tapestries were frequently encased in the woodwork.

In the West, tapestry traditionally has been a collective art combining the talents of the painter, or designer, with those of the weaver. The earliest European tapestries, those woven in the Middle Ages, were made by weavers who exercised much of their own ingenuity in following the cartoon, or artist's sketch for the design.

Though he followed the painter's directions and pattern fairly closely, the weaver did not hesitate to make departures from them and assert his own skills and artistic personality. In the Renaissance, tapestries increasingly became woven reproductions of paintings, and the weaver was no longer regarded as the painter's collaborator but became his imitator. In medieval France and Belgium, as well as now, a painter's work was always executed in tapestry through the intermediary of the weaver. Tapestry woven directly by the painter who created it remains an exception, almost exclusive to ladies' handiwork.

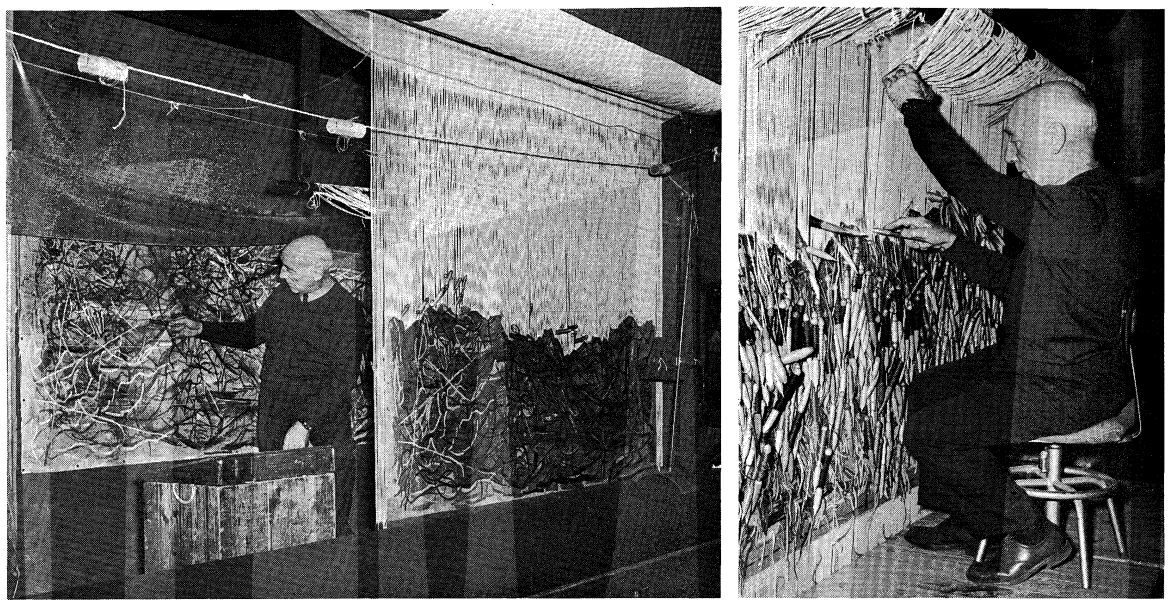
MATERIALS

Wool has been the material most widely used for making the warp, or the parallel series of threads that run lengthwise in the fabric of the tapestry. The width-running, weft, or filling threads, which are passed at right angles above and below the warp threads, thereby completely covering them, are also most commonly of wool. The advantages of wool have been its availability, workability, durability, and the fact that it can be easily dyed to obtain a wide range of colours. Wool has often been used with linen, silk, or cotton threads for the weft. These materials give variety and contrast of colour and texture and are better suited than wool to detail weaving or to creating delicate effects. In European tapestry, light-coloured silks were used to create pictorial effects of tonal gradation and spatial recession. The sheen of silk thread was often used for highlights or to give a luminous effect when contrasted to the dull and darkly coloured heavier woollen threads. In 18th-century European tapestries, silk was increasingly used, especially at the Beauvais factory in France, to achieve subtle tonal effects. Most of the Chinese and Japanese tapestries have both warp and weft threads of silk. Pure silk tapestries were also made in the Middle Ages by the Byzantines and in parts of the Near East. Wholly linen tapestries were made in ancient Egypt, while Copts, or Egyptian Christians, and medieval Europeans sometimes used linen for the warp. Cotton and wool were employed for pre-Columbian Peruvian tapestries as well as for some of the tapestries made in the Islāmic world during the Middle Ages. Since the 14th century, European weavers have used gold and silver weft threads along with wool and silk to obtain a sumptuous effect. These threads were made of plain or gilded silver threads wound in a spiral on a silk thread.

TECHNIQUES

Tapestry is first of all a technique. It differs from other forms of patterned weaving in that no weft threads are carried the full width of the fabric web, except by an occasional accident of design. Each unit of the pattern or the background is woven with a weft, or thread of the required colour, that is inserted back and forth only over the section where that colour appears in the design or cartoon. As in the weaving of plain cloth, the weft threads pass over and under the warp threads alternately and on the return go under where before it was over and

Weaving tapestry



Weaving on a high-warp loom.

vice versa. Each passage is called a pick, and when completed the wefts are pushed tightly together by various devices (awl, reed, batten, comb, or serrated fingernails in Japan). The weft threads so outnumber the warps that they conceal them completely. The warps in a finished tapestry appear only as more or less marked parallel ridges in the texture, or grain of the fabric, according to their coarseness or fineness.

The thickness of the warp influences the thickness of the tapestry fabric. In Europe during the Middle Ages, the thickness of the wool tapestry fabric in such works as the 14th-century "Angers Apocalypse" tapestry was about five threads to the centimetre (ten to 12 to the inch). By the 16th century the tapestry grain had gradually become finer as tapestry more closely imitated painting. Known for the regularity and distinctness of its tapestries the royal French tapestry factory in Paris known as the Gobelins used six to seven threads per centimetre (15 to 18 per inch) in the 17th century and seven to eight (18 to 20) in the 18th century. Another royal factory of the French monarchy at Beauvais had as many as ten or even 16 threads per centimetre (25 to 40 threads per inch) in the 19th century. These excessively fine grains make the fabric very flat and regular, tending to imitate the canvas of a painting. The grain of 20th-century tapestry approximates that used in 14th- and 15th-century tapestry. The Gobelins factory, for instance, uses five or six threads per centimetre (12 or 15 per inch).

In many 20th-century tapestries a finer grain is contrasted with the effects of a heavier weave. The grain of silk tapestries, of course, is much finer than those made of wool. It is not uncommon for the silk tapestries of China to have as many as 24 warp threads per centimetre (about 60 per inch).

Where the weft margin of a colour area is straight and parallel to the warps, it forms a kind of slit, or *relais*, which may be treated in any of five different ways. First, it may simply be left open, as in Chinese silk tapestries, which are called *k'o-ssu* (cut silk) for that reason. Second, it may be left open on the loom but sewed up afterward, as in European tapestries from the 14th to the 17th centuries and also in some later types. Third, the weaver may dovetail his wefts, passing from one side and from the other in turn over a common warp. This may be either "comb" dovetailing—single wefts alternating—or "sawtooth" dovetailing—clusters first from one side, next from the other. Dovetailing has the double disadvantage of making the fabric heavier at that point and of blurring the outline. Persian weavers of the 16th century developed a successful variant in silk tapestry rugs whereby a black outline weft was dovetailed over two warps—one of each of the adjacent colour areas—effectively hiding the coloured wefts in the compacting of the weave and providing a strong clear image. The same device is found in pre-Columbian Peru.

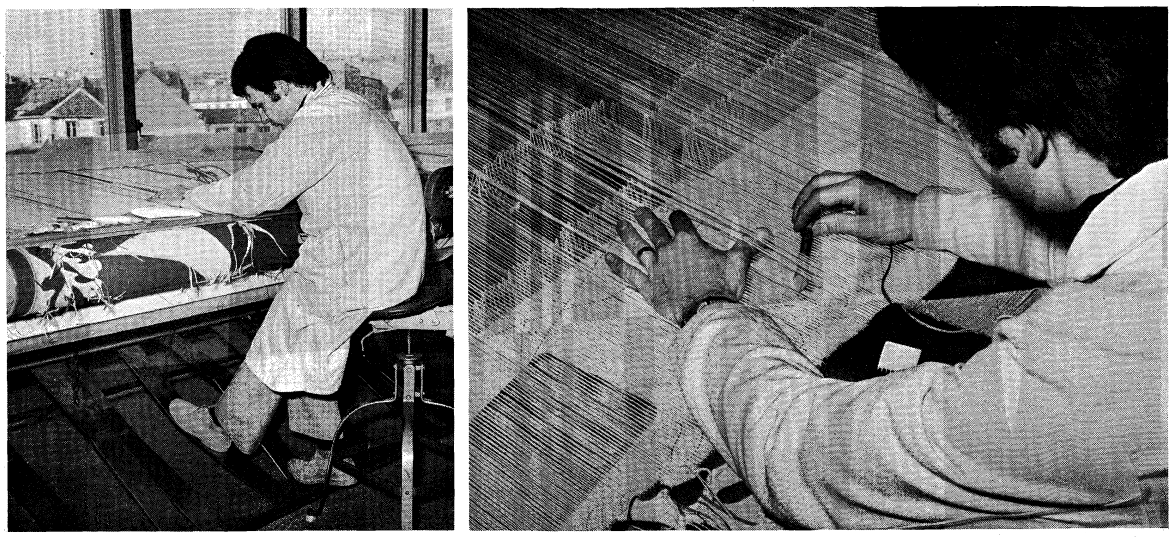
The fourth treatment—interlocking—was introduced in the Gobelins factory in the 18th century. Here wefts of juxtaposed colour segments are looped through each other between the two warps that mark, respectively, the margin of each colour. This gives a continuous surface of even weight and was prized by the French weavers because the resultant effect more closely approximated that of painting.

A curious variant of these weaving techniques is achieved when between every two rows of wefts there is a weft that runs the full width of the tapestry, thereby making the fabric solid. This technique, if strictly classified, would be called brocade weaving, but the principle is that of tapestry, with the cloth insert subordinate. Rarely used, the technique was employed in Japan in the 7th and 8th centuries, in eastern Persia in the 10th century, and in pre-Columbian Peru.

Twill technique of weaving

Instead of the plain-cloth method of weaving usually used in making tapestries, a twill technique can be used. In this type of weave the weft is floated over two or more warps, then under one or more warps, with this underpassage shifting always one to the right or left, thereby making a diagonal ribbing. As far as can be determined, this technique first appeared in medieval Persia and from the 17th century on was especially used in the Iranian provinces of Khorāsān and Kermān to make shawls of goat's hair or wool. It is also used to make the famed Kashmir shawls and, along with many other crafts, was probably introduced into Kashmir from Persia, in the 16th century. In contemporary European tapestries this technique, usually called eccentric weaving, occasionally has been used in making some of the experimental abstract hangings of the later 20th century.

European tapestry may be woven on either a vertical loom (high-warp, or *haute-lisse* in French) or a horizontal loom (low-warp, or *basse-lisse*). In early high-warp looms the warps were attached to a beam at the top, and groups of warp threads were weighted at the bottom. The weft was beaten up (*i.e.*, pushed) toward the top as the weaving progressed. Such looms are pictured on ancient Greek vases. In later high-warp looms the vertical frame



Weaving on a low-warp loom.
(Left) Weaver depresses the treadles with his feet, thereby controlling the space between warps through which the shuttle, held in his right hand, will be moved. (Right) Working on the reverse side of the tapestry with the cartoon positioned under the warps, the weaver passes the shuttle between the warps. (Photographs taken at the Beauvais factory, France.)
By courtesy of the Mobilier National, Paris; photograph, Visages de France

has heavy uprights holding a horizontal roller at top and bottom, on which the warps are stretched. Each warp passes through a loop of cord (the *lisses*), and the loops encircling the warps that correspond to uneven numbers are fastened to one slender cylinder; those to the even to another cylinder. Both cylinders are above the weaver but within reach so that he can pull forward with first one, then with the other set of warps (*i.e.*, form the shed) in order to pass his bobbin behind them. The bobbin (broche) is a short, pointed, slim cylinder of polished wood on which the weft yarn is wound.

The low-warp loom, on the other hand, has the rollers on the same level at table height so that the warps stretched between them are horizontal. To leave the weaver's hands free, the warps are attached to two slats, or poles, each of which is connected with a treadle so that the weaver's foot depresses the odd-numbered or even-numbered series of warps to form a passageway for the bobbin, called a shuttle on the low-warp loom. The cylinders in both instances serve to roll up the finished portion and unroll a further length of unwoven warps so that the section in process is always taut and in a convenient relation to the weaver. At both types of loom the weaver works from the back side, that is, he weaves the tapestry on the wrong side. He has, however, a hand mirror, which he puts through the unwoven warps holding it to reflect the right side of the portion in process. While the high-warp weaver can examine his finished work directly by walking round to the other side of his loom, the low-warp worker has to tilt up his frame.

Of the two techniques, low-warp is more commonly used. Of the great European tapestry works only one, Gobelins, has traditionally used high-warp looms. Several weavers can work simultaneously on either kind of loom. Depending on the complexity of the design and the grain or thickness of the tapestry texture, a 20th-century weaver at the Gobelins can produce three to seven square metres (about 32 to 75 square feet) a year.

The medieval cartoon

In Western tapestry the medieval cartoon, or preparatory drawing, was usually traced and coloured by a painter on a canvas the size of the tapestry to be woven. At the end of the 15th century the weaver probably wove directly from a model, such as a painting, and consequently copied not a diagrammatic pattern but the original finished work of the painter. At the beginning of the 17th century there arose a clear distinction between the model and the cartoon. The model was the original reference on which the cartoon was based. Cartoons were rapidly and freely used and were often copied.

More than one tapestry can be woven from a cartoon. At the Gobelins factory, for instance, the 17th-century "Indies" tapestry set was woven eight times, remade, and slightly altered by the late Baroque painter François Desportes (1661–1743); these cartoons were woven several more times during the 18th century.

The border of a cartoon was often redesigned every time it was commissioned, since each patron would have a different heraldic device or personal preference for ornamental motifs. Borders were frequently designed by an artist different from the one who conceived the cartoon for the central narrative or principal image. As an element of tapestry design, however, borders or frames were important only in European tapestry from the 16th to the 19th centuries. Medieval and 20th-century tapestries seldom use this device, which emphasizes the idea of the tapestry as a reproduction of or substitution for a painting.

Contemporary cartoons

A fully painted cartoon requires much of the painter's time and is tedious to make. In the 20th century, therefore, other solutions have been adopted. The cartoon may be a photographic enlargement of a fully painted model or, more simply, a numbered diagrammatic drawing. The latter type of cartoon was worked out by the famous French tapestry designer Jean Lurçat during World War II. In this method each number corresponds to a precise colour and each cartoonist has his own range of colours. The colours are not indicated in a photographic enlargement, but the weaver refers to a small colour model provided by the painter and from it makes a selection of wool samples.

The high-warp weaver has the full-size cartoon, which he follows as it hangs beside or behind him. The low-warp worker has the cartoon laid under the warps, so he follows it from immediately above. In both cases the main outlines are drawn with ink on the warps after they have been mounted, or attached to the loom. The design is executed, in all European work since the Middle Ages, at right angles to the loom, so that in the finished hanging the warps usually run horizontally rather than vertically as they ran on the loom. Though in certain pieces the warps run vertically, it is aesthetically advantageous for the tapestries to be executed horizontally, since the warp ribbing tends to create a texture more or less reinforced by linear shadows, which, if vertical, sever the design but if horizontal bind it into continuity. Practically, however, horizontal warps are disadvantageous, since the horizontal slits made in weaving will pull apart more rapidly than vertical slits because of the weight of the hanging.

PERIODS AND CENTRES OF ACTIVITY

Ancient Western world. Examples of tapestry weaving from the ancient world are so isolated and fragmentary as to make it uncertain either when or where the art

originated. The earliest known tapestry weaving was done in linen by the ancient Egyptians between 1483 and 1411 BC. Preserved by the dry desert climate of Egypt, three tapestry fragments were found in the tomb of Thutmose IV. Two of the fragments have cartouches of Egyptian pharaohs, and the third is a series of hieroglyphs. In the tomb of Tutankhamen (*c.* 1350 BC), a robe and glove woven by the tapestry technique have also been found.

Although no examples remain, writers of antiquity are unanimous in proclaiming the magnificence of Babylonian and Assyrian tapestries. Some scholars have speculated that the ancient Egyptians learned the art of tapestry from the ancient peoples of Mesopotamia. During that period when the few preserved Egyptian tapestry fragments were made, Mesopotamian ideas, techniques, and, perhaps, craftsmen were entering Egypt. These scholars conjecture that since tapestry weaving did not occur in quantity again in Egypt until the 4th century AD, it is likely that the craft was not indigenous.

Tapestry weaving continued to flourish in western Asia in the 1st millennium before Christ. Fragments of wool tapestries dating from the 4th or 3rd century BC have been found in graves in the U.S.S.R. near Kerch in the Crimean peninsula. The ornamental motifs of these fragments are of a widely diffused Hellenistic style that was especially prevalent in Syrian art at the time. Another fragment showing close Syrian connections is a piece of silk tapestry dating about 200 to 500 years later and found in China at Lou-lan in Sinkiang Uighur Autonomous Region. Other fragments have been found in Syria at the archaeological sites of Palmyra and Doura-Europus. If climatic conditions for textile preservation in the Near East had been more favourable, it might be possible to theorize that Syria was a great centre of tapestry weaving, especially at the start of the Christian Era.

Tapestry in ancient Greece and Rome

There are literary descriptions of the making of tapestry in ancient Greece and Rome. In the *Odyssey*, Homer (6th century BC?) describes Penelope working on a tapestry that was unravelled each night as she waited for Odysseus. The Roman poet Ovid (43 BC–AD 17) in the *Metamorphoses* describes the tapestry looms used by Minerva and Arachne in their mythological weaving contest. During the period of the empire the Romans apparently imported a considerable number of the tapestries used in their public buildings as well as in the homes of the wealthy. Since the Latin terms referring to tapestry and weaving are Greek in origin, it is generally supposed that the art of tapestry making was taught to the Romans by the Greeks.

Eastern Asia. Called *k'o-ssu* (cut silk), tapestry has long been produced in China, traditionally being made entirely of silk; Chinese tapestries are extremely fine in texture and light in weight. The weave is finished perfectly on both sides so that the tapestries are reversible. The warps are vertical in relation to the pattern, rather than horizontal as in European weaving. Sometimes the weaver uses metal threads to make his hangings more sumptuous or highlights the design by painting, although this is not considered a commendable expedient.

Many *k'o-ssu*, such as "T'ung Fung Stealing the Peaches of Longevity" (Ming dynasty, 1368–1644; Metropolitan Museum of Art, New York), imitated paintings and were mounted on scrolls or album leaves in the same manner as the pictures they copied. Tapestries to cover large wall surfaces, such as the *k'o-ssu* (2.20 by 1.75 metres; seven feet three inches by five feet nine inches) of "Feng-huang in a Rock Garden" (late Ming period, Metropolitan Museum of Art, New York), were usually brighter in colour, heavier in texture, and frequently woven with metal threads. Tapestry was also used to decorate furniture and clothing.

Early Chinese *k'o-ssu*

The earliest surviving examples of *k'o-ssu* date from the T'ang dynasty (AD 618–907). Eighth-century remains have been found in desert oases around Turfan in the Sinkiang Uighur Autonomous Region of China, and late T'ang fragments have been found in the Caves of the Thousand Buddhas (Ch'ien-fo-tung or Mo-kao-k'u) near the town of Tun-Huang in Kansu Province. It is thought that these weavings are probably not representative of the more fully developed *k'o-ssu* of the T'ang period because they show only simple repeating patterns of flowers, vines, ducks, lions, etc., and were found in relatively remote areas of Central Asia along the silk-trade route. In comparison is the more sophisticated 8th-century *k'o-ssu* that hangs in the Taima-dera, a temple near Nara, Japan. Based on the story of the T'ang dynasty priest Shan-tao, this four-square-metre (43-square-foot) weaving is the oldest known complete Chinese wall tapestry.

During the Sung dynasty (960–1279) the imperial family encouraged painting and patronized the art of tapestry. An important weaving centre was at Ting-chou in Hopeh Province. Under the Yüan dynasty (1279–1368) a government factory for weaving *k'o-ssu* was established at Hangchow (Lin-an) in Chekiang Province. Characterized by their rich ornamental designs, the Hangchow *k'o-ssu* were frequently woven with gold and silver thread. Examples of tapestry from the Ming period (1368–1644) are rare and exquisite. The *k'o-ssu* executed during the K'ang-hsi (1661–1722), or rule of the great Manchu emperor of China, Hsüan-yeh, are the finest tapestries produced during the Ch'ing dynasty (1644–1911). They are distinguished for their delicate colouring and the use of philosophical and religious themes. Later Ch'ing *k'o-ssu* has survived in great abundance and shows a decided artistic and technical decline. This is especially evident in the frequent use of painting to perfect design details in 19th-century *k'o-ssu*.

Japanese *tsuzure*

The tapestry technique travelled from China to Japan in the late 15th or early 16th century during the Muromachi (Ashikaga) period (1338–1573). Japanese tapestry called *tsuzure-nishiki* (polychrome tapestry) differs from the Chinese *k'o-ssu* in its more pronounced surface relief. This is achieved through the use of thick cotton weft threads covered with silk, gold, or silver thread.

Paralleling the great period of sumptuous brocade manufacturing, the production of *tsuzure* flourished during the Tokugawa (Edo) period (1603–1867), especially in the early 17th century and throughout the entire 18th century. These polychrome tapestries were primarily used to decorate garments and for wrapping gifts; on rare occasions they were also used as wall hangings. Although the tapestry industry declined in quality in the 19th century, it has been revitalized in the 20th century. Monumental wall hangings and theatre curtains are woven in the textile factories of Ōsaka and Kyōto by both traditional Japanese and European tapestry techniques.

The history of the art in Korea remains obscure. Rather coarse wool tapestry-woven rugs with stylized motifs, however, are still produced there.

Pre-Columbian Americas. The most skilled weaving in pre-Columbian America was achieved by the Andean

Indian cultures of ancient Peru. The origins of tapestry weaving among these peoples are believed to date as early as the beginnings of the Christian Era. By the 6th and 7th centuries the technique of tapestry weaving was established, and a large number of pieces in this medium have survived, particularly from the 8th to the 12th centuries. Most of these tapestry weavings have been found in Peruvian coastal burial sites, where the dry desert climate prevented their deterioration. The dead were buried in clothes that display some of the most varied and skilled techniques of weaving and needlework ever current in any culture. Tapestry weaving was used principally to make garment decorations that were usually integral to the garment fabric. Narrow strips to ornament the edges of clothing were common, as were panels covering the entire surface of the *cuzma*, poncho-like Indian shirt. Fragments of tapestry wall hangings have also survived.

According to chronicles written by Spanish colonizers and scenes painted on ancient Peruvian pottery, weaving was generally done by women whose great manual skill made up for the simplicity of the looms, which are still used by Indian craftsmen. The workmanship was extremely fine. Certain tapestry fragments have been found with 60 to 100 weft threads per square centimetre (150 to 250 per square inch). The warps of the tapestries are of undyed cotton, being, therefore, either white or brown. The wefts are of wool from the llama, guanaco, alpaca, or vicuña, with cotton sometimes used to obtain bright white. The tapestries are usually polychrome, for the range of available colours made with natural dyes was large. Strong colour contrasts were preferred to the use of subtly graded tones of colours, especially in the Inca period (*c.* 13th to 16th century). Compositions tended to bold conventionalized designs often of human or animal figures and elaborate geometric patterns. Plant motives are comparatively rare.

After the Spanish conquest, looms from Spain were imported by the viceroyalty of Peru, and the weaving of tapestry was continued during the colonial period. The skilled Inca and later mestizo weavers evolved a curious blending of European influences and Indian traditions.

Tapestry may also have been current in other developed pre-Columbian cultures of Central America and Mexico. Climatic conditions, however, have been destructive to textiles.

Middle Ages in Egypt and the Near East. Tapestry weaving was done by the Copts, or Egyptian Christians, from the 3rd to about the 12th century AD. Their tapestries are of great interest not only because of their artistic quality and technical skill but also because they are a bridge between the art of the ancient world and the art of the Middle Ages in western Europe. Fragments from the 5th to the 7th century are particularly numerous, and the largest number of examples have survived in the Egyptian cemetery sites of Akhmīm, Antinoë, and Saqqārah. As a result of a change in burial customs, perhaps attributable to Romanization and the widespread adoption of Christianity in Egypt, the ancient practice of mummification and its attendant ritual fell into disuse after the 4th century AD. The dead were subsequently buried in daily clothes or were wrapped in discarded wall hangings and tapestries. The clothing was ornamented with tapestry trimming, which was either woven into the fabric or attached to tunics and cloaks. Other burial furnishings included pillows and coverings. Tapestries were also used for the decoration of Christian churches, but few of these wall hangings have survived.

Coptic tapestry

Coptic and Persian tapestries.
(Left) Coptic Medallion tapestry with rabbit and grapes, Egyptian, 4th–7th centuries AD. In the Museum of Fine Arts, Boston. 21.5 × 21.0 cm. (Right) Fragment of Persian dovetailed tapestry with ibex, probably Sāsānian period (*c.* AD 224–651). In Yale University Art Gallery. 35.74 × 27.30 cm.

Coptic tapestries were woven with woollen wefts on linen warps, though a few with silk wefts have been preserved. Cotton wefts were occasionally used to obtain a brighter white. Primarily in the 7th century and perhaps also the 8th century, tapestry ornamentation was often supplemented by embroidery, as in border margins. In a special variant, which is not true tapestry, characteristic ornamental motifs such as meanders or other geometric repeats are executed with a free bobbin that follows the design without regard to consistency of weft direction.

Many of the early Coptic tapestries were done in a silhouette technique in which the motif or design was in a single dark colour, usually a tone of purple achieved by dying with madder and indigo, against a lighter background colour. After the 5th century, polychrome tapestries became increasingly common.

Many Coptic tapestry trimmings were woven with indigenous designs. Recurring motifs related to the ancient Egyptian funerary cult of Osiris and included the grape vine or ivy and the wine amphora. These motifs were considered appropriate to burial robes because of their relevance to revival in a life after death. Other favourite subjects were the hunter on horseback, boy-warriors, desert animals (especially the lion and the hare), creatures of mythology, dancing figures, and baskets of fruits and flowers. Christian subjects are as a rule late in date and are mostly figures of saints, standing or on horseback, against a red background. Depictions of biblical stories are rare. Some of the Coptic designs were copied, in a more or less distorted manner, from those woven into silk textiles imported from Syria.

Islāmic tapestry

After the invasion of Egypt by the Muslims in 640, the quality of Coptic tapestry began to deteriorate, although the industry continued to flourish by adapting itself to the tastes of the conquerors. During the Tūlūnid period (868–905) bands of tapestry trimming in wool or often in silk, occasionally with metal-thread enrichments, were

woven into white or dark green linen garments. In the Fātimid period (909–1171) silk tapestry weaving in golden yellow and scarlet became common. The motifs of the Islāmic period of Egyptian weaving were often interlacing geometric patterns frequently enclosing inscriptions or highly stylized small birds, animals, and flowers. Many of these inscriptions merely simulate writing, but many are legible. Giving religious phrases or the names and titles of rulers, they are in handsome angular Kufic scripts on earlier pieces and in cursive scripts later.

From the 6th to the 8th century AD, and doubtless from then on, striking wool tapestries were being made in Syria corresponding in style to the contemporary silk textiles with animals or birds in energetic heraldic stylization, framed in roundels, and almost always on a red ground. Later, from the 11th to the 13th century, highly distinctive silk- and gold-thread tapestries were produced in Syria incorporating pagan motifs from classical antiquity.

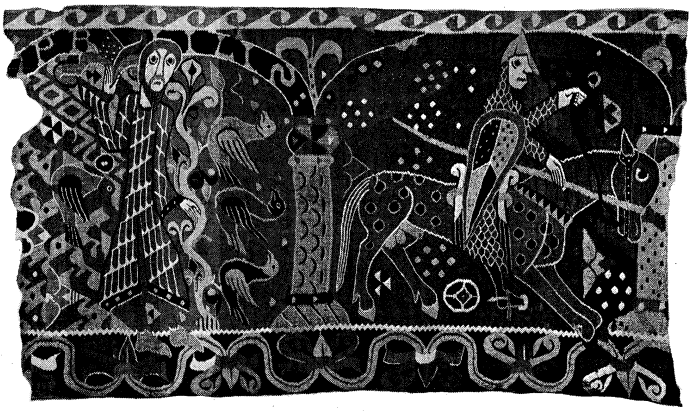
Fewer specimens of Persian tapestries have survived, but one notable fragment, now in the Moore Collection at Yale University, bears an ibex in the style of the Sāsānian period (*c.* AD 224–651). A single piece from the Seljuq period (11th century) established a continuation of the use of the tapestry technique, which reappears in the 16th century (intermediate examples apparently having all been destroyed) as the medium for rich silk- and metal-thread rugs, of which only three are known still to exist (also in the Moore Collection, New Haven, Connecticut), though others are illustrated in Persian miniatures. The modern descendants of these are kilims, or pileless carpets woven by the tapestry technique. Common to the entire Near East, these rugs are especially produced in the Caucasus and Asia Minor, as well as in parts of eastern Europe. Occasionally silk, they are more often wool with simple geometric patterns in bold colours.

Early Middle Ages in western Europe. Numerous documents dating from as early as the end of the 8th century describe tapestries with figurative ornamentation decorating churches and monasteries in western Europe, but no examples remain, and the ambiguity of the terms used to refer to these hangings makes it impossible to be certain of the technique employed. The 11th-century so-called Bayeux Tapestry depicting the Norman Conquest of England, for example, is not a woven tapestry at all but is a crewel-embroidered hanging.

Like the art of stained glass, western European tapestry flourished largely from the beginnings of the Gothic period in the 13th century to the 20th century. Few pre-Gothic tapestries have survived. Perhaps the oldest preserved wall tapestry woven in medieval Europe is the hanging for the choir of the church of St. Gereon at Cologne in Germany. This seven-colour wool tapestry is generally thought to have been made in Cologne in the early 11th century. The medallions with bulls and griffons locked in combat were probably adapted from Byzantine or Syrian silk textiles. The "Cloth of Saint Gereon" is thematically ornamental, but an early series of three tapestries woven in the Rhineland for the Halberstadt Cathedral were narrative. Dating from the late 12th and early 13th centuries, these wool and linen hangings are highly stylized and schematic in their representations of figures and space, with all forms being outlined. The "Tapestry of the Angels," showing scenes from the life of Abraham and St. Michael the Archangel, and the "Tapestry of the Apostles," showing Christ surrounded by his 12 disciples, were both intended to be hung over the cathedral's choir stalls and therefore are long and narrow. The third hanging called the "Tapestry of Charlemagne Among the Four Philosophers of Antiquity" is a vertical wall hanging related to works produced by the convent at Quedlinburg in the German Rhineland during the Romanesque period of the 12th and early 13th centuries.

Romanesque tapestry

Fragments of a tapestry with traces of human figures and trees reminiscent of hangings described in the Norse sagas were found in an early-9th-century burial ship excavated at Oseberg in Norway. One of the major works of Romanesque weaving is a more complete tapestry dating from around the end of the 12th or early 13th century that was made for the Norwegian church of Baldishol in the district of Hedemark. Originally a set of wool hangings on the 12 months of the year, only the panels of April and May have survived (Kunstindustrimuseet, Oslo). The pronounced stylization of the images relates these tapestries to those executed for Halberstadt Cathedral.



"April and May," fragment known as the "Baldishol Tapestry," after 1190. In the Kunstindustrimuseet, Oslo. 1.18 × 2.00 m.
By courtesy of the Kunstindustrimuseet, Oslo

14th century. In the 14th century the western European tradition of tapestry became firmly established. At that time the most sophisticated centres of production were in Paris and Flanders. Large numbers of tapestries are recorded in inventories. The more luxurious standards of living being adopted by the wealthy of the Gothic period extended the use of tapestries beyond the customary wall hangings to covers for furniture. Survivals of 14th-century workmanship, however, are rare, and the most important of these were produced by Parisian weavers. The outstanding example of their art is the famous Angers Apocalypse (Musée des Tapisseries, Angers, France), which was begun in 1377 for the Duke of Anjou by Nicolas Bataille (flourished *c.* 1363–1400). This monumental set originally included seven tapestries, each measuring approximately 16.5 feet in height by 80 feet in length (5.03 by 24.38 metres). Based on cartoons drawn by Jean de Bandol of Bruges (flourished 1368–81), the official painter to Charles V, king of France, only 67 of the original 105 scenes have survived. A slightly later series (*c.* 1385) possibly woven in the same Parisian workshop is the "Nine Heroes" (Metropolitan Museum of Art, The Cloisters, New York). This set is not a religious narrative but illustrates the chivalric text *Histoire des Neuf Preux* ("Story of the Nine Heroes") by the early-14th-century wandering minstrel, or jongleur, Jacques de Longuyon.

Paris tapestry

Flanders, particularly the city of Arras, was the other great centre of the tapestry industry in 14th-century Europe. The tapestry produced there had such an international reputation that terms for tapestry in Italian (*arrazzo*) and Spanish (*drap de raz*) and English (arras) were derived from the name of this Flemish city. Long a medieval centre of textile weaving, Arras became an important tapestry centre when the leading citizens decided to create a luxury industry to alleviate the economic crisis caused by a decline in the sale of Arras textiles due to the popularity of cloth from the Flemish region of Brabant.

15th century. The greatest tapestries of the 15th century were produced in the Flemish cities of Arras, Tournai, and Brussels. In the first half of the century it was Arras that particularly prospered under the patronage of the dukes of Burgundy. Duke Philip the Good (1396–1467) had a specially designed building erected in the city to allow for better conservation of his tapestry collection. Between 1423 and 1467 no fewer than 59 master tapestry weavers were working in Arras, but following the French siege of the city in 1477 under King Louis XI the industry declined. After approximately 1530 it was no longer active. While the importance of Arras waned, that of Tournai and eventually Brussels waxed—their tapestries be-

Arras tapestry

coming the most sought after in the late 15th century. Local identification marks did not become general until the 16th century, and continual intercourse between the various medieval centres of tapestry making, particularly Arras and Tournai, adds to the difficulty of determining where individual tapestries were made. Despite the prestige of Arras workmanship, it is ironic that only one set of tapestries dating from 1402 is inscribed with the actual name. Large fragments showing scenes from the lives of St. Piat and St. Eleutherius survive in the cathedral of Tournai, for which they were commissioned. The imagery of these tapestries, like that of most Gothic hangings, was closely related to the styles of painting current at the time. Other important examples of supposed Arras tapestries inspired by Franco-Flemish book miniatures or paintings on wood panels include the early-15th-century tapestry of "The Annunciation" (Metropolitan Museum of Art, New York), which was probably woven after a cartoon by Melchior Broederlam (active 1381–*c.* 1409), and the "Court Scenes" (Musée des Arts Décoratifs, Paris), related to the *Très Riches Heures* illuminated for the Duc de Berry by the brothers Limburg (active early 15th century).

Whether a tapestry is an Arras or not is usually determined by comparison with the "History of St. Piat and St. Eleuthère." One of the finest works so attributed is the early-14th-century fragment from the set in the Museo Civico at Padua, Italy, illustrating the *Geste of Jourdain de Blaye*, a medieval chivalric story adapted from the ancient Greco-Roman romance *Apollonius of Tyre*.

Tournai tapestry

The craft, practiced since the end of the 13th century at Tournai, proved so prosperous that in 1398 a regulation concerning production was published. It is the oldest known ordinance regulating the craft of tapestry weaving. Among partially surviving tapestries ordered in the late 15th century by the Court of Burgundy were two sets produced by the weaver and tapestry merchant Pasquier Grenier (died 1493) for Philip the Good. One set, "The Story of Alexander" (Galleria Doria-Pamphili, Rome), was purchased in 1459, and the other, "The Knight of the Swan" (St. Katherine, Kraków, Poland, and Österreichisches Museum für Angewandte Kunst, Vienna), was bought in 1462.

Cited by many scholars as an example of mid-15th-century Tournai weaving under the influence of Arras are the four renowned tapestries of "The Hunts of the Dukes of Devonshire" (Victoria and Albert Museum, London). Typical of the developed late Gothic Tournai style are the compacted vertical compositions of "The Story of Strong King Clovis" (mid-15th century; Musée de l'Oeuvre Notre-Dame, Reims, France) and "The Story of Caesar" (*c.* 1465–70; Historisches Museum, Bern, Switzerland). Many of the attributed Tournai weavings are heavily outlined and have a solemnity that contrasts to the more fanciful nature of Arras weavings. A sense of monumentality is created by the immense size of many of these supposed Tournai weavings and by the way the vast surfaces are densely filled with superimposed imagery.

A producer of tapestry since the 14th century, in the 15th century Brussels vied with Arras and Tournai. By mid-century, Brussels was noted for its highly skilled reproductions of religious paintings by Flemish masters of late Gothic realism, such as in the tapestry of "The Adoration of the Magi" (1466–88; Cathedral of Sens, France). These panels were called "altarpiece tapestries" because they were usually intended for churches or private chapels, where they either were used as an altar cloth or antependium or were hung behind the altar as an altarpiece or fabric retable. In scale, altarpiece tapestries approximated the dimensions of the painting they copied and were, therefore, much smaller in size than the muralesque wall hangings of Arras and Tournai. Silk was commonly used to obtain the greater degree of naturalistic detail essential in reproducing a painting.

Tapis d'or and mille-fleurs tapestries

In the late 15th and early 16th centuries, Brussels also became famous for its production of *tapis d'or*, or "golden carpets," so called because of the profuse use of gold threads. Examples such as "The Glorification of Christ," popularly known as the "Mazarin Tapestry" (*c.* 1500; National Gallery of Art, Washington, D.C.), are characterized by their richness of effect.

"The Adoration of the Magi," Brussels altarpiece tapestry, 1466–88. In the Cathedral of Sens, France. 1.38 × 3.31 m.
Giraudon

Perhaps the best known late Gothic hangings were the fanciful tapestries usually referred to as mille-fleurs thousand flowers). A red or dark-blue ground strewn with flora and fauna sometimes serves as a setting for heraldic devices such as in the late-15th-century tapestry with the coat of arms of Philip the Good (Historisches Museum, Bern, Switzerland) or acts as a background for scenes of the chivalric aristocratic life during the late Middle Ages, such as in "The Hunt of the Unicorn" (Metropolitan Museum of Art, The Cloisters, New York) or "The Lady with the Unicorn" (Musée de Cluny, Paris). The origin of mille-fleurs tapestries is disputed, but it is thought that they were woven in the Flemish workshops of Brussels and Bruges and by itinerant weavers in the Loire Valley of France.

Itinerant Flemish and French weavers, setting up their looms in cities where there was temporary employment, carried tapestry weaving to Italy as early as the 15th century. Before the 16th century, however, most tapestries were bought in France and Flanders. Small workshops attached to the courts of various Italian nobles sporadically appeared for brief periods in Siena, Brescia, Todi, Perugia, Urbino, Mantua, Modena, Genoa, and Ferrara. The only one of importance was the Flemish-directed workshop of Ferrara, established around 1445 by the duke Lionello d'Este, who commissioned the famous Ferrarese early Renaissance painter Cosmè Tura (*c.* 1430–95) to make cartoons for his weavers.

Ferrara tapestry

16th century. Two new trends became apparent in the 16th century. The first, brought about by war and persecution in Flanders, resulted in the widespread diffusion of the Flemish art of tapestry weaving. Many Flemish artisans in the 16th century were forced to become refugees. Some grouped together to live the life of travelling craftsmen, while others attempted to re-establish their trade abroad. Flemish weavers were welcomed everywhere as carriers of a great tradition. Such itinerant masters established shops from England to Italy. The second important new trend emanated from Italy and reflected the superiority attached by the Italian Renaissance to the art of painting. The decisive step, which was to bring about the subordination of weaving to painting for more than 400 years in the art of tapestry, was taken when Pope Leo X commissioned the famed weaver Pieter van Aelst (flourished late 15th–early 16th centuries) of Brussels to make a series of tapestries illustrating the "Acts of the Apostles" from cartoons produced between 1514 and 1516 by Raphael (1483–1520). Little or no concession had been made to the tapestry medium for which the cartoons were intended, but the tapestries were a great success, and numerous copies of them were subsequently made.

The ascendancy of Brussels tapestry

The occupation of Arras by the French in the late 15th century and successive sieges of Tournai in the early 16th century contributed to the rise of Brussels as the leading tapestry centre of Flanders—a position it maintained until the 17th century. The patronage of the papacy and the imperial houses of Spain and Austria, along with other European royalty and the skill of its weavers, who were among the finest in Europe, combined to establish the international reputation of Brussels tapestry. The indus-

try was controlled by a monopoly of rich merchants. Tapestry making proved so prosperous in the period between 1510 and the outbreak of the Peasants War in 1568 that the industry had to be protected by regulations against frauds and forgeries. A number of communal ordinances followed one another in rapid succession, the most important being that of 1528, requiring each tapestry woven in Brussels to bear the mark of the city—a flat red shield flanked by two *B*'s standing for Brussels and the province of Brabant. The same imperial edict issued by Emperor Charles V also required manufacturers and merchants to use the signature or monogram of the master weaver or workshop.

It is the designs of the Flemish painter Bernard van Orley (1492?–1541) that are most characteristic of the Renaissance style of Brussels tapestry. Van Orley attempted to reconcile the traditions of late Gothic northern realism and the monumentality and idealism of Italian Renaissance art with the artistic potential of the tapestry medium. His earlier works, such as "The Legend of Our Lady of Le Sablon" (Musées Royaux d'Art et d'Histoire, Brussels) and "The Revelation of St. John" (1520–30; Patrimonio Nacional, Spain), still show compositional elements that link them to medieval Flemish art. Later, his work was influenced by the cartoons of Italian artists that were woven in Brussels workshops, such as Raphael's "Act of the Apostles" and the designs for "The Story of Scipio" and "Fructus Belli," executed by Raphael's disciple, the Mannerist painter and architect Giulio Romano (1499–1546). Van Orley adapted the Italians' preference for monumentality and their feeling for depth and sculptural modelling to Flemish tastes and traditions for genre and naturalistic detail in sets such as "The Battle of Pavia" (Museo e Gallerie Nazionali di Capodimonte, Naples), "The Story of Abraham" (Madrid and Vienna), "The Story of Tobias" (Vienna), and "The Hunts of the Emperor Maximilian I" (before 1528; Louvre, Paris). Among his followers in the first half of the 16th century were the Flemish painters Pieter Coecke van Aelst (1502–50), Jan Vermeyen (*c.* 1500–59), and Michel Coxcie (1499–1592). It was not only the cartoonists of Brussels who achieved international reputations but also the weavers of the early 15th century. Among the best known are Pieter van Aelst, Pieter and Willem Pannemaker, and Frans (active *c.* 1540–90) and Jacob Geubels (active *c.* 1580–1605).

Other limited centres of tapestry making in 16th-century Flanders were Antwerp, Bruges, Enghien, Oudenaarde, Grammont, Alost, Lille, and Tournai. Perhaps the most distinctive type of tapestry produced in these cities was the *verdures* of Enghien and Oudenaarde. French tapestry weaving, after its eclipse in the 15th century when nomadic weavers seem to have been more active than established shops, owes much of its eventual prestige to an unusual degree of royal patronage. This resulted in the 17th century in the foundation of the Gobelins and Beauvais state factories, the names of which have now become household words. A prelude to this development was the factory established by Francis I in 1538 near Paris at the château of Fontainebleau to make tapestries for his royal residences. Staffed by Flemish weavers, the cartoons were largely furnished by two Italian Mannerist artists, Francesco Primaticcio (1504–70) and Rosso Fiorentino (1494–1540), who were court painters to the King.

French trompe-l'oeil tapestries

The six tapestries (Kunsthistorisches Museum, Vienna), based on their murals for the Galerie des Réformes in the château, are the first tapestries in which sculpture as well as painting is imitated in the highly illusionistic manner of a trompe-l'oeil (fool-the-eye) effect.

The Fontainebleau workshop, which was active for only 12 years, provided the springboard for subsequent developments in Paris, where in 1551 Henry II established and endowed with special privileges the Hôpital de la Trinité factory.

In the first third of the 16th century, Franco-Flemish weavers and small court workshops continued to supply the only indigenous Italian tapestry. Weaving was done in Genoa, Verona, Venice, Milan, and Mantua. The first internationally important Italian tapestry factory was established in 1536 in Ferrara by Duke Ercole II of the House of Este. The Arrazeria Medicea founded in 1546 in Florence by the Medici grand duke Cosimo I (1519–74) was the most important tapestry factory instituted in Italy during the 16th century and survived into the early 18th century. It was headed initially by the famous mid-15th-century Flemish weavers Nicolas Karcher and Jan van der Roost, both of whom had worked in the Ferrara workshop of Duke Ercole II.

Cartoons were designed by such leading Mannerist artists of Florence as Jacopo Pontormo (1494–1556/57), Francesco Salviati (1510–63), Bronzino (1503–72), and Bachiacca (1494–1557), who designed the "Grotesques" (*c.* 1550; Uffizi, Florence), one of the most famous and influential tapestry sets produced by the Arrazeria Medicea.

The major textile art in medieval England was embroidery. When woven tapestries were needed, they were imported from Flanders. Although occasional references to Arras weavers in England date from the 13th century and a few indigenous armorial tapestries have survived from the 15th century, it was only after the middle of the 16th century that the English organized tapestry works. The first important workshops were set up in Bercheston (Warwickshire) by a wealthy squire, William Sheldon (died 1570). They initially produced cushion covers and small hangings of heraldic and ornamental subjects. A later specialty of these shops was a series of topographic tapestries. Woven in 1588 from contemporary maps of the Midland counties, these tapestries featured bird's-eye views of hills, trees, and towns, surrounded, according to the custom of the period, by Flemish-styled borders of architectural and figural ornament. Many of the men who worked in these shops were Flemings who had fled the mid-16th-century religious persecutions in the Lowlands.

German court factories

Germany was one of the first regions to receive Flemish weavers fleeing religious persecution in the Lowlands. Their small workshops prospered in such cities as Cologne, Hamburg, Kassel, Leipzig, Torgau, Lüneburg, Frankenthal, and Stuttgart. Most of the works produced were in the Flemish style. In Switzerland, on the other hand, where tapestry making had flourished in the 14th and 15th centuries, the industry almost ceased to exist except around Basel and Lucerne.

17th and 18th centuries. It was due to the initiative of Henry IV, whose planning of his nation's economy emphasized the luxury production that has since been commercially important in France, that decisive steps were taken in establishing a French tapestry industry. In 1608 Henry gave official recognition to the French workshop (using the high-warp method) of Girard Laurent and Dubout by establishing them in the Louvre, and at the same time he encouraged the immigration of Flemish weavers practicing the low-warp method who would help Paris to compete with the flourishing industries of Brussels and Antwerp.

At the turn of the 16th–17th centuries, two Flemish weavers had been taken to France by government arrangement to establish low-warp looms in Paris: François de La Planche (or Franz van den Planken; 1573–1627)

and Marc de Comans (1563–before 1650). Satisfactory working conditions were found for them in the old Gobelins family dyeworks on the outskirts of the city, and so began the establishment commonly known by that name that has lasted ever since. One of its first ambitious productions was an allegorical invention lauding Catherine de Médicis under the guise of Artemisia. The cartoons for this set were chiefly by the French Mannerist painter Antoine Caron (*c.* 1515–93). The Baroque verve and vitality of the Flemish painter Peter Paul Rubens (1577–1640) and Simon Vouet (1590–1649) brought new life to French designs in the early 17th century.

De La Planche died in 1627 and was succeeded by his son, who broke with the Comans family and moved to the Faubourg Saint-Germain-des-Près, leaving the Comans at the Gobelins. Competition became bitter, but both continued to produce a considerable quantity, as well as good quality, until they were superseded in 1662 by the royal factory, which purchased the Gobelins works at its location.

Establishment of the Gobelins factory

The Gobelins was officially established in 1667, receiving the title Manufacture Royale des Meubles de la Couronne ("Royal Factory of Furnishings to the Crown"). Initially it included all the king's artisan corps (tapestry weavers, cabinetmakers, goldsmiths and silversmiths, etc.) that produced furnishings for the royal residences, especially the château of Versailles. Louis XIV's finance minister, Jean-Baptiste Colbert (1619–83), always alert to profitable opportunities, recruited skilled personnel not only from the de La Planche and Comans shops but also from the old Louvre enterprise and thus established a new tapestry works with both high- and low-warp looms. The Gobelins' first director was the painter Charles Le Brun (1619–90), who had managed the short-lived royal tapestry works established in 1658 by Colbert's predecessor, Nicolas Fouquet (1615–80), at his château of Vaux-le-Vicomte near Paris. Le Brun applied himself with prodigious energy to his new position and proved to have a special talent for the task of celebrating the glory of Louis XIV. Among the most important sets he designed were "The Elements," "The Seasons," "The Child Gardeners," "The Story of Alexander," and, above all, the "Life of Louis XIV" and the "Royal Residences" (most of these sets are in the possession of Mobilier National in Paris).

When Le Brun died, the painter Pierre Mignard (1612–95) became director. The draining of the royal treasury closed the Gobelins in 1694. The factory opened again in 1699, when a lighter spirit was introduced into tapestry design by the decorative inventions, especially grotesques, of Claude Audran III (1658–1734), who designed such sets as "The Grotesque Months" and "The Portières of the Gods."

Louis XV (1710–74), in his turn, was celebrated in a set of "Hunts" by the Rococo painter Jean-Baptiste Oudry (1686–1755). Oudry was director of the Gobelins from 1733 until his death in 1755, when he was succeeded by François Boucher (1703–70), the outstanding artist-director of the 18th century. Boucher and Charles-Antoine Coypel (1694–1752), a Rococo painter, designed many of the popular *alentours* tapestries, in which the central subject, presented as a painting bordered by a frame simulating gilded wood, is eclipsed by the rich use of ornamental devices surrounding it. Boucher's "Loves of the Gods" were also *alentours* and enjoyed a great success and popularity, especially among the English nobility. "The Story of Don Quixote" (Mobilier National, Paris) was designed by Coypel and woven nine times between 1714 and 1794.

Alentours tapestry

Oudry's sophistication and polished elegance posed new problems for the weavers. Now indeed it was necessary for them to learn to paint with a bobbin, and to this end hundreds of new dyes were perfected for both wool and silk, until about 10,000 hues were available, to effect almost imperceptible tonal modulations; and interlocking of the wefts was introduced to render the transitions practically invisible, while the finest textures practical were used.

The Gobelins succeeded in surviving the French Revolution. Napoleon as emperor, like Louis XIV, desired an art of apotheosis and ordered a set of tapestries (1809–15; Mobilier National, Paris) that were devoted to his reign. Paintings by such French Neoclassical painters as Jacques-Louis David (1748–1825), Carle Vernet (1758–1836), and Anne-Louis Girodet-Trioson (1767–1824) were woven into tapestries in the late 18th and early 19th centuries.

The Beauvais factory

Another major state-subsidized factory established in 1664 at Beauvais had been carried on by two Flemings, Louis Hinart for 20 years and Philippe Behagle for 27 more. It was administered in much the same way as the Gobelins. Beauvais, however, was a private enterprise with royal patronage intended to produce tapestries for the nobility and the rich bourgeoise, while Gobelins' work was only for the king.

Two types of decorative panels were particularly developed at Beauvais in the late 17th century, the architectural composition and the grotesque. The former, such as in the set of "Marine Triumphs" (1690; Banque de France, Paris), usually shows a complex fantasy architecture reminiscent of Baroque stage sets. In the latter, architectural tracery defines a complex of panels, framing a medley of festoons, scarves, vases, musical instruments, putti, masks, and comedy actors, such as in "The Rope Dancer and the Dromedary" (*c.* 1689; Mobilier National, Paris).

Both Oudry and Boucher designed for the Beauvais factory. The "Fables of La Fontaine," by Oudry, were among the most popular tapestries of the 18th century. In 1736 Boucher designed Italian genre scenes for the set "Village Festivities" and later in the "Second Chinese Set" did Chinese fantasies. He also designed various pastoral scenes with titillating overtones. The Beauvais factory became noted for tapestry to upholster furniture with and

Fauteuil (armchair) covered with Beauvais silk tapestry, first quarter of the 19th century. In the Mobilier National, Paris.

panels for screens. These were usually floral designs and in the 19th century were especially fashionable in finely woven silk. By the end of the century, though technical standards were maintained, artistic deterioration set in.

The Aubusson–Felletin factory

Factories at the neighbouring old tapestry-making communities of Aubusson and Felletin, which had operated for a century and a half as modest private undertakings, were allowed to use the royal Aubusson mark as of 1665. From a small house industry, in which weavers independently produced inexpensive tapestries on their own low-warp looms for a bourgeois clientele, the tapestry makers soon produced hangings, upholstery fabrics, and carpets in Aubusson. The most effective tapestries are the chinoiseries, or genre fantasies set in China, a theme popular in Rococo art. Those designed by Jean Pillement

18th-century French tapestry.
"The Pagoda," chinoiserie tapestry woven at Aubusson and designed by Jean Pillement, 18th century. In the Mobilier National, Paris. 2.85 × 5.84 m.

(1728–1808) are especially famous. Coarse and rather dull, the *verdures*, or "garden tapestries," which were the first Beauvais tapestries, were made in quantities. Aubusson architectural panels either imitate those of the Gobelins and Beauvais factories, often with more complex elements and the addition of animals, or depict a damasked wall hung with a painting or cluster of decorative objects and garlands. The factory was especially successful in its production of carpets with conventional geometric ornamental motifs or floral designs.

The dominant influence on the Brussels industry of the 17th century was the Antwerp painter Peter Paul Rubens, whose most famous set was the "Triumph of the Eucharist" (1627–28). Imitations and adaptations of his style were legion. Heavy and elaborate columns were often substituted for side borders. On a more modest scale are the tapestry versions of genre paintings by David Teniers the Younger (1610–90), in which the border frequently simulated the actual picture frame.

The first major tapestry factory to be established in Germany was founded in 1604 in Munich by Duke Maximilian of Bavaria. The designers and weavers were all Flemish. Although the factory closed after only 11 years of operation, the quality of its workmanship was outstanding. Following the loss of religious freedom in France when the Edict of Nantes was revoked in 1685, many French weavers, especially from the Aubusson factory, sought refuge from persecution in Germany as had the persecuted Flemish weavers of the 16th century. The workshop established in 1686 in Berlin by the great elector Frederick William of Brandenburg (1620–88) employed many of these displaced Aubusson weavers. It produced tapestries mainly for the palaces built by the Great Elector's son, King Frederick I of Prussia (1657–1713), after whose death the factory closed.

French designers and weavers continued to produce a large number of tapestries in the 18th century. Tapestry production was centred principally in Munich, Berlin, Würzburg, Dresden, Schwabach, and Erlangen.

Scandinavian folk tapestry

In Scandinavia tapestries for the Danish and Swedish royalty were woven in Copenhagen and Stockholm. The weavers and designers were usually French and Flemish. Norway and Sweden continued to produce folk tapestries. Of the nearly 1,300 registered Norwegian tapestries,

By courtesy of the Kunstindustrimuseet, Oslo

"The Feast of Herod," tapestry from Gudbrandsdal, Norway, 17th century. In the Kunstindustrimuseet, Oslo. 1.96 × 1.37 m.

approximately 1,250 originated in small rural communities. These tapestries were usually coarse in texture, stylized and schematic in design, and boldly coloured.

James I established in 1619 by royal charter a factory

of tapestry weaving at Mortlake near London. It was staffed by 50 Flemings. Philip de Maecht, a member of the famous late-16th- and 17th-century family of Dutch tapestry weavers, was brought from the de La Planche-Comans factory in Paris, where he had been the master weaver, to hold the same position at Mortlake. The royal factory flourished under the patronage of the Stuart monarchs James I and Charles I. Many of the early tapestries produced at Mortlake were modelled after hangings woven in Brussels. Rubens supplied cartoons and in 1623 suggested to Charles I the purchase of seven of the Raphael cartoons for the "Acts of the Apostles." A new set was woven from these cartoons at Mortlake and is preserved at the Mobilier National in Paris. The redesigned borders have been attributed to the renowned Flemish painter to the English court, Sir Anthony Van Dyck (1599–1641). Weathering the Puritan austerity of the Commonwealth period, the factory deteriorated under Charles II and closed in 1703.

From the late 17th century Francis Poyntz (died 1685) and his brothers had a studio in Soho, where a number of weavers originally employed in the royal factory produced a distinct style of tapestry based on Chinese and Indian lacquerwork.

Cardinal Francesco Barberini, the nephew of Pope Urban VIII, in 1633 established a tapestry factory in Rome. Even though it enjoyed papal patronage, it lasted only until 1679. Clement XI tried to establish another Roman tapestry works in 1710, which also failed. During the 18th century other small factories briefly existed in Turin and Naples. They were staffed mainly with weavers left unemployed by the closing of the Medici factory (Arrazeria Medicea) in Florence.

During the 15th and 16th centuries Franco-Flemish tapestries were imported in great quantities, and Flemish weavers were invited to Spain in order to repair and care for them. For a short time in the 17th century a factory, established by Philip IV (1605–65), operated at Pastrana near Madrid. It was not until Philip V (1683–1746) established the Real Fábrica de Tapices y Alfombras de Santa Barbara (Royal Factory of Tapestries and Rugs of St. Barbara) in 1720 at Madrid, however, that important tapestry was produced in Spain. Initially, the weavers and director were Flemings. The first tapestries made at Santa Barbara were woven from the cartoons of such Flemish Baroque painters as David Teniers the Younger (1610–90) and Philips Wouwerman (1619–68) or based on famous paintings by such Italian artists as Raphael (1483–1520) and Guido Reni (1575–1642). When the early Neoclassical painter Anton Raphael Mengs (1728–79) became director, the factory entered its most brilliant period of production. The Spanish painter Francisco Bayeu (1734–95) and his painter son-in-law Francisco Goya (1746–1828) were commissioned to make cartoons. From 1777 to 1790 Goya made 43 cartoons for the "Los Tapices" ("The Tapestries") series depicting Spanish daily life. The painted models for this are among the finest works of Goya's Rococo style.

The French destroyed the factory in 1808, but after the Napoleonic occupation, production was resumed until 1835. The tapestries produced during this period were largely copies of works woven in the 18th century.

A tapestry factory staffed by weavers from the Gobelins was established at St. Petersburg (now Leningrad) in 1716 by Tsar Peter the Great (1672–1725). Although tapestries were produced until 1859, production was often plagued with difficulties. The most striking designs were a set of grotesques (1733–1738) and a series of portraits, of which the ones of Catherine the Great (1729–96) are the most noteworthy.

19th century and 20th century. Most 19th-century tapestries reproduced paintings or previously woven designs. The influence of the Industrial Revolution was inescapable, of course, not only in tools, materials, and dyes but in the new middle class market and its demands. Machine-made tapestry, although an achievement in mechanical weaving, became a threat to the survival of the original handcraft.

The necessity for the revitalization and purification of the tapestry art was first recognized by the artists associated with the Arts and Crafts Movement in late-19th-century England. Decrying the loss of individual creativity, they revived the ideals of medieval craftsmanship in an attempt to counter the effects of industrialization on the decorative or applied arts. The leader and most important figure of the movement was the artist William Morris (1834–96), who established a tapestry factory at Merton Abbey in Surrey near London. For about 15 years he and his associates had been designing not only for looms but also for pictorial wall decorations and stained-glass windows. They were well prepared professionally, therefore, to design tapestries. Morris and the painter-illustrator Walter Crane (1845–1915) contributed cartoon sketches, but most Merton tapestries were designed by the Pre-Raphaelite painter Sir Edward Burne-Jones (1833–98).

Influence of the Arts and Crafts Movement

More venturesome than any of the Merton Abbey products were the tapestry designs made in the 1880s by the artist and architect Arthur Heygate Mackmurdo (1851–1942), who in 1882 founded the Century Guild, the first of many groups of artists-craftsmen-designers to follow the teachings of William Morris. This tradition, influenced by the tapestry revival in mid-20th-century France, has continued in Scotland. The most ambitious 20th-century tapestry designed by a British artist, Graham Sutherland's (1903–) enormous "Christ of the Apocalypse" (1962) for Coventry Cathedral, was, however, woven on Aubusson looms in France. This is the largest tapestry ever to have been made there (23.80 by 11.60 metres; 78 feet 1 inch by 38 feet 1 inch).

In Europe during the late 19th century there was a resurgence of tapestry based on folk traditions. This trend was already apparent in Norway shortly after 1890, when special efforts were made to base a modern tapestry art on native medieval weavings. The leaders were Gerhard Munthe (1849–1929), a well-known painter, and Frida Hansen (1855–1931), a weaver who studied the peasant craftsmanship of Norway and evolved an individual, light, and open weave. More recent developments in Scandinavia have been made in Sweden and Finland. Märta Måås-Fjetterström (1873–1941) is the best known Swedish tapestry artist, and her atelier continued to produce excellent works. In Finland a freer, more colourful art, more delicately scaled, has been practiced by many; among the best known are Martta Taipale, Laila Karttunen, and, for damask tapestry, Dora Jung (1906–).

Folk traditions in modern European tapestry

In Norway and to a lesser degree in Denmark similar work has been done. The church in the Scandinavian countries has been unusually receptive to this art. Traditional folk weaving has also been behind the revival of tapestry making in Czechoslovakia, Hungary, and Yugoslavia since World War I. Poland has produced especially original designs executed in a remarkably free technique. Following the tradition of heavy-grained native weaving, mid-20th-century Polish designer-weavers such as Magdalena Abakanowicz (1930–) and Wojciech Sadley (1932–) used unconventional materials such as jute, sisal, horsehair, raffia, etc., in abstract tapestries that emphasize the nature of the material, tactile stimulation, plasticity, or surface relief.

Germany, emulating Scandinavia, also began a revival of tapestry weaving around the turn of the century. In the state of Schleswig-Holstein a small tapestry industry was set up from 1896 to 1903 at Scherrebek, followed by similar enterprises at nearby Kiel and Meldorf. The most significant development, however, occurred at the design school of the Bauhaus, where tapestry was created during the 1920s and early 1930s. Abstract in composition, the Bauhaus designs were deeply rooted in the theory that the technology of the craft should be revealed in the work and in expressing the nature of the materials used, especially by the exploitation of heavy fibres as strong textural elements. Anni Albers, wife of the painter and Bauhaus instructor Josef Albers (1888–), became the chief practitioner of this kind of tapestry. Like most modern tapestry weavers, she also designed for the textile industry. After World War II, tapestry works were established in Munich and Nürnberg, and individual weavers worked throughout Germany and in Vienna. Among the Germans, unlike the French, stained glass, rather than tapestry, generated greater enthusiasm as a revived craft in the post-World War II period. A few individual designers worked on their own looms in the United States and Canada, where most large-scale tapestries continued to be imported from Europe. The Latin-American revival of indigenous folkcrafts aroused interest in tapestry making in Mexico and Panama. South American centres of tapestry art developed in Brazil, Chile, and Colombia.

Bauhaus tapestry

Modern tapestry design was hindered during the greater part of the 19th century in France by the academic administration of the state factories, although progressive artists began to be affected by the English Arts and Crafts movement in the late 1880s. The painters Paul Gauguin (1848–1903) and Émile Bernard (1868–1941) were among those who took an interest in tapestry weaving, though they did not actually do tapestry cartoons as did Aristide Maillol (1861–1944). It was not until after World War I that France initiated and led the 20th-century revitalization of tapestry as an art. Many of the great modern artists of the school of Paris—Pablo Picasso 1881–1973), Georges Braque (1882–1962), Henri Matisse (1869–1954), Fernand Léger (1881–1955), Georges Rouault (1871–1958), and Joan Miró (1893–), among others—permitted their works to be reproduced in 1932. It was done with extraordinary fidelity under the supervision of Marie Cuttoli, a Paris connoisseur and promoter of exceptional taste. The Aubusson factory, chosen for this important weaving, became once again a great centre for tapestry. The direct translation of painting into tapestry, however, left little scope for the weaver, and it is the trend begun simultaneously by Jean Lurçat (1892–1966) that may be said to have truly inaugurated the 20th-century tapestry renaissance. Although he began experimenting in 1916, Lurçat's art did not become definitive until the 1930s, when under the impact of Gothic tapestry, particularly the 14th-century "Angers Apocalypse," and in collaboration with François Tabard (1818–69), master weaver at Aubusson, he formulated the principles that were to make tapestry once again a joint creation between artist and weaver—an art in its own right. No longer merely an imitation painting, tapestry once again exploited the coarser texture and the bolder but more limited range of colours that characterized medieval hangings.

French revitalization of the tapestry art

In 1947 Lurçat founded the important Association des Peintures-Cartonniers de Tapisserie (Association of Cartoon Painters of Tapestry). Also active in this organization were the important French tapestry designers Marc Saint-Saëns (1903–) and Jean Picart Le Doux (1902–), who were Lurçat's foremost disciples. Lurçat was held in great esteem by Dom Robert (1907–), a Benedictine monk whose tapestries of poetic fantasy were largely inspired by Persian and medieval European manuscript illumination. Other major French designers of representational compositions were the artists Marcel Gromaire (1892–1971) and Henri Matisse and the architect Le Corbusier (1887–1965).

In the 1950s tapestry designs became increasingly abstract. Among the most notable pieces were those designed by the sculptor and printmaker Henri-Georges Adam (1904–1967). Using only black and white, his tapestries are monumental tonal abstractions that reflect his work as an engraver. The sculptor Jean Arp (1887–1966) and the painter Victor Vasarely (1908–) are other abstract designers of postwar tapestries.

After World War II the Belgians, influenced by the weaving activity in France during the 1930s, revived their tapestry industry. In 1945 the Forces Murales movement was organized in Tournai by a group of cartoon painters including Louis Deltour (1927–), Edmond Dubrunfaut, and Roger Somville (1923–), who became the leading designers of Belgian tapestries. This was followed in 1947 by the organization in Tournai of a collective tapestry workshop, Centre de Rénovation de la Tapisserie,

active until 1951. Small workshops continued to flourish in Belgium, especially in the cities of Tournai, Brussels, and Malines.

The renewed international interest in tapestry is clearly related to the austerity of modern architecture. Suitable settings for large-scale wall hangings are provided by the often vast expanses of bare wall surface in contemporary buildings. Le Corbusier not only used tapestries to decorate his architectural interiors but designed them. He frequently referred to tapestries as nomadic murals, recognizing their importance as movable and interchangeable decoration.

In 1962 the first international exhibition of tapestry was held at Lausanne in Switzerland, which after 1965 became an important biennial event. This exhibition clearly demonstrates the tremendous worldwide interest in the medium generated in the middle 20th century as well as indicating the immense variety of tapestry designs, materials, and techniques.

Tariffs

A tariff, or duty, is a tax levied on a commodity when it crosses the boundary of a customs area. The boundary may be that of a nation or a group of nations that have agreed to impose a common tax on goods entering their territory. Tariffs are often classified as either protective or revenue. Protective tariffs are designed to shield domestic production from foreign competition by raising the price of the imported commodity. Revenue tariffs are designed to obtain revenue rather than to restrict imports. The two sets of objectives are, of course, not mutually exclusive. Protective tariffs, unless they are so high as to keep out imports, yield revenue. Revenue tariffs give some protection to any domestic producer of the duty-bearing goods. A transit duty, or transit tax, is a tax levied on commodities passing through a customs area en route to another country. Similarly, an export duty, or export tax, is a tax imposed on commodities leaving a customs area. Finally, some countries provide export subsidies; import subsidies are rarely used.

Tariffs on imports may be applied in several ways. If they are imposed according to the physical quantity of an import (so much per ton, per yard, per item; etc.), they are called specific tariffs. If they are levied according to the value of the import, they are known as *ad valorem* tariffs.

Tariffs may differentiate among the countries from which the imports are obtained. They may, for instance, be lower between countries that have previously entered into special arrangements, such as the trade preferences accorded to each other by members of the British Commonwealth.

Tariffs may affect the economy of the country imposing them in a number of ways. By raising the prices of imported goods, tariffs may encourage domestic producers to increase production. As expenditures on domestic products rise, domestic employment tends to do likewise. This is why tariffs are favoured by industries that find themselves pressed by foreign competitors. The tariff may also encourage tendencies toward a monopolistic market structure to the extent it lessens foreign competition, with a resulting decrease in the incentive to modernize or innovate. But a tariff by increasing the price of a commodity may also reduce its consumption, depending on how consumers react to the higher price. If enough of them curtail purchases, the decrease in demand may be large enough in relation to the world market to force the price of the import down. This would register as an improvement in the tariff-imposing country's terms of trade. In other words, if export prices remained stable, the country would be paid the same amount for its exports but pay less for its imports.

Nontariff barriers. Other government regulations and practices may also act as barriers to trade. In some countries sales and turnover taxes are imposed on imports but are rebated on goods destined for export; if such taxes apply at identical rates to domestically produced commodities, foreign goods receive equal treatment. By contrast, excise taxes discriminate against foreign goods if they are levied on commodities that cannot be produced domestically.

Quotas or quantitative restrictions may prohibit the importation of certain commodities or limit the amounts imported. Such quotas are usually administered by requiring importers to have licenses to bring in particular commodities. Quotas raise prices just as tariffs do, but, being set in physical terms, their impact on imports is direct, with an absolute ceiling set on supply. Increased prices will not bring more goods in. There is also a difference between tariffs and quotas in their effect on revenues. With tariffs, the government receives the revenue: under

quotas, the import license holders obtain the revenue in the form of the difference between the high domestic price and the low international price of the import. Quotas are used to regulate oil imports in the United States; in other developed countries they serve to protect agriculture; and in a number of developing countries they are used in place of or in conjunction with tariffs, to prevent the outflow of money.

Still other barriers include state trading organizations and government procurement practices that may be used preferentially. In the United States, "buy American" legislation requires government procurement agencies to favour domestic goods. Finally, customs classification and valuation procedures, health regulations, and marking requirements may also have a restrictive effect on trade.

Measuring the effects of tariffs. It is difficult to gauge the effect of tariff barriers among countries. First of all, how import demand responds to changes in tariffs depends on a variety of factors—the reaction of producers and consumers to price changes, the share of imports in domestic production and consumption, the substitutability of imports for domestic products, and so on. And the responsiveness to tariff levels will differ from country to country as well as from commodity to commodity. Thus, the amount of a tariff does not necessarily determine its restrictive effect. For another thing, such comparisons also must be restricted to commodities for which tariffs are the major protective device. This is generally true for nonagricultural commodities in developed countries, but other devices are often employed to protect agricultural production. In the third place, a tariff levied upon imports of raw materials will protect domestic raw material producers but will increase the costs of manufacturers using those raw materials. It is necessary, therefore, to distinguish between nominal and effective rates of protection.

Figuring the effective rate of protection

One way of measuring effective protection is to take the value added in domestic production (*i.e.*, the value of output minus the costs of materials) after the imposition of tariffs and other protective measures and compare it with the value added before protection. To illustrate, consider a product (clothing) with an import price of 100, of which 60 represents the costs of material inputs (textile fabrics). The value added in manufacture is therefore 40. A 20 percent tariff on clothing would raise the domestic price by 20 to 120, while a 10 percent tariff on textile fabrics would increase material costs to the domestic producer by 6 to 66. Protection would thus enable the firm to operate with labour costs within a value-added margin of 54—the difference between the domestic price of 120 and the material cost of 66. The difference between the value added of 40 without tariff protection and that of 54 with it provides a margin of 14. That means that the effective rate of protection of the domestic processing activity—the ratio of 14 to 40—would be 35 percent.

The effective rate of protection also depends on the share of value added in the product price. Effective rates can be very high if value added to the imported commodity is a small proportion or very low if value added is a large proportion of the total price. Thus, effective protection in one country may be much higher than that in another even though its nominal tariffs are lower, if it tends to import commodities of a high level of fabrication with correspondingly low ratios of value added to product price.

The accompanying table shows the extent to which effective tariff levels differ from the nominal ones for principal industrial countries. The data pertain to manufactured products imported by the United States, the European Common Market, the United Kingdom, Sweden, and Japan—countries that between them account for four-fifths of world exports and about one-half of world imports of manufactured goods. The figures are estimated for the situation expected to obtain following the so-called Kennedy Round of tariff reductions negotiated in the 1960s. It is evident that effective rates of protection are generally much higher than nominal rates. This is explainable in part by the practice of setting higher tariffs on finished products in order to encourage the domestic processing of unfinished commodities, and in part by the absence of tariffs on nonmaterial inputs (services) that do not enter international trade. Among the five countries and country groups the overall average of nominal as well as that of effective tariffs is the highest in Japan, with the United Kingdom a close second, and Sweden at the opposite end of the scale. The United States and the European Economic Community occupy the middle ground.

Averages of Nominal and Effective Tariffs on Manufactured Products After the Kennedy Round

	percentages	
	nominal	effective
United States	6.8	11.6
United Kingdom	9.1	16.0
European Economic Community	6.6	11.1
Sweden	3.8	6.7
Japan	9.4	16.4

Efforts to liberalize trade. A great tide of protectionism rose during the depression of the 1930s, when industrial nations raised tariffs and other barriers to trade in an attempt to help domestic producers. Since most countries adopted these "beggar-my-neighbor" policies, the effect was to stifle trade. The gains to protected industries were offset by the harm to export industries. As the failure of these policies became apparent, proposals to stem the tide of protectionism and to reduce tariffs through multilateral agreement were put forward. Political and economic uncertainties prevented the realization of these goals in the years preceding World War II.

GATT, EEC, and EFTA

The post-World War II period witnessed several efforts to reduce tariff barriers. Prominent among these were the tariff reductions undertaken in the framework of the General Agreement on Tariffs and Trade (GATT) after that organization came into being in 1948. GATT members include virtually all major trading nations of the world, but only the more developed countries have participated in the successive rounds of tariff reductions. But such reductions are automatically applied to imports from developing member countries; under the most-favoured-nation clause, the contracting parties to GATT assume the obligation to extend to one another the tariff concessions accorded to any one member country.

Another central feature of GATT is the principle of reciprocity: mutual tariff concessions are designed to lead to equivalent increases in the exports and imports of each participant. The principles of nondiscrimination and reciprocity often conflict, since the agreed-upon tariff reductions are extended to countries not obliged to reciprocate. To lessen this effect of giving a "free ride" to third countries, much tariff bargaining was carried out on an item-by-item basis in the postwar period. This approach limited the scope of tariff reductions and, after initial successes, the progress of multilateral trade liberalization slowed down.

More comprehensive liberalizations occurred in the European Economic Community (EEC) and the European Free Trade Association (EFTA). The establishment of EEC and EFTA was made possible by Article 24 of the General Agreement on Tariffs and Trade, which provides for an exception to the principle of nondiscrimination; countries that mutually agree to abolish tariffs within a free-trade area or a customs union are not required to extend such concessions to other parties. The success of EEC and EFTA in reducing trade barriers was partly at the expense of outsiders, who were put in an unfavourable position in relation to member-country producers.

The Kennedy Round

This "trade diverting" effect of the EEC and EFTA, plus a desire to surmount the difficulties encountered with item-by-item tariff bargaining, underlay the U.S. initiative for trade liberalization under the Trade Expansion Act of 1962. Under that act, the Congress authorized the president to negotiate multilateral tariff reductions up to 50 percent on an across-the-board basis. The act brought about some important modifications in the traditional

method of tariff bargaining. The replacement of bilateral negotiations by across-the-board reductions in tariffs, with exceptions granted through an escape clause in the case of especially sensitive industries, made it possible to proceed with trade liberalization on a broad front. Firms injured by imports were to be given special assistance. The Trade Expansion Act led to the Kennedy Round of tariff reductions in 1967. In most cases tariffs were decreased by 50 percent, with smaller reductions for sensitive industries. On the average, tariff reductions on nonagricultural commodities amounted to about 35 percent. The Kennedy Round represented an important step toward international trade liberalization, but there was no indication that it would be followed by negotiations of a similar scope in years to come.

Protectionism in the less developed countries. The industrialization that has taken place in the postwar years in the developing countries has been characterized by the expansion of import-competing industries behind high tariff walls. In many of those countries tariffs and various quantitative restrictions on manufactured goods lie in the 100–200 percent range. The effective rates of protection are even greater, because the goods tend to be highly fabricated and the proportion of value added in production after importation is low. While some countries such as Hong Kong, Taiwan, and Korea have oriented their manufacturing industries mainly toward export trade, those are exceptional cases in the developing world. More commonly the new industries seek to compete with foreign-made goods for the domestic market. High protection in these countries has often contributed to a slowdown in the production and export of primary commodities and has discouraged expansion of exports of manufactured goods. Furthermore, while domestic production of nondurable consumer goods has permitted rapid economic growth at an early stage, developing countries have encountered considerable difficulties in producing more sophisticated commodities. They suffer the disadvantages of small domestic markets, along with a lack of incentives for technological improvement.

Arguments for and against tariffs. *The infant industry argument.* Advocates of protection often argue that new and growing industries, particularly in less developed countries, need to be shielded from foreign competition. They contend that costs decline with growth and that some industries must reach a minimum size before they are able to compete with well established industries abroad. Tariffs can protect the domestic market until the industry becomes internationally competitive and, it is often argued, the costs of protection can be recouped after the industry has reached maturity. This justification of tariffs is often abused. In many developing countries, industries have failed to attain international competitiveness even after 15 or 20 years of operation and might not survive if protective tariffs were removed. The infant industry is probably better aided by production subsidies than by tariffs. Production subsidies do not raise prices and therefore do not curtail domestic demand; and the cost of the protection is not concealed in higher prices to consumers. Production subsidies have the disadvantage of drawing upon government revenue rather than adding to it, which may be a serious consideration in countries at lower levels of development.

The employment argument. Tariffs raise import prices and tend to shift demand from imported to domestic products. Tariffs may therefore stimulate domestic employment. In developing countries, protection for the purpose of increasing employment may involve a misuse of scarce resources such as capital and entrepreneurship, but it is defensible if the employment objective is of paramount importance. In trade among developed countries, however, imposing tariffs for employment reasons means exporting unemployment to other countries, and it therefore invites retaliation.

Other arguments. One hypothesis in the theory of trade is that countries will tend to specialize in producing commodities that use relatively more of the factors of production that they have in abundant supply. For instance, a country with relatively more capital than labour will tend to specialize in goods that require more capital per unit of labour than other goods and to import labour-intensive goods. If, however, imports are restricted by tariffs, production will shift toward labour-intensive industries, increasing the demand for labour, and hence the wage rate.

Economists in developing countries have argued that, in order to attract labour, industry has to pay higher wages than agriculture and that tariffs are necessary to compensate the manufacturing sector for the higher cost of labour. The empirical evidence for such differential wage rates is not definitive, and therefore the worth of this argument must be evaluated case by case. Another frequently used argument for protection is based on the need to maintain so-called key industries that are vital for national defense. Domestic industries can be protected equally well, however, by subsidies. If the objective is to reduce dependence on foreign products, tariffs may be appropriate since they reduce both imports and the total consumption of the commodity in question. But the argument has lost much of its force in a world threatened by nuclear warfare.

Protection of key defense industries

As noted earlier, a country may be able to use tariffs to improve its terms of trade. But other countries may retaliate, and, furthermore, such power is not usually available to many countries over a long period. To the extent they restrict imports, tariffs also reduce the outflow of funds and thus may help remedy balance of payments deficits. This objective has been important in the less developed economies. A serious deficit in the balance of payments, however, calls for more fundamental treatment, such as devaluation of the currency.

In advanced industrial countries, tariffs result mainly from the political pressures of producers in particular industries. The costs of such protection are borne by consumers in general. The pressures of special interests on the parliaments and legislatures of industrialized countries are far more intense and sustained than the counterpressures from consumers, both in establishing tariffs and maintaining them once they exist.

BIBLIOGRAPHY. Elementary treatments of the theory and practice of tariffs may be found in standard textbooks on international economics, prominent among which are C.P. KINDLEBERGER, *International Economics*, 4th ed. (1968); and D.A. SNIDER, *Introduction to International Economics*, 4th ed. (1967). A more advanced treatment of the theory may be found in J. VANEK, *International Trade: Theory and Economic Policy* (1962).

Institutional and historical studies of tariffs are A. ISAACS, *International Trade: Tariff and Commercial Policies* (1948); and F.W. TAUSSIG, *The Tariff History of the United States*, 8th ed. (1967).

An analysis of the economic and political consequences of trade liberalization may be found in B.A. BALASSA, *Trade Liberalization Among Industrial Countries* (1967). Accounts of the General Agreement on Tariffs and Trade (GATT) may be found in G. CURZON, *Multilateral Commercial Diplomacy* (1965); and G. PATTERSON, *Discrimination in International Trade: The Policy Issues, 1945–65* (1966). On related issues, see also G. and V. CURZON, *After the Kennedy Round: What Trade Policies Now?* (1968).

Treatment of U.S. foreign economic policy may be found in P.B. KENEN, *Giant Among Nations* (1963); and W.B. KELLY (ed.), *Studies in United States Commercial Policy* (1963).

Tarim River

The Tarim River (T'a-li-mu Ho) is the chief river of the Sinkiang Uighur Autonomous Region of China, an area situated immediately north of the Tibetan Plateau. It flows for most of its length through the Takla Makan Desert, although part of the watershed is located within mountainous territory of the Soviet Union.

Physical characteristics. The word *tarim* means a bank of a river that flows into a lake or that is undifferentiable from the sands of a desert. This is a characteristic hydrographic feature of many rivers that traverse the sands of

the Takla Makan Desert. Another characteristic of the rivers of the Tarim Basin, including the Tarim itself, is their active migration—*i.e.*, the shifting of their beds and banks.

The Tarim is formed by the confluence of the K'a-shih-ka-erh (Kyzylsu in the U.S.S.R.) and Yarkand rivers in the west, and by the A-k'o-su Ho and the Ho-t'ien Ho (Khotan) some 230 miles downstream. Only the A-k'o-su Ho flows for the entire year. It is the Tarim's most important tributary, supplying 70–80 percent of its water volume. The name Tarim is used after the Ho-t'ien Ho confluence. The total length of the Yarkand–Tarim river system is 1,260 miles (2,030 kilometres), although as the Tarim frequently changes its channel, the length tends to vary over the years. The area of the Tarim River Basin, including the basins of T'ai-t'e-ma Hu (T'ai-t'e-ma Lake), which is also known as Kara Buran Köl, and Lop Nor (Lop Lake), is 367,400 square miles (951,500 square kilometres). A considerable part of the Tarim is unformed, following no clearly defined riverbed. Here, as a result of extensive evaporation, the downstream volume of river water regularly decreases. This natural process of dispersion of the river's water is abetted by the diversion of water for irrigation. In the past, the waters of the Tarim merged with those of the Kunlun Mountains: the Ni-ya, the K'o-li-ya, and other smaller rivers. Presently, however, these rivers have been lost in the sands of the Takla Makan.

Irregularity of the Tarim's course

From the confluence of the Yarkand, Ho-t'ien, and A-k'o-su to the populated point of Sha-ya, the Tarim winds through a valley with cultivated bottomlands, the valley having widths to 3,300 feet and a clearly defined terraced relief with elevations of 13–20 feet. East of the settlement of Sha-ya, the river strays over the alluvial valley floor, generating many streams of varying size and nourishing numerous lakes and marshy areas. Below the village of Wei-li, the river valley narrows, and the Tarim approaches the K'ung-ch'iao Ho flowing toward the east and Lop Nor. In some years when the main volume of water in the Tarim is contributed by the K'ung-ch'iao, Lop Nor is filled; but if, as a result of the migration of the riverbed, the waters of the Tarim flow to the southeast along the ancient lake plain, then Lop Nor dries up, and the waters fill T'ai-t'e-ma Hu, located several hundred miles to the south of Lop Nor.

The Tarim's low-water period is from October through April. The spring and summer high waters begin in May, continuing through September.

The Lower Tarim Basin is a plain bordered by massive mountain ranges and composed of alluvium and lake sediments. A low, rocky ridge is situated in the western parts between the Yarkand and the Ho-t'ien rivers. The basin is the driest region of Eurasia and one of the most extraordinary regions in the whole world. The predominant part of the basin is occupied by the Takla Makan Desert, the sand area exceeding 105,000 square miles. In addition, there are several comparatively small sand massifs with areas of from 300 to 1,700 square miles. Sand dunes are the predominating desert relief. The large symmetrical ridges of friable sand, covered with sand dunes, have lengths up to 8 miles, widths of from 850 to 1,000 feet (sometimes up to 1,650 feet), and heights of from 100 to 500 feet. Outside the limits of the Takla Makan, there are wide stretches of salt flats, often having very thick salt crusts. The mineral content of the water increases from 200 milligrams per litre to 800 milligrams per litre from source to mouth.

Climate. Precipitation in the Tarim Basin is extremely scanty and, in some years, is nonexistent. In the Takla Makan Desert and in the Lop Nor plain, the average annual total of precipitation is 0.4–0.5 inch. In the foothills it increases to 1.6–2.4 inches. The western Kunlun mountains receive about 12 inches of precipitation a year, and in the remaining regions the total amounts to from two to four inches a year. In the Tien Shan (Tien Mountains) it is much wetter, precipitation often exceeding 20 inches. This decreases to from two to four inches a year in the ranges in the eastern end of the Tien Shan. The western part of the Tarim Basin receives westerly winds and the eastern part northeasterly winds. Maximum temperatures are around 104° F (40° C). The Tarim freezes over every year from December through March.

Vegetation and animal life. Vegetation in the Tarim Basin is mainly located along the river and its branches. Here, at the edge of the sands, shrublike vegetation and stunted trees, especially wormwood, is found. A thin forest of poplar is found in the Tarim Valley. Underbrush consists of willows, sea buckthorn, and dense growths of Indian hemp and Ural licorice. Poplar forests along the banks of the Tarim disappear downriver near the settlement of T'ieh-kan-li-k'o.

The Tarim is rich with fish, and animal life on the Tarim and the surrounding desert is varied. Such rare animals as the kulan (*Equus hemionus*), the wild two-humped camel (*Camelus bactrianus*), and the Siberian reindeer (*Cervus elaphus*) have survived. The wild boar (*Sus scrofa*), the jaran (a gazelle), and the hare (*Lepus tolai*) are frequently encountered. Predators include wolves and steppe foxes. Lynx and wildcat are occasionally found, and in the recent past tigers inhabited the region. The valley and lakes of the Tarim are used by migratory birds as a temporary stopover, those most frequently encountered including pintail duck, redbills, grey goose, cormorant, pochard, white tern, and long-legged heron.

Economic activity. The population of the area consists of various nationalities, basically Turkic. Uighurs and Uzbeks live along the Tarim and in the oases of the Tarim Basin, Tadzhiks in the western Kunlun Mountains and the Pamirs. Kirgizians and Mongols roam as far as the Nan Shan (Nan Mountains).

Irrigation works

The waters of the Tarim since ancient times have been used for irrigation. Such major oases as Kashgar, Khotan, Wei-li, and others are located in the basin. In recent years the area of irrigated land along the shores of the Ho-t'ien, Yarkand, A-k'o-su, and their main tributaries has rapidly increased. In addition to the irrigation system on the main rivers, dams have been created in the areas of the oases, protecting the surrounding land from flooding during the crest peaks of high water.

The lack of transport development has kept connections uncertain and movement both slow and costly. The Chinese have plans for marked development of several localities of the basin, but the comparatively small opportunities make them of relatively low priority, and, by the 1970s, little was achieved other than the political organization of the region and the settling of Chinese nuclei in most of the important oases. A few agricultural processing plants were established and resource exploration was begun.

Oasis agriculture remains the mainstay of the scattered settlements. Grains, cotton, silk, fruits, and wool are the chief agricultural products, and Khotan jades are the only other important item. Little is exported from the basin, but local surpluses find a market among travellers passing through when conditions permit. (N.T.K.)

Tasman, Abel Janszoon

Abel Janszoon Tasman, the greatest of Dutch navigators and explorers, was the discoverer of Tasmania, New Zealand, Tonga, and the Fiji Islands.

He was born at Lutjegast in Groningen in the Netherlands, probably in 1603. He entered the service of the Dutch East India company in 1632 or 1633 and made his first voyage of exploration to Ceram (modern Seram) Island (in modern Indonesia) as captain of the "Mocha" in 1634. He sailed in 1639 under Comdr. Mathijs Hendrickszoon Quast on an expedition in search of the "islands of gold and silver" in the seas east of Japan. After a series of trading voyages to Japan, Formosa, Cambodia, and Sumatra, he was chosen by the governor general of the Dutch East Indies, Anthony van Diemen, to command the most ambitious of all Dutch voyages for the exploration of the Southern Hemisphere.

By 1642, Dutch navigators had discovered discontinuous stretches of the western coast of Australia, but whether these coasts were continental and connected with

Tasman's voyage of 1642 to 1643

the hypothetical southern continent of the Pacific remained unknown. Tasman was to answer this problem, following instructions based on a memoir by Frans Jacobszoon Visscher, his chief pilot. He was to explore the Indian Ocean from west to east, south of the ordinary trade route, and, proceeding eastward into the Pacific (if this proved possible), to investigate the practicability of a sea passage eastward to Chile, to rediscover the Solomon Islands of the Spaniards, and to explore New Guinea.

Leaving Batavia (modern Djakarta) on August 14, 1642, with two ships, the "Heemskerk" and "Zeehaen," Tasman sailed to Mauritius (September 5–October 8), then southward and eastward, reaching his most southerly latitude of 49° S at about 94° E. Turning north he discovered land on November 24 at 42°20′ S, and he skirted its southern shores, naming it Van Diemen's Land (now Tasmania). A council of officers on December 5 decided against further investigation, so he missed the opportunity of discovering Bass Strait. Continuing eastward, he sighted on December 13, at 42°10′ S, the coast of South Island, New Zealand, and explored it northward, entering the strait between North Island and South Island supposing it to be a bay. He left New Zealand on January 4, 1643, at North Cape, under the impression that he had probably discovered the west coast of the southern continent, which might be connected with the "Staten Landt" (Staten Island), discovered by W.C. Schouten and Jacques LeMaire south of South America —hence the name of Staten Landt, which Tasman gave to his discovery in honour of the States General (the Dutch legislature).

Convinced by the swell that the passage to Chile existed, Tasman now turned northeast, and on January 21 he discovered Tonga and on February 6 the Fiji Islands. Turning northwest, the ships reached New Guinea waters on April 1 and Batavia on June 14, 1643, completing a ten-month voyage on which only ten men had died from illness. Tasman had circumnavigated Australia without seeing it, thus establishing that it was separated from the hypothetical southern continent.

The second voyage of exploration

The council of the company decided, however, that Tasman had been negligent in his investigation of the lands he discovered and of the passage to Chile. They sent him on a new expedition to the "South Land" in 1644 with instructions to establish the relationships of New Guinea, the "great known South Land" (western Australia), Van Diemen's Land, and the "unknown South Land." He sailed from Batavia on February 29, steering southeast along the south coast of New Guinea, coasting Australia's Gulf of Carpentaria, sailing northeast into Torres Strait, which he mistook for a shallow bay, and then following the east coast of Australia to 22° S.

Although he was rewarded with the rank of commander and was made a member of the Council of Justice of Batavia, his second voyage was also a disappointment to the company because it had failed to reveal lands of potential wealth. In 1647 Tasman commanded a trading fleet to Siam (now Thailand), and in the following year he commanded a war fleet against the Spaniards in the Philippines. He had left the service of the Dutch East India company by 1653 and died probably before October 22, 1659. (H.M.W.)

Tasmania

Location and general character of the state

The island state of the Commonwealth of Australia, Tasmania, lies about 150 miles (240 kilometres) south of the State of Victoria, from which it is separated by the relatively shallow Bass Strait. Physically, Tasmania forms part of the Great Dividing Range; culturally, it is part of Melbourne's metropolitan sphere of influence. The state comprises a main island called Tasmania; Bruny Island, nestling close to the southeast coast near Hobart, the capital; King and Flinders islands in Bass Strait; numerous smaller islands off the coast of the main island; and sub-Antarctic Macquarie Island, some 1,000 miles to the southeast. The main island is roughly heart-shaped, and its latitude and climate are broadly comparable to those of northern California and northwestern Spain. Its 26,383 square miles (68,332 square kilometres), although slightly larger than the area of Sri Lanka, comprise less than 1 percent of Australia.

The state owes its name to the Dutch navigator-explorer Abel Tasman, the first European to discover the island, in 1642, though until 1856 it was known as Van Diemen's Land, after the governor of the East Indies who had sent Tasman on his voyage of exploration. The island of Tasmania contains some of the most spectacular mountain, lake, and coastal scenery in the continent, has much of the country's hydroelectric-power potentiality, and displays a great diversity of natural resources. The Tasmanian population of 390,000 at the 1971 census was only 3 percent of the Australian total, however, and its growth rate lags behind that of the mainland. Throughout much of its history, Tasmania has experienced a net out-migration that has deprived the state of a wealth of talent but has contributed, perhaps disproportionately, to the leadership of the nation. Although insularity renders much of the political, economic, and social life distinctive, proximity to Melbourne and modern air travel make the island less isolated and more progressive than is often assumed in other states. (For related information, see AUSTRALIA; AUSTRALIA, COMMONWEALTH OF; AUSTRALIA, HISTORY OF.)

THE NATURAL AND HUMAN LANDSCAPE

The physical environment. *Topography.* Tasmania is essentially mountainous. In the west, where Mt. Ossa reaches 5,305 feet (1,617 metres), the landscape comprises parallel northwest–southeast ridges and valleys; eastward lies a series of plateaus at various altitudes, the highest being Ben Lomond at 5,160 feet (1,573 metres) in the northeast. But the dominant feature is the glaciated, lake-studded Central Plateau, bounded on the north and east by a 2,000-foot fault scarp and sloping gently southeastward from 3,500 to 2,000 feet (1,100 to 600 metres). Much of the east is made up of a low, dissected plateau averaging about 1,200 feet (365 metres). Extensive plains are confined to the far northwest, the lower South Esk River Valley, and the northeast. The Bass Strait islands represent outliers of the northern coastal platforms. In the southeast, postglacial submergence has produced one of the finest drowned coastlines in the world.

Major river systems

Drainage. There are two major river systems—the Derwent in the southeast and the South Esk in the northeast—many small systems, especially westward flowing to the west coast, and innumerable lakes. The Central Plateau is studded with more than 4,000 lakes in a landscape similar to northern Canada and Finland; almost all, including Great Lake, are shallow. Lake St. Clair, the deepest lake in Australia (over 700 feet [215 metres]), is a piedmont lake similar to the lakes of northern Italy. Several lakes, notably Lake King William, have been created by hydroelectric-power development.

Soils. Most Tasmanian soils are leached, acidic, poorly drained, high in humus, and low in fertility. Least fertile and most extensive are the soils, especially the moor peats, of the west and northeast. Fertile areas occur extensively in the northwest and locally elsewhere, notably in the northeast. Brown earths occupy the drier areas east of the Central Plateau; black earths, the southeast; and alluvial soils, the narrow valley floors to the east. Other fertile soils are those of former swamps in the far northwest and the Bass Strait islands.

Climate. Tasmania, located in the mid-latitude westerly wind belt and dominated by southern maritime air masses, enjoys a moist, equable climate, with mild to warm summers, mild winters in most settled areas, and rain during all seasons. Yet the occasional incursion, in summer, of tropical continental air masses and, in spring and autumn, of tropical Tasman air masses along the east coast, together with the mountainous surface, results in greater annual rainfall variability, seasonal moisture deficiencies, and temperature changes than are the norm in similar climates elsewhere. Climatic averages thus mask considerable variations. The average annual precipitation exceeds 100 inches (2,500 millimetres) on the western

Rainfall and temperature ranges

ranges and declines eastward to under 20 inches in some places; along the north coast it exceeds 30 inches in all locations. The seasonal incidence in the north and west is greatest in winter, and in the south and east it is greatest in spring. Summer rainfall may vary markedly from year to year, especially in the drier east. Mean January temperatures are higher in the north and east than elsewhere, reaching 64° F (18° C) at Launceston; mean July temperatures are 46° to 49° F (8° to 9° C) in all coastal stations, declining sharply with altitude. Almost everywhere, the mean daily range of temperature exceeds the mean annual range.

Vegetation and animal life. In general, the wettest areas have temperate rain forest, especially the beech or myrtle; areas having 30 to 60 inches of rain annually carry good-quality eucalypt forest; and the drier areas carry poor-quality eucalypt forest or savanna woodland. In certain areas, particularly in the forest of the south and southwest, an almost impenetrable thicket known as horizontal scrub develops. This is caused by the growth of a remarkable small tree called the horizontal (known scientifically as *Anodopetalum biglandulosum*). The slender trunk of the tree falls over under its own weight, and from it branches arise that behave in the same way. On the mountain plateaus are found many plants having subantarctic affinities. These include Tasmania's only deciduous tree or shrub, myrtle beech, and certain cushion plants. Rain forest would be more widespread in the absence of fires. Other vegetation includes the sedgeland along the west coast, the high moorlands, and the coastal heaths of the far northwest, the far northeast, and the Bass Strait islands.

Mammals

Animal life is virtually absent from the true rain forest but abounds in the extensive eucalypt forest. The avian fauna includes the honey eaters, the black jay, black magpie, the black cockatoo, and various parrots. Among the mammals are the wallaby, brush and ringtail possum, and the marsupial carnivores—the native cat, tiger cat, Tasmanian devil, and the rare thylacine. The sedgeland and moorland are distinctive for the wombat, and the coastal heath for the green rosella, the platypus, and the echidna.

The human imprint. The inhospitable terrain of much of Tasmania naturally has had much influence on settlement patterns. The nomadic original Tasmanians have left a few archaeological traces, including geometric designs on exposed rock surfaces and evidence of cremations and corroborees, or ceremonial gatherings. The European settler has left his imprint according to economic activity, whether it be in the mining settlements of the west; the intensive cropping or dairying of the northern coastal belt, or of the southeast lowlands; the intensive beef fattening of the northwestern tip; or the dryland sheep farming of most of the eastern sector. The southwestern segment of the island is scarcely utilized by man.

Traditional regions. A widely recognized regionalism bears witness to the diversity of the Tasmanian landscape. In the north the distinctive regions are the far northwest around Smithton; the northwest coast extending along the north coast west of Port Sorell; the Tamar Valley; the northeast around Scottsdale and Lilydale; and the far northeast from Ringarooma eastward. In central Tasmania the regions are the west coast, usually comprising only the Queenstown and Rosebery area; the Central Plateau and the Derwent Valley; the midlands, comprising the area east of the Central Plateau between Hobart and Launceston; and the east coast. Southern regions are the southwest, the Huon Valley, and the southeast. Numerous subdivisions, such as the north midlands comprising the South Esk plains around Launceston and the lower midlands around Tunnack, are also recognized.

Rural building and town patterns

Rural and urban settlement. While the pattern of rural settlement differs strikingly by region, the basic contrasts stem from farm size and the length of settlement. In general, the older settled areas, including the midlands, the central north, the east coast, and the southeast, have larger properties, dispersed homesteads, buildings often of stone or brick, architecture that typically is early Georgian, and nucleated villages laid out on a grid. Higher rainfall areas settled since 1850, chiefly the northwest, the northeast, and the Huon Valley, have generally small farms, buildings mainly of weatherboard, and houses and villages mainly aligned along roads. In all areas, villages normally contain a post office and store, but most villages also have a primary school, public hall, church, service station, and transport services.

Tasmania is less urbanized than other Australian states and exhibits a dispersed pattern of peripheral growth that falls into three urban regions. Hobart (population 130,000 in 1971), located at the foot of Mt. Wellington on the Derwent estuary, is not only the capital city, the premier port, and leading industrial centre but the metropolitan focus for the southeast, the upper Derwent, the Central Plateau, the midlands south of Woodbury, and the east coast south of Swansea. Launceston (62,000), at the head of the Tamar Valley, is a secondary administrative centre and hub of the state's transport network, with important textile and engineering industries. Its sphere of influence extends westward to Elizabeth Town and incorporates the entire north and northeast. The third region centres on both Burnie (20,000) and Devonport (18,000); it includes the northwest and the west coast. Significantly, the Hobart region contains only one full-fledged town; the Launceston region, three; and the Burnie–Devonport region, five. Each, however, has six or seven minor towns.

THE PEOPLE OF TASMANIA

The Aboriginal Tasmanians

Ethnic and religious groups. The original Tasmanians were an anthropologically interesting Negritoid people, with the widest nasal index ever recorded and shorter and broader heads than the Aboriginal peoples of the continental mainland. They may have originally drifted across from the mainland or arrived from as far as the New Hebrides, several thousand miles to the northeast. Their five tribal groups numbered only some 2,000 people at the onset of European settlement in the early 19th century, and the last full-blooded Tasmanian died in 1876. As a consequence of the "black war" and attacks from white outlaws, they were removed in the interim to Flinders Island, off the northeast tip of Tasmania, where the survivors languished and died. Within Australia as a whole, the population of Tasmania has a distinctive composition both by birthplace and nationality. Of all the Australian states Tasmania has the highest proportion born in Australia (over 90 percent in 1966), the lowest proportion born in the British Isles (5 percent), the lowest proportion born in continental Europe (3.5 percent), and the lowest proportion born elsewhere in the world. Nationality is thus overwhelmingly British by descent, the proportion (98.5 percent) being higher than that of any other state.

The origins and nationality of the population are reflected in its religious affiliations. Of the four major denominations, Tasmania has, relative to its population, more Anglicans and Methodists but fewer Roman Catholics and Presbyterians than Australia as a whole. In the postwar years, the only major denomination to show a relative increase has been Roman Catholicism, partly because of immigration from Catholic countries and partly because of stringent religious beliefs regarding the use of modern birth-control methods.

Birth and death rates and migratory patterns

Contemporary demography. Tasmania continues to display a higher birth rate than any other state, but, as in Australia generally, crude birth rates have tended to fall. In the 1950s, they averaged 25 births per 1,000 persons and in the 1960s, 23; in the early 1970s the rate had dropped to just over 20. Birth rates are lower in the cities than in the smaller towns and rural areas. Death rates remain fairly constant (8.1 in the early 1970s); partly because the ratio of children to adults in the population is high, death rates tend to be among the lowest in Australia. Infant mortality rates are also among the lowest.

After World War II Tasmania experienced a net in-migration of population from other states and overseas, but since 1959 there has been, in most years, a resumption of net out-migration to the mainland, particularly of young persons, chiefly men, entering the work force. This out-migration has been accompanied by a pronounced in-

ternal rural-to-urban migration, largely through the increasing scale of farming and the substitution of capital for labour in the farming sector. As a result, Tasmania differs from the mainland in having the smallest proportion of population in the labour force and the lowest growth rate of any state.

Since more than two-fifths of the island in the west and the south is too rugged and too wet for agriculture, the population is largely confined to the north and the southeast, with the sparsely settled midlands connecting them with an isolated cluster on the west coast. Hobart has one-third of the state's population in its metropolitan area and nearly one-half within its sphere of influence; the rest of the people are distributed more or less equally between the respective spheres of influence of Launceston and the Burnie–Devonport area. No other state has so equitable a balance of population among the capital city, other urban centres, and the rural areas, the nearest equivalent being Queensland. One-quarter of the population live in centres of less than 1,000 inhabitants and on farms.

THE STATE'S ECONOMY

The Tasmanian economy enjoys many comparative advantages, notably in its mineral, water, and tourist resources, in the diversity of the economic activity, and in fairly stable labour relations. It suffers markedly, however, from the small scale of much of its resource base, from restricted local markets, and from problems of transport to external markets. At the 1966 census, 14 percent of the work force was in the primary sector (the production of raw agricultural and mineral resources), 23 percent in the secondary (manufacturing and processing), and 63 percent in the tertiary (services).

Resources and primary industries. Resources are highly diversified. Important mineral deposits include iron at Savage River, zinc, lead, and copper at Rosebery, copper at Queenstown, and tin and tungsten in the northeast; poor-quality coal abounds in the Fingal Valley but is of declining importance. The heavy, well-distributed rainfall and the rugged terrain in the centre and the west facilitate hydroelectric-power development. The western forests furnish not only excellent hardwoods but also the raw material for pulp-and-paper industries, while the drier eastern forests yield wood chips. Dairying and mixed farming characterize the wetter north; extensive sheep grazing, the drier midlands and the east coast; and specialized horticulture, notably for apples and hops, the southeast. Apples and pears are also locally important in the Tamar and Mersey valleys, potatoes and canning peas in the northwest, and vegetables in the northeast. Fisheries occur in all coastal waters, the catch mainly comprising crayfish, abalone, shark, barracouta, and scallops. A tourist potential lies in variety of landscape.

Agriculture and fishing

The diversity of resource development is reflected in the relative contribution of each primary industry to the net value of primary production: mining generally contributes about one-quarter, dairying one-fifth, wool growing one-sixth, fruit growing one-seventh, and forestry one-eighth. Iron ore mined by the opencut method at Savage River is converted to slurry, piped to Port Latta near Stanley, pelletized, and exported to Japan. Copper ore mined underground at Queenstown and Rosebery is shipped directly to Japan, Tasmania accounting for nearly one-sixth of the Australian copper output. Tin production fluctuates with market conditions. Butter, wool, and fruit are exported mainly to Britain. Tasmanian hops meet almost all of Australia's requirements. In timber production, Tasmania furnishes about one-sixth of the Australian total; wood chips are exported to Japan. The fishing industry depends largely on exports, fairly evenly distributed between mainland and overseas markets.

Manufacturing. Secondary industries are twice as important in net value of production as are the primary industries. Foremost among them are the electrometallurgical and electrochemical specialties dependent on cheap, bulk power provided by the Hydro-Electric Commission. Thus Tasmania, with only 3 percent of Australia's population, produces more than 10 percent of its electricity. The resultant industries include the electrolytic refinery in Risdon, which treats zinc concentrates from Broken Hill (New South Wales) and Rosebery, the aluminum and ferro-manganese plants at Bell Bay, near George Town, pulp-and-paper mills in Burnie and Boyer near New Norfolk, a pulp mill in Port Huon, and a cement plant in Railton. Other important industries include the manufacture of chocolate near Hobart, titanium pigments (Burnie), textiles (Launceston and Devonport), carpets (Devonport), and alginate from sea kelp (Orford).

Promotion and management. Government intervention is largely at the federal level in the primary industries and at the state level in the secondary industries. The Directorate of Industrial Development seeks to foster manufacturing growth by the provision of financial and other assistance. The state government also is active in promoting tourism and trade. Tourist development is favoured by Tasmania's highly diversified and spectacular scenery, its equable climate, its coastal, lake, and mountain recreation areas, and its colonial heritage of Georgian architecture. As a result, Tasmania is visited by more than 100,000 tourists each year. The private sector has well-established chambers of commerce, a chamber of manufacturers, a tourist council, and more than 100 trade unions.

Transportation. Given its island setting and dispersed pattern of development, transportation is especially important to Tasmania. The Transport Commission regulates and, where necessary, provides internal transport. Tasmania has the highest density of roads per square mile of any Australian states: The government railways comprise about 500 miles (805 kilometres) of line. Of the intrastate freight movement, 60 percent is by road, 30 percent by rail, and 10 percent by sea; virtually all passenger movement is by road. Almost all interstate and overseas freight moves by sea and almost all passengers by air. Of the major seaports, Hobart has about one-third of the trade and Launceston, Burnie, and Devonport each about one-fifth; port administration is decentralized. Minor ports are Stanley, Currie, and Strahan. Of the airports, Hobart handles the most passengers (with Launceston close behind) and Launceston the most freight. Regularly scheduled air services also operate from Devonport, Wynyard, King Island, and Flinders Island.

ADMINISTRATION AND SOCIAL CONDITIONS

Government and politics. The state parliament comprises a House of Assembly, with 30 members, and a Legislative Council, by tradition a largely nonparty house, with 19 single-member constituencies. The system of elections for the House of Assembly is proportional representation by the single transferable vote; the system for the Legislative Council is the preferential system, with an obligation to record preferences, used for the federal House of Representatives. The main political parties are the Australian Labor Party and The Liberal Party of Australia; the Australian Centre Party affiliated with The Australian Country Party dates from 1966. The Labor Party was in power from 1934 to 1969, when it was replaced by a Liberal–Centre party coalition; in May 1972 the Labor Party once more regained office. Executive government is by the Cabinet system, the governor representing the British monarch and the Executive Council of Ministers of State giving Cabinet decisions where necessary to legal form. Local government is exercised through cities and municipalities, which comprise the 49 divisions of the state.

Legislative, executive, and judicial institutions

Although the state now administers some of the lower courts, most are still administered by municipal authorities, a feature unique to Tasmania; in other states the administration is vested in a state department. Courts of petty session have jurisdiction over all summary offenses and certain indictable offenses at the option of the defendant. Minor civil proceedings are dealt with by courts of request in the cities and some municipalities or by courts of general sessions. The Supreme Court of Tasmania sits regularly in Hobart, Launceston, and Burnie; it has jurisdiction over all causes save those reserved to the high court of Australia under the commonwealth constitu-

tion. The high court normally sits in Hobart each year, but Tasmanian cases are also heard in Melbourne and Sydney. Children's courts have jurisdiction over persons under the age of 17.

The social milieu. Wages and working conditions of Tasmanian employees are regulated either by awards of the Commonwealth Conciliation and Arbitration Commission or by state wages boards. Tasmania tends to have the lowest average weekly earnings per employed male of all the states except Queensland and, usually, South Australia. That weekly earnings are not the lowest is in line with the cost of living, which is relatively high, partly because of freight charges on imported goods. Although the standard of public health is good, there is a high incidence of hydatids in some rural areas, and goiter is endemic locally. Social status, as in Australia generally, derives primarily from occupation, but Tasmanians accord a lower ranking to professionals and a higher ranking to businessmen than do Australians as a whole. The standing and numerical importance of small and medium property owners is reflected in the relatively conservative tendency of the two main political parties. There are no great extremes of wealth or poverty.

The general standards of living

Education. School attendance is compulsory between the ages of six and 16. Government schools include infant, primary (some with preschool facilities), area, district, and high schools (nonselective, comprehensive, mostly coeducational), together with matriculation colleges (a Tasmanian innovation) and special schools. Independent (nongovernment) schools with one-sixth of the school population are mostly controlled by religious denominations, the great majority being Roman Catholic; since 1967 they have received state aid. Institutions of higher learning include technical colleges, teachers colleges at Hobart and Launceston, the University of Tasmania (founded 1890) at Hobart, and the College of Advanced Education (opened 1972), which provides technical, education, liberal arts, and various courses.

Health. The state government controls directly or through hospital boards the general hospitals at Hobart, Launceston, Latrobe, and Burnie–Wynyard; numerous district and district nursing hospitals; a mental hospital at New Norfolk; maternity hospitals at Hobart and Launceston; a chest hospital at New Town; and hospitals for the aged at Hobart, Launceston, and Wynyard. It also provides district medical officers for the more remote areas, a district nursing service, a school medical service, a school dental-health service for which it trains dental nurses, and a child-health service. Private institutions include seven hospitals and numerous nursing homes. Annual X-ray examinations for adults are compulsory by law. Public water supplies are fluoridated at Hobart, Launceston, and Beaconsfield.

Welfare. Commonwealth social-service benefits include maternity allowances; child-care payments; unemployment, sickness, and special benefits; age, invalid, and widows' pensions; and funeral benefits. The commonwealth also provides paid employment for the disabled, a rehabilitation service, and subsidies for aged persons' homes. The state Department of Social Welfare assists deserted wives or husbands with children, wives with husbands in prison, and neglected or deserted children. It also maintains homes for maladjusted and delinquent children and wards of the state.

Housing. Three-quarters of all Tasmanian houses are owner occupied, and two-thirds are built of weatherboard; apartments make up less than one-tenth of all dwellings. The Commonwealth Housing Commission administers the homes-savings-grant plan, which makes a gift to young persons with certain minimum savings for a first home, a housing-loans-insurance plan, and assistance to certain former members of the armed forces. The State Housing Commission caters to the lower income groups, providing mainly three-bedroom timber units for families to rent or buy and apartments for elderly persons to rent. Rental rebates are allowed as necessary. Advances for home building are made available by the Agricultural Bank of Tasmania and cooperative building societies.

Public aid for housing

CULTURAL LIFE AND INSTITUTIONS

The arts. For its population, Tasmania has a remarkably vigorous cultural life. At the amateur level, there are numerous musical groups, ranging from the full orchestra to the ensemble, as well as several choral societies and repertory companies. The College of Advanced Education incorporates a conservatorium of music and a school of art. The Australian Broadcasting Commission, with financial support from the Hobart and Launceston city councils, maintains the Tasmanian Symphony Orchestra, which gives regular concerts in the main centres, often with visiting artists from the mainland or overseas. The National Theatre and Fine Arts Society of Tasmania, in association with the Elizabethan Theatre Trust, is responsible for bringing drama and opera from the mainland to the Theatre Royal in Hobart, Australia's oldest theatre (1834), and the National Theatre in Launceston. Both cities have museums and art galleries that exhibit paintings, pottery, and sculpture. Tasmania has well-established film festivals and eisteddfods (Welsh poetry festivals); in 1972 it also held its first arts festival. At Hobart's Battery Point, Narryna, a Georgian town house dating from 1839, has been preserved as the Van Diemen's Land Folk Museum, with furniture and furnishings of the early 19th century. Other Georgian houses that have been restored for public benefit include Franklin House and Entally House, both near Launceston, and Runnymede, at New Town, Hobart.

Library services. The state provides lending-library services to adults and children, including a central service with film and recorded music in Hobart, regional services in Launceston and Burnie, and country services in almost all municipalities. Bookmobiles operating from Hobart, Launceston, and Burnie serve schools and other institutions as well as rural areas that lack library facilities. A state reference library and the state archives are located in Hobart.

The communications media. Tasmania has three daily newspapers, in Hobart, Launceston, and Burnie, and dailies from Sydney and Melbourne are available. Each of the smaller centres also publishes a weekend paper, and weeklies of regional interest are published in Queenstown, Smithton, George Town, Scottsdale, New Norfolk, and Huonville.

In Tasmania, as throughout Australia, broadcasting and television services are produced by both the Australian Broadcasting Commission and commercial transmitters. National radio stations operate from Hobart (two), Launceston, and Queenstown, while commercial radio stations relay from Hobart (two), Launceston (two), Devonport, Burnie, Queenstown, and Scottsdale. There are four television stations, two national and two commercial, Hobart and Launceston both having one of each. Tasmania's rugged relief necessitates the provision of an elaborate network of translator stations to ensure reception in all districts. The Australian Broadcasting Control Board exercises control in certain fields over the commercial private-enterprise services. The island is connected with the mainland by a broad-band radio link that enables television programs to be relayed directly from other states.

PROBLEMS AND PROSPECTS

Compared with the major growth areas of southeastern Australia, the island state of Tasmania is underdeveloped, limited in potential, distinctively more rural, and industrially less mature. Manufacturing continues to be dominated by the first-stage processing of primary products; economic expansion will almost certainly focus increasingly on tertiary activity—especially in the great tourist potential of the extensive areas of spectacular wilderness, in which case the island's face may become its fortune. The greatest potential for economic growth lies in the western half of the island; the eastern half, particularly in the north, displays symptoms of relative economic debility.

Given Tasmania's population dynamics, the most important single export is likely to remain human talent. With a population decentralized yet homogeneous, small

yet culturally vigorous, conservative yet independently innovative, remote yet close to both wilderness and metropolis, Tasmania will long remain the quietest state in a quiet continent.

Tasso, Torquato

The greatest Italian poet of the late Renaissance, Torquato Tasso wrote the epic *Gerusalemme liberata* (*Jerusalem Liberated*). This poem, through the imitation of classical models, marks stylistically the culmination of the Renaissance poetic manner and anticipates the Baroque trend of the 17th century. It also reveals the "modern" sensibility of its author and the half-morbid feelings of his melancholic disposition, which made such a disconcerting impression on his contemporaries.

Tasso, oil painting by F. Zuccheri, 1594. In a private collection.

Early life and works

Tasso was born in Sorrento, near Naples, on March 11, 1544, the son of Bernardo Tasso, a poet and courtier, and of Porzia de'Rossi. His childhood was overshadowed by family misfortunes: his father followed the Prince of Salerno into exile in 1552; the family estates were confiscated; his mother died in 1556; and there was subsequent litigation about her dowry. Tasso joined his father in Rome in 1554 and two years later at the court of Urbino, where he was educated with the Duke's son. His imagination had already been fired by stories of the Crusades, and he was struck in 1558 by news of an attack by the Turks on Sorrento, where his sister Cornelia narrowly escaped the accompanying massacre. While in Venice the following year, Tasso began to write an epic in ottava rima (an Italian stanza' of eight 11-syllabled lines), *Gierusalemme*, about the First Crusade (which recovered Jerusalem from the Turks in 1099). He soon interrupted its composition, probably realizing that he was too inexperienced to write a historical epic, and turned to themes of chivalry. The resulting *Rinaldo* exhibited his technical ability but not as yet his poetic genius. In 1560 he was sent to study law in Padua and there met the Humanist and critic Sperone Speroni, under whose guidance he studied Aristotle's *Poetics*. It was probably then that he started writing his *Discorsi dell'arte poetica* explaining therein his qualified acceptance of the rules supposedly laid down by Aristotle in 4th-century-BC Greece. (For instance, Tasso maintained that unity of action should not exclude a variety of episodes.) In 1562 he also wrote love poems to Lucrezia Bendidio, a maid-in-waiting to Princess Leonora of the powerful Este family.

In 1565 Tasso entered the service of Luigi, cardinal d'Este, and frequented the court of Duke Alfonso II d'Este at Ferrara, where he enjoyed the patronage of the Duke's sisters, Lucrezia and Leonora, for whom he wrote some of his finest lyrical poems. In 1569 his father died; the following year Lucrezia left Ferrara, and Tasso followed the Cardinal to Paris, where he met a fellow poet, the Frenchman Pierre Ronsard. Back in Ferrara in 1571, he became one of the Duke's courtiers and devoted himself to intense poetic activity. In 1573 he wrote the pastoral drama *Aminta*, which transcends the convention of artificial rusticity with the sensuous, lyrical inspiration of its picture of Arcadia. The play reflects in its idealization of court life the ephemeral period of happiness he enjoyed at Ferrara. In the same year he also began a tragedy, "Galealto re di Norvegia."

Composition of the *Gerusalemme liberata*

In 1575 Tasso completed his masterpiece, the *Gerusalemme liberata*, on which he had been working since his stay in Padua. In this epic poem Tasso narrates the actions of a Christian army led by Godfrey of Bouillon (*Goffredo* was an early alternative title for the poem) during the last months of the First Crusade. In its composition he tried to establish a balance between the moral aspirations of his times and his own sensuous inspiration, and between the requirements of the formal rules laid down for the epic by Renaissance scholars and the impulse of his own lyrical fantasy. He succeeded in reconciling invention with historical truth by adding a number of romantic and even supernatural episodes to the firm groundwork of the principal historical action. Aware of his epic's poetic novelty, Tasso went to Rome in order to arrange its revision by a group of critics. Back in Ferrara in 1576, he started revising his work in a contradictory mood, in which he felt the urge both to accept the criticism he himself had sought and yet to rebel against this kind of authority. He developed a persecution mania, accompanied by unwarranted scruples about his own religious orthodoxy, and the following years were characterized by sudden departures from Ferrara and by violent crises, the latter culminating in his incarceration in the hospital of S. Anna (1579–86) by order of the Duke of Ferrara. During his confinement Tasso wrote a number of philosophical and moral dialogues that, together with his numerous letters, are among the best examples of 16th-century Italian prose. In 1581 the first editions of the *Gerusalemme liberata* and portions of the *Rime e prose* were published. A long controversy started among Italian critics on the respective merits of his epic and of his immediate predecessor Ariosto's chivalric poem *Orlando furioso*, Tasso himself taking part in the controversy with an *Apologia*.

In July 1586 Tasso was released from S. Anna, thanks to the intervention of Vincenzo Gonzaga, prince of Mantua, who received him at his court. After a revival of creative inspiration—at Mantua he completed his tragedy *Galealto*, re-entitled *Re Torrismondo*—he relapsed into his usual inquietude and fled from Mantua, wandering mainly between Rome and Naples, where he composed his religious poems *Monte Oliveto* and *Le sette giornate del mondo creato*. In May 1592 he was given hospitality in Rome by Cardinal Cinzio Aldobrandini, a nephew of Pope Clement VIII. To this patron he dedicated a new version of his epic (*Gerusalemme conquistata*, published 1593), a poetic failure that reveals the extent of Tasso's final submission to the moral and literary prejudices of the times. After writing two more religious poems (*Lagrime di Maria Vergine* and *Lagrime di Gesù Cristo*), in

June 1594 he went to Naples again, where his *Discorsi del poema eroico* was published. In the *Discorsi* he tried to justify the new version of his epic according to his modified conception of art. On Tasso's return to Rome in November 1594, the Pope granted him an annual pension and promised to make him poet laureate. But Tasso fell ill in the following March, was moved to the Convent of S. Onofrio, and died on April 25, 1595.

Reputation and influence

It was not long before *Gerusalemme liberata* was translated and imitated in many European languages, but its mixed reception following publication aggravated Tasso's melancholic disposition. This melancholy was partly caused by a contrast between his hedonistic ideals—as displayed in his pastoral drama *Aminta*—and his religious aspirations in accordance with the rigid morality of the Counter-Reformation, the Roman Catholic Church's movement of revival in answer to Protestantism. The restlessness of the poet's life, his mental illness, his supposed romantic loves, and his alleged persecutions all gave rise to a legend about the man: Tasso became a literary subject first in 17th-century Italy and then in 18th- and 19th-century Europe, being finally represented as the man of genius who is misunderstood and persecuted. Modern criticism refers the peculiarities of his life and character to the moral incertitude of the times.

MAJOR WORKS

POEMS: *Rinaldo* (1562; trans. by J. Hoole, 1792); *Rime* (1581–87; a few poems translated into English, including those by C. Chorley, *From the Italian of Tasso's Sonnets*, 1867); *Gerusalemme liberata* (pirated ed. pub. as *Il Goffredo*, 1580; 1st authorized ed., 1581; trans. by R. Carew, *Godfrey of Bulloigne; or, the Recoverie of Hierusalem*, with Italian text, 1594; by E. Fairfax as *Godfrey of Bulloigne; or, the Recoverie of Ierusalem*, 1600; J.K. James, 2 vol., 1884); *Gerusalemme conquistata* (1593); *Monte Oliveto* (1605); *Mondo creato* (*I due primi giorni del mondo creato*, 1600; *Le sette giornate del mondo creato*, 1607).

DRAMA: *L'Aminta* (performed 1573; pub. 1581; trans. by A. Fraunce, 1591; by L.E. Lord, 1931); *Re Torrismondo* (1587).

PROSE: *Discorsi del'arte poetica* (pub. 1587; rewritten as *Discorsi del poema eroico*, pub. 1594); *Apologia*, 2 pt. (1585); *Dialoghi* (written 1578–94; pub. 1581 and afterward); *Lettere* (1587 and afterward).

BIBLIOGRAPHY

Standard editions: *Le Rime de Torquato Tasso* by ANGELO SOLERTI, 3 vol. (1898–1902), is still fundamental while a new critical edition is in preparation; *Gerusalemme liberata*, by LANFRANCO CARETTI (1957), is the nearest to a critical edition; *Aminta*, by BARTOLO T. SOZZI (1957); *Gerusalemme conquistata*, by LUIGI BONFIGLI (1934); *Dialoghi*, by EZIO RAIMONDI, 3 vol. (1958), a critical edition; *Le Lettere di Torquato Tasso*, 5 vol. (1852–55) and *Le Prose diverse di Torquato Tasso*, 2 vol. (1875), by CESARE GUASTI; *Appendice alle opere in prosa*, by ANGELO SOLERTI (1892); *Opere minori in versi*, by ANGELO SOLERTI, 3 vol. (1891–95); *Mondo creato*, by G. PETROCCHI (1951), a critical edition; *Il re Torrismondo* in *Opere*, by BARTOLO T. SOZZI, vol. 2 (1956); *Discorsi dell'arte poetica e del poema eroico*, by LUIGI POMA (1964), a critical edition.

Biographical and critical studies: ANGELO SOLERTI, *Vita di Torquato Tasso* (1895), a detailed biography with an appendix of documents; LANFRANCO CARETTI, *Ariosto e Tasso* (1961), a valuable introduction to the study of Tasso's poetry considered in relation to the contemporary historical climate; C.P. BRAND, *Torquato Tasso: A Study of the Poet and of His Contribution to English Literature* (1965), includes a revaluation of the *Gerusalemme conquistata* and an original study of the poet's fortunes in England.

(G.A.)

Taxation

This article is concerned with taxation in general, its principles, its purposes, and its effects; specifically, the article discusses the nature and purposes of taxation, classes of taxes, the history of taxation, canons and criteria of taxation, shifting and incidence, and the structure of national tax systems in various countries. A more extended discussion of particular kinds of taxes will be found in the articles INCOME TAX, PERSONAL; INCOME TAX, CORPORATION; PROPERTY TAX; SALES AND EXCISE TAXES; TARIFFS; and DEATH AND GIFT TAXES.

THE NATURE AND PURPOSES OF TAXATION

In modern economies taxes are the most important source of governmental revenue. They are compulsory levies that are regularly imposed and, as a rule, not designated for a special purpose; they are regarded as a contribution to the general revenue pool from which most government expenditures are financed. Taxes differ from other sources of revenue in that they are unrequited—*i.e.*, they are not paid in exchange for some specific thing, such as the sale of public property or the issue of public debt. While taxes are presumably collected for the sake of the welfare of taxpayers as a whole, the liability of the individual taxpayer is independent of any benefit received.

Tax legislation customarily distinguishes between the tax *object* and the tax *base*. The tax object may consist of goods, transactions (*e.g.*, sales, purchases of real estate, imports, etc.), or sums of money (*e.g.*, income, net wealth, inheritances). The tax base is the physical unit or monetary amount to which the tax rate is applied. For example, a levy on automobiles (the tax object) may use as the tax base the weight of the automobile, its horsepower, its age, its value, etc. Similarly, the property tax may be based on gross value or rental; an excise duty on sugar may be levied as a percentage of the retail price or as a fixed sum per ton of the finished product, etc.

The various functions of taxation

During the 19th century the prevalent idea was that taxes should serve mainly to finance the government. In earlier times, and again today, governments have utilized taxation for other than merely fiscal purposes. Current theories suggest that governments should not use the tax instrument as a revenue-raising device exclusively. Taxes are considered to have three functions: (1) fiscal or budgetary, to cover government expenditures insofar as they are not financed from other sources (fees, profits from public enterprises, the issue of public debt, the creation of money); (2) economic, to promote such general goals as full employment, monetary stability, and a satisfactory rate of economic growth within the framework of a market economy; and (3) social or redistributive, to lessen inequalities in the distribution of income and wealth to the extent they are considered excessive and unjust.

Since these three functions are interrelated, there are likely to be conflicts among them. Thus the level or composition (or both) of taxes considered necessary for budgetary reasons may tend to hold back the rate of economic growth. Or taxes that are highly redistributive may also conflict with the desired goal of economic growth. On the other hand, a relatively high and steady rate of economic growth will bring with it higher tax revenues, which in turn will enable the government to pursue other aims, fiscal and redistributive.

Aside from its main functions, taxation has many lesser purposes. Certain consumption goods considered undesirable, such as alcoholic beverages and cigarettes, may be taxed heavily on the grounds of national health (though more often than not this justification has been put forward to conceal a purely fiscal desire for more revenue). Income taxes and succession duties have been used since ancient times to affect population growth; the most conspicuous examples are bachelor taxes and income taxes on childless couples graduated according to the length of time they have been married. It is doubtful whether such tax inducements actually achieve the objectives sought; even if they do, there are probably more efficient ways of influencing human behaviour.

CLASSES OF TAXES

In the literature of public finance, taxes have been classified in various ways according to who pays them, who bears the ultimate burden of them, the extent to which the burden can be shifted, and various other criteria. The most common distinction is between direct and indirect taxes, an example of the former being the income tax and of the latter the sales tax. There is much disagreement among economists as to the criterion for distinguishing between direct and indirect; it is usually said that a direct tax is one that cannot be shifted by the taxpayer to someone else. Some theorists have attempted to show that in principle any tax may be shifted, in whole or in part,

depending upon the conditions under which the tax is levied. Nevertheless, it is conceded that some taxes are more likely to be shifted than others.

Direct taxes. Direct taxes are primarily taxes on persons; they are aimed at the individual's ability to pay as measured by his income or his net wealth. The main types of direct taxes are the following:

Individual income taxes. These are taxes levied on the total personal net income in excess of some stipulated minimum. They are adjusted to take into account the circumstances influencing the ability to pay of the individual, such as family status, number and age of children, financial burdens resulting from illness, etc.

Taxes on net worth. These are levied on the total net worth of a person—that is, the value of his assets minus his liabilities. As with the income tax, the personal circumstances of the individual are taken into consideration. Very often there is double taxation when a net worth tax falls upon both corporations and individuals.

Death duties. Taxes at death take two forms: the inheritance tax, where the tax object is the bequest received by the person inheriting, and the estate tax, where the object is the total estate left by the deceased. Inheritance taxes usually allow for the personal circumstances of the taxpayer, including his net worth before receiving the bequest and his relation to the donor. Estate taxes are generally graduated according to the size of the estate, although in some countries they make allowance for the number of children involved. In order to prevent the death duties from being circumvented, any rational and efficient system has to include a tax on gifts between living persons, particularly those made in anticipation of death.

General expenditure or spending taxes. These are taxes on all income that is not channelled into savings. In contrast to indirect taxes on spending, such as the sales tax, an expenditure tax can be adjusted to an individual's ability to pay by allowing for marital status, age, number of dependents, etc.

Indirect taxes. Indirect taxes include taxes on sales of consumer goods, on goods in the process of production, on legal transactions, etc., where the assumption (sometimes erroneous) is that the tax will be shifted in whole or in part to the ultimate consumer of the goods, who presumably has the ability to pay.

Consumption taxes and customs duties. The tax objects in these instances are commodities or services. They are levied on almost everything, from necessities such as bread, meat, and salt, to nonessentials such as cigarettes, wine, liquor, coffee, and tea, to luxuries such as jewels and furs. Taxes on specific commodities are called excises, as distinguished from sales taxes and other general consumption levies.

Taxes on consumer durables. In former times these taxes were applied to luxury commodities such as pianos, saddle horses, carriages, and billiard tables. Today the main tax object is the automobile.

Taxes on intermediate goods and production factors. These are levied on raw materials, intermediate goods (*e.g.*, mineral oil, alcohol), machines, or labour; in the last case, the tax base may be the number of persons employed, as in the British "Selective Employment Tax," or the employer's payroll, as in the German *Gewerbesteuer*.

Taxes on legal transactions. Examples of these are taxes on the issue of shares, on the sale of houses and land, and on stock exchange transactions. They are frequently levied in the form of stamp duties.

Taxes that may be direct or indirect

Some taxes cannot be said with certainty to be either direct or indirect. This is because they may, under certain assumptions, be shifted by the taxpayer to someone else. The current prevailing opinion is that corporation income taxes are partially or wholly shifted, although the results of some empirical studies are not altogether convincing on this point. (When the corporation income tax is accompanied by a personal income tax, it also involves double taxation of the dividend element in profits.)

Other taxes that are ambiguous in their incidence include the so-called real taxes on elements of income or net worth, including real estate, business enterprises, and earnings on capital investment. In the 19th century they were common in western Europe. They are found now mainly in the less developed countries (on the national level) and at the local community level of advanced economies. Property taxes are the mainstay of local tax revenue in the United States.

There are other ways of classifying taxes. Some taxes are specific—*i.e.*, they are levied on the basis of weight, length, volume, and other specific characteristics of the tax object. Other taxes are ad valorem—levied on the value of the goods as measured by the price.

One can also distinguish between taxes on the basis of the effect they have on the distribution of income and wealth. A proportional tax is one that imposes the same relative burden on all taxpayers—*i.e.*, where the tax liability and the tax base grow in equal proportion. A progressive tax is characterized by a more than proportional rise in the tax liability relative to the increase in the tax base, and a regressive tax is characterized by a less than proportional rise in the relative burden. Examples of taxes that are generally considered progressive are income taxes, expenditure taxes, and death duties. Taxes that are nominally proportional include, as a rule, the corporation income tax, the various taxes on elements of income or net worth, and ad valorem excises and stamp duties. But there is more to be said: an ad valorem tax on cigarettes or sugar that is nominally proportional will turn out to be decidedly regressive in practice, because the share of personal income spent on cigarettes and sugar declines as the level of personal income rises. Poll taxes, levied as a fixed amount per capita, obviously are regressive. Even income taxes that are nominally progressive may become less so in the upper income categories, when it is possible to reduce the tax base by means of deductions or by the exclusion of certain income components from taxable income; on the other hand, in the lower income categories to which a proportional tax rate applies, some progression is introduced through the personal exemptions.

Progressive and regressive taxes

HISTORY OF TAXATION

Taxes played a relatively minor role in the ancient world. Taxes on consumption were levied in Greece and Rome. Tariffs—taxes on imported goods—were often of considerably more importance than internal excises so far as the production of revenue went. As a means of raising additional funds in time of war, taxes on net worth would be temporarily imposed. For a long time these net worth taxes were confined to real property, but later they were extended to other elements of net worth. Real estate transactions also were taxed. In Greece free citizens had different tax obligations from slaves, and in Rome the tax laws distinguished between nationals and residents of conquered territories.

In Rome, along with consumption taxes and customs duties, there were certain "direct" taxes. The principal of these was the *tributum* paid by citizens and usually levied as a head tax; later, when additional revenue was required, the base of this tax was extended to real estate holdings. In the time of Julius Caesar a 1 percent general sales tax was introduced (*centesima rerum venalium*). The provinces relied for their revenues on head taxes and land taxes; the latter consisted initially of fixed liabilities regardless of the return from the land, as in Persia and Egypt, but later the land tax was modified to achieve a certain correspondence with the fertility of the land, or, alternatively, a tenth of the produce was collected as a tax in kind (the "tithe"). It is noteworthy that at a relatively early time Rome had an inheritance tax of 5 percent, later 10 percent; however, close relatives of the deceased were exempted. For a long time tax collection was left to middlemen or "tax farmers," who contracted to collect the taxes for a share of the proceeds; under Caesar collection was delegated to civil servants.

In the Middle Ages many of these ancient taxes, especially among the direct levies, vanished and gave way to a variety of obligatory services and a system of "aids" (most of which amounted to gifts). The main indirect taxes were transit duties and market fees. In the cities, the concept developed of a tax obligation encompassing all residents: the burden of taxes on certain foods and beverages was

intended to be borne partly by consumers and partly by producers and tradesmen. During the latter part of the Middle Ages, some German and Italian cities introduced several direct taxes: head taxes for the poor and net worth or occasionally crude income taxes for the rich. (The income tax was administered through self-assessment and an oath taken before a civic commission.) The use of land taxes and taxes on houses gradually spread.

Modern trends

The development of taxation in recent times can be summarized by the following general statements, although allowance must be made for considerable national differences: The level of most taxes has risen substantially and so has the ratio of tax revenues to the national income. Taxes today are collected in money, not in goods. Tax farming has been abolished; taxes are assessed and collected by civil servants. There has been a reduction in special excises and a shift from the taxation of necessities to taxes on nonessential commodities of general consumption and on luxuries. Many countries increasingly rely on sales taxes and other general consumption taxes (including turnover taxes paid by manufacturers, wholesalers, and retailers on their gross sales and value-added taxes levied on the difference between gross returns and the costs of materials, supplies, packaging, and overhead). While objective taxes on selected elements of income or net worth, especially those levied on business and real property, played a considerable part in the tax systems of the 19th and early 20th centuries, they have since lost ground and are important today mainly as revenue sources for local communities. The general tendency seems to be toward a closer correspondence between individual tax liability and ability to pay; consequently, the absolute and relative weight of direct personal taxation has been increasing in most of the developed countries. Income taxation, both of individuals and of corporations, occupies a leading position in modern tax systems. The income tax has ceased to be a rich man's tax; it is now paid by the general populace, and in several countries it is complemented by a tax on net worth. The growing emphasis on the ability-to-pay principle and on the redistribution of wealth has led to graduated rates, especially in the case of income and inheritance or estate taxes and sometimes in the case of the net worth tax. A good deal of fiscal centralization has occurred, as reflected in the kinds of taxes levied by central governments. The latter now control the most important taxes (from an economic and social point of view, as well as budgetary): income and corporation taxes, inheritance or estate duties, turnover and value-added taxes. The authority of the sovereign to levy taxes in a more or less arbitrary fashion, however, has been lost, and the power to tax now generally resides in parliamentary bodies.

Taxes as an issue in politics, revolutions, and wars

Taxes have been a major subject of political controversy throughout history, even before they constituted a sizable share of the national income. A famous instance is the rebellion of the American colonies against Great Britain when the colonials refused to pay taxes imposed by a Parliament in which they had no voice; hence the slogan, "No taxation without representation." Another instance is the French Revolution of 1789, in which the inequitable distribution of the tax burden was a major factor. It is worth noting that revolutions often bring with them radical tax reforms (usually including high capital levies) but that these mostly fail to achieve their aims. In the long run, however, such reforms often become reality; for example, in 19th-century France some of the tax proposals of the Revolution—elimination of tax exemption for clergy and nobility, lower taxes for farmers, craftsmen, and other small businessmen—were finally put into effect.

Wars have influenced taxes much more than revolutions. Many taxes, notably the income tax (first introduced in England in 1799) and the turnover or purchase tax (Germany, 1918; Great Britain, 1940) began as "temporary" war measures. Similarly, the withholding method of income tax collection began as a wartime innovation in France, the U.S., and Britain.

It is hardly necessary to mention the role that tax questions play in peacetime politics, where the influence of powerful, well-organized pressure groups is great. Arguments for tax reform, particularly in the area of income and inheritance taxes, are at issue in the domestic politics of many countries today.

PRINCIPLES OF TAXATION

Adam Smith first systematized the rules that should govern a rational system of taxation. In *The Wealth of Nations* (Book V, Chapter II) he set down four general canons: that taxes should be based on the individual's ability to pay, and that they should be certain, convenient, and economical.

> I. The subjects of every state ought to contribute towards the support of the government, as nearly as possible, in proportion to their respective abilities; that is, in proportion to the revenue which they respectively enjoy under the protection of the state. . . .
>
> II. The tax which each individual is bound to pay ought to be certain, and not arbitrary. The time of payment, the manner of payment, the quantity to be paid, ought all to be clear and plain to the contributor, and to every other person. . . .
>
> III. Every tax ought to be levied at the time, or in the manner, in which it is most likely to be convenient for the contributor to pay it. . . .
>
> IV. Every tax ought to be so contrived as both to take out and keep out of the pockets of the people as little as possible over and above what it brings into the public treasury of the state. . . .

Today only the first of these canons is considered of prime importance. The other three have been overshadowed by more recent developments in the theory of taxation. A history of tax theory would include a number of other criteria such as "moderation," "distributive neutrality," "preservation of a purely fiscal orientation," "imperceptibility," and "insensitivity to business cycles"—all of them swept away in the fiscal revolution of the mid-20th century. A similar fate befell the "cost" or "benefit" principles of taxation, based on the idea that there should be some equivalence between what the individual pays and the benefits he derives from governmental activities.

Nowadays the criteria of a good tax system are wide ranging and complex. Some of them fall under the heading of *revenue productivity*. Others involve considerations of *social justice*. There is a further category of considerations having to do with *economic goals*. And finally there are the Smithian criteria of *ease of administration and compliance*. With regard to the first category, revenue productivity, a tax system should fulfill two requirements.

Revenue productivity

The principle of adequacy. A national tax system should guarantee revenues adequate to cover the expenditures of government at all levels. Since public expenditures tend to grow at least as fast as the national product, taxes as the main vehicle of government finance should produce revenues that grow correspondingly. In developed economies this criterion would give first place to income, sales, and turnover or net-value-added taxes; other productive taxes are levies on net worth and, to a limited extent, property taxes and taxes on nonessential articles of mass consumption such as tobacco products, alcoholic beverages and—to a lesser degree—sugar, coffee, etc. (Automobile and gasoline taxes are omitted in this connection because of their special nature and because the revenue derived from them tends to be designated for particular purposes.)

The principle of adaptability. A tax system should be flexible enough to produce additional revenue at short notice (when this is necessary to cover unforeseen expenditures) without causing economic disruption. The need may be to finance a war or to pay for an important social reform (*e.g.*, the introduction of old-age pensions). The most important taxes in time of war are income tax surcharges, excess profits or turnover, or net-value-added taxes. While an increase in net worth, consumption, and inheritance taxes is of much less budgetary importance, it may be a useful psychological accompaniment of the other tax increases.

Social justice

The modern conception of social justice requires in addition that taxes be universal, equal, and responsive to the individual's ability to pay. In the modern welfare state, furthermore, taxes are expected to be more or less redistributive of income or wealth or both.

The principle of universality. This postulates that all persons able to pay should be taxed uniformly, and that exemptions from any tax must serve overall economic, social, and other goals. The universality principle is not violated by the basic exemption from the income tax, the purpose of which is to leave some minimal level of income untouched, nor by the exemption of necessities from a general consumption tax. But differentiations based on such factors as nationality, social class, religion, or race do violate the universality principle.

The equality principle. This requires that persons in the same or similar positions so far as tax purposes are concerned be subject to the same tax liability. In practice the equality principle is often disregarded, both intentionally and unintentionally. Intentional violations of it are usually motivated by considerations of policy (*e.g.*, the tax advantages granted to farmers, artisans, or members of the middle class in general; the exclusion of interest on government securities; the preferred treatment of capital gains). It is debatable whether income splitting for tax purposes, as practiced in the U.S., France, and Germany, is compatible with the equality principle: on the one hand, it seems inequitable for a married couple to pay higher taxes than two unattached individuals with the same total income, as happens in the absence of income splitting; on the other hand, a married couple may have certain economic advantages over two single persons, so that the optimal solution may be some modified form of splitting (like that introduced in the U.S. by the tax reform of 1969).

The ability-to-pay principle. This requires that the total tax burden be distributed among individuals according to their capacity to bear it, taking into account all of the relevant personal characteristics in such a way that the relative loss in economic capacity resulting from the tax is equal. The primary indicator of ability to pay is income, complemented by the subsidiary consideration of net wealth. To include the wealth criterion is desirable not only because wealth produces income but also because its ownership implies some degree of tax capacity even if it generates no tangible income (*e.g.*, collections of art or jewelry). The most suitable taxes from this standpoint are personal levies (income, net worth, expenditure, and inheritance taxes). Indirect taxes such as excise, sales, turnover or net-value-added taxes can be adapted to the ability-to-pay criterion only to a limited extent—for example, by the exemption of necessities or the differentiation of tax rates according to "urgency of need." The ability-to-pay principle also requires that direct personal taxes have a progressive rate structure, although there is no way of demonstrating that any particular degree of progression is the right one.

The principle of redistribution. Currently it is felt that the distribution of the tax burden among individuals ought to have the effect of reducing the large disparities of income and net wealth that result from the functioning of the market economy. This is a complete volte-face from the 19th-century liberal view that the distribution of income ought to be left alone. The modern argument is that because of various restrictions and monopoly elements, the market mechanism does not necessarily (even in the long run) distribute income and wealth according to effort and merit; moreover, poverty may result from some work disability or from an unfavourable social or family background. The most suitable means of carrying out this redistribution is through progressive income and inheritance (or estate) taxes. But since a considerable part of the population does not pay income or inheritance taxes at all, such taxes ordinarily need to be supplemented by direct income transfers such as subsidies or "negative income taxes" if a satisfactory redistribution is to be achieved.

Consistency with economic goals

As governments have come to play a larger part in controlling their national economies, they have had to consider the ways in which taxes help or hinder them in achieving their economic goals. To the extent that tax policy helps to bring about a higher level of economic activity or to moderate downswings, it also helps to produce higher revenues.

Taxes as countercyclical measures. Modern fiscal policy advocates tax flexibility as a way of promoting overall economic stability. One may distinguish two kinds of flexibility: automatic flexibility that is tied to changes in the level of economic activity, without intervention by the authorities, and "discretionary" flexibility involving decisions by the authorities to change tax rates or the tax base. *Automatic flexibility* implies a tax system that cushions the cyclical fluctuations in prices, employment, and production through variations in tax liabilities (and, consequently, revenues) without changes in the tax laws and without detrimental effects on long-term economic growth. Taxes differ in their cyclical characteristics: individual and corporation income taxes show the strongest sensitivity to cyclical movements, their returns varying more than the variations in the national product; moreover, since they account for a huge portion of total tax revenues, their cushioning effect is quite large. Of course, such built-in flexibility requires that the extra revenues received by the government in boom periods be taken out of circulation through a budgetary surplus and not spent, while the decreased revenues received during recessions must register as a budgetary deficit—*i.e.*, the government must not cut back its expenditures during a recession but instead must cover its deficit through additional short-term borrowing. *Discretionary flexibility* calls for more active measures, primarily changes in the tax rates themselves, to increase the anticyclical effects of tax receipts. The effectiveness of discretionary changes depends on the speed at which they can be carried out and the time required for the changes to be felt in the economy. Since the normal legislative process is very time consuming, this policy would be facilitated by giving to the executive limited authority to change tax rates. The West German federal government was given the power in 1967 to change individual and corporation income tax rates by decree (to a maximum of 10 percent up or down in a given year) with the consent of the legislature. The British chancellor of the exchequer can vary the rates of the purchase and excise taxes without requiring approval by Parliament. In the U.S., Presidents John F. Kennedy and Lyndon B. Johnson asked Congress in the 1960s for "standby authority" to make a limited reduction of federal income tax rates but failed to obtain it.

Taxation and economic growth. Policies that promote cyclical stability are generally considered to be favourable to long-term economic growth as well. But since numerous factors influence growth, some economists have proposed separate criteria for shaping tax policies so as to specifically promote growth. These would require that tax policies eschew measures hindering growth and emphasize measures stimulating it. The precise measures would depend on the situation. In general, this approach implies a qualitative restructuring of the tax system (for example, the substitution of indirect taxes for direct taxes to some extent) or special tax advantages to stimulate saving, labour mobility, research and development, etc.

Other economic ends. Additional requirements of an efficient tax system arise from the nature of a market economy. Tax policy should refrain from pursuing particular ends to the point where it leads to the misallocation of economic resources. It should not discriminate in favour of, or against, particular means of transportation, particular forms of retail organization, or particular industries. It should not seek to manipulate the balance of payments, as does the German interest tax on bonds held by foreigners, the U.S. "Interest Equalization Tax," and the British "Selective Employment Tax." In general, so far as the efficient working of a market economy is concerned, taxation should imply a minimum of interference with individual privacy and freedom of activity. This does not mean, of course, that major social and economic goals may not take precedence over these considerations.

Ease of administration and compliance

In discussing these general principles one must not lose sight of the fact that taxes have to be administered. This imposes certain limitations on the fiscal process. There are four general requirements for the efficient administration of tax laws.

The requirement of clarity. Tax laws and regulations must be comprehensible to the taxpayer; they must be unambiguous and certain, both to the taxpayer and to the tax administrator. While the principle of certainty is better adhered to today than in the time of Adam Smith, and arbitrary administration of taxes has been reduced, every country has tax laws that are far from being generally understood by the public. Not only does this result in a considerable amount of error; it also tends to discriminate against the ignorant and the poor, who cannot take advantage of the various legal tax-saving opportunities that are available to the educated and the affluent.

The requirement of continuity. Tax laws should be changed seldom, and when changes are made they should be carried out in the context of a general and systematic tax reform.

The requirement of economy. The costs of assessing, collecting, and controlling taxes should be kept to the lowest level consistent with other goals of taxation. This principle is of secondary importance; obviously, equity and economic rationality should not be sacrificed to cost considerations. The costs to be minimized include not only government expenses but also those of the taxpayer and of private fiscal agents such as employers who collect taxes for the government through the withholding procedure.

The requirement of convenience. The payment of taxes should cause the taxpayer as little inconvenience as possible, subject to the limitations of higher ranking tax principles. Governments usually allow the payment of large tax liabilities in installments and set generous time limits for the completion of returns. (F.N.)

SHIFTING AND INCIDENCE

It is fundamental that the real burden of taxation does not necessarily rest upon the person who pays the tax. General sales taxes are paid by retailers, but most of the burden is assumed to rest upon those who buy the goods that are taxed. In other words, the tax is shifted from the retailer to the consumer. Previously in this article "direct" and "indirect" taxes were distinguished according to whether they were borne entirely by the taxpayer or were shifted to someone else. Taxes may be shifted in several directions. *Forward shifting* takes place if the burden falls entirely on the user, rather than the supplier, of the commodity or service in question. (Thus an excise tax or tariff on luxuries increases their price to the purchaser, a tax on bonds leads to a rise in the before-tax price of the bond, etc.) *Backward shifting* occurs when the price of the article taxed remains the same and the cost of the tax is borne by those engaged in producing it—*e.g.*, in lower wages and salaries, less employment, lower prices for raw materials, or a lower return on capital. *Tax capitalization* occurs if the burden of the tax is incorporated in the value of long-term assets—*e.g.*, if the price of land declines by an amount that offsets an increase in property taxes. At first glance, capitalization does not seem to imply any shifting, since the present owner of the asset takes a capital loss. But when he sells the asset, its price will be lower by the capitalized value of the increased tax payments.

Who ultimately pays

The difficulty with this classification is that a tax may be partly borne by the taxpayer and partly shifted—in any or all of three directions. What actually happens will depend on all of the forces at work. In a market economy the introduction of any tax triggers a whole series of adjustments in consumption, production, the supply of productive factors, and the pattern of foreign trade. These adjustments in turn will have repercussions on the prices of various commodities, productive factors, and assets that may be far removed from the area of the initial impact. In other words, a tax levied on a certain object may affect the prices of nontaxed goods and services that are not even used in the production of the tax object. Thus the initial impact of a tax does not indicate where the ultimate burden will rest unless one knows what repercussions the tax will have throughout the system of interrelated economic variables—*i.e.*, unless recourse is made to general economic theory. In what follows, the attempt will be made to isolate some of the factors involved.

The basic principle of tax shifting

The direction and extent of tax shifting is determined basically by one principle: The user of a tax object can avoid the tax burden to a greater (lesser) extent the easier (the more difficult) it is for him to find nontaxed or less-taxed alternatives or substitutes for the tax object; the supplier of a production factor that is taxed itself or used in the production of a taxed good can avoid the tax burden to a greater (lesser) extent the easier (the more difficult) it is for him to find equivalent nontaxed or less taxed alternative employment opportunities for this factor. Since the demand for substitute goods will increase, their prices may rise, thus placing part of the tax burden on those individuals who used them before the tax was imposed. Likewise, the productive factors that seek alternative employments to avoid the tax will tend to receive lower returns in those employments, thus placing part of the burden on individuals who supplied the factors in those sectors before the tax was imposed. For example, if wine is taxed while beer is not, and these two beverages are regarded as perfect substitutes and the price of beer does not rise with increased demand, the tax burden will fall on the owners of land used for viticulture and on the workers engaged in it. It will fall mainly on the landowners if the soil is specific to winegrowing and if labour has alternative employment possibilities. If, on the other hand, wine drinkers are determined to drink only wine, they will bear most of the tax burden. If some substitution of beer for wine takes place and the price of beer rises somewhat, both wine and beer drinkers will bear the burden.

If a tax causes a significant redistribution of real income, then, in addition to the substitution effect discussed above, one must take into account an income effect: if different income classes have different propensities to save and different patterns of consumption, then income redistribution will influence the demand for various goods and for the labour and materials used in making them.

There are other considerations that affect tax shifting, but they are derived from the basic principle of substitution. The following are most common.

The time period. The direction and extent of shifting may vary over time, depending on how long it takes to adjust consumption patterns, reallocate land and capital, retrain labour, etc. Those users and suppliers who have the most difficulty in adjusting will bear the largest burden.

The kind of tax. The broader (narrower) the tax base (*i.e.*, the more [less] inclusive the scope of the tax from the user's point of view), the higher (lower) his tax burden, since the range of nontaxed or less taxed substitutes at his command is narrower (wider). Thus an excise tax allows partial shifting through a change in the consumption pattern, while a general consumption tax does not. In a similar fashion, the returns on capital will be affected less by the taxation of corporation profits alone than by the taxation of both corporation and noncorporation profits.

The geographical unit affected. The smaller the jurisdictional unit imposing the tax, the easier it tends to be for a user to obtain nontaxed or less-taxed substitutes from outside the jurisdiction and for a supplier to find nontaxed or less-taxed outside employment opportunities for his goods and services. Unless there are border tax adjustments for commodity, labour, and capital movements between jurisdictions (as there are today at national borders), tax differences among regions usually will be shifted to the users or suppliers of commodities and productive factors that are immobile. In small communities the only really immobile factors are likely to be real estate, certain local services, and poor families.

Market imperfections. The rigidities of imperfect markets are likely to increase the uncertainty of the shifting response. Thus a monopolist may absorb part of a tax in lower profits rather than shift all of the burden to the user of the product. In industries where there are few firms (oligopoly), the price behaviour of a firm is mainly determined by what it expects its competitors to do. There is also the phenomenon of "money illusion," which leads individuals to adjust their saving and consumption decisions to changes in their money income rather than their real income; this makes them less responsive to price

increases than they are to decreases in their pay, and thus a tax increase may have very little effect on their consumption. Rigid prices are likely to increase the incidence of taxes on employment, unless monetary policy allows the tax-induced changes in relative prices to take place in the setting of a generally rising price level.

Empirical studies

All of these considerations are analytical and theoretical. Efforts have been made to measure the impact of taxation by studying the actual effects of a particular tax on income and employment. These studies reflect the obvious difficulty that the tax impact cannot be isolated from the economic consequences of other events. For example, studies of corporation income tax shifting vary in their results from the conclusion that the tax is not shifted at all to the conclusion that it is shifted by more than 100 percent, depending mainly on the methods used to isolate the tax impact. Table 1 shows an estimate of the incidence

Table 1: Taxes as Percent of Income, Canada, 1961
(family income class in dollars)

kind of tax	under 2,000	2,000 to 2,999	3,000 to 3,999	4,000 to 4,999	5,000 to 6,999	7,000 to 9,999	over 10,000

of taxes in Canada on various income classes, based on certain assumptions as to the degree and direction of shifting. It suggests that individuals in the lower income classes were unable to shift their tax burden while property owners and rich stockholders were. The greatest impact on the lower income classes came from consumption taxes, as one would expect, but the table also suggests that the corporation income tax and property tax were largely shifted to these classes. The extreme tax regression at the lower end of the income scale may overstate the inequity, since the underlying assumptions are biassed toward the hypothesis of "forward" shifting—*i.e.*, taxes shifting toward consumers and away from property owners.

In the United States the tax burden is also highly regressive, falling much more heavily on the lower income levels than on the middle and upper income classes, but this is offset by so-called transfer payments from the government such as social security, veterans' benefits, pensions, and welfare benefits. Table 2 shows how these compare, according to one estimate. (M.Sc.)

Table 2: Taxes and Transfer Payments as Percent of Income, United States, 1965

income classes	federal taxes	state and local taxes	total taxes*	transfer payments	taxes less transfers*
Under $2,000	19	25	44	126	−83†
$2,000–$4,000	16	11	27	11	16
$4,000–$6,000	17	10	27	5	21
$6,000–$8,000	17	9	26	3	23
$8,000–$10,000	18	9	27	2	25
$10,000–$15,000	19	9	27	2	25
$15,000 and over	32	7	38	1	37
Total	22	9	31	14	24

*Detail will not always add to totals because of rounding. †The minus sign indicates that families and individuals in this class received more as a group from federal, state, and local governments than they paid to these governments in taxes.

THE TAX STRUCTURE IN VARIOUS COUNTRIES

The share of the Gross National Product taken by taxes varies considerably at different times and in different countries. This is partly explained by differences in economic development: the most productive taxes, such as general income and turnover or net-value-added taxes, can be applied effectively only in the more developed countries. Ideological differences also play a part; in countries where conservative beliefs about the role of government prevail, the level of taxation is likely to be lower than in countries where public opinion favours a relatively high degree of government intervention. There may also be some correlation between taxation and per capita income: lower levels of taxation in respect to national income tend to be found in countries where the levels of per capita income are low. One might suppose that a country with high per capita incomes would have less need for high government expenditures, especially in the form of social welfare, but the fact is that the demand for government services tends to increase with the level of national income. (Some countries in the middle range do, however, collect relatively more tax revenues than the very rich countries.) Wars are another factor that are an influence on the level of taxation, since they create the need for greatly increased government expenditures not only while they are being fought but sometimes for many years afterward.

International comparisons such as the foregoing make sense only if they take into account the taxes imposed by all levels of government. One frequently finds comparisons limited to the taxes levied by central governments, but these are misleading, since the share of central governments in total national tax revenues varies greatly. It is also important to include compulsory social security contributions as well. Finally, it should be emphasized that the comparability and reliability of statistics are not to be taken for granted; so far as tax revenues are concerned the figures may be taken as accurate, but estimates of Gross National Product involve complex procedures that are not the same in every country.

Table 3 shows total taxes, social security contributions, and Gross National Product for nine industrial countries. Keeping in mind the qualifications made above, it can be said in general that differences among these countries with respect to the per capita burden of taxes are relatively minor except for Italy, where per capita tax revenues are rather low ($312), and Sweden and the U.S., where they are very high ($1,083 and $888, respectively). If taxes and social security contributions are considered together, there seems to be a strong (but not complete) correlation between the per capita burden (column 11) and per capita income (column 9). Scrutinizing the figures in column 8, it is not surprising that Sweden as the prototype of a modern welfare state shows the highest ratio of taxes and social security contributions to Gross National Product (40.4 percent). The corresponding ratio for Switzerland, one of the richest and at the same time most conservative countries, which has not been involved in a war for more than a century, is only 21.8 percent. One also may note that national differences in the ratio of social security contributions to GNP (column 7) are in most cases much more substantial than those in the ratio of taxes to GNP (column 6).

National tax systems also vary in the emphasis they give to different types of taxes. Comparisons are difficult because of differences in terminology and practice, but Table 4 presents an estimate for seven Western countries of the relative weight of different taxes in their national revenues. In France and Italy, indirect taxes bulk larger than direct taxes as a source of governmental revenues. Property taxes figure heavily in state and local revenues in the United States and in the United Kingdom, but they are at a minimum or wholly nonexistent in the other countries listed.

Finally, it is of some interest to compare the distribution

Table 3: Share of Taxes and Social Security Contributions in Gross National Product and Their Per Capita Amounts

revenues. The chief differences among these countries obviously relate to the national constitutional structures. The share of revenues going to the central government tends to be lower in federal states (ranging from 56 percent to 65.8 percent), and the share of revenues going to local government tends to be lower in unitary states (ranging from 10.9 percent to 25.6 percent).

BIBLIOGRAPHY. Problems of taxation are treated in every textbook on public finance and fiscal policy. Outstanding examples are: U.K. HICKS, *Public Finance*, 2nd ed. (1955); R.A. MUSGRAVE, *The Theory of Public Finance* (1959), probably the most influential contemporary work in this field; G. COLM, *Essays in Public Finance and Fiscal Policy* (1955); H. BROCHIER and P. TABATONI, *Économie Financière* (1959); C. COSCIANI, *Principii di Scienza delle Finanze* (1953); J.M. BUCHANAN, *Fiscal Theory and Political Economy* (1960); E.E. ROLPH and G.F. BREAK, *Public Finance* (1961); H.M. GROVES, *Financing Government*, 6th ed. (1964); A.R. PREST, *Public Finance in Theory and Practice*, 3rd ed. (1967); J.F. DUE, *Government Finance: Economics of the Public Sector*, 4th ed. (1968); and C.S. SHOUP, *Public Finance* (1969).

Among older studies in tax problems and principles, the following are still of great importance: A. SCHAEFFLE, *Die Steuern*, 2 vol. (1895–97), the most comprehensive monograph on both theoretical and empirical tax problems; J. STAMP, *The Fundamental Principles of Taxation*, new ed. (1936); and A.C. PIGOU, *A Study in Public Finance*, 3rd ed. (1952).

A modern theory of taxation is developed in H. HALLER, *Die Steuern* (1964); and a more eclectic view in G. SCHMOELDERS, *Allgemeine Steuerlehre*, 4th ed. (1965).

Tax theory, as well as the tax policies of many countries, is treated by European and American authors in W. GERLOFF and F. NEUMARK, *Handbuch der Finanzwissenschaft*, 2nd ed., 4 vol. (1962–65). Contemporary issues of U.S. fiscal policy are examined in the various publications of the Joint Economic Committee of the U.S. Congress; one of the most important is *Federal Tax Policy for Economic Growth and Stability* (*Papers*, 1955 and *Hearings*, 1956). For Canadian problems, see *Report of the Royal Commission on Taxation* (known as the Carter Report), 5 vol. (1966).

Important works on specific tax problems include the following: O. VON MERING, *The Shifting and Incidence of Taxation* (1942); W.S. VICKREY, *Agenda for Progressive Taxation* (1947); N. KALDOR, *An Expenditure Tax* (1955); C.A. HALL, JR., *Fiscal Policy for Stable Growth* (1960); and C. GREEN, *Negative Taxes and the Poverty Problem* (1967).

Useful works on the historical development of fiscal thought include: F.K. MANN, *Steuerpolitische Ideale* (1937), a comprehensive history of the ideals, ideologies, and theories of taxation from both the economic and the political-sociological standpoints; R.A. MUSGRAVE and A.T. PEACOCK (eds.), *Classics in the Theory of Public Finance* (1958); and AMERICAN ECONOMIC ASSOCIATION, *Readings in the Economics of Taxation*, selected by R.A. MUSGRAVE and C.S. SHOUP (1959). A contemporary monograph on principles of taxation is F. NEUMARK, *Grundsätze gerechter und ökonomisch rationaler Steuerpolitik* (1970).

(F.N.)

Taxila

Taxila (Takṣaśilā), an ancient city of northwestern India, was from the 5th century BC a meeting place of Indian, Iranian, and Greek cultural influences. Its site is between the Indus and the Jhelum rivers, about 22 miles northwest of Rawalpindi in the country of Pakistan. Its prosperity in ancient times resulted from its position at the junction of three great trade routes: one from eastern India described by a Greek writer, Megasthenes, as the "Royal Highway," the second from western Asia, and the third from Kashmir and Central Asia. When these routes ceased to be important the city sank into insignificance and was finally destroyed by the Huns in the 5th century AD.

History. Taxila is known from references to it in Indian and Greco-Roman literary sources and from the accounts of two Chinese pilgrims, Fa-hsien and Hsüan-tsang.

Legendary origins

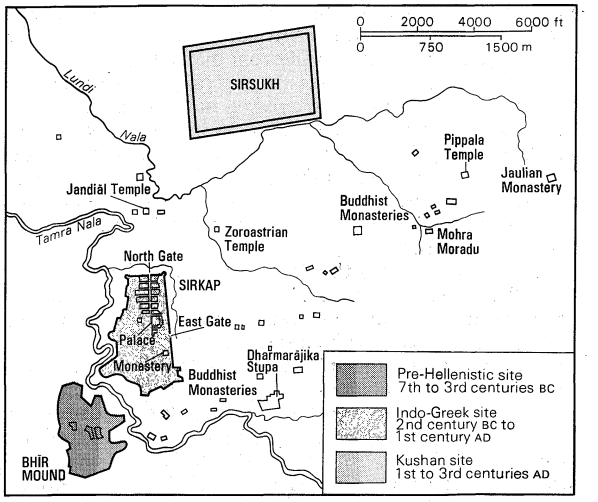
Literally meaning "the city of cut-stone" or "the rock of Takṣa," Takṣaśilā (rendered by Greek writers as Taxila) was founded, according to the Indian epic *Rāmāyaṇa*, by Bharata, younger brother of Rāma, an incarnation of the Hindu god Viṣṇu. The city was named for Bharata's son, Takṣa, its first ruler. The great Indian epic *Mahābhārata* was, according to tradition, first recited at Taxila at the great snake sacrifice of King Janamejaya, one of the heroes of the story. Buddhist literature, especially the Jātaka, mentions it as the capital of the kingdom of Gandhāra and as a great centre of learning. Gandhāra (Gandarii) is also mentioned as a satrapy or province in the inscriptions of the Achaemenian (Persian) king Darius I in the 5th century BC. Taxila, as the capital of Gandhāra, was evidently under Achaemenian rule for more than a century. When Alexander the Great invaded India in 326 BC Āmbhi (Omphis), the ruler of Taxila, surrendered the city and placed his resources at Alexander's disposal. Greek historians accompanying the Macedonian conqueror described Taxila as "wealthy, prosperous, and well governed."

Within a decade after Alexander's death, Taxila was absorbed into the Mauryan empire founded by Candragupta Maurya, under whom it became a provincial capital. But this was only an interlude in the history of Taxila's subjection to conquerors from the west. After three generations of Mauryan rule, the city was annexed by the Indo-Greek kingdom of Bactria. It remained under the Indo-Greeks till the early 1st century BC. They were followed by the Śakas, or Scythians, from Central Asia, and by the Parthians, whose rule lasted till the latter half of the 1st century AD.

According to early Christian legend, Taxila was visited by the Apostle Thomas during the Parthian period. Another distinguished visitor was the Neo-Pythagorean sage Apollonius of Tyana (1st century AD), whose biographer Philostratus described Taxila as a fortified city that was laid out on a symmetrical plan and compared it in size to Nineveh.

Taxila was taken from the Parthians by the Kuṣāṇas under Kujūla Kadphises. The great Kuṣāṇa ruler Kaniṣka founded Sirsukh, the third city on the site. (The second, Sirkap, dates from the Indo-Greek period.) In the 4th century AD the Sāsānian king Shapur II (310–379) seems to have conquered Taxila, as evidenced by the numerous Sāsānian copper coins found there. There is little information about the Sāsānian occupation, but when Fa-hsien visited the city at about the beginning of the 5th century AD, he found it a flourishing centre of Buddhist sanctuaries and monasteries. Shortly thereafter it was sacked by the Huns. Taxila never recovered from this calamity. Hsüan-tsang, visiting the site in the 7th century AD, found the city ruined and desolate, and subsequent records do not mention it. Excavations begun by Sir Alexander Cunningham, the father of Indian archaeology, in 1863–64 and 1872–73, identified the local site known as Saraikhala with ancient Taxila. This work was continued by Sir John Marshall, who over a 20-year period completely exposed the ancient site and its monuments.

Archaeology. The structural remains at Taxila include the Bhīr mound area, the palace area at Sirkap, the Jandiāl and Pippala temples, the Giri fortress, the Mohra Moradu and Jaulian monasteries, and the Dharmarājika, Bhallar, and Kuṇāla *stūpas* (burial mounds). Different types of masonry used in the monuments indicate their period of origin. The earliest remains are those of the Bhīr mound. The palace area, modelled on the same lines as its Assyrian counterpart, has several entrances and outer fortifications. It reveals traces of successive settlements with the oldest parts of the buildings consisting of rubble masonry. Uncovered there were a spacious Buddhist temple, several small shrines, and blocks of dwelling houses. The shrine of the double-headed eagle is interesting for its pilasters of the Corinthian order on the front and niches in the interspaces. Other antiquities of the palace area include terra-cottas and potteries; small bronze, copper, and iron objects; beads, gems, and coins of Indo-Greek, Parthian, and early Kuṣāṇa rulers. The stratigraphic relation between the dated structure inside the palace area and the stone city wall in the southern sector was revealed in the 1944–45 excavations directed by the British archaeologist Sir R.E. Mortimer Wheeler.



Taxila.
Adapted from *Westermann Grosser Atlas zur Weltgeschichte*, Georg Westermann Verlag, Braunschweig

The Dharmarājika *stūpa*, popularly known as the *Chir tope*, is a circular structure with a raised terrace around its base. A circle of small chapels surround the great *stūpa*. Three distinctive types of masonry in the buildings around the main *stūpa* suggest the contributions of different periods to the building activity. A silver scroll inscription in Kharoṣṭī, and a small gold casket containing some bone relics of Buddha were found in one of the chapels. The inscription refers to the enshrinement of the relics by a Bactrian named Ursaka from the town of Noacha in the year 136 BC for the bestowal of health on "the great King, Supreme King of Kings, the Son of Heaven, the Kuṣāṇa" (probably Vīma Kadphises, son of the Kuṣāṇa conqueror Kujāla). This site also contained several statues of the Buddha and *bodhisattvas*.

The Jandiāl temple, set up on an artificial mound, closely resembles the classical temples of Greece. Its Ionic columns and pilasters are composed of massive blocks of sandstone. Built in the Scythio-Parthian period, it is probably the temple described by Philostratus in his *Life of Apollonius of Tyana*. Though the Jandiāl temple is not Buddhist, the Jaulian remains are. These include a monastery and two *stūpa* courts.

Taxila, besides being a provincial seat, was also a centre of learning. It was not a university town with lecture halls and residential quarters, such as have been found at Nālandā in Bihar. At Taxila, the preceptor housed his own pupils, who paid for their board and lodging in cash or in the form of service to the teacher and his family. The Buddhist monasteries also catered to the needs of the students and monks.

BIBLIOGRAPHY. JOHN MARSHALL, *Taxila*, 3 vol. (1951), provides the most exhaustive material for the history and archaeological excavations of Taxila. The report of Sir Mortimer Wheeler's excavations at Sirkap in Taxila is published in *Ancient India*, no. 4 (1947–48). RADHA KUMUD MOOKERJI, *Ancient Indian Education*, 2nd ed. (1951), includes a comprehensive account of Taxila as a centre of learning. For a general study of Taxila as an ancient city see S. PIGGOT, *Some Cities of Ancient India* (1945); and also B.N. PURI, *Cities of Ancient India* (1966).

(B.N.P.)

Tax Law

Tax law is the body of rules under which the public authority has a claim on taxpayers requiring them to transfer to the public authority part of their income or their property. Tax law is concerned only with the legal aspects of taxation, not with its financial, economic, or other aspects. The making of decisions as to the merits of various kinds of taxes, the general level of taxation, and the rates of specific taxes, is not a legal but a political

The nature of tax law

process; and a question such as whether it is advisable to grant privileged tax treatment to capital gains is not a legal problem but a matter of economic policy.

The power to impose taxes is generally recognized as a right of governments, not only of national governments but also, in most countries, of local communities. It also has been recognized recently as a right of an international or supranational community (as in the case of the levy introduced in December 1953 by the European Coal and Steel Community on steel-producing enterprises in the member countries).

Tax law falls within the domain of public law—*i.e.*, the rules that determine and limit the activities and reciprocal interests of the political community and the members comprising it—as distinguished from relationships between individuals (the sphere of private law). The specific purpose of the relationship between the individuals and the community regulated by tax law is the imposition on individuals (and corporations) of a contribution to cover public expenditure. International tax law is concerned with the problems arising when an individual or corporation is taxed in several countries. Tax law can also be divided into material tax law, which is the analysis of the legal provisions giving rise to the charging of a tax; and formal tax law, which concerns the rules laid down in the law as to assessment, enforcement, procedure, coercive measures, administrative and judicial appeal, and other such matters.

The development of tax law as a comprehensive, general system is a recent phenomenon. One reason for this is that no general system of taxation existed in any country before the middle of the 19th century. In traditional, essentially agrarian, societies, government revenues were drawn either from nontax sources (such as tribute, income from the royal domains, and land rent) or, to a lesser extent, from taxes on various objects (land taxes, tolls, customs, and excises). Levies on income or capital were not considered an ordinary means for financing government. They appeared first as emergency measures. The British system of income taxation, for example, one of the oldest in the world, originated in the act of 1799, introduced by the younger Pitt as a temporary means for meeting the increasing financial burden of the Napoleonic Wars. Another reason for the relatively recent development of tax law is that the burden of taxation—and the problem of definite limits to the taxing power of public authority—became substantial only with the broadening in the concept of the proper sphere of government that has accompanied the growing intervention of modern states in economic, social, cultural, and other matters.

THE TAXING POWER

Predominance of the legislature

The limits to the right of the public authority to impose taxes are set by the power that is qualified to do so under constitutional law. In a democratic system this power is the legislature, not the executive or the judiciary. The principle of the legality of taxation has been asserted by constitutional texts in many countries, including the United States, France, Brazil, and Sweden. In Great Britain, which has no written constitution, taxation is also a prerogative of the legislature.

The historical origins of this principle are identical with those of political liberty and representative government —the right of the citizens

> to take cognizance, either personally or through their representatives, of the need for the public contributions, to agree to it freely, to follow its use and to determine its proportion, basis, collection and duration

(in the words of the Declaration of the Rights of Man and the Citizen proclaimed in the first days of the French Revolution, August 1789). Other precedents may be found in the English Bill of Rights of 1689 and the rule "no taxation without consent" laid down in the Declaration of Independence of the United States.

Under this principle all that is necessary is that the rights of the tax administration and the corresponding obligations of the taxpayer be specified in the law; that is, in the text adopted by the people's representatives. The implementation of the tax laws is generally regulated by the executive power (the government or the tax bureau).

There have been many encroachments on the principle of the legality of taxation: sometimes the base or the rate of taxation is determined by government decree rather than by law. The encroachment of the executive power on the territory reserved to the legislature in matters of taxation is generally explained by the need to make tax policy more flexible; urgent amendments may be required by sudden changes in the economic situation, changes so sudden that recourse to relatively slow parliamentary procedure would take too long. A compromise may be reached between the orthodox doctrine of the legality of taxes and the need, under special circumstances, to amend texts on taxation almost immediately, by modifying the text through a decree or an order of the executive (treasury) and ratifying it by the legislative power as soon as possible thereafter.

Limitations on the taxing power. While the legislature is omnipotent in its exercise of the taxing prerogative, certain restraints on the legislative power are imposed by tradition, custom, and political considerations. In many countries there are also constitutional limitations. But tax (or other) legislation once enacted cannot be nullified by the courts on the ground that it is in opposition to constitutional principles—except in countries such as the United States, where no tax may be imposed by an act of Congress if it has been found unconstitutional by the judiciary power.

Jurisdictional limitations

Certain limitations on the taxing power of the legislature are self-evident. Since the power to raise taxes is a prerogative of the public authority, a government only has the right to impose a levy insofar as it is competent to do so. There must be a minimum connection between the subject of taxation and the taxing power. The extent of income-tax jurisdiction, for example, is essentially determined by two main criteria: the residence (or nationality) of the taxpayer, and his source of income. As for the first criterion, the test in almost all countries is residence; *i.e.*, the generally permanent home place of the individual, or the place in which control of a corporation is situated. Some countries (including the United States) exercise the right to tax the whole income of their nationals even if they reside abroad. The second basic criterion is the source of income: almost all countries consider it their right to tax income arising within their borders, whether or not the income is earned by individuals or corporations having their residence or exercising their management and control in the country. The application of both criteria together often results in burdensome double taxation, which can be avoided (or restricted) by international treaties.

Taxes other than income taxes—such as retail-sales taxes, turnover taxes (sales taxes levied on production and distribution), death taxes, registration fees, and stamp duties—are imposed by the authority (national or local) on whose territory the goods are delivered or the taxable assets are located.

Another self-evident limitation on the taxing power of the public authority is that the same authority cannot impose the same tax twice on the same person on the same ground.

Taxes are generally not levied retroactively, except in special circumstances. One example of retroactive taxation was the taxation of wartime benefits in some European countries by legislation enacted in 1945 when the war and enemy occupation were over.

The requirement of uniformity

A common limitation on the taxing power is the requirement that all citizens be treated alike. This requirement is specified in the United States Constitution. A similar provision in other constitutions is that all citizens are equal and that no privileges can be granted in tax matters. Unfortunately, the rule is often violated through the influence of pressure groups; it is also difficult to enforce. In countries in which local governments are under the control of the national government, a local tax can be nullified by the central authority on the ground that it violates the rule of uniformity and equality of taxpayers.

Aside from the foregoing constitutional, traditional, or political limitations, there is no restraint on the power of

the legislative body to determine the object or the rate of a tax and the circumstances under which such special adjustments as exemptions or deductions will be granted. The amount of taxation may be excessive: only the legislature can decide that point, by rejecting or amending a tax bill before it is passed. Once enacted by the legislature, a tax cannot be judicially restrained.

Taxation need not be intended for revenue purposes. In modern societies in which government revenues comprise up to 35 percent or more of the gross national product, taxation is shaped by ideology and by economic policy. Taxes may be adjusted to provide an incentive to save (for example, by reducing the registration duties on the purchase of small properties), to encourage business concentration (through tax exemptions for mergers of corporations), business investment (through higher depreciation allowances in corporation income taxation), and to achieve other purposes. Taxes may be punitive (as in the above-mentioned taxation of wartime benefits or intended to discourage unwanted social phenomena such as gambling or alcoholism.

There is no way of mounting a legal attack upon a tax law on the ground that it is arbitrary or unjust. But the application of the law must be correct; it is a matter of public interest that taxpayers be protected against unlawful decisions and actions by the authorities administering the tax laws. The constitutional and legal guarantees protecting the citizen are outlined in the last part of this article.

Double taxation. The problem of double and concurrent taxation by overlapping governmental authorities has become increasingly important, particularly in international law. The growth of international contacts has multiplied the possibility of an individual or corporation being taxed in several countries. Moreover, the expanding financial needs of states have led them to extend their powers of taxation as far as possible, with the result that cases of double taxation are becoming increasingly frequent and serious.

International tax law

International tax law has two parts. One consists of the provisions of internal tax law whereby national taxes are made applicable to nonresidents and to facts or situations located outside the frontiers. The other part has its source in the growing number of international agreements designed to prevent double taxation, either by defining the field of application of the tax laws of each of the contracting states or, without limiting the field of application, by providing for the granting of credits in each of the contracting states for taxes paid under the legislation of the other.

Nearly all the agreements aimed at preventing international double taxation are bilateral; that is, between two countries. Among the few multilateral treaties are the Geneva Convention of 1931, which concerns the tax system applicable to motor vehicles registered abroad, and the conventions concerning the immunities of certain international or supranational organizations. Many bilateral conventions are intended not only to prevent double taxation but also to enable cooperation between the fiscal administrations of the contracting states in combatting tax evasion.

Problems of internal double taxation exist in federal countries (including the United States, Switzerland, and West Germany). A state legislature may, for example, tax all income arising in the state, whether received by residents or nonresidents, or all income received by residents, even when the source of income is located outside the state borders. Therefore, interstate arrangements must be made, similar to international conventions, delimiting the amount of state and federal taxes or granting a credit against the state tax in calculating the federal tax paid on the same object.

Special tax problems arise when countries are involved in economic integration with each other. When two or more countries form a customs union (free-trade zone), each member state keeps its own system of taxation. The aims of an economic union are more ambitious, entailing far-reaching limitations on the sovereignty of the member states; when countries decide to form an economically integrated area, as have the member countries of the European Economic Community (Common Market), they agree to establish a unified economic and financial market. In tax terms, this means the abolition of all tax (and other) discriminations and distortions, since they are likely to give rise to abnormal movements of goods and capital. To this end the sales and turnover taxes of the European Economic Community were "harmonized," as provided in the Rome Treaty of March 1957; all member countries have had to change their sales and turnover taxes to conform to a model prescribed by the Community.

ADMINISTRATION OF TAX LAWS

Whereas the right to impose taxes and to determine the circumstances under which they will be due is a privilege of the legislative power, administration of the tax law is the responsibility of the executive power. The head of tax administration in a central government is the minister of finance, secretary of the treasury, or chancellor of the exchequer. The actual administration is generally separated into departments because taxes differ so greatly in their bases and methods of collection. In most countries the ministry of finance has three branches charged with the levying of taxes. One collects income taxes; another levies taxes on the transfer of goods and on such legal transactions as stamp fees, inheritance taxes, registration dues, and turnover taxes; a third is responsible for customs and excise duties.

The levying of taxes can be divided into three successive phases: (1) assessment, or the definition of the exact amount subject to taxation under the statute; (2) computation or calculation; and (3) enforcement.

Assessment. The definition of the amount subject to taxation under a particular statute requires an analysis of the taxpayer's situation and of the legal provisions that apply to him. With the income tax (and also some taxes on the transfer of property, such as the inheritance tax), the taxpayer submits a tax return providing information as to his occupation, his real and personal property, his professional expenditures, and other pertinent matters; a corporation supplies, additionally, copies of the balance sheet, profit and loss statement, and minutes of the general meeting that approved these financial reports. The return, with the attached reports and statements, is meant to provide such complete information that the assessing tax official can rely on it to compute the correct tax. In the United States, the income taxpayer's liability is computed by himself subject to review by the taxing authority. Most tax systems also collect information in other ways, in order to inform the authorities as to potential tax liabilities. Records are kept of such matters as the allocation of income by partnerships, trusts, or estates, or the payment of fees, interest, dividends, and other sums exceeding a certain minimum amount.

Tax returns

In the case of an annual levy such as the income tax, a return must be filed every year. In many countries, however, individuals who, on the basis of the return previously filed, appear to earn an income below the taxable limit do not have to file a new return annually (this facility is subject to revision at any time). Because it is not easy for some categories of taxpayers to determine the precise amount of their occupational net income, the tax administration frequently reaches an agreement with professional associations, fixing an estimated basis on which the net taxable income of their members will be determined for a period usually exceeding one year; members are then allowed to provide the tax administration with simplified factual information (*e.g.*, for farmers the area of land cultivated, for butchers or bakers the amount of goods sold), instead of filing the standard return.

In many countries a separate assessment procedure has been organized for income from real property; such is the case in the various European countries in which the French system of land register (cadastre) was introduced at the end of the 18th century. The theoretical income of each piece of real property is then determined by the administration of the land register and remains fixed for a relatively long period, except when important changes

are made in the property. In examining tax returns, the basic principle is that a return is assumed to be correct until the assessing official determines otherwise. In countries such as the United States, where the self-assessment method prevails, a minority of returns is selected for audit; most, however, are only checked as to timely arrival, inclusion of all required forms and attachments, and arithmetical accuracy. Except in special circumstances—when, for example, the statute introduces a suspicion of fraud (*e.g.*, if no return has been filed) or creates certain presumptions (as when personal living expenses exceed the reported income)—the administration has no right to shift onto the taxpayer the burden of the proof that he has complied with his liabilities. The golden rule of the tax administrator consists not only in getting as much money as possible for the treasury, but in displaying fairness. The rules of taxation naturally have an authoritarian character, but tax law does not grant the taxing authority a privileged position nor deprive the individual of means of defense against arbitrary taxation.

Tax auditing

In all countries, the assessing officials have extensive powers in determining the amount subject to taxation. In addition to the routine check, there are numerous sources of information. The return of one taxpayer can be checked against that of another: whenever an individual or a corporation includes within deductible expenses the interest paid on borrowed money or the fee paid to a professional expert, the return must show the name and address of the payee, and when this information is placed before the appropriate assessing official he can readily determine whether the payee has included the payment in his declared income.

The procedure varies from one country to another, and depends largely on the circumstances of the case. An audit may be performed either in the office of the tax agent, by correspondence, or in the taxpayer's office. The tax agent is entitled to examine the books and records kept by the taxpayer, within reasonable limits. He is, within the same limits, entitled to question not only the taxpayer but other persons acquainted with the case. There are, however, legal guarantees, protecting confidential communications. In the United States, for example, federal and common law protect communications between husband and wife, or between a client and his attorney acting as such. Under Belgian income-tax law, certain taxpayers, in the course of the assessing official's interrogation, may assert that they are bound by professional secrecy and unable to communicate what they claim to be privileged information; the assessing officer may then consult a special advisory board, composed of the president and two members of the taxpayer's professional or occupational group (lawyers, doctors, notaries, etc.), which will give its opinion as to the taxpayer's probable income.

The problem of bank secrets is a very important one. In some countries, such as Switzerland, banks are legally entitled to refuse information to tax agents concerning their clients. But banks in most countries are required to make reports of cash deposits or similar transactions. In most countries, a safe-deposit box in a bank cannot be opened after the death of the client unless a tax official is present.

Tax authorities do a great deal of intelligence work, using tips from informers such as employees, competitors, and neighbours of the taxpayer. In the United States, informers are encouraged by the payment of fees of up to 10 percent of the additional tax collected. But it is a fundamental principle of tax law that information cannot be used against the taxpayer if it has been obtained by unlawful means, and that no evidence or testimony is a valid proof of tax liability unless the taxpayer has had the opportunity to discuss it.

Assessment consists primarily of an analysis of the facts giving rise to taxation and of the legal provisions applicable to a particular case. The assessor may find himself in disagreement with the taxpayer, either as to the facts (the amount of income, of deductible expenses, etc.) or as to the manner in which the taxpayer has resolved a question of law or a mixed question of law and fact. The tax agent may use his discretion as to questions of fact, and frequently a compromise is reached on those questions between the taxpayer and the tax agent.

Whenever the tax agent decides questions of law, he is bound by the treasury's position on the particular problem. On unresolved issues, lower taxation officers (field offices) usually request the advice of a higher echelon. In some countries, including the United States, written rulings are issued by the administration in advance, thus avoiding disputes at the level of the assessment official. In countries in which this is not done, officials at all levels are free to give informal advice concerning the tax effects of proposed transactions. But the taxpayer can file a petition with the competent administrative or judicial authority whenever he believes that the interpretation of the law by the assessing official is wrong.

Computation of the tax. The second phase in levying taxes is the calculation of the amount to be paid. In the American self-assessment method, the liability for income tax is primarily established by the taxpayer himself. Under this method, as a rule, the tax liability reported on the return forms the basis of the assessment record. If the tax administration discovers that additional tax is due, a deficiency statement is issued. Many countries provide for prepayment of the withholding tax on dividends and other income from personal property, and have set up a "pay-as-you-go" system for professional income. Such provisional payments are calculated by the taxpayer. Advance payment of all or part of the income tax (on a voluntary or compulsory basis) before the return is filed, on the basis of expected income or of the taxable income of the previous year, is also provided for in some countries. In general, however, the final computation of taxes levied on income, on inherited property, or on the transfer of property is made by the tax administration. Turnover taxes, sales taxes, and value-added taxes (*e.g.*, taxes on a manufacturer's sales minus taxes included in his production costs) are calculated by the taxpayers.

Enforcement. If the taxpayer fails to pay within the legally prescribed period, or within a very short time afterward, the competent tax office undertakes to collect the amount due. In proceedings against the taxpayer, the tax administration is not in the position of an ordinary creditor suing an ordinary debtor. In political communities where powers are divided among the legislative, the executive, and the judiciary arms of government, the application of the tax law is the privilege of the executive power—the tax administration. The collecting agent will not embark upon civil litigation to obtain payment of the delinquent taxes or to secure adequate guarantees from the taxpayer.

Civil and criminal sanctions

In addition to interest charges on the amount due, various kinds of coercive measures are available to ensure payment. Civil penalties consist generally of a fine added by the collecting agent when the violation is the result of negligence rather than of willful neglect or bad faith. Examples of negligence are the failure to file a required return on time, and understatement or underpayment of the tax liability without intent to mislead. Civil penalties are fixed by assessment, so that the procedural remedies of the taxpayer are identical with those provided for the assessment of the tax itself. The law also confers a privileged position on the tax administration among the creditors of the taxpayer.

Criminal tax fraud is severely punished in all tax legislation. Certain tax crimes are classed as misdemeanours (such as willful failure to pay certain taxes, to file certain returns, to keep proper records, and to supply proper information); these are punishable by fines or imprisonment or both. Heavier punishment is provided for crimes classed as felonies (such as the making of false statements and, in the United States, tax evasion). In most countries the criminal penalties can be combined with the civil penalties.

Criminal penalties cannot be imposed by the tax administration. Offenses against tax law, whether misdemeanours or felonies, must be tried by courts. The procedure in criminal tax cases is almost identical with that in other criminal cases. The accused is deemed to be innocent

until proved guilty; the burden of the proof inevitably rests upon the prosecutor and not upon the taxpayer-defendant.

THE JUDICIARY AND TAX LAW

The taxpayer has a guarantee against unfairness or error in the application of taxes in the right to appeal to impartial authorities when he disagrees with the determination of the assessing officer.

In some countries disputes between taxpayers and the authorities are settled by special commissions consisting of high-ranking civil servants (and also of members of various occupational organizations). In others, the decision is the privilege of the judiciary power. But in the vast majority of countries a combination of both systems prevails. "Out-of-court" jurisdictions—commissions composed of tax officials and laymen—frequently act as preliminary settlement committees that decide factual questions, leaving the interpretation of the tax law to the courts. In general, when a taxpayer disagrees with the amount of the tax as calculated by the administration, or thinks he has paid too much, he files a petition with a tribunal, which is either a specialized court or the ordinary court competent for civil litigation. Even if he must exhaust the administrative processes before he may take a dispute with the tax authorities to court, he can still invoke the jurisdiction of a judicial court to re-examine the case, in respect both of the facts and of the legal arguments.

In almost all countries, the judiciary is headed by a supreme court whose jurisdiction is limited to questions of law. The supreme court is generally competent in tax matters, but an appeal to the court must be based solely on an alleged misapplication of law; should it appear that questions of fact or mixed questions of law and fact are involved, the claim, under most judicial systems, is dismissed. (The United States Supreme Court can also decide on the constitutionality of an act of the legislative power.) The judiciary thus has final authority to interpret the tax statute. This interpretation is binding only in the matter submitted to the tribunal. But, in any legal system, reference to interpretative decisions of the courts in comparable cases, especially of the supreme court, is obviously the best argument in a litigation about a disputed point of tax law.

Interpretation of tax laws

When a legal text—in tax law or in other law—requires interpretation because there is a reasonable doubt as to its meaning or scope, the first step is to determine the meaning of the words used, according to the rules of grammar and syntax, not in isolation but in their context and taking into account the subject discussed. As stated by R.E. Paul, "the meaning of a sentence may be more than that of the separate words, as a melody is more than the notes" (*Taxation in the United States,* 1954). This is the necessary "literal" interpretation of the law: when the current sense of a term is its wide sense, then it must be accepted in its wide sense in a tax law as in any other, unless it can be shown that the legislature used the term in a narrower sense. If the meaning of the text cannot be determined with certainty by the literal method, then the interpreter, in seeking the legislature's intention, will resort to the "historical" method (the study both of the preparatory work and of the place occupied by the text in successive laws on a specific matter) and to the "systematic" or "teleological" interpretation (the position occupied by a legal provision in a legal system as a whole, and the object pursued by the legislature in producing that system).

In addition to these general principles common to the interpretation of all legal texts, some special rules apply to the interpretation of tax laws. One rule is the autonomy of tax law, meaning that tax laws pursue aims that are different from those of other bodies of law. The tax claim is a claim under public law. Its cause lies not in a contractual obligation but in an expression of unilateral will, a decision by the public authority. The function of taxes in the organization of the budget is incompatible with the principles of the law of contracts; such principles apply only to relationships under private law and, therefore, cannot be invoked to interpret provisions of tax law.

Other special rules of interpretation of tax laws derive from the nature of the tax obligation. In a democratic system, a tax can only be imposed by law. Thus the courts or the administration do not have a "creative power" to make things or operations taxable through an analogic interpretation of the text, in cases where it is not proved that the legislature wished them to be taxable. On the other hand, the rule of legality of taxation does not always operate in favour of the taxpayer: the person or body entrusted with the task of applying or interpreting the law cannot introduce any attenuation or relaxation of its effect, even though this might be more than amply justified by circumstances, except in cases where the legislature has authorized the judge or the administration to apply the rules of equity within certain legally prescribed limits.
