The complex significance of the original squatting ancestor figure enabled it to be used in a variety of contexts. It might have combined associations of the fetus, the fetal burial position, and female birth and intercourse positions, as well as a ceremonial posture assumed by the living. It came to be used primarily in wooden sculpture on all scales, but also in woven textiles (*e.g.*, Iban), to represent the continuing power informing human existence, both in the purely ancestral sense of family continuity and identity and in the sense of the fertility of the land. Its earliest recorded appearance may be on Chinese Yang-shao painted pottery (*c.* 2000 BC); but it appears in essentially the same form over a range of territory including Sumatra, Nias and Sunda islands, Java, Borneo, New Guinea, Taiwan, the Philippines, and out into northern Australia and Melanesia. It may be used purely as an ancestral image in a family shrine house or as a motif added to any one of a variety of implements to potentiate them; for example, large bowls (Sumatra), kris or sword handles (Java, Sumatra, Borneo), spoons (Timor, the Philippines), musical instruments (Borneo), and magicians' staves (Borneo).

The treatment of such figures may be invested with more or less of the characteristics of the ornamental–fanciful style, in those regions where this style prevails (*e.g.*, Batak, Dayak). There are also special versions of the squatting figure that seem to belong especially to important magical crafts, such as the Javanese kris handle, on which miniature carvings can give an extraordinarily monumental effect. Sumatran Dayak hereditary magical staves may be carved with a "tower" or "tree" of such ancestor figures. On Nias, for example, along with the squatting figure, a standing figure in the bent-knee posture common in Polynesia also appears as a variant. In the Philippines similar variants are sometimes interpreted as vestiges from a remote Indian mythology, adopted probably for the sake of their cultural prestige. In southern Borneo the figure appears carved in the full round and as a pattern for woven textiles; it often has a protruding tongue and, sometimes, antlers—a combined motif known in the Ch'ang-sha art of southern China (*c.* 300 BC). Antlers also appear on certain Sumatran knife-hilt figures. A variety of designs, some of them "abstract," are based on this figure. Among the Jarai of Vietnam, for example, a pattern of lozenges represents an abstraction from a group of these figures. Especially in the textiles of Sumba and other Indonesian islands, similar patterns, often referred to as decorated triangles, represent the same phenomenon. When, as in textiles, the anthropomorphic reference of the abstract pattern is lost, the male genitals may remain to assert the ancestor significance.

Cult of the skull

The association between the squatting figure and the widely practiced cult of the skull is manifested in the combined cult of ancestors, headhunting, and head worship. Among the Wa of Upper Burma, for example, the squatting figure in a lozenge abstraction decorates the chests in which the severed heads of enemies are stored. Virtually everywhere among the early farmers of Southeast Asia, such heads were regarded as repositories of great spiritual power. The cult of the skull has produced a version of the squatting figure that is commonly known by the Indonesian word *korvar*; it is a figure with an ancestral skull in place of a carved head. Such figures are especially common in the more easterly island cultures. The ghostly power of the deceased ancestor can thus become present and available to his descendants—to give oracular advice, for example. A related idea is incorporated in the masks used in a wide variety of rituals and dance-dramas throughout Southeast Asia; for example, among the Batak of Sumatra and the Dayak of Borneo, where especially fine examples are made. There can be little doubt that the same idea (blended with imagery from the imported Hindu epics) underlies the range of elaborate masks once used in the Javanese and now in the Balinese *wayang* dances. It is possible that the flamboyant flame skull protuberances and winglike flanges ornamenting the head in so much of the Buddhist art produced in Burma and Thailand reflect a persistent but submerged interest in the cult of the skull.

Another major motif is the snake, which (even in areas where direct Indianizing influence was not strong) is frequently combined with imagery derived from the cult of the powerful, magical Hindu *nāga*; often many-headed, this serpent is the patron and guardian of water and

treasure, both material and spiritual. The snake motif has also been blended with images of the Chinese dragon, going back perhaps to Chinese Han ornamental designs. Outstanding examples are found on the elaborate relief-carved doors of Sumatran Batak houses; "flying" roof finials in many parts of Indonesia; and in much Borneo Dayak ornament, from tattoos to carved bamboos and bronze body ornaments. The snake is the magico-mythical creature that gives both its bodily shape (either straight or undulant) and its metaphysical power to the kris. Distributed from Malacca to Celebes, these swords (the earliest known dated 1342) reached their high point of artistic development in Java. A variety of other motifs originating on the mainland of Asia is found in many of the surviving folk arts of Indonesia. Among them are the "man in the embrace of an animal" (Dayak kris handles) and animals "stacked" one above the other (Timor, Indonesia).

The ornamental–fantastic style. The styles in which these variations on basic motifs are carried out vary principally according to the preponderance of the sinuous curves and spirals of the ornamental–fantastic style. This style serves as the basis for decoration and as a method of artistic phrasing. It may have made its way into Southeast Asia as late as the 1st millennium BC, being formally related to the spirals used in Chinese Neolithic, Shang, and Chou bronze art. (It should, perhaps, be mentioned that Chinese art, certainly until well into the Christian Era, was itself far more "tribal" than later Chinese tradition recognizes.) Probably connoting spirituality, the spiral imagery appears in Southeast Asian magical art at all levels, from the textiles of Java and the incised bamboo implements or carved doors of Dayak Borneo to the ornament on the costumes of sculptured dancers or deities at every major city site. Given a fiery upward inflection, it appears in the finials on major Indianized stone architecture and on the carved wooden gables of Burmese and Thai Buddhist halls. There is not always complete stylistic consistency within any one cultural group. For example, the fantastic snake-dragon creatures carved in deep relief on the housedoors of the Batak may be extravagantly sinuous, with many spirals, while their figure sculpture adheres to the sterner plastic idiom, virtually without any linear sinuosity. Among the Dayak of Borneo the fantastic style may be confined entirely to surface ornament. On Indonesian islands, ancestral figures may be relatively static and foursquare, while the decorative carving and textiles may display considerable linear fantasy. A special version of the ornamental–fantastic style characterizes the surviving Indianized arts of Bali and Java, intruding even into sculptural inventions derived from strongly three-dimensional medieval Indianizing patterns. Thus, the decoration on the *wayang* cutout leather puppets, with its somewhat stereotyped curlicues, has proliferated at the expense of the three-dimensional sense (see above *Indonesia*). Balinese *wayang* masks may be carved entirely out of curling surfaces and completed in paint with sinuous eyebrows and moustaches. In many parts of Southeast Asia, including Thailand, Vietnam, Burma, Sumatra, and Indonesia, designs originally based upon Indian flowering-scroll patterns can be found in architecture, textiles, theatre costumes, musical instruments, and wooden utensils, all efflorescing with extravagant curling ornament. It is unfortunately true that only in a few of its most serious manifestations does this kind of ornament display substantial artistic invention, with carefully varied, asymmetrical, complementary, and counterchanged curves. Usually, it degenerates into repetitive space filling, without variety or formal meaning.

Use of curves and spirals

Textiles. Perhaps the types of folk art best known in the West are the textiles, especially batik and *ikat*. Both names refer to techniques practiced by different groups of people, who must have learned it from each other. Essentially Javanese but known in other islands, batik may have resulted from the imitation with dyes of South Indian painted cloths, probably before 1700. The essence of the technique is that melted wax is poured from a small metal kettle onto areas of a plain cotton cloth, which is then dyed, only the unwaxed parts taking the colour. The process can be repeated with several different colours. The oldest basic colours are indigo and brown; red and yellow were used later. The possible patterns range from lozenges and circlets through a large repertoire of cursive animal and plant forms. The batik technique can produce sumptuous and complex designs that not even the most elaborate weaving techniques can duplicate. It was encouraged by the Muslim rulers as a major element of social expression in garments and hangings.

Batik and *ikat*

Ikat is known among the Batak, in Cambodia, and especially among the dispersed Dayak people. It, too, probably originated in India. The extraordinarily difficult *ikat* textiles (woven cotton and occasionally silk, especially in Cambodia) are made primarily for use in important ceremonials and were regarded by their makers as major works of art. Before being woven, the thread is tightly tied at carefully calculated points in the hank (coiled or looped bundle); this is then dyed, the tied parts not taking up dye. The process may be repeated for different colours. As a consequence of the predyeing, designs appear as the thread is woven. In most *ikat* only the warp (the series of yarns extended lengthwise in the loom and crossed by the weft) is so treated; but in southern Suma-

tra a tie-dyed floating weft is added to the plain weft. Naturally, *ikat* designs tend to be static and more or less rectilinear. In the finest *ikat*, however, birds and animals, spirits and houses, and, in Cambodia, a vestigial iconography of royal Buddhism may be formalized into extremely beautiful banded compositions. (P.S.R.)

Music: WILLIAM P. MALM, *Music Cultures of the Pacific, the Near East, and Asia*, ch. 2 and 5 (1967), discusses the music of the Southeast Asian region; LAWRENCE PICKEN, "The Music of Far Eastern Asia and Other Countries," in *The New Oxford History of Music*, vol. 1, *Ancient and Oriental Music*, pp. 83–194 (1957), discusses intercultural and musical relationships between Far Eastern and Southeast Asian countries. (*Burma*): U KHIN ZAW, "Burmese Music: A Preliminary Inquiry," *Journal of the Burma Research Society*, pp. 387–466 (December 1940), appends several pages of music notations to a discussion of music history and the structure of Burmese scales. (*Cambodia and Laos*): ALAIN DANIELOU, "La Musique du Cambodge et du Laos" (1957), is a brochure that discusses with the help of illustrations traditional musical instruments of both countries. (*Indonesia*): JAAP KUNST, *Music in Java*, 2 vol. (1949), an important work with a comprehensive bibliography including works of many Dutch scholars, treats matters regarding history, vocal and instrumental music, structure, notation, and tonal systems of the East-Central and the West-Javanese gamelan; MANTLE HOOD, *The Nuclear Theme As a Determinant of Patet in Javanese Music* (1954), modal structure of patet is analyzed according to basic elements in themes of several gamelan pieces of music; COLIN MCPHEE, *Music in Bali* (1966), gives detailed descriptions and specific musical examples of repertoire played in many gamelan ensembles; WALTER KAUDERN, "Musical Instruments in Celebes," in *Ethnological Studies in Celebes*, vol. 3 (1927), a detailed study with a long list of names of musical instruments, 130 figures, and 19 maps showing the geographical distribution of musical instruments; JAAP KUNST, *Music in Nias* (1939), describes both vocal and instrumental music, classifies musical instruments (Hornbostel-Sachs divisions), and illustrates their distribution in 7 maps; *Music in Flores* (1942), lists in a table the native names of 54 instruments of the five divisions of the archipelago; CHARLES S. MYERS, "A Study of Sarawak Music," *Sammelbände der Internationalen Musikgesellschaft*, 15:296–308 (1913–14), 13 gongs from different cultural groups and music of some instruments are analyzed with the help of musical examples; HENRY L. ROTH, *The Natives of Sarawak and British North Borneo*, 2 vol. (1896)—vol. 1, ch. 9 deals with feasts, festivals and dancing, while vol. 2, ch. 26 discusses music in general; EDWIN H. GOMES, *Seventeen Years Among the Sea Dyaks of Borneo* (1911), terms for songs and names of musical instruments that the author cites are still known in Sarawak; IVOR EVANS, *Among Primitive Peoples in Borneo*, ch. 14 (1922), devoted exclusively to a discussion of musical instruments, music, and dancing; JAAP KUNST, *Music in New Guinea* (Eng. trans. 1967), comprises three works first published in 1931 and 1950 that treat of vocal and instrumental music of the Papua in the north and the central range of mountains, of songs in the north and the West, and of music in the West Central range, Southwest, North and West coasts (many musical examples and a distribution map of musical instruments). (*The Philippines*): JOSE MACEDA, "The Music of the Magindanao in the Philippines," (1963, Ann Arbor University Microfilms), discusses instrumental and vocal music of the whole culture with copious musical examples and two long-playing records available at Folkways Records, New York; and "Drone and Melody in Philippine Musical Instruments," paper read at an International Conference on Traditional Drama and Music of Southeast Asia, Kuala Lumpur, August 27–31 (1969), discusses age, spread, and variety of combinations of drone and melody as a root structure. (*Thailand*): DAVID MORTON, "The Traditional Instrumental Music of Thailand," (1964, Ann Arbor University Microfilms), a study that covers both the historical and structural aspects of Thai music. (*Viet Nam*): TRAN-VAN-KHE, *La Musique Vietnamienne traditionelle* (1962), detailed and important information about history, musical instruments, and musical theory (references abound with criticism of some works); and *Vietnam* (1967), a clear and concise presentation, containing valuable new historical material.

Dance and theatre: JAMES R. BRANDON, *Theatre in Southeast Asia* (1967), a general survey of major theatre forms, incorporating firsthand observation. (*Burma*): MAUNG HTIN AUNG, *Burmese Drama* (1937), a detailed history and translations of plays, four complete and eight in excerpts; KENNETH SEIN and J.A. WITHEY, *The Great Po Sein* (1965), a lively chronicle of the Burmese stage of the last century, cast in the first person narrative, by a famous contemporary actor; U POK NI, *Konmara Pya Zat* (1952), a complete English translation of a 19th-century play with interpretive notes. (*Cambodia*): JACQUES BRUNET, "Nang Sbek, Danced Shadow Theatre of Cambodia," *World of Music*, 11:18–37 (1969), a brief and excellent description and history of Cambodian shadow theatre; SAMDACH CHAUFEA THIOUNN, *Danses cambodgiennes*, 2nd ed. (1956), the most complete history and analysis of plays, music, and dance of female and male dance-drama. (*Indonesia*): BENEDICT R.O'G. ANDERSON, *Mythology and the Tolerance of the Javanese* (1965), major *wajang* characters are described and their significance as behavioral models is treated; JAMES R. BRANDON (ed.), *On Thrones of Gold: Three Javanese Shadow Plays* (1970), translations, with description of action, music indication, and photographs, of three *wajang kulit* plays; CLAIRE HOLT, *Art in Indonesia* (1967), excellent chapters on *wajang kulit*, dance, and dance-drama in all parts of Indonesia; JAMES L. PEACOCK, *Rites of Modernization* (1968), the plays, structure and content, of *ludruk* in Java as seen through the eyes of a modern anthropologist; W.H. RASSERS, *Pañji, the Culture Hero* (1959), a disputed but brilliant theoretical discussion of the origin and meaning of Indonesian theatre; H. ULBRICHT, *Wayang Purwa: Shadows of the Past* (1970), useful for its extended translations of synopses of Pandawa plays found in J. KATS's famous Dutch work *Het Javaansche tooneel*, vol. 1, *Wajang Poerwa* (1923); BERYL DE ZOETE and WALTER SPIES, *Dance and Drama in Bali* (1938), an authoritative and encyclopaedic pre-World War II description of Bali's performing arts. (*Malaysia*): JEANNE CUISINIER, *Le Théâtre d'Ombres à Kelantan*, 2nd ed. (1957), Malaysian shadow theatre described and illustrated, with a partial play translation; RICHARD WINSTEDT, *The Malays: A Cultural History*, 6th ed. (1961), contains background information on Malaysian drama, including translations of pre-performance invocations. (*The Philippines*): JEAN EDADES (ed.), *Short Plays of the Philippines* (1950), a collection of recent one-act plays in English; ALBERTO S. FLORENTINO, *Outstanding Filipino Short Plays* (1961), short plays with two appendixes on traditional and modern drama in the Philippines; FRANCISCA TOLENTINO, *Philippine National Dances* (1946), descriptions and brief histories of many folk dances. (*Thailand*): UBOL BHUKKANASUT (trans.), "Manohra," in *Traditional Asian Plays*, ed. by JAMES R. BRANDON (1972), a translation with stage directions of the *lakon jatri* play "Manohra"; H.H. BRIDHYAKORN, "The Nang," 3rd ed. (1956), a short booklet on *nang yai* shadow play; and with DHANIT YUPHO, "The Khon," 3rd ed. (1956), a short booklet on *khon* masked pantomime; DHANIT YUPHO, *Classical Siamese Theatre* (1952), 52 folk and clas-

sical dance sequences described and illustrated; and *The Khōn and Lakon* (1963), synopses, commentary, and illustrations for 32 classic dance plays as performed by the Bangkok Department of Fine Arts between 1947 and 1960. (*Vietnam*): SONG-BAN, *The Vietnamese Theatre* (1960), brief descriptions of theatre in North and South Viet Nam.

Visual arts: PHILIP S. RAWSON, *The Art of Southeast Asia: Cambodia, Vietnam, Thailand, Laos, Burma, Java, Bali* (1967), a comprehensive survey with many illustrations and plans; BENJAMIN ROWLAND, *The Art and Architecture of India*, 3rd ed. rev. (1967), sets the art of the region in relation to South Asian, or Indian art; WIM SWAAN, *Lost Cities of Asia* (1966), a pictorial study of Ceylon, Pagan, and Angkor; detailed articles in the *Encyclopedia of World Art* (1960–67): GEORGE COEDES, "Burmese Art," "Khmer Art," and "Cham Art"; A.B. GRISWOLD, "Siamese Art"; MADELEINE HALLADE and ROBERT HEINE-GELDERN, "Indonesian Art"; LOUIS BEZACIER, "Vietnamese Art"; and J.M.R. RIVIERE, "Philippine Art"—all these articles have extensive bibliographies. (*Burma*): A.B. GRISWOLD, CHEWON KIM, and P.H. POTT, *Burma, Korea, Tibet* (U.S. title, *The Art of Burma, Korea, Tibet;* 1964), the only survey of Burmese art; BURMA RESEARCH SOCIETY, *Fiftieth Anniversary Publications*, vol. 2 (1960), source material including important articles in English by G.H. LUCE and W.B. SINCLAIR. (*Champa*): The basic studies are PHILIPPE STERN, *L'Art du Champa (ancien Annam) et son évolution* (1942); and LOUIS BEZACIER, *Relevé des monuments anciens du Nord Viêt-nam* (1959). (*Siam and Laos*): Three basic sources include SILPA BHIRASRI, *Thai-Mon Bronzes* (1957), and *The Origin and Evolution of Thai Murals* (1959); and L. BORIBAL BURIBHAND and A.B. GRISWOLD, "Sculpture of Peninsular Siam in the Ayuthya Period," *Journal of the Siam Society*, 38:1–60 (1951). PIERRE DUPONT, *L'Archéologie mône de Dvāravatī* (1959), is the most authoritative study of this topic so far. The chief illustrated source for dating Buddhist art is A.B. GRISWOLD, *Dated Buddha Images of Northern Siam* (1957). (*Indochina*): JEAN BOISSELIER, *La Statuaire khmère et son évolution*, 2 vol. (1955), an exhaustive study of the development of Khmer sculpture; GEORGE COEDES, "Le Culte de la Royauté divinisée . . . ," *Série Orientale*, conference vol. 5 (1952), a basic iconographic study; PIERRE DUPONT, *La Statuaire préangkorienne* (1955), the authoritative book on pre-Angkor sculpture; LOUIS FREDERIC, *Sud-Est Asiatique: ses temples, ses sculptures* (1964; Eng. trans., *The Temples and Sculptures of Southeast Asia* (U.S. title, *The Art of Southeast Asia: Temples and Sculpture;* 1965), a well-documented pictorial survey; BERNARD P. GROSLIER, *Indochine: carrefour des arts* (1961; Eng. trans., *Indochina: Art in the Melting Pot of Races*, 1962), the most comprehensive survey in English; and with JACQUES ARTHAUD, *Angkor, hommes et pierres* (1956; Eng. trans., *Angkor: Art and Civilization*, rev. ed., 1966), a thoroughly documented pictorial survey. (*Indonesia*): F.A. WAGNER, *Indonesia: The Art of an Island Group* (1959), a comprehensive survey of Indonesian art in English; A.J. BERNET KEMPERS, *Ancient Indonesian Art* (1959), a comprehensive illustrated book. Major works on Borobudur include T. VAN ERP, *Beschrijving van Barabudur*, vol. 2, *Bouwkundige beschrijving* (1931); N.J. KROM, *Barabudur: Archaeological Description*, 2 vol. (1927); and PAUL MUS, *Barabudur, esquisse d'une histoire du bouddhisme fondée sur la critique archéologique des textes* (1935), which covers the subject of the role of Indian philosophy and theology as a background to Borobudur.

(M.H.Au./Jé.Ma./J.R.B./P.S.R.)

Southern Africa, History of

The subcontinent of southern Africa is a vast region that includes the independent states of Angola, Botswana, Lesotho, Malawi, Mozambique, Rhodesia, South Africa, Swaziland, Transkei, and Zambia and the United Nations Trust Territory of South West Africa (Namibia).

Until the 1960s the history of this area was treated only in terms of the political struggles of white elites during the colonial period. Since then, however, it has become clear that the history of the region must also take into account the historical experience of all the peoples of southern Africa, over a period far longer than the colonial era. Although the realization poses a good many problems in methodology, interpretation, and organization and there are still many facts to be ascertained, major advances have nonetheless been made in showing the evolution, interaction, and ultimate interdependence, as well as the conflicts, of the diverse peoples who inhabit the subcontinent. This article is divided into the following sections:

I. Southern Africa to 1800
- Early man and the Stone Age
- The coming of the Iron Age
- The Portuguese
- The Dutch at the Cape

II. Southern Africa in the 19th century
- The Mfecane and its effects
- The slave and ivory trade north of the Zambezi
- British occupation of the Cape
- The Great Trek
- The Transvaalers and their neighbours
- The Orange Free State and Lesotho
- The British colonies of the Cape and Natal
- The era of mineral discoveries and confederation
- The scramble for southern Africa
- Angola and Mozambique
- The Germans in South West Africa

III. Southern Africa, 1900–45
- White settlers south of the Limpopo
- White settlers north of the Limpopo
- Land, labour, and colour bars
- The African responses

IV. Southern Africa since 1945
- South and South West Africa
- The High Commission Territories
- British Central Africa
- Angola and Mozambique

I. Southern Africa to 1800

EARLY MAN AND THE STONE AGE

The story of man in southern Africa may go back some 3,000,000 years—that is, close to the beginnings of man himself. Some of the most exciting fossil discoveries connected with early man have been discovered in the subcontinent, suggesting that for hundreds of thousands of years it stood in the forefront of human development and technological innovation. With East Africa, southern Africa has seen the evolution of hominids into the erect being who, deliberately fashioning tools to a regular and set purpose, is commonly defined as man.

The hominids' way of life

For a long time, small groups of manlike creatures roamed the open savanna lands of southern and Central Africa, collecting fruits and berries—and perhaps roots—and also perhaps catching small wild animals to supplement their diet. During the Early Stone Age, the hominids, using first pebble tools and, later, all-purpose stone axes and natural traps, gradually became more skilled as hunters, and by the second half of this period (about 200,000 to 100,000 years ago) they had also become more mobile, making their camps not only in watercourses in the dry savanna and coastal areas to which they had previously been restricted but also in the more heavily wooded country in what are now Zambia and Angola. This extension in the range of suitable habitats was made possible by the controlled use of fire, as is evidenced by living floors at Kalambo Falls dating from 200,000 years ago.

After hundreds of thousands of years of relatively undifferentiated tools, the Middle Stone Age, 80,000 to 100,000 years ago, was one of experimentation, regional development, and diversification. It was at the end of this period that early *Homo sapiens* gave way to modern man. Gradually, too, the large, crude stone tools were replaced over most of the area with a new, broadly similar range of small, light cutting and projectile tools; this culture is known, after its typesite in the eastern Cape Province (South Africa), as the Wilton. Within this single culture, such distinctions as exist are now thought to reflect changing fashions and local adaptations rather than any clearcut cultural or ethnic distinction between the toolmakers. A larger, more mobile population with more varied settlement and subsistence patterns was able to exploit its environment more effectively than ever before.

Apart from the widespread Wilton culture, the Late Stone Age also saw the evolution of a specifically woodland tool industry in northeastern Zambia and northern Malawi, known as Nachikufan. This is characterized by

heavier tools, including bored stones for weighted digging sticks, and suggests greater emphasis on food-gathering than on hunting.

Though there is considerable controversy and terminological confusion over the nature of Middle and Late Stone Age skeletal remains, it seems clear that the Late Stone Age population of southern Africa encountered in historic times—Pygmies, San (commonly called Bushmen), and Khoikhoi (conventionally, but incorrectly, Hottentots)—were basically genetic developments of an ancient African stock that had evolved in the subcontinent. Khoisanoid (a composite term used to refer to the racially identical San hunter-gatherers and Khoikhoi herders) remains are associated with the Wilton culture over much of southern and eastern Africa. There is some slight evidence also of a small non-Khoisan element, which may be associated with the stone bowl cultures of East Africa and just possibly with the origins of sheep and cattle pastoralism in southern Africa.

During the Late Stone Age, hunter-gatherers, organized in loosely knit bands of which the family was the basic unit, achieved greater dominance over their environment by the use of bows and arrows, often tipped with poison, and a variety of snares and traps. With hooks, barbed spears, and wicker baskets, they were able to catch fish and to exploit rivers, lakeshores, and seacoasts in a new way. Each group of hunter-gatherers had its own territory in which special importance was attached to natural resources, such as staple plant foods, water holes, or wild bees' nests; in many instances, bands moved from summer to winter camping sites, following the game and vegetation, as they were to do later in historic times.

Stone Age art

Also associated with the Late Stone Age are magnificent cave paintings and engravings on rocky outcrops throughout southern Africa. Whereas in the northern woodlands the art is stylized and schematic, that of the savanna and coastlands is naturalistic—showing scenes of hunting and fishing, of ritual, and of celebration—and vividly conveys the life of the Late Stone Age hunter-gatherer. It is in the rock art, too, that there appears the first hint of the new groups of herders and farmers who were to revolutionize the way of life that had developed over the past hundreds of thousands of years.

At a number of coastal sites in the Cape Province, dating from about the beginning of the Christian era, there is clear evidence of the presence of sheep, associated with the distinctive pointed base, lugged pottery found in middens from Swakopmund in the north to at least as far as East London, as well as along the Orange River. Although as yet no cattle bones have been discovered so early, one of the outstanding problems for Late Stone Age research is to elucidate the spread of sheep and cattle pastoralism, which was later to be so closely associated with the Khoi herders encountered by the first Europeans to round the tip of the subcontinent. (For further information see AFRICANS, PREHISTORIC.)

THE COMING OF THE IRON AGE

Since there is no evidence in southern Africa of a Neolithic culture similar to that of the east and north, the coming of the Iron Age to the subcontinent appears to have brought with it the food-producing revolution—one of the most significant developments in its history. Agriculture combined with pastoralism supported far larger settled communities than had been possible with Stone Age techniques of hunting and gathering and enabled more complex social and political organizations to develop; and it is with the evolution of these Iron Age farmers' communities into present-day African societies that the precolonial history of the region is concerned.

As in the Stone Age, it is the archaeologist (with the help of linguists, anthropologists, and ethnobotanists) who provides the evidence—incomplete though it may be—of the coming of agriculture, new forms of pottery, and ironworking to southern Africa.

Early Iron Age

Though documentary evidence and oral tradition go back at most 500 years, archaeological finds make it increasingly clear that the complex of traits that is labelled the Iron Age first appeared in southern Africa in the first half of the 1st millennium AD. From the 4th to 7th century AD, pottery, ironwork, traces of agriculture, and the bones of domestic animals appear in many southern African sites, as far south as the Transvaal, Swaziland, and Natal. Virtually no Early Iron Age sites have been excavated in Mozambique, while the couple of Early Iron Age dates for Angola—one of which is for AD 700–800—are disappointingly meagre for an area that shows so many signs of having had a rich Iron Age past. The spread of these Iron Age sites, nevertheless, is generally consistent with what is known of the spread of the closely related Bantu languages; and it is reasonable to suggest that, on the whole, these Early Iron Age sites represent the first settlements of Bantu speakers, the precursors of the majority of southern Africa's present-day population—though in certain areas, especially in the south, ironworking techniques and food production may well have been adopted by the earlier Khoisan population.

Spread of Bantu languages

This movement into southern Africa was part of the wider expansion of Iron Age culture. Penetrating to the woodlands south of the moist forest zone of Central Africa, it seems to have spread rapidly over the subcontinent, to areas with an adequate water supply and soils suitable for cereal cultivation. While the Early Iron Age farmers probably had cattle and therefore had to avoid the dangerous tsetse-fly belts, they also tended at first to avoid the more arid western half of the subcontinent, which was suited only to a specialized pastoral way of life. Here the first Iron Age dates appear to be later than in the better watered easterly regions.

As they spread, the Iron Age minority probably absorbed the earlier Stone Age population in a variety of ways, leaving small remnant groups in the southern and western fringes of the continent. The result is that today the Bantu-speaking peoples of southern Africa do not constitute a racially or genetically uniform group and include a number of physical types; the term Bantu is, in fact, only linguistic.

Most of the Early Iron Age communities in the subcontinent appear to have shared a common culture, which from the earliest times showed considerable regional variation. The regional diversity within the common pottery tradition suggests a rapid differentiation and proliferation; either groups broke off from a central or parent chiefdom, or new trickles of related peoples arrived from neighbouring areas. In the later period, for which oral tradition exists, both processes were at work, and the movement described is extremely intricate and difficult to unravel. It seems likely that the patterns were similar earlier, when the availability of sparsely occupied land led people to found new settlements for various social, economic, and political reasons. The old picture of invading hordes of Bantu speakers moving into southern Africa, brandishing iron weapons, and wiping out the earlier inhabitants is not supported by the evidence, which suggests small trickles of migration and the cultural and genetic absorption of earlier peoples.

From early times, Iron Age farmers made use of metals, settled near mineral as well as salt deposits, and engaged in short-distance trade. Iron implements, such as hoes, and possibly pottery as well, passed from hand to hand, as some communities became known as specialist craftsmen or settled near exceptionally good iron or clay deposits. From potsherds and iron implements found in otherwise Late Stone Age sites, it is clear that a good deal of trade also passed between the Iron Age farmers and the earlier hunter-gatherers. From about the turn of the 1st millennium AD there is a sharp break in the earlier cultural traditions over most of what are now central Zambia, southwestern Rhodesia, and parts of Malawi and the Transvaal, as shown by the markedly new ceramic wares. The new culture, Leopard's Kopje II, was apparently strongly pastoral; for the first time, large numbers of cattle bones appear in the archaeological record, as well as cattle figurines. It is plausible to suggest that this break represents the entry of immigrants into the subcontinent. Again, however, it is not necessary to posit the movement of large numbers of people; the expansion of both human and cattle populations at this time may

Later Iron Age

well have been the result of the absorption, on a relatively large scale, of earlier Iron Age farmers and Khoisan hunter-gatherers and herders into the new culture complex. From this time on, there is a broad continuity in the archaeological record, until colonial times—an essential unity within which widely disseminated political, social, and technological ideas were developed and refined as a result of local circumstances. It was in this period that the foundations of the contemporary Bantu-speaking societies of southern Africa were laid.

From the 12th century on, a number of sites in southern Africa bear witness to the beginnings of more complex state structures, increased social stratification, new religious and ritual ideas, and more sophisticated techniques of agriculture and metalworking, and in particular gold mining, probably initiated by an increase in long-distance trade. From the late 1st millennium, Iron Age cultures included mining in copper and some gold. In Rhodesia alone there are more than 1,100 prehistoric gold mines and 150 copper mines, associated predominantly with Leopard's Kopje II, while in the Transvaal there are literally thousands of prehistoric iron, copper, and tin mines. While most of these date from the 2nd millennium and are associated with the stone buildings of the Uitkomst and Buispoort cultures of the southern and central Transvaal, at Phalaborwa in the eastern Transvaal iron was being mined by the 8th century, and a little later the area became one of the richest sources of copper. By the 10th century, alluvial gold and copper were not simply being traded internally but were also finding their way to outlets on the east coast, though still in small quantities.

Prehistoric mining

In the early centuries of the Christian era, the northeast African coast was well-known to the traders of the Greco-Roman world. These contacts diminished with the rise of Islām, and the east coast became part of the great Indian Ocean trading network; by the 8th century, Arab traders from settlements on the northeast coast began to visit the more southerly harbours, where gold and copper were the most valuable exports. By the 10th century, the gold trade of Sofala (now Nova Sofala) was well known in the Muslim world, and by the 14th century the trade was being controlled by Kilwa, off the coast of what is now southern Tanzania. Between the 11th and 15th centuries some 37 new towns were founded along the coast, and there were trade routes between the coast and the gold-producing area of Penhalonga and Inyanga in present-day Rhodesia, the copper-bearing regions of the interior, and possibly Lake Malawi (Nyasa), with its large herds of elephants.

Though these towns never united politically, they developed a common Afro-Arab or Swahili culture and a splendour that amazed the Portuguese when they arrived on the east coast at the end of the 15th century. On the whole the Arabs relied on African intermediaries to bring their valuable exports to the coast, and a good deal of the trade depended on the older regional networks, although by the 15th century Arab traders had also established overland routes into the interior of south central Africa.

The later Iron Age and its trading networks are best known from three sites in southern Africa—though they may not typify the later Iron Age as a whole. They are Zimbabwe in southwestern Rhodesia, Ingombe Ilede in Zambia, and Mapungubwe, just south of the Limpopo River in the northern Transvaal. These sites all show a broad cultural similarity and were linked to the coastal trade. The most northerly, Ingombe Ilede, on the north side of the middle Zambezi, dates to the 14th or 15th century, and is associated with several settlements of the same people in the extreme northwest of Mashonaland. Its heyday was probably contemporary with that of both Zimbabwe and Mapungubwe. In a strategic position astride the Middle Zambezi and close to mineral and salt deposits, it probably exported chiefly copper. By the middle of the 2nd millennium it was a flourishing trading centre. The archaeological evidence suggests that, as in the case of Zimbabwe and Mapungubwe, the trade was in the hands of a wealthy ruling elite who could afford to be buried in gold and copper ornaments, imported beads, and exotic cloth; their graves are in striking contrast to the stark burials of the common folk at the site. The agricultural economy of the latter closely resembles that of the recent Tonga inhabitants of the area.

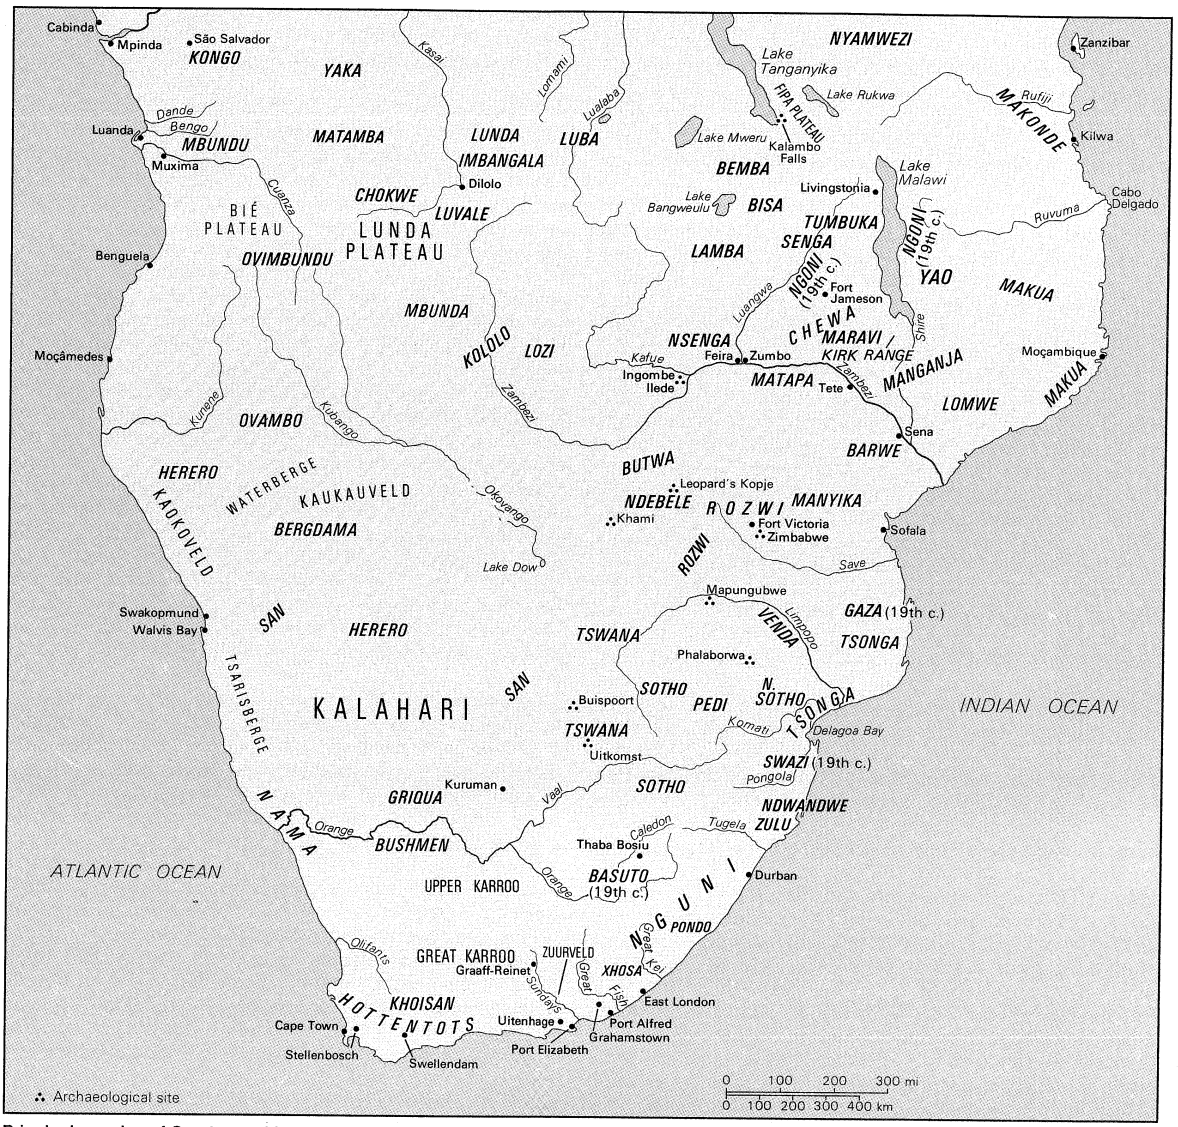
Zimbabwe, Ingombe Ilede, and Mapungubwe

It is, however, Zimbabwe, with 60 acres (24 hectares) of imposing ruins, that has dominated the discussion of the Late Iron Age of southern Africa. Long the subject of mystery and romance, the Zimbabwe complex—Great Zimbabwe is simply the largest of more than 150 similar ruins extending from southwest Rhodesia into Mozambique—has now been clearly established as of African origin and of medieval date. A ritual centre until the 19th century, concerned with rain making and the cult of Mwari, the great god of the Shona, in the 14th and 15th centuries Great Zimbabwe was also the centre of a powerful and wealthy empire, which owed its rise to the east coast gold trade. By the latter half of the 15th century, however, Zimbabwe had experienced an abrupt end to its prosperity, and the focus of power had shifted elsewhere.

The first references to Zimbabwe and Mbire, its 14th-century semi-mythical founder, come from oral traditions: from the 15th century the traditions are clearer. Mbire's great-great grandson Nyatsimba, the first *mambo,* or ruler, to earn the title Mwene Matapa (or Mwene Mutapa; also Monomotapa), or Ravager of the Lands, launched ambitious military campaigns to create an empire, which, at its height, is reputed to have stretched from the Zambezi to the Limpopo and from the Kalahari to the Indian Ocean. Zimbabwe hegemony probably also extended over the hill site at Mapungubwe in the middle Limpopo Valley.

Fierce controversy has raged around the racial identity of the occupants of Mapungubwe Valley. Their culture, however, is both contemporary with and similar to the Leopard's Kopje II culture of Rhodesia, whereas the Mapungubwe hill site itself, which dates from the 14th and 15th centuries, belongs firmly to the Zimbabwe tradition, with its extensive stone walling, imported glass beads, spindle whorls, gold, copper, and bronze jewelry, gold sheeting, and solid mud and clay huts.

The reasons for the shift, during the reign of Nyatsimba, of the Zimbabwe empire's focus from southwest Rhodesia to Mt. Fura on the Zambezi bend may be explained by the poor agricultural or mineral resources of the Zimbabwe area; the overextension of its human and natural potential in an effort to maintain the opulence of its buildings and exotic imports; and the importance, by the 15th century, of the Zambezi as a waterway linking the east coast with the interior.



The decline of Great Zimbabwe

Though the empire of the Mwene Matapa owed its creation and consolidation to the prowess of Nyatsimba and to his very able son and successor, it was so large and unwieldy—given the nature of the communications and technology of pre-industrial Iron Age societies—that by the end of the century the Mwene Matapa was forced to relinquish his hold over Butua, the older centre of the empire in the southwest, and to recognize by the first half of the 16th century that power was already more restricted than it had been at the end of the 15th.

By this time, it appears, the Iron Age ancestors of South Africa's contemporary Bantu-speaking peoples to the south had stabilized as farming communities in roughly their present-day habitats, reaching their ecological frontier along the 40–50-centimetre rainfall isohyet on the Highveld and gradually clearing the forests along the southeast coast.

THE PORTUGUESE

In the hope of outflanking Islām, finding a sea route to the riches of India, and discovering additional sources of food, the Portuguese had edged their way around the African coast from the 15th century onward. They reached the Kingdom of the Kongo, to the north of present-day Angola, in 1482–83; early in 1488 Bartolomeu Dias rounded the tip of the continent; and just over a decade later, Vasco da Gama sailed along the east coast

Principal peoples of Southern Africa, 17th to mid-19th century.

of Africa, before striking out to India. Within eight years of their arrival, the Portuguese had seized all of the important centres along the east coast, including Sofala, Kilwa, and Mombasa, and by 1507 they had built a fortress and refreshment station on Mozambique Island, which soon became the key port of call for ships on the way to the Indies.

The Portuguese in southeast Africa. The immediate result of the Portuguese conquests was the economic and cultural decline of the east coast cities. The Portuguese soon discovered that they were unable to control the vast area they had conquered. Throughout the 16th century they faced resistance from the Swahili communities on the coast, and the profits that they had expected from the gold trade at Sofala failed to materialize.

Portuguese expansion

In an attempt to control the trade and to discover the precious minerals for themselves, the Portuguese began to expand into the Zambezi Valley. In the 1530s they established fortresses at Sena and at Tete, where Portuguese captains, elected by Portuguese residents, were delegated certain powers by the Mwene Matapa. Individual Portuguese and Goans, who followed in their wake, were also able to get land grants and jurisdiction rights from local African chiefs. Out of these early grants grew the system of landholding along the Zambezi known as the *prazo* system. Between the 17th and 19th centuries the *prazo* holders became immensely powerful and were able to resist attempts by the Portuguese crown to reform their landholdings and to interfere actively in local African politics. The Afro-Portuguese society of the lower Zambezi Valley that was produced by this process showed remarkable resilience well into the 19th century.

Despite the gradual spread of the Portuguese along the Zambezi Valley and their desire to control the gold trade, there was little impetus for exploration until King Sebastian gained control of Portugal in 1568. In the following year Francisco Barreto was sent as governor to Mozambique with instructions to explore the mineral resources of the Mwene Matapa's kingdom. Despite a military victory in 1572, Barreto's expedition made little impact in southeast Africa, but by the end of the 16th century the Portuguese presence was being felt increasingly, both in the Zambezi Valley and beyond. Though mainly interested in the gold trade south of the Zambezi, the Portuguese also disrupted the ivory trade north of the river.

This disruption and the effect it had on the earlier configuration of power and wealth north of the Zambezi may have contributed to the changes evident in the area of present-day Malawi toward the end of the century. These are chiefly known from the sudden irruption of the so-called Zimba, who appeared along the Zambezi in the 1580s, attacking Sena and Tete between 1592 and 1593 and then the Portuguese settlements along the coast. The Zimba—a term indiscriminately applied to any marauding group—were followers of the *lundu* (chief) living to the south of the Shire River, and their migrations were probably set off by rivalries between the two most powerful Maravi kingdoms in the Shire Valley.

Through the 17th century Maravi was a powerful and widely recognized confederacy, able to dominate the lesser peoples to the east and control the access of traders to Mozambique. By the end of the century the rise of the Yao traders on the east of Lake Malawi and of the Bisa to the west contributed to the disintegration of the Maravi confederacy into several more or less autonomous fragments.

Though the Maravi empire flourished in the 17th century despite, or even because of, the Portuguese presence, direct contact with the Portuguese proved hazardous to the Mwene Matapa. After an unsuccessful attempt by the reigning Mwene Matapa to drive all the Portuguese out of his domains in 1629, he was replaced by a puppet king from whom the Portuguese, taking advantage of internal dissensions, extracted trading and mining privileges. Yet this appearance of Portuguese power and prestige was deceptive, for even vassal kings could rebel, and the Portuguese never had the resources to really control the interior. The *prazo* holders were as much an African as a Portuguese force and acted with increasing independence from the Portuguese crown, while the gold trade probably never did more than balance the administrative costs of Mozambique.

Decline of Portugal in southeast Africa

There were, moreover, external factors weakening the hold of Portugal in southeast Africa. From the beginning of the 17th century the Portuguese faced increasingly severe competition from Dutch and British ships in their colonial waters, while north of Cabo Delgado the Arabs took advantage of Portuguese weakness. In 1631 the first of a series of revolts began, which, by the first decades of the 18th century, had driven the Portuguese from the coast north of the Ruvuma River and had turned African trading interests southward.

Even before this, Portuguese power in Mashonaland had crumbled completely. When, between 1693 and 1695, the Mwene Matapa had, in desperation, called for the help of Dombo, the *changamire* (or ruler) of the powerful Rozwi kingdom (which had been established in the 17th century in the old centre of the Mwene Matapa's empire in southwestern Rhodesia), Dombo responded with alacrity. Sweeping up to the Zambezi, he forced a Portuguese retreat. His intervention, however, was as disastrous for the Mwene Matapa as for the Portuguese. Completely shadowed by the rising power of the Rozwi empire, the Mwene Matapa was reduced to ruling a small chiefdom in the northeastern corner of Rhodesia. The hegemony of the *changamire* was probably recognized over much of present-day Rhodesia until the early 19th century, though the area of polychrome pottery and stone building in southwest Rhodesia probably represents the Rozwi heartlands. Heading a confederacy rather than a unified state, the *changamire* had both religious prestige and military power. His wealth was based on the agricultural and pastoral resources of his kingdom, internal tribute, and trade with his African neighbours as well as with the Arabs, Indians, and Portuguese.

In addition to gold, the Portuguese were also interested in ivory and in other mineral resources. A search for silver mines first led them into Malawi in the 17th century, and by the early 18th century they had penetrated into present-day Zambia. In 1714 they established a trading fair at Zumbo, and in 1732 Feira was founded. Though there were no highly organized broker kingdoms in the area, a number of different African peoples were trading with the Portuguese by this time.

Similarly, from the mid-16th century onward the Portuguese sent trading expeditions down the coast from Mozambique Island to Delagoa Bay, where they found the local Tsonga inhabitants willing and keen intermediaries in the local ivory trade. As the Portuguese position on the southeast coast weakened in the 18th century, their expeditions diminished, and they were supplanted in the dominant trading role by British and Dutch rivals until the end of the century. Nevertheless, the ivory trade and European competition in Delagoa Bay and its hinterland significantly affected political relationships and the rise of state systems in the area in the course of the second half of the 18th century.

The Portuguese in west central Africa. Though the Portuguese influence in west central Africa radiated over a far wider area and was far more permanent, dramatic, and destructive than that on the east coast, it was, paradoxically, initially more constructive. The Portuguese arrived in the north of present-day Angola in 1483 and there encountered the Kingdom of the Kongo, one of the most highly centralized and complex states in southern and Central Africa. The Kongo Kingdom seems to have originated in the 14th century. Like the kingdom of the Mwene Matapa, it was not the only centralized state of its kind in the area, but it is the best known example of similar state structures in west central Africa. At its head was the king, or *manikongo,* around whom everything revolved. The kingdom, which stretched from beyond the Congo River in the north to the Dande in the south, was divided into six provinces, each of which was headed by officials appointed by the king. Below the province was the village, organized around matrilineages. Though the economy was essentially agricultural, it appears that even before the arrival of the Portuguese there was a flourishing trade in shells, salt, and palm cloth. The *manikongo* also appears to have extracted tribute from neighbouring chiefdoms in recognition of Kongo paramountcy.

The Kingdom of the Kongo

Within a few years of their initial contact with the Kongo Kingdom, the Portuguese had conceived a vast scheme for technical aid and education; this was attributable as much to the desire of the Kongo ruling elite to adopt those aspects of European culture they saw as most attractive and useful as to the desire of the Portuguese to spread Christianity and Western education. This period of idealism did not last. The Portuguese had neither the material nor the psychological resources necessary to implement the plan of selective acculturation; and their other innovations, scarcely penetrating beyond the ruling elite, created tensions and schisms in Kongo society. Above all, however, the difference between precept and practice turned the experiment into disaster. Almost from the outset, slave traders followed in the wake of priests and teachers to tie west central Africa to the demands of the transatlantic slave trade. Though the kings of the Kongo and their subordinates all had their household slaves and vassals, Portuguese demands outstripped anything known to their traditional society, as the needs of the plantations established on the West Indian islands and, later, in Brazil grew. By the 1530s, between 4,000 and 5,000 slaves were being exported from Mpinda alone, and by the 17th century the Kongo Kingdom was producing up to 15,000 slaves a year. Attempts by the *manikongos* to stem the outflow of their able-bodied male population simply turned the attention of the raiders southward, toward the ascendant Mbundu (Kimbundu) state of Ndongo. The consequent tensions within the society and the hostility toward the Portuguese erupted into open warfare in 1622, in 1665, and in 1681. Each war left a trail of destruction and fomented social unrest and internal rebellion.

By the end of the 18th century, Kongo had been reduced from one of the most highly organized and sophisticated of west central African kingdoms to a series of fragmented and virtually autonomous villages, although Portuguese influences and Christianity lingered on among the elite at the capital, São Salvador do Congo. In the second half of the 19th century, the Kongo area, with its impoverished rival and warring local chieftains, was annexed as the northern province of Angola.

The end of Kongo

If Portuguese pressure resulted in the progressive disintegration of the Kongo Kingdom, it was ultimately equally disastrous for the Mbundu people. They had been united with the Ndongo kingdom, on the Lunda Plateau to the south, in the course of the 16th century, under a ruler called the *ngola.* After some 50 years of sporadic contact with them, the Portuguese, believing reports of great mineral wealth in the interior and anxious also to acquire the salt mines of Ndongo, expanded their political dominion to Ilha de Luanda. In 1575 Paulo Dias de Novais was appointed captain general, or governor, of an undefined area between the Dande and Cuanza rivers, which became known as Angola, and granted wide per-

sonal control over any areas he might conquer or colonize. He founded what became the city of Luanda in 1576. Portuguese plans to colonize the kingdom of the *ngola*s were greatly hampered, however, by tropical disease, the unsuitability of the region for agriculture, and strenuous African resistance to settler encroachments.

Though the *ngola*s were initially eager for contact with the Portuguese, they soon discovered that their immediate presence spelled destruction. Within a few years the first war of a century of almost constant warfare had begun. Originating as a means of territorial expansion and establishment of Portuguese control, the wars soon resolved themselves into efforts to acquire slaves on Portuguese terms. Almost from the outset, the Portuguese relied on African auxiliaries or allies in their campaigns. Though these "allies" were capable of considerable independent action, they had to pay tribute in slaves, ivory, and probably salt.

The effects of the slave trade

Although it is not possible to compile an exact balance sheet of the devastation caused to west central Africa by the slave trade, by the early 17th century some 5,000 to 10,000 slaves were being exported from Luanda annually —and this figure does not include those smuggled out of the bays and inlets along the coast in order to escape official taxation. The figure may indeed have represented a relatively small proportion of the total population of the area, but it also represented the economically active young adults. While it has been argued that there—as elsewhere in the slave-trading societies of Africa—their loss was balanced by new food crops, such as manioc and maize (corn), which the Portuguese imported from South America and which probably led to increased populations, in parts of Angola the very direct and damaging campaigns of the Portuguese and their African allies probably made slave trading more destructive than elsewhere. Accounts of Ndongo in the 16th century as rich and populous give way to lamentations about its desolation in the 17th. In addition to the direct depopulation wrought by the slave trade, by the 1630s large groups of people had moved out of the territory, beyond the raiders' reach.

Of these migrations, the two best documented, and perhaps the most significant, were the movements of a section of the Mbundu, under Queen Nzinga, and that of the Mbangala, under their ruler, the *Kasanje*. Nzinga, who has been described as one of the most remarkable women in Central African history, dominated the politics of the area for nearly half a century. When, in 1618, the Portuguese finally conquered the Ndongo kingdom, Nzinga attempted to use the Portuguese to secure her leadership in Mbundu politics. When this failed, she moved eastward with her followers. Conquering the state of Matamba, she developed it into a powerful slave-trading centre, with networks reaching north to the Kongo and Luanda and eastward to the Lunda of Katanga.

At the same time as Nzinga's migration, the Mbangala (Imbangala) established their new state of Kasanje in the Kwango Valley. Like the ferocious and cannibalistic Jaga raiders who had disrupted the Kongo Kingdom in 1569, the Mbangala probably originated in the Luba-Lunda kingdoms of Katanga, though their date of departure is thought to be the late 15th century. By the end of the 17th century, Kasanje had become the leading slave-trading kingdom in the area and the chief entrepôt between the coast and the Lunda in the east. Like the *manikongo* and the *ngola* of Ndongo, both Nzinga and Kasanje welcomed the Dutch conquest of Luanda in 1641, though their relief was short-lived. By 1648 the Portuguese had reconquered Luanda and were thus free to reconsolidate their hold on their African possessions. Nzinga herself ended her days as a Roman Catholic collaborating with the Portuguese in the slave trade; in 1681 her successor as *ngola* of Matamba was finally conquered, 10 years after the remnant Ndongo kingdom farther west had been completely dismantled.

At the beginning of the 17th century, as they were penetrating inland from Luanda, the Portuguese were also exploring southward in the hopes of expanding the slave trade and of finding a navigable waterway across the continent. In 1617 they established a colony at Benguela, which, like the Kongo Kingdom, was annexed as part of Angola in the 19th century. There was, however, little expansion inland from Benguela until the 18th century, when soldiers followed slave traders to the fringes of the Ovimbundu kingdoms. Though very little is known of the early history of the Ovimbundu kingdoms, they appear to have originated in the late 16th and 17th centuries with the arrival of Lunda, Mbangala, and Mbundu raiders and refugees fleeing from the Portuguese. By the end of the 17th century the slave trade from Benguela may have exceeded that from Luanda, while in the 18th century the Ovimbundu rivalled Kasanje as slave-trading kingdoms, with routes going from Ovimbundu not only to the official Portuguese outlets but to Dutch, French, and British interlopers at the coast as well.

The Ovimbundu kingdoms

These interlopers were a major concern of the Portuguese in the 18th century. Portuguese attempts to control the coastal trade and Ovimbundu resistance led to a war and to the Portuguese conquest of the Ovimbundu heartlands between 1774 and 1776. By this time the Ovimbundu were a formidable enemy, having adopted Portuguese military strategies and being well equipped with firearms. Despite their military victory on this occasion, the Portuguese were unable to exert political control over the Ovimbundu until more than a century later.

Through the 18th century and for the first third of the 19th, the slave trade remained at the centre of Angola's economic existence. Routes stretched well into the centre of Africa, with most of the trade in the hands of the African and half-caste intermediaries, known as *pombeiros*. The area of actual Portuguese colonization was smaller, consisting of a number of estates huddled round the inland forts and along the Bengo and Dande rivers. The estate holders were never to acquire the position and following of the *prazo* holders of Mozambique.

The late 18th century saw Portuguese fortunes in both Angola and Mozambique at a low ebb. In both, they found themselves unable to control the trade, either inland or on the coast. The number of settlers was small—about 1,000 in each colony—and the economies were poor and the administrations weak and corrupt. Though both these territories recovered somewhat during the Napoleonic Wars, it was not until the last quarter of the 19th century that the Portuguese regained anything of their initial colonizing energy.

Despite Portuguese mythology that the Portuguese did not differentiate according to race in their colonies, from quite early times whites had superior status, prestige, and power in Angola as in Mozambique; attitudes toward race in the 17th and 18th centuries were perhaps not so different as is generally asserted from those of the Dutch colonists. (The history of west central Africa during this period is also dealt with in the article CENTRAL AFRICA, HISTORY OF.)

THE DUTCH AT THE CAPE

In some ways, the end of the 18th century also found the only other enclave of European settlement in southern Africa threatened, though for very different reasons. This was the colony at the Cape of Good Hope, established as a stopping point on the way to India in 1652 by Jan van Riebeeck and some 125 men on behalf of the Dutch East India Company. In the late 16th and 17th centuries, as the Cape had become a regular port of call, the crews of European ships there found herders ready to barter some cattle in exchange for iron, copper, beads, tobacco, and brandy. By the time of the Dutch settlement in the mid-17th century, a class of Khoikhoi (Hottentot) intermediaries had grown up and a network of trade stretched far into the interior. Relationships established in this half century of trading profoundly affected the nature of contact between the Khoikhoi and the Dutch when the Dutch East India Company established its outpost there.

The Cape of Good Hope

Though initially intended as a refreshment station, almost imperceptibly and despite the company's reluctance, the outpost grew into a colony of settlement. In 1657

the company released a number of its servants to become free burghers in order to cultivate land and herd cattle on its behalf; and in the same year the first slaves were imported into the colony from Angola and the East Indies to perform the labour which the San (Bushman) and Khoikhoi (Hottentot) inhabitants were reluctant to undertake. In contrast to the Portuguese, the Dutch feared to imperil the cattle trade on which the colony depended, and from the first they prohibited the enslavement of the indigenous population. Moreover, at the Cape there was no indigenous slavery and local chiefs had neither the people nor the power to engage in the slave trade.

Dutch expansion and the trekboers. If the Dutch did not raid the local inhabitants for slaves, they were soon to undermine the loosely organized social structure of the Khoikhoi by their increasing demands for cattle and by encroaching on their grazing and hunting lands. As one Khoikhoi group became impoverished and reluctant to trade, another would take its place. Though the Khoikhoi did not crumble as rapidly after the arrival of the Dutch as is often suggested, and offered considerable resistance to Dutch expansion, their small numbers enabled the Dutch to move beyond their base at the coast far more easily than the Portuguese had been able to do in Angola. Moreover, the gentle Mediterranean climate of the Cape was well suited to European settlement. While the Portuguese in Angola and Mozambique were ravaged by tropical diseases, at the Cape it was the non-immune Khoisan who were affected by epidemics brought by the whites.

The greatest geographical barrier to Dutch expansion was the ranges of mountains inland from Cape Town. Once these had been crossed and settlers had ascended the flat inland plateau lands, expansion to both east and north was relatively rapid. There, in the arid scrubland, economic necessity and geography dictated a semi-nomadic, pastoral way of life for the white settler, as it had for the indigenous peoples before him. Poor soil and inadequate rainfall could be compensated for by the appropriation of vast farms, and 6,000 acres (2,400 hectares) rapidly became the norm.

Stellenbosch, Swellendam, and Graaff-Reinet

Despite one or two sporadic attempts, the Dutch East India Company made little effort to follow the cattle farmers, or trekboers, as they came to be known. Though the new districts of Stellenbosch (1685), Swellendam (1745), and Graaff-Reinet (1785) were formed, they were large and unwieldy, and their centres were far from the expanding trekboers. Governmental authority was remote, and the trekboers, though they never built up the same kind of power as the *prazo* holders of Mozambique, became accustomed to handling emergencies on their own and to ruling over their slaves, servants, and clients as they saw fit.

The numbers of white settlers at the Cape grew slowly in the 17th century, but in the 18th, largely through natural increase but also through immigration, they rapidly outstripped the thousand or so whites in Angola and Mozambique. From 200 inhabitants in the 1660s they increased to between 4,000 and 5,000 by the 1750s, and to about 15,000 in the last decades of the century. Despite the different origins of the inhabitants, an official policy of integration, the shared vicissitudes, and their common Calvinist religion molded the whites into a relatively homogeneous group that became the Afrikaners. By the 18th century their differences were socio-economic rather than ethnic. Tensions between the various groups of settlers and the company to some extent contributed to a sense of identity from the beginning of the 18th century.

As the white population increased, so did the number of slaves. Experiments in the use of white labour were unsuccessful; and, as in the Portuguese colonies, working for a master became the stamp of an inferior status, which was inevitably associated with a black skin.

As in the Portuguese colonies, too, there was no bar in the early days of the colony to intermarriage between the Dutch and either the Khoisan inhabitants or freed slaves, and religion may have been the determining factor in ethnic identification. By the late 17th century, intermarriage was officially frowned upon, but concubinage with nonwhite women continued. The mixed population that resulted became known as the Cape Coloureds—a new amalgam, sharing many of the cultural attributes of its white, slave, and Khoisan forebears.

Assimilation of the Khoisan peoples. The Khoisan peoples of the Cape were quick to assimilate new cultural traits—indeed, their virtual disappearance as an ethnically identifiable group by the 19th century can, in large measure, be attributed to their genius for acculturation. As they lost their cattle and grazing lands, they became virtual serfs of the white man, on the vineyards and wheat farms of the Cape and on the cattle farms of the interior, though some groups were able to escape by moving both north and east. In the east they continued the long process of mingling with the Xhosa peoples, while on the Orange River, where they became known as Griqua in the early 19th century, they established a number of polities that bore a strong resemblance to the republics later established by the Dutch settlers.

Khoisan response to the Dutch

Throughout this period the responses of the Khoisan peoples to the Dutch displayed many of the same complexities and ambiguities that the Bantu-speaking peoples of Angola displayed toward the Portuguese. On the one hand, they were eager to trade and therefore to collaborate with the Dutch. On the other, when the demands of the intruders became intolerable, they opposed them by trying to retain control over the terms of trade. This opposition erupted into guerrilla warfare in 1659 and the 1670s. Though many secondary sources suggest that thereafter Khoisan resistance was at an end, it is clear from the documentary evidence that the cattle raids that punctuated almost every decade of the 18th century were a continuation of this guerrilla warfare.

The raids and counter-raids mounted in violence until, in the last quarter of the 18th century, the entire northern frontier of the colony was under arms and some white farmers were being driven out of their lands. Those who were not ruined by the cattle raids were being worn down by constant military service, which was left to the settlers themselves. Though ultimately the Khoisan peoples were vanquished by pure bloodletting, they prevented further colonial expansion northward for some 30 years.

Trekboer–Xhosa conflict. This was the more serious in that white expansion came up against a major block on its eastern flank at the same time that the trekboers encountered the populous and settled agricultural Xhosa people in the area of the Fish River. Trading contact had existed between the trekboers and the Xhosa from quite early in the 18th century. In the last quarter of the century, friction between black and white increased, over grazing grounds, water, and the terms of the cattle trade. Demands for fresh meat at Cape Town increased during the Anglo-French wars and during the American Revolution; Khoikhoi reserves of cattle had been exhausted, and the trekboers had now expanded up to the very edge of Xhosa settlement. Various attempts to draw a frontier between the colonists and the Xhosa were equally useless; by the time the governor himself visited the eastern frontier in 1778 and decreed the upper Great Fish River as the boundary between black and white, there were Xhosa to the west of the Great Fish River and trekboers embedded in Xhosa society to the east of it.

The establishment of the new district, Graaff-Reinet, with a full-time government official, hardly improved matters. The area of his jurisdiction was vast, its frontiers ill-defined, and its inhabitants hardly disposed to listen to the commands of a government that had left them to their own devices for more than half a century. Before the 18th century was out, minor cattle raids had developed into two frontier wars. They were the prelude to a struggle that lasted almost 100 years, and ultimately the trekboers were able to re-expand only after outflanking the Xhosa in the 19th century.

Despite the firearms of the Dutch, the two combatants were by no means unevenly matched, for the Xhosa were superior in numbers and social organization. The trekboers suffered from internal divisions and were facing an even more severe threat from the Khoisan resisters on their northern frontier. The commando system, which

had evolved through the 18th century as a method of local defense, was ill adapted to concerted warfare against a well-organized foe. Nor was the Dutch East India Company prepared to aid the frontiersmen. As a result, the last quarter of the 18th century saw a stalemate, with the trekboers probably getting the worst of the encounters.

Between 1799 and 1802, the third and most disastrous war erupted, when conflict with the Xhosa coincided with an uprising of Khoisan servants, who deserted with their masters' guns and horses. By this time the Cape had passed temporarily into the hands of the British (1795–1803), who were anxious to bring the war to an end as swiftly as possible. They managed to divide the African forces by making land and labour concessions to the Khoisan peoples but were quite unable to dislodge the Xhosa from the area west of the Great Fish River. It was only with the appearance of regular British troops on the Cape frontier in 1811 that the balance was tilted more definitely in favour of the white man, though the Xhosa were not finally defeated until well into the 19th century.

II. Southern Africa in the 19th century

After 1800, new internal and external forces radically changed the demographic, social, political, and economic configurations established over the preceding two centuries in much of southern Africa. Though certain areas were not to be affected by change till the last decade, for the area as a whole the first three-quarters of the 19th century brought many new developments. Some, like the rise of the Zulu Empire, which sent its offshoots in every direction, and the expansion of white settlement from the Cape, reversed the north–south direction of change in Iron Age times. Others, like the intensification of the slave trade from the east coast and the parallel drive of ivory hunters into west central Africa, were more a shift of emphasis than totally new developments.

19th-century missionary activity

The 19th century, too, was the age of missionary expansion. In the footsteps of traders came Christian missionaries, who, by the end of the period, had reached most of the peoples of southern Africa, not only evangelizing and educating a new elite but frequently acting as the closest political advisers of the old, as well as preparing the ground for the age of European territorial acquisition.

THE MFECANE AND ITS EFFECTS

The first of these changes began at the end of the 18th century in the area of present-day Zululand, where the Zulu were simply one of numerous Bantu-speaking Nguni chiefdoms, closely related to the Xhosa on the Cape's eastern frontier. Yet their rise to power in the second decade of the 19th century profoundly altered the demography and political relationships of the entire subcontinent. Their expansion and its repercussions are known in the south as the Mfecane—the "Crushing"—a term that vividly conveys the destructiveness and social disorder caused by marauding tribes on the move. For many, the choice was to join the invader or to set off themselves. Yet out of the Mfecane new polities were formed; and the invaders, for those not crushed by their advent, brought a challenge and an example of military and social organization that the invaded were to turn to advantage in resisting later intruders.

Though it has been customary to attribute the Mfecane to Shaka (*q.v.*), who became king of the Zulu people in 1816, the entire pattern of the Mfecane, the way in which tribe was sent reeling against neighbouring tribe once he began his campaigns, suggests that Zululand was an area of high population and cattle density in relation to its ecology and technology; and it may be that the pressure of people and cattle on land at a time of reduced rainfall gave the rise of the Zulu its explosive force.

By the end of the 18th century there seem to have been five or six larger chiefdoms in Zululand that were beginning to absorb their neighbours, but these new corporate kingdoms had much in common with the smaller chiefdoms that had preceded them, and they employed diplomacy as much as warfare to achieve their ends.

All this was changed, however, when Shaka became chief of the Zulu people, at that time simply one of the tributary states of the wider Mtetwa (Mthethwa) confederacy, ruled by Dingiswayo, their paramount chief. Shaka, who was a military genius, revolutionized traditional methods of warfare. In the Mtetwa confederacy and, indeed, in many of its neighbouring chiefdoms, regiments composed of men of the same age and recruited from all the villages and clans of the kingdom were now organized for war. In addition, Shaka was a master of strategy and surprise tactics. Fighting became a matter of total war, not simply of limited raidings.

In 1817 Dingiswayo was killed, and Shaka took over the Mtetwa hegemony. In a short time he had brought under his control all of the peoples within striking distance of Delagoa Bay to the north and Pondoland (now part of the Transkei) to the south. Out of the numerous chiefdoms between the Tugela and Pongola rivers he welded a highly centralized military kingdom; to the south he created a buffer zone of havoc and devastation.

Zwide and Shaka

In the first years of his empire building, the Ndwandwe confederacy, under Zwide, was Shaka's most formidable rival. Indeed, even before his major campaigns, the Ndwandwe had pushed the Ngwane and Dhlamini under their chief Sobhuza to the north of the Pongola River, where Sobhuza and his successor, Mswati, conquered and absorbed the local Nguni and Sotho chiefdoms and created the Swazi nation. Though under frequent attack from the rising Zulu power, the Swazi, by withdrawing northward to rocky fortresses, escaped the fate of those who remained within the Zulu orbit.

By 1820 Shaka had decisively beaten Zwide's armies, which then broke into three groups. Zwide himself retired, but two of his commanders, Soshangane and Zwangendaba, fled northward, to be followed shortly thereafter by Nxaba, heading the Msane and Maseko peoples. Battles between the three on the middle Save River left Soshangane victorious, and he proceeded to build up the Zulu-type Gaza empire, which at its height stretched between the Zambezi and Komati rivers, reduced both the Portuguese and the Shona to tributary status, and incorporated many of the Tsonga and Shona peoples of south Mozambique.

After their defeats, both Zwangendaba and Nxaba swung westward, fighting one another and totally disrupting the old Matapa and Rozwi empires. In 1835 Zwangendaba crossed the Zambezi, while Nxaba's followers split in two, one section remaining in what is now Rhodesia, the other eventually settling in the highland country of the Kirk Range in the 1860s. From that location they raided a wide area west of the Shire and, after 1875, to the east of Lake Malawi (Nyasa) as well.

Zwangendaba and the Ngoni

Across the Zambezi, Zwangendaba's Ngoni—as these offshoots of the Nguni came to be known—raided the defenseless Chewa, Nsenga, and Tumbuka people, incorporating some into Zwangendaba's following, though the original Nguni nucleus retained its political and cultural dominance. In about 1845 Zwangendaba died, having established a settlement on the Fipa Plateau.

On his death, the tensions inherent in a constantly raiding society came to the fore, and a bitter and complicated succession dispute culminated in the fragmentation of his kingdom. Two groups now moved into present-day Tanzania, while Zwangendaba's sons, Mpezeni and Mbelwa (or Mombera), moved southwestward and southward, respectively. Having conquered the already enfeebled Bisa, Mpezeni clashed fiercely with the Bemba, by then becoming one of the most powerful polities in northeastern Zambia, and then moved to Fort Jameson (now Chipata) in about 1865, conquering more Nsenga and Chewa peoples en route. Mbelwa, with the largest fragment of Zwangendaba's people, moved back into Tumbuka country, where in 1855 he overthrew the Kamanga confederacy, already weakened by the activities of Swahili slave traders. From his vantage point in the healthful uplands, he also raided to the south and west. Although his composite following threatened to break up into its component parts in the 1870s, Mbelwa's Ngoni maintained their cohesion into colonial times.

While these fragments of the Ndwandwe confederacy were making their way northward into east central Africa, chaos was being spread southward and westward by Shaka's campaigns against the chiefdoms of Zululand and Natal. The ever-widening circle of disorder reached the westerly Sotho and Tswana groups across the Vaal, in Botswana, and in the northwestern Cape as raiders and refugees ricochetted in all directions.

Many moved south to join fugitives making their way from Shaka's campaigns in Natal to the territory east of the Cape Colony. All of these refugees, whose social structures had been disrupted if not shattered by the years of warfare, became known as Mfengu (or Fingos). Their presence added another complicating factor to the tense situation on the Cape eastern frontier. Some shattered peoples scrambled to safety in the mountains of modern Lesotho, where Mshweshwe, one of the most outstanding of the leaders produced in these years, built up a kingdom based on the rocky fortress of Thaba Bosiu.

Other dislodged Highveld peoples joined the Griqua polities along the Orange River or continued raiding along the Vaal and in the western Transvaal, where the disorders prepared the way for the coming of Mzilikazi, who, with 300 of his followers, who became known as the Ndebele (or Matabele), moved out of Zululand in 1823. Over the next 15 years or so he moved westward across the Transvaal in flight from the Zulu armies, until finally, in 1837, after a triple conflict with the Zulu, with Griqua raiders from the Orange River, and with the expanding white farmers, or Voortrekkers, from the Cape, he led his following (which had now increased to between 15,000 and 20,000) across the Limpopo River into what is now southwest Rhodesia.

The flight of Mzilikazi

Across the Limpopo, Mzilikazi found it easy to establish himself, for the once prosperous Rozwi empire and the various Shona paramountcies had been weakened by drought and the wars with the Ngoni. As in the Transvaal, so in Rhodesia, Mzilikazi rapidly absorbed large numbers of the local populace into his age-set regiments; a castelike society evolved, with the original Nguni nucleus at the top, the Sotho in the middle, and the Shona constituting the lowest rung in society. Beyond their immediate settlement, the Ndebele established a variety of relationships with the surrounding peoples, ranging from regular tributary status to occasional raiding and warfare. The first whites to enter the kingdom of Mzilikazi regarded all the Shona as totally subjected to the Ndebele, but in fact, beyond the range of Mzilikazi's raiding armies, many Shona chiefdoms continued in their old independent ways; in the second half of the 19th century, they were building up a stock of firearms to resist the Ndebele.

Yet another group dislodged by the Mfecane made its mark in Central Africa. This was the composite Sotho people known as the Kololo, under Sebetwane, who fled across the Zambezi; there, in about 1840, they conquered the Lozi (Barotse) kingdom, which had been built up in the 18th century and by the beginning of the 19th was one of the most important in present-day Zambia. Weakened, however, by an internal succession dispute and deserted by some of its subjects, the ruling Lozi dynasty was swiftly crushed, and Sebetwane established his own administration over the kingdom by appointing members of his family as headmen in every village. By 1864, however, the ravages of malaria, the accession of a weak and diseased Kololo king, and the revival of Lozi royal fortunes put an end to Kololo hegemony, though Sotho is still the language of the area.

THE SLAVE AND IVORY TRADE NORTH OF THE ZAMBEZI

At roughly the same time that east central Africa saw the incursions of the Ngoni warriors from the south, equally disruptive forces were making themselves felt from the east. Long before the beginning of the 19th century, Central Africa was crisscrossed by trade routes to both east and west coasts. By the second half of the 18th century there was probably a route all the way from Luanda in the west to Mozambique in the east.

Until the middle of the century the Luanda trade was mainly concerned with slaves. With the demand in Europe for ivory and the increasing movement toward abolition of slavery in the early 19th century, however, and with the attempted legal abolition of the slave trade in Angola and the lifting of the royal monopoly on ivory trading in 1836, ivory increasingly became the most important export, and Benguela replaced Luanda as the main outlet. As ivory replaced the slave trade, so the Mbangala of Kasanje and the Portuguese traders on the coast were displaced as intermediaries by the Ovimbundu of the Bié Plateau, whose Chokwe neighbours were already renowned as daring elephant hunters in the 18th century. Now they penetrated deep into Central Africa and with their firearms decimated the elephant population in one area after another. By 1850 they were in the Luvale and Lozi country and were reaching the south Congo forests, where, in the 1880s, they brought Mwata Yamvo's Lunda empire to an end.

The paramount importance of ivory

East of the Lunda the ivory trade was more significant in the 18th century, and so it remained in the 19th. To the south, however, the slave trade—which had gained momentum from the second half of the 18th century, spurred by the labour demands of the plantations of Réunion, Mauritius, Pemba, and Zanzibar, and later of Brazil and Cuba—became as important as ivory. British pressure to abolish slavery in east central Africa had little effect until the last quarter of the century. In Mozambique the slave trade was officially abolished in 1836 and slavery itself legally ended some 20 years later, but this merely led to new ways of extracting forced labour from the African population. Farther north, British pressures on the sultan of Zanzibar to ban the slave trade from Zanzibar to Oman were easily circumvented, and though an abolition treaty forced on the Zanzibaris in 1873 was more effective, the reduced coastal demand for slaves led to even more ruthless methods in the interior, as slaves, no longer needed as merchandise for export, were exploited locally.

The Arabs now began to play a much more dynamic role in the interior. Though initially they were prepared to work through local chiefs, they soon came to exercise a wide military and political jurisdiction over the northern routes from their strategically placed commercial centres, while establishing alliances with African raiders to the south.

The most important area of the slave raiders appears to have been in present-day Malawi and northeastern Zambia, where predatory overlords such as Msiri (leader of the Nyamwezi) and the Arab Tippu Tib devastated a wide area from their bases in the Congo. In addition, to the east of Lake Malawi, the Yao—keen traders since the 17 century—moved from ivory trading to slave raiding, obtaining firearms from the Arabs, subjugating the Nyanja agriculturalists, and building up powerful polities under successful new commercial and military leaders. Similarly, the Bemba, who raided the loosely organized Maravi to the west of the lake from their stockaded villages on the infertile plateau of Zambia, were also able to increase their power through the slave and ivory trade. It was in this area of east central Africa, too, that the Ngoni intruded in about 1850, and though they never became slave raiders, the turmoil in their wake swelled the number of people torn loose from their social setting. Yet the extent of the destruction should not be overestimated; as with the Mfecane, European observers may have exaggerated the degree of depopulation and devastation.

Ngoni intrusions

It is against this changing situation that the arrival of the first European missionaries and traders, inspired by crusades against the slave trade, needs to be seen. In 1875, after an abortive earlier attempt, the Free Church of Scotland established the Livingstonia Mission, while the Church of Scotland started to work among the Yao. From Lake Malawi (Nyasa) the Scottish missions spread inland to northeast Zambia, to be followed by a bewildering array of other denominations in the last two decades of the century. In general, the missionaries soon found that whereas weaker, raided peoples, like the lakeside Tonga, were prepared to accept Christianity, the

Arab, Ngoni, Yao, and Bemba raiders were more resistant; some were even ready to take up arms against the missionaries and European traders who threatened their entire way of life.

In part as a result of pressure from the missionaries and the African Lakes Company (a Glasgow-based firm working closely with them), in 1883 a British consul was appointed for Mozambique and Lake Malawi, with a watching brief on the slave trade. Increasingly, the British government became embroiled in struggles with the Arab traders—which resulted in open warfare in 1887–88—and with the Portuguese. It was not, however, until the appointment of Harry (later Sir Harry) Johnston (an associate of Cecil Rhodes) as consul in 1889 that the British came to play a more aggressive imperial role in the area.

BRITISH OCCUPATION OF THE CAPE

By the beginning of the 19th century, the small outpost of the Dutch East India Company at the Cape had grown into a sprawling multiracial settlement, in which 22,000 whites constituted the top stratum over a labouring class of some 25,000 slaves and an indeterminate number of Khoisan peoples and Xhosa in the eastern districts. In 1806, after a short period (1803–06) of rule by the Batavian Republic had been ended by the renewal of the Napoleonic Wars, the British, anxious to guard their vital sea routes to India, occupied the Cape again.

Most of the early British governors at the Cape were military men who saw the problem of the eastern frontier in military terms: how to defeat and drive back an external enemy. They were tied, moreover, by the reluctance of the British Treasury to spend more than the barest minimum on the colonies. At the same time, neither the African nor the white inhabitants of the frontier zone wanted the complete segregation that the government at the Cape—whether Dutch or British—was eager to impose, and every attempt to establish boundaries between them broke down in the face of their intractability.

The Cape Frontier Wars

In 1811, 1819, 1834–35, and 1846 the almost constant unrest on the frontier exploded into open conflict, and though each conflict pushed the Xhosa closer in on one another and the tensions in Xhosa society increased as the colony was extended farther into the eastern Cape, the problem remained unsolved. Each war, moreover, left the Xhosa more formidable and desperate. They were able to develop guerrilla strategy during the wars, and by 1850 they had also acquired and were able to use effectively a considerable number of firearms; thus, the eighth war, in 1851, was the most drawn-out and expensive of them all. Furthermore, a combined Khoisan and Coloured uprising broke out in the Kat River settlement (established in 1828 to solve the problems of Coloured landlessness), to exacerbate the situation.

In the end it was not so much British arms or settler prowess that defeated the Xhosa as the internal tensions that had built up as a result of the expansion of the colonial economy and ideology. The pressures on the Xhosa increased when the Mfengu refugees from Natal and the interior arrived in the eastern Cape. During the war of 1834–35, the Mfengu fought on the British side and were rewarded for their services with Xhosa lands and cattle —a pattern that was to be repeated in each subsequent war. In 1857 the Xhosa, exhausted by years of attrition and in the face of a new aggressive policy of assimilation inaugurated by the governor of the Cape, Sir George Grey, turned to millenarian prophecies and slaughtered all of their own cattle and destroyed their own crops in the hopes that their ancestors would rise from their graves and drive the white man into the sea. When the awaited salvation failed to materialize, an estimated 20,000 to 30,000 Xhosa streamed westward across the frontier to seek work in the colony, while an equal number died of starvation in the Transkei. Although there was war on the eastern frontier yet again, from 1877 to 1878, the back of Xhosa resistance had been broken. The annexation of the remaining African territories between the Cape Colony and the frontiers of Natal proceeded peacefully, if piecemeal, for the next three decades.

If the Cape eastern frontier saw some of the fiercest and most prolonged resistance to white expansion anywhere in 19th-century Africa, it was also the scene of the closest black and white interaction. Trading relations in the frontier zone existed from the early 18th century, and by the 19th, with the coming of the British settlers, there was a great expansion in trade. The advent of the missionaries at the beginning of the 19th century also had its effect, encouraging the growth of new peasant communities.

Mfengu collaboration

The first converts in the Cape were the Khoisan and mixed groups along the Orange River. In the eastern Cape, Mfengu refugees were soon the focus of mission activity. By 1850 the Mfengu were regarded as the most progressive element in the eastern Cape and were developing into prosperous peasant cultivators. In the 19th century their example seemed to illuminate the advantages of collaboration with the colonial power. After the cattle killing of 1857 and even more after the last wars on the eastern frontier in 1877–78, an increasing number of Xhosa also turned to Christianity and to new political techniques with which to oppose colonialism. By the last quarter of the century, missionaries of almost every denomination were working among the African peoples of southern Africa. Nevertheless, though most of the territories east of the Great Kei conquered in the Cape Frontier Wars remained as reserves in African hands, subject to white overrule, by the end of the century their productivity was already grossly undermined through a combination of ecological and political factors.

THE GREAT TREK

Though the colonial experience came first and in its most concentrated form on the Cape's eastern frontier, by the middle of the 19th century the frontiers of white settlement had been vastly extended. There were few African societies south of the Limpopo, if not of the Zambezi, that were not aware of its implications. This was largely the result of the "Great Trek," or migration, of Afrikaner Voortrekkers (Pioneers) from the Cape Colony in the 1830s, but in part also was a result of British missionary and trading activities in the interior.

The Great Trek is generally regarded as a seminal event in South African history, as in some ways it certainly was, though in the short term it was far less revolutionary than the Mfecane. In part it was simply a continuation of 18th-century trekboer expansion. Blocked from expanding into the high-rainfall area of the eastern Cape, by the 1820s many trekboers were moving northward to the Orange River, where Khoisan resistance had at last been overcome.

Unlike the earlier trekboers, however, the Voortrekkers of the 1830s left the colony with a deep sense of grievance against rulers with very different notions of social order and, in particular, property and labour relationships. Although early British attempts to reform the land law at the Cape were inept, the labour question was even more vexed. Apart from slaves, the basic labour force of the colony was the Khoisan and Coloured (partly of European ancestry) peoples. On the whole, their condition was serflike; they were extremely poorly paid, had little security or freedom of movement, and had no legal redress.

Though the first attempts of the British government to regulate master–servant relations were cautious, Ordinance 50, passed in 1828, was a serious attempt to improve the lot of Cape Coloured servants. In particular, it relieved them of the obligation to carry a pass—a document that previously any servant had had to have signed both by his master and by local officials if he wished to leave his registered place of abode. Ordinance 50 caused a furor among the whites, many of whom were anxious over impending changes in the status of their slaves. (In 1807 trade in slaves had become illegal in British possessions, and in 1833 the remaining slaves at the Cape were emancipated.) Though only 2 percent of slaves were owned in the eastern districts from which the bulk of the Voortrekkers came, Ordinance 50 and slave emancipation aimed to change the basis of labour relations.

For the frontiersmen, however, the last straw came when, after the 1834–35 war on the Cape eastern frontier, an attempt by the governor to annex Xhosa territory was rejected by the British colonial secretary. At the end of 1835, some 4,000 Boers, organized in small groups, left the colony, their movement gathering momentum through the 1830s and slowing in the 1840s. The Mfecane had cleared a great swathe of country for them, though, as the trekkers soon discovered, it had also created a number of powerful and well-organized chiefdoms, such as the Zulu, Ndebele, Sotho (Basuto), Pedi, and Swazi, with whom they would have to come to terms.

The most important of the first parties of Voortrekkers were those under Hendrik Potgieter, Gerrit Maritz, and Piet Retief. In the first instance, all groups made their way across the Orange River, where Potgieter led his supporters toward the Vaal, while Retief and Maritz, eager to secure an outlet to the sea, crossed the Drakensberg to Zululand, hoping to make arrangements with the king, Dingane, who had succeeded his half brother, Shaka, in 1828. Potgieter's party soon clashed with the Ndebele, and by 1837 Mzilikazi had decided to move northward across the Limpopo, leaving the Voortrekkers the dominant power on the western Highveld.

The Natal Voortrekkers were less immediately successful. In 1838 Dingane wiped out a negotiating body under Retief before falling on the encampments of the trekkers, who had followed him and had scattered over northwestern Natal. Dingane's triumph was short-lived. In the second half of 1838, reinforcements arrived from the Cape, and the Voortrekkers, forming an alliance with his brother Mpande, deposed Dingane (1840) and established their rule in Natal, south of the Tugela River.

The Voortrekkers soon found, however, that initial conquest was easier than overcoming their own divisions or establishing their rule permanently over large numbers of African people—especially as they had to contend also with the opposition of the British government. In 1838 a small British force occupied Natal, and five years later the British annexed it in a bid to protect their sea route to India and to prevent pressure on their eastern frontier through further upheavals among the Africans in Natal, which threatened to result from trekker land and labour policies. Even before this, the Afrikaner republic threatened to break down, as thousands of refugees streamed back to Natal from Zululand, once the hold of the despotic Shaka and Dingane had been broken.

British annexation of Natal

Most of the Voortrekkers now recrossed the Drakensberg to join their compatriots on the Highveld. In the 1820s and '30s the British relied for law and order in the interior on a series of treaties with African rulers such as Mshweshwe of the Sotho and the Griqua leaders Andries Waterboer and Adam Kok. With the dispersion of considerable numbers of whites in the interior, however, these treaties inevitably broke down. In 1848 the governor of the Cape annexed the territory across the Orange River in an attempt to control the colony's turbulent frontiers; but mid-Victorian Britain had little real desire to follow the trekkers into the vast interior. In 1852 and 1854 independence was granted to the trekkers across the Vaal and Orange rivers, respectively. At the same time, the alliances with African chiefs, except for that with Adam Kok, were unilaterally disclaimed. Trade in firearms was allowed to white Afrikaners but was forbidden to Africans—a factor that in the future effectively weakened the Africans' resistance against the Afrikaners.

THE TRANSVAALERS AND THEIR NEIGHBOURS

With the abdication of British authority over the interior, the trekkers had first to overcome their own divisive tendencies and then to come to terms with the surrounding African peoples. In the Transvaal in mid-century there were about 20,000 whites—a figure which had risen to about 30,000 by 1870—grouped in four main centres, each the headquarters of an independent "republic." Between these centres the remaining Boers were scattered in farms of from 6,000 to 9,000 acres. Between 1845 and 1864 political life in the ramshackle republics was racked by bitter personal, religious, and political feuds. Even after 1864, when the different centres merged to form the South African Republic, central authority was weak and there was little sense of national unity.

Like the Africans, the trekkers were fundamentally cattle farmers in search of land and water, though they had very different concepts of land ownership and usage. When they moved into the Transvaal, they claimed all the lands and peoples the Ndebele had ruled and dealt as overlords with the peoples living in the lands that the trekkers apportioned to themselves.

As the land between the Vaal and the Limpopo was appropriated—either by the Boers or by the British and colonial land speculators who followed—African tribes were often able to live under their chiefs who had, however, now to provide labour for the European farmers. Itinerant traders, mainly British, served the needs of both communities, bringing the essential firearms as well as such luxuries as tea, coffee, and sugar, in exchange for ivory, cattle, and a little wool. From the early 1860s considerable numbers of Africans migrated to the Cape Colony to earn money and obtain firearms.

Administration of the Transvaal

With their near-subsistence economy, the Boers' demands for labour could not have been great. Nevertheless, in addition to the labour tax, they had to use force to get sufficient labour. Each raid against an African chiefdom left numbers of so-called orphans, who were "apprenticed" to individual farmers. Virtual slaves, they constituted an important part of the labour force. This apart, Africans suffered not so much from systematic exploitation as from the sporadic plunder and occasional terrorism that served to remind tribesmen of the white man's firepower.

Encircling white settlements in the Transvaal to the east, northeast, and north were a number of relatively powerful chiefdoms with which the Boers made alliances, both in pursuit of their own internal politics and because of their lack of power. To the west, they were faced with the Tswana chiefdoms, regrouping after the Mfecane and powerfully supported by missionaries. Whatever the relationships with their labourers, the Voortrekkers in their dealings with African chiefs were circumspect and also inferior in position. As late as 1877 the Boers were threatened by the Zulu and unable to defeat the Pedi. The conquest of all these peoples (except the Venda) in the last quarter of the 19th century was left to the British with their superior armaments.

THE ORANGE FREE STATE AND LESOTHO

When the British withdrew from Transorangia in 1854, it too had a relatively small white population owning vast quantities of land in the midst of a large African population. By 1875 this white population had risen to about 26,000. Though there were only about 97,000 Africans in the Orange Free State at this time, on its eastern frontier was the well-organized state of Basutoland under Mshweshwe. Unlike the Transvaalers, the Free State tackled the problems of government effectively, establishing a Volksraad, or parliament, and drawing up a clearly defined constitution. With both the Cape government and Mshweshwe on their doorstep, the Orange Free State could not indulge in excessive internal strife.

Basutoland and the Free State

Even before the British withdrawal from Transorangia in 1854, there had been constant friction between the Sotho and settlers over land. As refugees streamed back to their old homes after the Mfecane, Mshweshwe's following increased to an estimated 80,000 in 1848. By the time they returned, however, they found that the Boers had begun to infiltrate into the fertile lands between the Caledon and Orange rivers. The Sotho, overcrowded, now spilled over onto Boer farms as well as onto lands occupied by other African groups, and conflict arose.

Despite Mshweshwe's attempts to keep the peace, cattle raiding from those of his subjects who saw no hope of recovering their land by negotiation, together with increased demands for land by white sheep farmers, led to war in 1858 and again in 1865. On the first occasion the Orange Free State was forced to sue for peace. On the second, however, Basutoland, starved of arms and torn by internal jealousies, was beaten. Some chiefs, es-

pecially in the north, offered their allegiance to the Boers and, with their followers, became labour tenants on white farms; others fled into the Transkei. In 1868, in response to repeated appeals from the Sotho, the governor of the Cape intervened to declare the Sotho British subjects and their land British territory—much to the chagrin of the Free Staters. Nevertheless, the Orange Free State gained control of the fertile land in the Caledon Valley and gained in security.

In 1869 the frontiers of Basutoland were delimited, and shortly thereafter it was handed over to the Cape. In 1881, however, when the Cape government tried to disarm the Sotho, war broke out, and the Cape returned the territory to Britain in 1884.

THE BRITISH COLONIES OF THE CAPE AND NATAL

The two British colonies of the Cape and Natal, though their social organizations differed considerably, were far more closely tied to the 19th-century world economy than were the interior republics.

Natal. White settlers in Natal were outnumbered by blacks in a ratio of 10 to 1 and surrounded on all sides by powerful African kingdoms. At the same time, their interests were divided, as land speculators, plantation owners, and small farmers vied for control over Natal's native policy. For much of the 19th century, black–white relations were dominated by Theophilus Shepstone, diplomatic agent to the African tribes and secretary for native affairs from 1846 to 1875.

Achievement of Shepstone

Shepstone's first task was to control the enormous reflux of Africans to their homelands after Dingane's defeat. It is estimated that the numbers of Africans south of the Tugela increased from about 20,000 in 1840 to 200,000 in 1845. Between 1846 and 1864, eight reserves, totalling 2,250,000 acres (900,000 hectares), were set aside for African occupation. Shepstone reconstituted the chiefdoms broken by the Mfecane and placed them on the reserves, which he governed through the hereditary chiefs. Customary law was recognized, and the governor held the position of supreme chief. Though provision was made for educated and Christian Africans to be exempted from customary law and to acquire the franchise, it was so complicated that by the turn of the century only 1,000 or so Africans had certificates of exemption.

Shepstone's achievement was to keep the peace in Natal for some 30 years. The only violent resistance to his rule came in 1873, when Chief Langalibalele of the Hlubi people, refusing to obey summonses from Shepstone, fled with his followers over the Drakensberg to Basutoland. The ruthlessness with which he was pursued and the summary way in which he was brought to trial roused a humanitarian outcry in Great Britain and led in part to Britain's paring down Natal's limited representative institutions. Natal achieved full self-government only in 1893.

To some extent Africans in Natal were prepared to accept white rule because of their memories of the Mfecane. To the north the Zulu state, though restricted, was still formidable, and in the middle years of the century the small white population of Natal was careful to maintain good relations with its kings. They, in turn, were eager to use the British connection as a counterweight to the encroachments of Transvaal farmers.

While they had adequate land, Africans saw little reason to work for the white man. Initially, too, land speculators were prepared to settle for African rents rather than labour. As the demands of the smaller farmers became more powerful, however, a hut tax of seven shillings a year was imposed; it was doubled in 1875. Initially the Africans were able to pay the tax by disposing of their surplus agricultural products on the new European market; but as the reserves became more crowded, increasing numbers of Africans were forced to work for the white man. This was too slow for the white sugar planters, and in 1860 the first indentured Indian labourers arrived in Natal, soon to be followed by Indian, mainly Muslim, traders.

Despite the undoubted prosperity Indian labour brought to the colonists, the Indians were bitterly discriminated against and by the end of the century had few social or political rights. On the expiration of their indentures, labourers were subject to a £3 poll tax, and every endeavour was made to repatriate them. By the 1890s they outnumbered the white population of Natal and had spread to the South African Republic, where they were equally discriminated against. Largely in response to this situation, Mahatma Gandhi founded the first Indian political organizations in the Transvaal and Natal.

Cape Colony. The Cape, as the oldest and most populous of the colonies in South Africa, had the most complex society. Its economy was based on agriculture and mercantile capital with the labour force drawn from the Coloured population with an increasing number of Bantu speakers as the Ciskeian and Transkeian territories became less and less productive.

Representative institutions in the Cape

In 1853 the colony was granted representative institutions. Elections were based on a colour-blind franchise, low enough to enfranchise sufficient Coloured voters to support British interests and counteract the enfranchisement of the Afrikaner population. As African territories were progressively incorporated, the franchise was also extended to qualified Africans. In 1872 the Cape received responsible government and the colour-blind franchise was retained, though in 1887 and 1892 the qualifications were raised in an effort to restrict the number of African voters. Even the Afrikaner Bond, the colony's first and most important political party, which consistently attacked the franchise, came to accept its basic colour-blind principle. Predicated on a loose affinity of interest between Cape merchants and African peasants, Cape liberalism proved fragile in the face of South Africa's industrial revolution.

THE ERA OF MINERAL DISCOVERIES AND CONFEDERATION

The pressures of Africans to seek work in the white economy were vastly accelerated by the mineral discoveries of the last third of the century. In 1868 diamonds were found by some children playing along the Orange River; and in 1886 the even more important gold reefs of the Witwatersrand (Rand) were discovered.

Until 1868 the South African economy had been poor, backward, and pastoral, with wool the most important export. There was little to attract the great stream of European immigration that was making its way to Australia, New Zealand, and the Americas. In 1820 some 5,000 British emigrants had been settled in the eastern Cape, in order to defend the frontier, and in the 1840s and '50s there were numerous schemes of immigration to Natal. Between 1858 and 1862 more settlers were brought to the eastern Cape, but many left during the prolonged economic depression of the 1860s.

With the diamond discoveries, immigration no longer needed official encouragement. As thousands of fortune seekers made their way to the diamond fields, a fierce ownership dispute raged between the Voortrekker republics, the Griqua (mixed European and Khoisan people) on the Orange River, and the Tswana; ultimately the entire diamondiferous area, known as Griqualand West, came under British, and then Cape, control. Afrikaners of the Orange Free State were thereby incensed, even though the British lieutenant governor of Griqualand West had difficulty in controlling the near-anarchic mining town of Kimberley, with its unruly white miners and its thousands of migrant black labourers.

As events in Griqualand West threatened the equilibrium of the whole region, it appeared to the colonial authorities that some unification or federation of the divided South African territories was essential. Their timing was so bad, however, and their handling of the situation so tactless that in the long run it served only to kindle pan-Afrikaner nationalist feeling.

British annexation of the Transvaal

In an attempt to push through the confederation of the South African territories, Britain annexed the Transvaal in 1877. The pretext was the inability of the bankrupt republic to subjugate the Pedi in the Zoutpansberg. Under their chiefs Sekwati (died 1861) and Sekhukhune (ruled 1861–81) the Pedi had successfully withstood the onslaughts of the Mfecane, had attracted many of the surrounding Africans into their orbit, and had built up a

state powerful enough to resist white demands for taxation and labour services. This war was one of the cluster with similar origins that broke out all over South Africa in the late 1870s.

At the time of the Transvaal–Pedi war, it seemed as if conflict were imminent also on the Transvaal–Zulu frontier. There Cetshwayo, who had succeeded his father, Mpande, in 1872, was disputing Transvaal encroachment on Zulu lands. In 1879 a war broke out that was very largely engineered by the newly appointed British high commissioner for South Africa, Sir Henry Bartle Frere, who believed the Zulu to be a threat to the security of whites in Natal and the Transvaal and a stumbling block in the way of confederation. Despite early disasters and tremendous logistic problems on the imperial side, Cetshwayo was captured after the Battle of Ulundi in July 1879, deposed, and deported.

Though the spirit of confederation was completely discredited by the aggressive and expansionist policies it had engendered, and Zululand was not annexed, the divisive settlement after the war led to bitter civil war in Zululand and to further encroachments by the Boers. Britain proclaimed a crown colony in Zululand in 1887, and in 1897 Zululand was finally handed over to Natal.

Ironically enough, with the recession of the danger to the Transvaal from Zululand, which had provided one of the excuses for British intervention, the Transvaalers were able to rise against an increasingly unpopular administration and defeated the British resoundingly at Majuba in 1881. In 1881 the Convention of Pretoria stipulated the continuance of an ill-defined British "suzerainty" over the Transvaal, while handing over internal self-government; though major concessions were made to the Boers in the Convention of London in 1884, the suzerainty clause was left ambiguous.

Battle of Majuba

THE SCRAMBLE FOR SOUTHERN AFRICA

Over the next 15 years the ambiguity of British suzerainty in the interior proved a constant source of friction between the South African Republic and Britain, which formed a pretext for the South African War of 1899–1902. Though in the early 1880s the Liberal government in Britain seemed to favour withdrawal from the interior, by the middle of the decade a new phase of intervention began, spurred on by the European scramble for African territories, a battle over borderlands caused by the continued drift into African territory of land-hungry Boers, the grandiose schemes of Cecil Rhodes, and the discovery of gold in the Transvaal.

The response of Africans to these events ranged from outright resistance to some form of accommodation, depending on their previous experience of contact with the white man, on their observation of what had happened to neighbours already subjected to colonial power, on the advice they received (especially from missionaries), on their relationships with neighbouring African chiefs, and on calculations of their internal political interests. As the first small numbers of concession hunters appeared, many chiefs tried to play the British, Boer, German, or Portuguese intruders off against one another. Though a few chiefs even emerged from the scramble with enlarged domains, most Africans in the south were to lose out to white-settler and capitalist expansion.

German intervention. The new assertion of British claims and prior rights in southern and Central Africa was caused by the sudden interest of Germany in the area. In 1883 the Germans landed at Lüderitz Bay, and in 1884 they annexed the whole of southwestern Africa, much to the dismay of colonists in the Cape.

German interests in southern Africa were not confined to the arid coastal lands of the southwest. German movements along the coast farther east led in 1885 to the declaration of a British protectorate over Pondoland (which became absorbed into Cape Colony 10 years later) and to the establishment of a crown colony in Zululand in 1887. Germany's apparent interest in the hinterland of South West Africa and, thus, in a possible linkup with the South African Republic probably gave the necessary urgency to the impassioned pleas for aid that Tswana chiefs, their missionary advisers, and Cape traders and politicians were directing to the British Colonial Office against the incursions into their territory of Transvaal Boers. When, in 1882, Boer adventurers, initially invited in to aid rival chiefs, had established the two small republics of Stellaland and Goshen, they not only undermined the African polities but also threatened to disrupt the missionaries' and traders' "Road to the North." Moreover, by this time, rumours of rich mineral wealth beyond the Limpopo had begun to interest Cecil John Rhodes, the man who was to dominate imperial expansion in southern Africa.

Rhodes and the era of expansion. The story of how Rhodes went to South Africa to repair his frail health and stayed to become a millionaire on the diamond fields before he was 30 is legendary (see RHODES, CECIL). At Kimberley, chaotic underground conditions—the result of the uncontrolled enterprise of individual miners and the unrestricted flow of diamonds to the world market—had, by the 1880s, made some form of centralized planning or amalgamation necessary. By the late '80s Rhodes had bought up all his rivals and had created the vast consortium of De Beers. Having secured the "Suez Canal" to the north, as he called it, by the British action in Bechuanaland, Rhodes next planned to take control of the area lying to the north of the Limpopo, to acquire its rumoured mineral wealth and to encircle the Transvaal.

De Beers consortium

His schemes were given added potency by the discovery in 1886 of the deep seams of gold of the Witwatersrand; this had led to a vast strengthening of the South African Republic and to an apparent threat to British dominance in the region, especially since at this time the president of the Transvaal, Paul Kruger (*q.v.*), was bent on expanding both eastward through Swaziland to the sea and northward, across the Limpopo, where one of his agents had secured an alliance with the Ndebele in 1887. Both of these projects were foiled by the British government, though in 1894 Britain granted the Transvaal sovereignty over Swaziland, despite the bitter protests of its rulers.

At the beginning of 1888, Lobengula, king of the Ndebele, surrounded by concession seekers and swayed by the apparently official British support for Rhodes, granted the magnate's representatives complete and exclusive mining rights in his territory, Matabeleland. Lobengula was soon to regret his decision, but by then it was too late: in 1889 Rhodes immeasurably strengthened his hand by forming his British South Africa Company, which was authorized by the British government to extend administrative control over a vast area of southern and Central Africa.

In 1890 Rhodes sent a 200-strong "Pioneer" Column into Ndebele raiding grounds in Mashonaland. The resentment of the Ndebele mounted as they saw land parcelled out to the first Pioneers; the King's power was further undermined by European demands for Shona labour. In 1893 a deliberately provoked war between the two broke out. The kingdom was destroyed to solve the financial problems of the British South Africa Company, open Matabeleland's reputed gold mines for exploitation, and secure the region for white settlement. Ndebele cattle were confiscated and land was alienated.

The Ndebele War

In neighbouring Barotseland, Lewanika, head of a complex centralized state, had deliberately invited in missionaries and then requested British protection. He had not, however, reckoned on the British South Africa Company, whose agents misconstrued the nature of their connection with the British government and made wide promises of technical and financial assistance in order to secure major mining concessions. The promises remained largely unfulfilled; and though Lewanika undoubtedly welcomed the defeat of the Ndebele, he must have watched events to the south with trepidation. Though Lewanika took care to concede mineral and, later, land rights in the territories of his subject peoples, and the Lozi were able to expand territorially by playing the company off against Portuguese claims on their western and northeastern borders, ultimately Lewanika's fears were warranted. Although subject to the same pressures from whites as

Colonial South Africa 1884–1905.

the Ndebele, the Lozi chose accommodation and manoeuvre rather than resistance. Nevertheless, by the end of company rule in Barotseland, the King's position had been seriously undermined, and his realm was as underdeveloped as that of his neighbours, despite a certain favoured legal position, which fostered a local Lozi nationalism even after independence had been granted to Zambia in 1964.

In northeastern Zambia and Malawi, too, Rhodes's company had been busy through the mediation of the British consul, Harry Johnston, who had accepted from Rhodes £2,000 toward the administration of east central Africa and the commission to obtain treaties from chiefs as far as copper-rich Katanga. Although Rhodes was beaten to Katanga by Leopold II of Belgium, treaties were obtained from a number of chiefs over a wide area between Lakes Malawi and Tanganyika.

In 1889–90 a British protectorate was declared over the Shire Highlands against Portuguese claims, and the following year this was extended to the area around Lake Malawi. British administration was gradually extended into what is now northeastern Zambia over the next five to six years. In the area that became known successively as the British Central Africa Protectorate (1893–1907), Nyasaland (1907–63), and Malawi, Johnston became embroiled in campaigns against the most prominent chiefs, many of whom feared the loss of their livelihood as slavery was stamped out and as Johnston encouraged British and Indian immigration. Here Yao resistance was the most prolonged, though it never threatened British control.

In northeast Zambia, where British settlers and concessionaires had begun to infiltrate and conflict with chiefs by 1896, Mpezeni's Ngoni put up the fiercest resistance but were forced to submit to British rule in 1898. Kazembe, king of the eastern Lunda, faced with a punitive force, fled from his capital, while the Bemba, despite their warlike reputation, remained discreetly quiescent.

The Jameson Raid

While Johnston was engaged in these punitive expeditions in the northeast, however, Rhodes had far more serious problems on his hands south of the Zambezi. By 1895, despite the progress of his plans all over southern Africa, Rhodes's hopes of rich gold deposits in Matabeleland were disappointed, and his deep-level mines on the Witwatersrand were an extremely heavy drain on capital —a situation that was exacerbated by the policies of the Transvaal regime. Making use of the largely fomented clamour of British immigrants in the Transvaal, known as Uitlanders (aliens; *i.e.*, non-Afrikaners), over their lack of voting rights, Rhodes, with the full knowledge of the British colonial secretary, Joseph Chamberlain, plotted the invasion of the republic by his lieutenant, Leander Starr Jameson, and a number of armed followers.

The affair was a complete fiasco. The hoped-for uprising of Uitlanders failed to materialize, and Jameson was soon arrested by the Boers. Nevertheless, the Jameson Raid had profound repercussions, both in South Africa and to

its north, where the Ndebele, still smarting from their harsh treatment after the 1893 war, took the opportunity of Jameson's absence to rise against their white rulers. Within a week of the raid, the Ndebele had killed more than 100 whites, and they were soon joined by the Shona in what was probably the most devastating resistance to colonialism in central Africa in this period. British troops had to be called in, and as a result greater imperial control came to be exercised over the activities of the company, both in Southern Rhodesia, as it now came to be called, and north of the Zambezi.

The South African War. Though Rhodes retired from active politics in the Cape after the Jameson Raid, the series of events he had set in train gathered momentum in the next five years. Whereas in the early 1890s Rhodes successfully united English and Afrikaners of the Cape in his imperial schemes, now many Cape Afrikaners, formerly antagonized by the restrictive policies of the Kruger regime in the Transvaal, united behind the republics in a Pan-Afrikaner nationalist opposition to British imperialism, while most of the English-speaking community, both in the Cape and elsewhere in South Africa, became infected with the spirit of jingoism that marked the last years of the century. The dispatch of Sir Alfred Milner as British high commissioner to South Africa exacerbated the situation; and in 1899 the war, which Milner had regarded as inevitable from the outset, broke out.

Growth of the Pan-Afrikaner opposition

The clash between Kruger and the representatives of British imperialism in southern Africa—Rhodes and Milner—has often been portrayed in personal terms. Yet, essentially, the clashes of these years were economic and political. The South African (or Anglo-Boer) War was a struggle for supremacy over an area that contained the richest gold mines in the world; and though it has become fashionable to discount economic explanations for the war and to stress the strategic calculations of the British, the nature of the state controlling gold production and the new markets of the southern African interior was a crucial British interest. It gave rise to the most bitter and closely fought colonial war in Africa, which left its mark on South African politics for more than half a century.

ANGOLA AND MOZAMBIQUE

The European bid for African territories in the last quarter of the 19th century was accompanied by a reawakening of Portuguese colonial ambitions. Throughout much of the 19th century the Portuguese in Angola and Mozambique had been confined to a few towns and forts on the coast, where Portuguese traders eked out a petty existence.

Tensions among the Portuguese government in Lisbon, local officials, white settlers, *assimilados* (as the assimilated Africans were called), and the Africans in the interior existed in the 19th century, as they had in earlier times, with conflict flaring up when local groups found their interests ignored by the metropolitan power or in moments of Portuguese vulnerability. Thus, revolts in Luanda and Benguela coincided with the declaration of Brazilian independence, while Portuguese attempts to abolish the slave trade in the 1830s led to widespread resistance by local whites and African intermediaries. Between 1835 and 1860, the energetic but largely abortive policies inspired by the liberal Portuguese statesman the Marqués da Sá de Bandeira provided fresh occasion for local uprisings; and his attempts to extend Portuguese control in the interior led to a series of wars in Angola with the Ndembu (Dembo), Kongo (Bakongo), Mbangala (Imbangala), and Mbundu (Ovimbundu) peoples, who, nonetheless, were able to remain independent until the 20th century.

In Mozambique, the Portuguese experienced even less success. Despite official abolition of the slave trade and of slavery by 1858, the practice still continued until at least the 1880s. Several attempts, including major military campaigns, to outlaw the *prazo* system in Zambezia were ineffectual; and even, in 1880, the declaration that they were crown property brought little change to their essentially feudal nature. Until 1895 the Gaza kingdom controlled a wide area between the Komati and Limpopo rivers, while the Portuguese had little control over the Africans in the rest of the territory.

The only bright spot in Portuguese fortunes in southeastern Africa was the growing prosperity of Delagoa Bay as trade with the Boers in the Transvaal increased. In 1875 Portuguese rights to Delagoa Bay were formally recognized, and in the 1880s, with the discovery of gold on the Witwatersrand, Delagoa Bay acquired a new importance as the closest outlet for the rapidly growing metropolis of Johannesburg. In 1888 Delagoa Bay became capital of Mozambique, and the focus of Portuguese colonization in eastern Africa shifted southward.

The rise in importance of Delagoa Bay

Despite the failures of the expansionist plans in the mid-century, the continued criticisms of foreign observers and the activities of explorers brought to Portuguese statesmen a new awareness of the need to repair their fortunes in Africa actively—especially when the late 19th-century scramble for African territories threatened even those areas the Portuguese considered theirs by historical right. The dream of linking Angola and Mozambique was revived, although with the weakness of Portugal in Europe, with its slaving record and its monopolistic trade policies, it received short shrift from the other imperial powers. At the Berlin West Africa Conference of 1884–85, Portugal received the Cabinda exclave and a portion of the left bank of the Congo—considerably less than it had claimed. In the hinterland of northwestern Mozambique it fared even worse: in 1890 Portugal was pushed out of the Shire Highlands, and the expansion of the British South Africa Company in Southern Rhodesia led to further retractions in western Mozambique. Skirmishes with the British South Africa Company in Rhodesia and Barotseland continued through the 1890s, and competition with the Germans on the southern frontier of Angola and the northern frontier of Mozambique dragged on into the 20th century. Though Portugal's more ambitious plans were doomed by the end of the century, it had nevertheless acquired about 800,000 square miles (2,000,000 square kilometres) of African territory, of which it controlled less than one-tenth.

Portuguese plans to develop the colonies hinged on attracting immigration and foreign capital to provide the necessary economic infrastructure. Even before the scramble proper, the arrival of 300 Afrikaner pastoralists from the northern Cape was a welcome addition to the white population on the Huíla Plateau in southern Angola, where they helped to subdue the Ovimbundu. In Mozambique, the *prazos* were adapted to the needs of three foreign chartered companies, which were granted wide mining, agricultural, and commercial concessions. For the Africans on the estates, however, the system of forced labour, taxation, and tribute continued to impoverish the local economy.

As Portugal began to extend its control and policies in the interior of both Angola and Mozambique, it was faced with fresh waves of resistance. In Mozambique in 1894 an uprising by peoples around Lourenço Marques was forcibly suppressed; and in 1895 the Portuguese opened the attack on Gungunhana's already weakened Gaza kingdom. With the conquest of the kingdom, which took three years, Portugal removed the most formidable threat to her position in southern Mozambique. Nevertheless, from 1897 to 1903 the Shona peoples of Barwe also rose against Portuguese rule, and the revolt spread among Shona speakers in Rhodesia in a continuation of the 1896–97 rebellion. As late as 1917, in response to the Portuguese demands for carriers in the war, a major Shona rebellion broke out in the Zambezi Valley, which totally disrupted the Portuguese administration for a period of several months.

Resistance to the Portuguese

Resistance to taxation, forced labour and crop production, unfair trading and administrative practices, and military recruitment lay behind African opposition to Portuguese rule in Angola also. The Ovimbundu, who were extremely successful in the wild rubber trade from eastern Angola between 1870 and 1911, were conquered in 1902–03, the Ndembu between 1907 and 1909, and

the Kongo in 1913–14. Portuguese attempts to control the Kwanyama, an Ovambo (Ambo) group who lived on the Kunene River, led to further resistance, made the more formidable by German intervention and Kwanyama stockpiling of trade guns. Conquered in 1915, the last Kwanyama king, Mandume, fled into South West Africa, where he was killed in 1917.

Though sporadic outbreaks of resistance to Portuguese rule continued till 1930, Portugal's military control of its colonies was greatly strengthened after World War I as the result of foreign, largely British, economic investment. This brought little benefit to the African population, and for many the only escape from the combination of oppressive rule and absence of local economic opportunity was to migrate temporarily or permanently to neighbouring territories.

THE GERMANS IN SOUTH WEST AFRICA

The Germans were the last imperial power to arrive in Africa; they annexed South West Africa in 1884. At that time the region was inhabited by groups of San (Bushman) and Bergdama (Damara) hunter-gatherers, as well as by the purely pastoral Nama and Herero in the south and centre and by Ovambo (Ambo) agriculturalists in the north.

By the third decade of the 19th century, the sharpening competition between the Nama and Herero over the grazing lands of central South West Africa led the leading Nama group to ask for aid from Jonker Afrikaaner, the head of a well-armed, mixed Khoikhoi (Hottentot) and half-caste chiefdom on the Orange River. The Herero were subjugated by Jonker and the Nama between 1835 and 1860. Jonker Afrikaaner established himself at Windhoek, where he controlled the trade from both Walvis Bay and the Cape.

Throughout the 19th century, displaced Khoikhoi and half-Khoikhoi communities from the Cape Colony, known as Oorlams, had entered South West Africa, adding to the competition for water and grazing lands. The last and most important of these were the followers of Hendrik Witbooi, who, arriving in the 1850s, soon dominated the Nama and the so-called Baster community who settled around present-day Rehoboth in the 1870s.

After Jonker Afrikaaner's death in 1861, the Herero shook off the Nama yoke under the leadership of their new chief, Maharero. As both sides acquired increasing numbers of guns, the conflict between them became more destructive and, apart from a breathing space between 1870 and 1880, continued from 1863 to 1892, opening the way to German annexation in 1884.

Initially, the Germans secured their hold through treaties with the Herero and Nama chiefs, though that with Witbooi was extracted only by force. There was further fighting when the Germans extended their landholdings beyond the environs of Windhoek into the grazing grounds of eastern Herero and Mbandieru people and confiscated their cattle.

Anti-German rebellions

With the growth of the white-settler population, the demands for African land, labour, and cattle, the contemptuous attitudes of whites toward blacks, unfair German trading practices, and the absence of legal redress led to a series of revolts between 1903 and 1907, which began and ended with the Bondelswarts (a Coloured group) in the south of the country but which also involved the Herero and Witbooi's followers. The rebellions were put down at tremendous cost to the African population. These wars, among the most destructive waged against Africans in colonial times, opened up South West Africa to German settlement and exploitation, though in the event their dominion only lasted until World War I, when the territory was conquered by South African troops. After the war, South West Africa was handed over to the Union of South Africa (now the Republic of South Africa) as a mandate of the League of Nations.

III. Southern Africa, 1900–45

For black and white southern Africa, the 20th century has wrought vast changes, though north of the Zambezi and in the Portuguese territories, where colonial development was hampered by the two world wars and a depression, they were initially less dramatic. Nevertheless, by 1945 in most areas Western administrative, medical, and educational practices, however inadequate, were established, roads and railways built, minerals exploited, and Africans drawn into the world economy more intensively than ever before. New frontiers had been created, which have become the boundaries of modern states; and everywhere the demands of new rulers were undermining traditional authority and small-scale precolonial societies and creating new class and political alignments.

Farther south, where this process had first begun, whites increased their political, economic, and military hold through the unification of the South African colonies, creating, by 1945, the most highly industrialized state in Africa. The Union (later Republic) of South Africa has dominated its neighbours throughout the 20th century. Capital expansion northward was initiated by the south and was paralleled by a vast labour migration to the mines and farms of South Africa. At the same time, class and colour relations shaped by the early days on the diamond and gold fields and given characteristic form by the first decades of the century in South Africa were repeated both in the development of secondary industries in the union and in the mines and the industries of the Rhodesias.

In all the territories, the economic exploitation of blacks was facilitated by the development of a racist ideology. Africans were seen essentially as a source of cheap unskilled labour, not, as elsewhere in colonial Africa, as cash-crop producers. Discriminatory policies, whether described as segregation or parallel development, were prompted by settlers' fears of African political and economic competition and lent respectability by anthropologists and paternalist administrators anxious to preserve African societies from rapid social change. Though in the Portuguese colonies "native policy" was theoretically to assimilate Africans to a Portuguese way of life, obstacles to the *assimilado* progress were in practice greater in the 20th century than they had been in the 19th; and the *indigenato* policy, in force from 1926 to 1961, while granting equal rights to a very small handful of assimilated Africans, established separate administration, lawcourts, institutions, and status for the vast majority.

WHITE SETTLERS SOUTH OF THE LIMPOPO

If the South African War was the high-water mark of direct British intervention in South Africa, the tide rapidly receded in the next five years. In 1906–07 the British granted self-government to the defeated republics, and by 1910 the four self-governing colonies had been unified. This unification was dictated largely by the demands of the industrial revolution consequent on the mineral discoveries. With the South Africa Act, the 1,250,000 enfranchised whites achieved complete political control over approximately 4,250,000 unrepresented Africans, 500,000 Coloureds, and 165,000 Indians.

The unification of South Africa

Though there was talk of incorporating the landlocked British protectorates, or High Commission Territories, of Basutoland (now Lesotho), Bechuanaland (now Botswana), and Swaziland, the opposition of the Africans of the protectorates, as well as that of the radical lobby in Britain, led to their exclusion from the union. Until the mid-20th century, however, it was thought in Britain that the protectorates would ultimately be incorporated, and on a number of occasions—especially during the 1930s—South African politicians demanded this. Strong African opposition, the effective lobbying of radical groups in Britain, and, finally, the outbreak of World War II prevented this from happening; nevertheless, the assumption meant that the territories were fully locked into South Africa's migrant labour system and became increasingly impoverished. Administrators were often South African; and local chiefs, subject to a virtually unassailable paramount chief, were left to run their tribes as they saw fit. Though this dual administration, as well as the stagnant economy of the territories, was severely casti-

gated by the so-called Pim Commission of 1934–35, and moderate reforms were instituted, the High Commission Territories remained backward and neglected.

Though South Africa failed to incorporate the High Commission Territories, after World War I it acquired the vast German colony of South West Africa. Despite a League of Nations mandate that the territory be administered as a "sacred trust," white settlement was encouraged and subsidized from the outset. Though almost half of the German population was repatriated at the end of the war and the rest were naturalized in 1924, Nazi demands in the 1930s for the return of German colonial possessions had a counterpart in South West Africa; by that time there were about 30,000 whites in the territory, largely from South Africa, and considerable vested interests had grown up, especially in diamond mining and fishing. There were almost annual criticisms from the Permanent Mandates Commission of the League about the lack of economic and educational development for Africans, and the League was much disquieted by the violent confrontations between the South African government and the Bondelswarts (1922), the Rehoboth community (1924–25), and the Ovambo (1932). Nonetheless, the major preoccupation of the mandatory power continued to be to foster white prosperity, generally at the expense of African tribesmen.

White politics in the union

Within the union, between 1910 and 1948, whites were divided by class and ethnicity. Until 1924 the South African Party (SAP) was in power under the leadership of two successive prime ministers, Louis Botha (1910–19) and Jan Smuts (*q.v.*; 1919–24), representative of the more successful Afrikaner farmers and in close alliance from 1914 with the Unionists, the party of mining capital, which the SAP absorbed in 1920. The SAP's essential aims were to reconcile the English- and Afrikaans-speaking communities, to maintain the imperial connection, and to promote commercial farming and mining interests. This led to an increasingly bitter conflict with the white working class on the Rand as well as with the Afrikaner nationalists, who broke away from the SAP in 1913–14 under the leadership of Gen. J.B.M. Hertzog.

In 1924 a coalition of Hertzog's Nationalists and the predominantly British Labour Party removed Smuts from power. Between 1924 and 1929 legislation protected white workers from African competition, while the state sponsorship of industrial and agricultural development was accelerated in an attempt to help solve the "poor white" problem. Largely through Hertzog's efforts, the nature of the British Commonwealth connection was redefined in 1929–30, and the concept of dominion independence was fully enunciated.

In 1933, in the face of South Africa's worsening economic position during the Great Depression and the crisis of confidence surrounding its abandonment of the gold standard, the Afrikaner generals Smuts and Hertzog formed a coalition government, and in 1934 their parties fused as the United Party. The outbreak of World War II destroyed their somewhat precarious consensus. As in World War I, when fierce civil war erupted between the Afrikaners on the issue of South Africa's participation on the British side, Afrikaners again were divided over the country's contribution to the Allied forces. When South Africa voted by a narrow margin to fight the Germans, Hertzog resigned.

Purified Nationalist Party

Even before this, in 1934, a group of nationalists—largely members of the extreme Broederbond, a secret society that aimed at Afrikaner economic advance and ultimately Afrikaner dominance in a republic—had left the United Party to form the Purified Nationalist Party. Though their electoral support remained relatively small in the '30s, the Purified Nationalists built up their power through the establishment of extensive welfare and economic subsidiary organizations, directed on the one hand at promoting the interests of Afrikaner petty bourgeoisie and on the other to gaining the support of the Afrikaner rural poor and workers in the towns through the provision of cultural, social, and trade union organizations outside the predominantly English-speaking Labour and Communist parties.

Though Hertzog now rejoined the Purified Nationalist Party, the alliance was uneasy; the history of the Nationalists during the war is a complicated series of manoeuvres by disunited factions. Through the war years, General Smuts, by this time a prominent world statesman and for the second time a member of the British War Cabinet, headed the government and the United Party, which was now supported by virtually all English-speaking whites and contained within its ranks both extreme right-wingers and liberals. The Afrikaner divisions, however, masked the fact that Smuts had lost the support of the group that by this time made up the clear majority of the South African white population.

WHITE SETTLERS NORTH OF THE LIMPOPO

Though the Union of South Africa had by far the most powerful and complex settler polity, in the first half of the 20th century settlers acquired firm control over Southern Rhodesia (now Rhodesia), too, while even in Nyasaland and Northern Rhodesia (now Malawi and Zambia), which came under the jurisdiction of the British Colonial Office in 1892 and in 1924, respectively, it was accepted that white settlers would provide the necessary economic development. Until 1923, Rhodesia was administered by the British South Africa Company. In 1898 a Legislative Council was established, and by World War I the 25,000 settlers had an elective majority in it. The colour-blind franchise qualifications, modelled on those of the Cape, were sufficiently high to exclude all but a handful of Africans. In 1922, when the company handed over formal responsibility for the territory to the British crown, the settlers rejected a proposal to join the Union of South Africa in favour of self-government. Again there was no attempt to include Africans in government; though the constitution provided for an imperial veto over discriminatory legislation, the veto was never exercised, and complete control of the police and armed forces was handed over to the minority government.

Though a number of white political parties flourished under a variety of names between the 1920s and 1950s, there were basically two parties of importance: (1) the "government" party, closely allied to big business interests, and (2) the "opposition" party, more eager to secure the position of white farmers and workers in the face of African competition. Outside formal politics, farmers, mining companies, and trade unions formed crucial pressure groups. Apart from socio-economic issues, the major issue in the late 1920s and '30s, as indeed later on, was over relations with Northern Rhodesia, where the wealth of the Copperbelt proved a considerable attraction.

Colonial rule in British Central Africa

Across the Zambezi the handful of white settlers were in a far weaker position than those farther south. In Northern Rhodesia, white traders and farmers, largely from South Africa, were granted an advisory council in 1918, but it had very little real power. When, in 1924, the company withdrew from its administration, the territory came under crown colony rule. Settler numbers jumped to 11,000 by 1930, with the discovery and exploitation of the rich deposits of copper by British, South African, and American capital. Various attempts by the whites of Northern Rhodesia in the 1920s and '30s to amalgamate with Southern Rhodesia in order to bolster their political position and to secure independence from imperial control were defeated by the Colonial Office, which enunciated a doctrine of trusteeship. Nevertheless, in crucial areas, such as the stabilization of African labour, equal pay for white and black, and the job colour bar, the Colonial Office was not prepared to counter the opposition of either the copper companies or white workers.

In Nyasaland, also, though the principle of African "paramountcy" was frequently proclaimed, it has been shown that British imperial interests generally prevailed and led to the territory's depressed economy. The Shire Highlands were considered highly suited to white settlement, and the demands of the planters there for labour and communications were acceded to. Moreover, in railway construction more attention was paid to the needs of British capitalist strategy than to those of the territory, which was saddled with huge public indebtedness.

Though the number of settlers in the Portuguese colonies was roughly comparable with those in Southern Rhodesia, they never achieved comparable political power. Despite the transfer to civilian government in the colonies during the republican period in Portugal (1910–26) and supposedly greater local autonomy, real power was in the hands of the governor general, or, as he became in 1921, the high commissioner, the highest colonial representative of the Portuguese government.

Republican Portugal

The republican period saw a flurry of activity among settler political groups, some of them in alliance with African *assimilados* and *mestiços* angry at Portuguese neglect and maladministration. This culminated in Angola in 1930 when the governor was forced temporarily to withdraw from Luanda. With the consolidation of António Salazar's regime in Portugal, however, strict government vigilance was exerted over all economic and political activity in the interests of stability, though in 1942 municipal politics were revived among the settlers. Though the greater control in the hands of the administration could, and at times did, restrain the exploitation of Africans by foreign interests, the final conquest of Africans, the greater power in the hands of the government, and increased demands for African labour and crop production led to their everyday lives being ever more strictly controlled.

LAND, LABOUR, AND COLOUR BARS

At the root of relationships between black and white in the 20th century in southern Africa are the closely connected issues of land and labour.

Alienation of land. At the beginning of the century, the vast majority of Africans in the subcontinent lived on the land, which in many areas is now claimed by white settlers. South of the Limpopo, the century-long battle over land and water was largely won by whites, though increasingly crowded pockets of land were reserved for Africans in the Transkei, Zululand, and the three High Commission Territories. In the latter, further land alienation to whites could not take place without the express agreement of the high commissioner, although in Swaziland land concessions granted to whites by chiefs in the 19th century had already alienated one-third of the land resources of the kingdom and constituted a continuing source of unrest and friction.

In the reserves and protectorates of southern Africa, governments retained African tribal organization and governed through sufficiently compliant chiefs and headmen. Economically, these areas were largely based on subsistence agriculture.

In the union about 40 percent of the African population lived on reserves, and about the same number lived on white-owned farms either as labour- or rent-paying tenants or sharecrop farmers (squatters). The poorly paid labourers were immobilized by master-and-servant laws and Pass Laws, which made strikes and desertion criminal offenses. Small numbers of Africans, from the second half of the 19th century, were successfully producing cash crops for the new markets; increasingly, however, because of government subsidizing of white farmers and preventing further land purchase by Africans, and because of African population pressure and soil erosion, these initiatives were crushed.

Natives Land Act of 1913

Probably the crucial blow to the Africans in South Africa was the Natives Land Act of 1913, a complex measure aimed at securing a supply of cheap labour by limiting African land ownership to the already existing reserves and by transforming African sharecroppers and tenants into wage labourers. Under this act and the complementary Native Land and Trust Act of 1936, about 12–13 percent of the land was scheduled for more than 4,000,000 Africans, while 87 percent of the land was reserved for 1,250,000 whites. Though the 1913 act prevented the total dispossession of Africans and ensured a rural base for migrant labourers where their welfare costs could be borne, it also led to the dislocation of thousands of Africans, who were to swell the numbers already working for whites.

In South West Africa, the white farming population increased at the expense of both the Herero and Nama. In 1921 the administration set aside apparently large reserves for the two indigenous groups, pursuing the policy of segregation established by the South African Natives Land Act, but these were generally in the dry hinterland of the Kalahari or on sandveld unsuited to man or beast. By the 1930s settlers were in control of more than a third of the land.

In Southern Rhodesia the pattern was not dissimilar, though Africans retained a higher proportion of land. After the Shona and Ndebele rebellions, the administration sold large tracts of land to settlers and speculators, with little concern for African rights. As hopes of vast mineral wealth were disappointed, the British South Africa Company turned to the development of white commerical agriculture—maize (corn), cattle ranching, and tobacco. By the 1920s, of 96,000,000 acres of land in Southern Rhodesia, 31,000,000 were in the hands of about 11,000 whites; 22,500,000 had been reserved for the 676,000 Africans; and 45,500,000 acres remained open to purchase and occupation by people of any race. In 1930 the Land Apportionment Act, modelled in part on South African legislation, attempted to define areas of ownership by barring African land purchase outside the reserves and by a special native purchase area of 8,000,000 acres, which soon proved inadequate.

As in South Africa, a considerable number of Africans "squatted" on white-owned and crown lands in Southern Rhodesia. By the 1920s, with the increased utilization of land by commercial farmers and their demands for labour, there was little room for such practices, while the initiatives of the Shona at cash-crop production were also crushed by the artificially created land shortage, discriminatory marketing practices, and the distance of the reserves from roads and railways. The rapid growth of the African population and its stock in the limited reserves, combined with its lack of security in urban areas, made the land question increasingly acute through the 1930s and '40s. Though in 1951 the Native Land Husbandry Act was adopted, allegedly to grapple with the problems of overstocking and erosion in the reserves and to implement the necessary agrarian reform, for a variety of reasons it remained unimplemented.

The Native Land Husbandry Act of 1951

In Northern Rhodesia, land never became as crucial an issue, except along the railway line in Tonga country and at Fort Jameson, where white settlers, mainly from South Africa, established themselves; in the reserves drawn up in 1928–29, however, there were problems of overcrowding and overstocking.

In Nyasaland, despite Johnston's attempts to control land alienation after 1896, about 15 percent had passed to whites by the turn of the century, particularly in the Shire Highlands, where tobacco, cotton, coffee, and tea plantations were established. On their lands, planters charged rent or demanded labour of Africans who wished to remain. Though by the end of World War II the amount of land in settler hands had been reduced to 5 percent, about 10 percent of the African population lived on white-owned plantations as tenants-at-will, squatters, or labourers. In the first three decades of the century, the administration favoured white plantation agriculture over African cash-crop production, though this gradually changed. In 1936 the bulk of the land was vested in a Native Trust. By the end of the war there was serious overcrowding in the southern provinces of Nyasaland, especially in Cholo and Mlanje districts, where, in 1953, the population density was estimated at 250 to the square mile. This congestion led to very serious rural discontent, which erupted in riots in Blantyre in 1943, in Cholo in 1945, and in Cholo and Mlanje in 1953.

In Angola and Mozambique at the beginning of the century, despite the then sparse settler population, a land policy was initiated by which all land not privately owned was in the hands of the state. Though Africans were to be left on their communally owned lands, the way was open to their expropriation in response to the demands of the concession companies and, later, of white settlers. In the Portuguese territories, however, land alienation never became the key method of forcing out

African labour, which was more directly provided for in the labour codes of 1878, 1899, and 1928. The codes institutionalized a variety of forced labour practices.

In addition, from the 1930s until 1961, with economic development directed solely to Portugal's benefit, Africans in certain areas had to pick stipulated cotton or coffee quotas, which had to be sold to the companies or government at a fixed price below the world market level.

African labour. In the British-controlled territories, as in South Africa in the 19th century, before Africans felt the effects of land shortage, the most important method of forcing out labour was taxation, which had the double advantage of producing revenue for administration. In Nyasaland, tax collection started in 1892 and extended over the entire territory by 1904. In Southern Rhodesia, the British South Africa Company imposed a hut tax in 1898, which was doubled in 1904, while in Northern Rhodesia the whole country became subject to tax in the first decade of the 20th century. Taxation increased steadily in all of the territories until World War II, though in many areas Africans working for whites received rebates.

Taxation

At the beginning of the century by far the most dramatic demand for labour resulted from the mineral discoveries in South Africa, and it was here that much of the subsequent pattern of southern Africa's industrialization was established. Initially, Africans went to the diamond fields and later to the gold mines for short periods, leaving their families behind on the reserves. The mineowners soon realized the advantages of employing unorganized migrant workers, who could be paid low wages on the grounds that they were single men who worked only for specific targets. On the diamond fields, Africans were housed in closed compounds to maximize control and prevent desertion. Both the compound system and migrant labour became features of the gold mines of South Africa and Southern Rhodesia, as well as of the copper mines of Northern Rhodesia in the 1920s and '30s.

With the opening up of the gold mines, demands for African labour expanded far beyond the frontiers of the Union of South Africa. In 1889 the Chamber of Mines was formed and soon came to control African wages by monopolizing the labour supply. By the early years of the century the chamber's recruiting agents had spread as far afield as Barotseland and Nyasaland.

From the first decade of the 20th century, by far the largest number of workers for the gold mines came from Mozambique. Under conventions signed between Portugal and the South African government in 1903, 1909, and 1928, Mozambique received a grant for every worker sent to the mines, while the bulk of the Africans' wages was handed over to Portuguese officials for repayment in the territory. The grant constituted a major source of the colony's income. In Angola this system had its counterpart in the contract labour sent to the cocoa plantations of São Tomé. In South Africa, where the effect of this ready supply of powerless labour enabled the Chamber of Mines to prevent any rise in real wages for Africans between 1911 and 1971, the system was relatively unremarked. In 1911 African wages in the mines were lower than they had been in 1897.

The justification for low wages

Part of the justification for the very low wages paid to black migrants in the white economy was, and still is, the assumption that their families were able to subsist on agriculture in the reserves. Nevertheless, the continual absence of the majority of adult men broke up families and contributed to the impoverishment, underdevelopment, and demoralization of the rural areas, while hampering the growth of working class consciousness in the towns and thus the improvement of urban wages and living conditions.

The job colour bar. While it was possible for the mining industry to acquire cheap unskilled labour through a variety of administrative techniques, skilled labour had to be attracted from overseas to the interior of South Africa by the promise of extremely high wages. Though by the turn of the century many Africans had acquired the requisite skills, and it was in the economic interests of the mineowners to substitute Africans for the increasingly expensive white labour, the political power of white workers and, later, trade union organization, together with the powerlessness of the Africans, enabled white workers to establish a job colour bar, which was legally entrenched in South Africa in the Mines and Works acts of 1911 and 1926.

In 1922 the Chamber of Mines in South Africa attempted to relax the job colour bar and cut white wages, but this led to a wave of strikes on the Witwatersrand that culminated in a five-day battle between white workers and troops and resulted in the firmer entrenchment of the job colour bar.

Though the job and wage colour bars had their counterparts in the Rhodesias and the Portuguese territories, on the Copperbelt of Northern Rhodesia white unionists were ultimately too weak to protect their privileged position. The major copper companies were the Anglo American Corporation of South Africa and the Rhodesian (later Roan) Selection Trust, with mainly American capital.

Though production slumped during the Great Depression, by 1935 the copper mines were already recovering. Ten years later Northern Rhodesia was one of the world's greatest copper producers, and the job colour bar, the enormous differential between black and white wages, and discriminatory practices had become essential features of the Copperbelt. By the mid-century, however, the growth of trade unionism and skills among Africans and the political weakness of the white working class enabled the mining magnates to replace white miners with trained Africans. Today the well-organized African miners on the Copperbelt constitute a highly paid elite.

Urbanization of white and black Africans. Although the first major battleground over the colour bar appeared in the mining industry, the presence of an increasing number of Africans in the urban areas outside the mining compounds brought new problems for government in southern Africa from the 1920s onward. By the turn of the 20th century, indeed, there was already a substantial number of Africans in the four major cities of South Africa, and by 1921 there were more than 500,000 Africans in towns. These numbers increased sharply to 1,250,000 in the late 1930s, as South Africa's economy recovered from the world depression and the growth of secondary industry led to greatly increased demands for African labour. By the end of World War II there were probably 2,000,000 Africans in the towns and by 1970 more than 3,500,000.

African and Afrikaner migration to the towns

From the beginning of the 20th century the stream of black migrants making their way to the towns was paralleled by a stream of Afrikaners displaced from the land. By the early 1930s the drift had become a flood, and one in five of the white population was classified as "poor white." Poor, unskilled, semi-literate, they were in direct competition with the equally poor and semi-literate Africans, some of whom had more industrial skills.

Although commission after commission attributed the plight of the "poor whites" to their refusal to do what was designated Kaffir work (*i.e.*, manual labour, Kaffir having been a derogatory name for the Xhosa), the Afrikaners were at a double disadvantage in the towns. Whereas the black Africans left their families to subsist, at however low a level, with their kin in the reserves, the Afrikaner was totally dependent on his urban wage. At the same time, at the high wages demanded by organized labour, he was unemployable. Not surprisingly, therefore, Afrikaner nationalism in the first half of the 20th century had a distinct anti-capitalist edge.

In the territories of Central Africa, also, by the third decade of the 20th century, Africans were increasingly making their way to the urban centres, pushed out of the rural areas by economic necessity and attracted by the higher wages and wider experience of the towns. Until the end of World War II, however, white administrators, capitalists, and settlers alike were determined that the towns should be the white man's preserve. Nowhere were authorities prepared to see the establishment of a perma-

nent African urban population. The results were low wages, appalling living conditions, poverty, and broken family life. It was only after World War II, when change was speeded up all over the continent, that more serious consideration was given to the problems of African urbanization, although even then, administrations, whether colonial or later independent African, could never keep pace with the move to the towns.

THE AFRICAN RESPONSES

The reactions of the African peoples who had been drawn painfully into the settler-dominated capitalist society of southern Africa and subjected to ever-increasing administrative, economic, and political control were varied. Once their traditional economic and social structures had been defeated and undermined, it became necessary to find new ways of expressing their opposition to white rule. In certain areas, dreams of resistance organized along traditional lines continued well into the 20th century, especially in the Portuguese territories but also in Mashonaland in the 1930s and in the High Commission Territories in the 1950s and '60s. Indeed, in isolated rural regions, there may still be small groups of traditionalists who have been relatively unaffected by the 20th-century nationalist struggles against colonialism.

Royal family politics

In some regions—pre-eminently those in which large centralized states had existed at the time of the colonial takeover—royal family politics continued to be of greatest significance. In Barotseland, Swaziland, and Basutoland, where the paramount chiefs were given special recognition by colonial regimes, the traditional aristocracy combined with the educated to protect their position and to demand redress of their grievances. In Matabeleland, the first decades of the 20th century were marked by an attempt to see a restoration of the kingship, while in Nyasaland in the 1930s the elite combined with traditionalists to seek a Tonga paramountcy and to restore the Ngoni king. In general, these attempts were most successful during the 1930s, when theories of indirect rule generally prevailed, and in areas where the settlers were weakest. In all territories, tribal and regional divisions and rivalries, despite African attempts to overcome them, continued to shape African responses to colonial rule and have remained easily exploitable in some areas.

The experience of white rule for Africans has been longest and most intense south of the Limpopo and in the Portuguese territories, although the existence of a substantial but unprivileged Coloured and Indian minority in the former and of *assimilados* and *mestiços* and settlers lacking political rights in the latter gave an extra dimension to anti-colonialism.

In South Africa, between 1906 and 1913, Gandhi led the first large-scale nonwhite, nonviolent resistance campaigns against anti-Indian legislation and gained very limited successes, though restrictions on Indian movement and immigration to South Africa remained in force. After his departure (1914), however (despite the formation of the South African Indian Congress in 1919), the initial militancy of Indian opposition was lost until after World War II, when younger, more radical groups won power from their moderate middle-class precursors who had dominated the party.

Compared to the Indians, the Coloureds of the Cape and Transvaal were never as successfully mobilized, though the African Political (later People's) Organization, founded as a South Africa-wide body in 1902, was the first large nonwhite political organization. It was, however, soon eclipsed by more vigorous African nationalist movements, and for most of the century the marginal Coloured population has been divided and relatively voiceless, though the predominantly Coloured Non-European Unity Movement, founded in the 1940s, has influenced African political thought.

The African response to settler rule in South Africa has in many ways been paralleled in the territories farther north. As early as the time of the unification of South Africa, educated Africans—teachers, preachers, clerks, small traders, and more prosperous farmers, as well as a sprinkling of professional men—had begun to feel the need for some organization larger in scale than the local vigilance and welfare associations that had grown up in the Cape in the last decades of the 19th century.

These were paralleled elsewhere in South Africa immediately after the South African War and in the Central African territories in the second and third decades of the 20th century. In 1912 the South African Native National Congress, which became the African National Congress (ANC) in 1917, was founded to represent African grievances, to overcome African tribal divisions, and to attempt to gain acceptance within the white polity through self-help, education, and the accumulation of property. Though demands for industrial education, individual land tenure, and some form of representation in Parliament later broadened to include attacks on the Pass Laws, the industrial colour bar, and the Natives Land Act of 1913, their methods remained strictly constitutional and they appealed mainly to the black middle class. Again, the territory-wide ANC has had its counterparts in Central Africa: in Southern Rhodesia in 1934, Nyasaland in 1944, and Northern Rhodesia in 1949–51. Though there have been local differences, the methods were similar, at least until after World War II, with South Africa leading the way.

African National Congress

Despite the increased numbers of Africans in industry in South Africa by the end of World War I, African trade unions were hampered by the Pass Laws, nonrecognition, and police harassment; spontaneously organized strikes were regarded as criminal offenses and often suppressed with violence. Nevertheless, in 1920 the Industrial and Commercial Workers' Union (ICU) was founded in Cape Town by the fiery Clements Kadalie, a migrant worker from Nyasaland. Based initially on Coloured workers in Cape Town, the ICU spread rapidly among Africans, both in towns and on the reserves and white farms of the countryside, claiming at its height some 100,000 members and establishing branches in Rhodesia and South West Africa by the mid-1920s. ICU, however, like the ANC, soon divided between those who wished to proceed constitutionally and those who demanded greater militancy and mass participation; by 1929 it had virtually disintegrated.

From the early 1920s in South Africa and from the 1930s in Central Africa, governments attempted to provide channels for the expression of African grievances through a variety of local consultative councils, often with a strong component of chiefs. Despite their powerlessness, educated Africans participated in them in the hope of gaining greater concessions, though by the end of World War II they were increasingly disillusioned with the prospects for reform.

Assimilado goals

In Angola and Mozambique during the republican period in Portugal (1910–26) the Congress movements and ICU had their counterpart in *assimilado* political organizations, trade unions, and a local press. For a brief period in Angola it seemed as if the *assimilados* and Europeans would fight for common reformist goals; but the Africans soon broke away from the less radical European organizations to form their own Liga Angolana and Centro (later Grêmio) Africano, which had their equivalents in the Grêmio (later Associação) Africano in Mozambique. These associations engaged in petitions to demand limited educational and welfare benefits and to make African grievances more widely known. In this they were partly inspired by the formation of political associations among colonial Africans in Lisbon from 1910 onward; these, by the 1920s, were influenced by broader Pan-African diaspora movements. In general, however, they were dominated by middle-class moderates and had little influence beyond the urban areas. Even before the advent of the Salazar regime, these nationalist stirrings were crushed by the autocratic governor of Angola Norton de Matos (1921–26). Though the associations revived as ostensibly social and educational organizations, officially recognized by the government in the 1930s and '40s, it was not until the 1950s that they returned to militantly political expression.

Political participation and organized political movements, even at the height of their popularity, never reached more than a fraction of the African population.

For the aspirations of many, however, independent churches, which broke away from the orthodox white-controlled missions, provided another outlet. In South Africa the first independent church was founded in the 1880s; by the turn of the century European administrators noted with alarm the growth of Ethiopianism, as it was called, with the existence of some 15 to 20 independent sects; by the 1960s there were well over 2,000, ranging in size and organization from little more than a family group to vast churches with thousands of members and links with the overseas world.

In the early years of the century, Europeans in South Africa interpreted the separatist church movement as politically dangerous and in some areas sought to crush it administratively. By and large, however, the independent churches in South Africa probably diffused African energies. The only violent episode involving the separatists in South Africa took place in 1921, when nearly 200 members of a sect known as the Israelites were killed by police gunfire when they refused to move from an African location near Queenstown in the eastern Cape, where they were living peacefully, if illegally, awaiting the millennium.

In northern Nyasaland in the first decades of colonial rule and in Northern Rhodesia in the 1930s, the millennial doctrines of the Watch Tower movement (Jehovah's Witnesses) were far more politically explosive. Within a year of its establishment in northern Nyasaland in 1909, Watch Tower had more than 10,000 adherents, who were partly attracted by its prophecies that British rule would end in 1914. In 1915 John Chilembwe, greatly influenced by its millenarianism as well as by his own colonial experiences, led an unsuccessful rebellion against British rule.

For the rural Shona, also faced by severe economic crises in the late 1920s, the millennial dreams of Watch Tower provided the most adequate substitute for traditional religious and political supports. As in Nyasaland, however, the outburst of Watch Tower was replaced relatively quickly by more subdued Christian independency, which, by the mid-century, had tens of thousands of followers and offered solutions to contemporary problems by drawing on fundamental ideas of Shona religion as well as by providing form and discipline in times of social upheaval.

Prophet movements

In Angola, too, and especially among the Kongo (living in northern Angola and the Belgian and French Congos), prophet movements, influenced by the Protestant missionaries and Watch Tower, drew on traditional religious and cultural beliefs, imparting as well a specifically anti-European message, which partly prepared the ground for the anti-colonial war of the 1960s.

Though the initial break with the mission church betokened a desire for independence from the white man, there were many motives, including the religious, for separatism. The prophet movements and independent churches expressed the millennial dreams of an insecure and poverty-stricken population torn from its traditional moorings.

By 1945, despite the fact that Africans had not established mass nationalist movements anywhere in the subcontinent, a remarkable range of protest movements existed, which became merged in many areas in the next decade to produce modern nationalist parties and give them their characteristic shape.

IV. Southern Africa since 1945

If, in the first half of the 20th century, policies in the southern African territories were remarkably similar, after World War II their political destinies diverged. During World War II, politics all over southern Africa appeared to stand still. Nevertheless, when the colonizers turned their attention once again to the African colonies, it was in the context of a very different world. The colonizing nations emerged from the war as secondary powers, under attack from the United States and the Soviet Union, which, for their own reasons, demanded rapid decolonization. The Bandung Conference of Asian and African nations (1955), the founding of the United Nations, and the liberation of South Asia were significant milestones also for the colonized peoples of Africa. There was increased awareness in Britain that the African territories, too, had to be prepared for independence, and the tentative beginnings of colonial development were accelerated. The indirect rule policies of the 1930s were abandoned, and in all territories steps were taken toward granting representative institutions.

The economic effects of the war had been profound. In South Africa and Southern Rhodesia it had brought about a tremendous increase in urbanization and secondary industry. The boom on the Copperbelt shifted the economic focus in Central Africa northward and further radicalized African politics; and in the Portuguese territories, greatly accelerated white immigration and the coffee boom in Angola had a similar effect in the 1950s.

In the south these developments led to the victory of the (Afrikaner) National Party, determined that whites should maintain total social, political, and economic control in both South and South West Africa. In the British Central African territories, after a short-lived experiment in multiracial federation, they resulted in 1964 in the emergence of independent African states in Malawi (formerly Nyasaland) and Zambia (Northern Rhodesia) and in 1965 in the unilateral and unconstitutional declaration of independence by white settlers in Rhodesia.

Independent states in the 1960s and '70s

For the High Commission Territories, the "winds of change" in Africa also brought political independence: Lesotho (formerly Basutoland) and Botswana (formerly Bechuanaland) in 1966 and Swaziland in 1968. In Angola and Mozambique violent anti-colonial struggles that lasted more than a decade led to the downfall of the Salazar regime in Portugal and to the ultimate independence (1975) of the territories themselves.

Despite the political differences, in socio-economic terms the subcontinent has been welded together into areas of high capital development, supported by rural areas of increasing impoverishment that provide a large reservoir of cheap labour. Most striking has been the very rapid industrial growth in South Africa, which accounts for 74 percent of production in the area.

As in the first half of the century, white South Africa, with its immense wealth, dominates its neighbours, black and white. The Portuguese withdrawal, however, together with increasingly explosive internal pressures, has opened a new era of uncertainty for white rule in the subcontinent.

SOUTH AND SOUTH WEST AFRICA

In 1948 the tentative and ambiguous moves in South Africa toward less rigid social policies were swept aside by the electoral victory of the National Party, which had reunited after the dissensions of the war years under the leadership of Daniel F. Malan (prime minister 1948–54). Though the Nationalists fought the election on the "race issue" under the new slogan of apartheid, the essence of the change was over which group of whites was to control the South African economy. Whereas up to 1948 every Cabinet had drawn its members from both language groups, the Nationalists were able, unlike any previous Afrikaner party, to unite the majority of their people behind them and to consolidate the victory in the following 20 years. Initially, the Nationalists secured only 40 percent of the vote, but by 1966 this had increased to 60 percent. By this time an increasing number of English-speaking voters had accepted the government claim that it alone was capable of securing white dominance—this despite the fact that in 1960–61 South Africa was forced out of the British Commonwealth and declared a republic.

Behind the Nationalists' electoral success lay South Africa's accelerated industrialization. Although this process was already under way by the end of World War II, South Africa's economic growth between 1948 and 1970 was surpassed only by that of Japan, undoubtedly partly the result of government intervention in the control of labour, the direction of investment into industry, and the provision of essential infrastructure through the increased number of para-state corporations designed to increase

Industrialization in South Africa

the Afrikaner hold on the economy. Apart from 1948 and 1960–61, when there was a flight of foreign capital from South Africa in response to the regime's apparent political instability, capital investment from the United Kingdom, the United States, and western Europe, attracted by the high rate of profit, contributed greatly to South Africa's economic growth. Since 1945 secondary industry has replaced mining and agriculture as the major economic sector.

Thus, by the 1960s, if not before, white South Africans enjoyed one of the highest standards of living in the world. It was achieved very largely at the expense of Africans, through the rigorous control of their labour power. The reverse of the high per capita income of the small white population is the extremely low per capita income of the blacks. Thus, in 1969, the average monthly wage of a white man was $133, that of a black man $10. Despite wage increases, in real terms wages were little different in the mid-1970s, while the absolute white–black wage gap had widened.

Extending the philosophy that only those Africans who were of service to the whites were to be allowed in towns, remaining African rights in the urban areas were removed, and thousands of Africans returned to their so-called tribal homelands. The basis of the black work force, both in the towns and on white-owned farms, reverted to the system of migrant labour, which had been breaking down since the 1930s. As a result, in the mid-1970s some 2,500,000 Africans were arrested each year for statutory offenses—750,000 for infringing the Pass Laws alone.

In the 1950s Hendrik Verwoerd, the minister for native affairs and from 1958 to 1966 prime minister, developed the second aspect of the National Party's apartheid policies. Verwoerd argued that the only solution to racial antagonisms in South Africa was to balance African rightlessness in the white areas with the establishment of ethnically defined "Bantu Homelands," where Africans could develop semi-autonomous states, or "Bantustans." The territorial bases for the Bantustans were the African reserves set aside in 1913 and 1936. In 1954–55, the government-appointed Tomlinson Commission, which produced a plan for territorial segregation, admitted that the reserves were incapable of carrying their current population, let alone the increase necessary if Africans were to be removed from the white areas. Nor was it ever intended that this should happen; though more than 3,000,000 Africans have been forcibly moved out of white rural areas and so-called surplus Africans have been moved from towns under a variety of apartheid laws to the poverty-stricken reserves, the number of rightless Africans returning regularly to so-called white areas has nonetheless steadily increased to keep pace with labour demands.

Authority of the chiefs

Legislation in 1951 and 1959 attempted to resurrect the authority of the chiefs in the reserves and establish tribal, regional, and territorial advisory councils. While many hereditary chiefs still retained some popular support, the new policy created profound discontent in the rural areas as chiefs walked a tightrope between popular hostility if they implemented government policy and government anger if they failed to do so. In several rural areas there was violent resistance and apartheid chiefs were assassinated, while in the Transkei, which held its first Bantustan elections in 1963, a state of emergency had to be declared and was still in force in the 1970s. Under the constitution granted to the Transkei and later to the other Bantustans, the South African government still controls crucial aspects of internal and external affairs. "Full independence" was demanded by the Transkei. This was opposed by other African leaders, who feared the fragmentation of their cause, but the Republic of Transkei was nonetheless proclaimed on October 26, 1976. Despite the militant tone of some Bantustan leaders, notably Chief Gatsha Buthelezi, whose Zulu constituency in KwaZulu is the largest of any "homeland," their room for manoeuvre is limited by their total economic dependence on South Africa. In the 1960s the Bantustan policies were also extended to South West Africa.

The Coloured and Indian minorities, who cannot be repatriated to "tribal homelands," have also suffered from such segregatory legislation as the Group Areas Act and the Population Registration Act, which led to widespread removals of people.

During the 1950s the practices and policies of apartheid in South Africa were under heavy fire both internally and abroad. India's complaints in the United Nations in 1946 about South Africa's treatment of the Indian population initiated a series of UN resolutions condemning South Africa. Its treatment of Africans in South West Africa became a serious point of contention at the United Nations from the 1950s. The issue was taken to the International Court of Justice at The Hague, which finally gave judgment against South Africa in 1970. With the admission of new African nations to the UN and the formation of the Organization of African Unity in 1963, the international attitude became increasingly hostile.

Internally, too, the 1950s was a decade of unprecedented opposition to government policies. The growth of African and Indian militancy after the war may have contributed to the National Party victory. The measures of the Nationalist government gave the deliberations of the African National Congress new urgency. With the suppression of the Communist Party in 1951, many white radicals joined the liberation struggle, while the increasing awareness of the need for a united opposition among Indian, African, and Coloured leaders found expression in a passive resistance campaign in 1952 and in the founding of the Congress Alliance by African, Indian, and white opponents of the government in 1955. Despite the arrest in 1956 of more than 150 Congress leaders on charges of treason (all of them were subsequently released), the later 1950s saw increased militancy among the African nationalists. In 1958 the Pan-Africanist Congress (PAC) was formed, and in 1960 it launched a campaign against the Pass Laws. It was during this campaign that police fired on a peaceful crowd of unarmed demonstrators at Sharpeville, killing about 70 persons and wounding hundreds of others; this led to an even greater outcry overseas against South Africa's racial policies and to the South African government's banning of both the ANC and the PAC.

Growth of Indian and African militancy

Though underground sabotage movements were founded in 1961–64, the wide use of spies and informers —a regular feature of the regime—and draconian security legislation led to their swift collapse. Many Africans fled to Zambia and Tanzania, where guerrilla training was undertaken and outside support sought.

Since 1945 a liberal tradition has continued in South Africa, with the emergence of a Liberal and later a Progressive Party, and there have been constant protests against government policies from students at English-language universities, from prominent church leaders, and from such organizations as the Springbok Legion, the War Veterans' Torch Commando (which faded away after the election of 1953) and the Women's Defence of the Constitution League (called the Black Sash). Essentially, however, the opposition movements were weak and divided. White liberals were never wholeheartedly behind the destruction of white law and order, while the ANC, though increasingly militant, was easily overwhelmed by a government with vast military and security resources.

Opposition movements

After 1973, however, black opposition again began to mount within the country. Initially, most serious for the government was the industrial unrest, particularly in Durban and in the gold mines, where much violence occurred, at a time when the future of the external migrant labour supply on which the mines are dependent was diminishing. A variety of black worker organizations was formed, while black students, partly influenced by the black power movement in the United States, formed the militant South African Students Organization, with African, Indian, and Coloured members; this had its counterpart in the Black Peoples' Convention. All these groups were encouraged to more militant aspirations by the Frelimo victory in Mozambique (see below).

Nevertheless, despite a number of ambiguous statements by the prime minister, B.J. Vorster, and at the

United Nations, there was no lessening in the essentials of apartheid. From 1975, increasing inflation and black unemployment (officially estimated at more than 17 percent in 1976) exacerbated tensions in the African townships. By April 1976, Chief Buthelezi was warning of serious trouble ahead if the government did not change its course, and this erupted in June, ostensibly over the enforced use of Afrikaans as the medium of instruction in black schools. Although the government retracted this policy, it was only after police had fired on thousands of demonstrating schoolchildren and the disturbances had spread over most of the republic, especially to the black townships around Cape Town. Unrest continued through the second half of the year, with thousands dead, injured, and imprisoned. Key symbols of apartheid were destroyed—beer halls (the proceeds of which are used to finance "Bantu" administration) and administrative buildings and schools—and the protest extended far beyond the original language issue. Thus increasing internal strains within South African society were paralleling the changing external pressures, and the widely held assumption that economic growth would improve the lot of Africans had been proved false both by events since June 1976 and by the increasing evidence of black unemployment and rural impoverishment.

South Africa and its black neighbours

The weak and divided black African states—despite their protests of the early 1960s—posed little threat to South Africa, which until the Portuguese coup seemed a corner of stability in the continent. In improving its diplomatic and economic relations with its black African neighbours, South Africa established close trade and diplomatic relations with Malawi and improved its customs agreements with the former High Commission Territories. The Cabora Bassa hydroelectric scheme aimed at uniting South Africa even more closely with the territories of Central Africa, while roads and railways connected South Africa with South West Africa and Angola. With the growth of secondary industry, South Africa found it increasingly essential to establish markets in Africa. The Anglo American Corporation of South Africa, with its vast interests in the subcontinent, played an important role in fostering the policy of "détente" and in maintaining overseas confidence in the regime.

With the withdrawal of the Portuguese from the region, détente became more urgent for security reasons. Realizing Rhodesia's vulnerability once Mozambique and Angola achieved independence, South Africa joined with black African leaders to try to achieve a negotiated settlement of this issue.

In August 1976 a constitutional committee (the Turnhalle Committee) in South West Africa (Namibia), with the tacit approval of the South African government, announced plans for a form of political independence in the territory by the end of 1978. The South West Africa People's Organisation, however, which the UN recognizes as representing the territory's inhabitants, was excluded from the committee's discussions, and the guerrilla struggle intensified on the northern frontier.

THE HIGH COMMISSION TERRITORIES

Their proximity to the economically dominant South Africa has been most acutely felt by the three High Commission Territories. Despite British abandonment of the idea of their political incorporation into South Africa after 1948, the absence of a large proportion of the working population as migrant labour in South Africa—as high as 43 percent in Basutoland and 28 percent in Swaziland in the 1960s—stultified economic and constitutional advance. From the mid-1930s, British aid, though inadequate, was made available, agricultural improvement schemes were instituted, and a Native Treasuries Finance Committee and advisory councils were established; attempts were also made to reform the courts and, most importantly, the system of chieftainship, a necessity in Basutoland in particular, where petty chiefs had proliferated. Most of these reforms became more effective after World War II, and by 1960–61 legislative councils had been established in all three territories. Basutoland and Bechuanaland became the independent states of Lesotho and Botswana in 1966; Swaziland, where the existence of a number of white settlers and considerable South African economic interest complicated the transfer of power, became independent in 1968.

In all three territories, but especially in Swaziland, where traditional chiefs have remained extremely powerful, modern nationalist movements emerged relatively late. In all three, conservative governments anxious to avoid provoking their powerful neighbour emerged in the first elections after independence, though Swaziland, with greater economic potential and a shrewd, if autocratic, king, and Botswana, with its outlet to the north and sophisticated leadership, have had greater scope for manoeuvre than small Lesotho, which is entirely surrounded by South Africa.

BRITISH CENTRAL AFRICA

In the colonies of British Central Africa—Northern and Southern Rhodesia and Nyasaland—the immediate postwar years also brought significant economic and political changes. In Southern Rhodesia as in South Africa, secondary industry overtook mining and agriculture as the main sector of the economy; and from 1946 the influx of emigrants from Britain averaged 10,000 a year, increasing the white population to 125,000 by 1953. At the same time, in Northern Rhodesia the copper boom set off new conflicts as the colour bar intensified, while as early as 1935 and 1940 widespread strikes by African miners showed the potential of the African working class. Settlers, led by the white labour leader and former railway worker Roy Welensky, began agitating for some form of amalgamation with Southern Rhodesia.

Powerful economic arguments were used; and big business, especially the powerful Anglo American Corporation of South Africa, with its interests in both territories, gave the movement its backing. The National Party victory in South Africa in 1948 gave it further impetus. The British Colonial Office, anxious to strengthen Nyasaland's weak economy, insisted on its inclusion in any form of closer union. In 1953 the Federation of Rhodesia and Nyasaland (Central African Federation) was formed.

Federation of Rhodesia and Nyasaland

In all three territories, where economic developments and the general trend of world opinion had strengthened the African political organizations of the interwar period, politically articulate Africans were almost unanimously opposed to federation. As talk of closer union mounted among whites between 1949 and 1953, the Congress movements became more widespread and representative. In all three, Africans feared that federation would lead to further land alienation, undermine the position of chiefs, prevent political advance, and extend farther north the colour bar and discrimination of Southern Rhodesia.

With the establishment of the federation, however, the Africans, especially in Southern Rhodesia, were initially cooperative. But by the mid-1950s, the economic advantages of federation seemed so exclusively to benefit the whites of Southern Rhodesia that African hostility was re-aroused. Though federal leaders preached racial partnership, and in Southern Rhodesia urban African housing was improved and a multiracial university built, greatly increased white immigration from South Africa and Britain intensified black–white conflict. The continued demands by federal leaders for dominion independence status confirmed the Africans' worst fears.

In Nyasaland by 1955 a group of young radicals had emerged to demand universal suffrage and self-government and for the first time turned to the masses to achieve their ends. By 1957 they claimed 60,000 members and were developing a modern mass nationalist party. Feeling the need for a leader of standing they invited Hastings (later H. Kamuzu) Banda, at that time practicing medicine in Ghana, to return and take over the leadership of the Congress movement. Banda returned in 1958 and vigorously denounced federation.

In Northern Rhodesia, African political opposition revived in 1957 after a period of quiescence, when the Congress organization had been eclipsed by the rise of the millenarian Lumpa Church of Alice Lenshina. In

1958–59 the removal of the more conservative president of Congress and the influx of new militants under the leadership of Kenneth Kaunda transformed the organization. Like its counterpart in Nyasaland, it became far more radical and created branches all over the country.

Southern Rhodesian opposition became more radical in the later 1950s also, as urban and rural discontents were united for the first time, and a group of young leaders formed the Southern Rhodesian African National Congress under Joshua Nkomo in 1957. This was later to become the Zimbabwe African People's Union (ZAPU).

The rise of mass nationalist movements brought direct confrontation between the Africans and the colonial and federal authorities. In 1959, after sporadic disturbances in Nyasaland, a state of emergency was declared, nationalist leaders were arrested and their parties banned, to be replaced in all the territories by new parties under new names by 1960. The banning of the nationalist parties was followed by disturbances and disorders all over the federation, but particularly in Southern Rhodesia, where the worst rioting occurred in the impoverished African townships. While in Nyasaland and in Northern Rhodesia the rioting was sufficient to persuade a distant Colonial Office to grant majority rule, in Southern Rhodesia it increased white determination to hold more tightly onto their position. In 1961 Nyasaland and Northern Rhodesian leaders were released, and new constitutions were granted to the territories; and in 1963, after further disorder in Northern Rhodesia, the federation was finally dissolved. In the following year Northern Rhodesia and Nyasaland became the independent states of Zambia and Malawi, governed by the nationalist leaders who had fought for independence.

Despite independence, however, many problems remained in both territories. In Malawi the unity of the nationalists was short-lived, and after an abortive uprising in 1965 Banda stifled all internal opposition. Regional differences—the result of Malawi's uneven economic and educational development—continued, while Banda's policy of close ties with settler regimes was resented by many black Africans, large numbers of whom were still dependent on the white south for wage employment.

Independent Zambia

When, in 1964, Zambia achieved its independence, it was still a poverty-stricken and backward country, despite the potential of the Copperbelt. Indeed it was not until 1964 that the British South Africa Company ceded its concession rights to copper royalties, which had, over the years, gone to enrich the company and the British treasury rather than the territory itself. The result was that very little capital had been made available for investment in the increasingly impoverished rural areas or for welfare and educational services. Despite attempts, since independence, at reform, the countryside continues to be drained of manpower as thousands of hopeful young people make their way to the towns. In the towns, however, neither housing nor welfare is adequate, and unemployment grows. Fluctuations in the world price of copper and the oil crisis in the 1970s greatly aggravated Zambia's weakness; regional, ethnic, and rural–urban divisions persisted also. During the period of the transference of power, Lozi separatism was a serious problem, while the Lumpa Church became increasingly opposed to the government. In 1964 open warfare broke out between the church and the state; more than 700 people were killed and the church was banned.

In both Malawi and Zambia, but especially in the latter, the problems were compounded by developments in Southern Rhodesia. There, the violence in the early 1960s as well as events in the rest of Africa roused white fears and led to an increasing number of emergency laws against political opponents. Though limited concessions were made to Africans by the government in 1961, these were rejected both by the African nationalists, who refused to participate in the new elections, and by white farmers and artisans, whose support for the new right-wing Rhodesian Front Party led to its electoral victory in 1962.

With the end of federation, the Rhodesian Front, after crushing African opposition and increasing its internal support, renewed its demands for independence. Britain was unwilling to concede to these demands without evidence of progress toward majority rule and of the end of racial discrimination. In 1965, in a highly emotional atmosphere, the Rhodesian Front, under the leadership of Ian Smith, unilaterally declared Rhodesian independence. Total opposition to the prospect of black rule became policy.

Rhodesian independence

Despite international pressure, Britain refused to use force against the illegal regime, though it did support the economic sanctions imposed by the UN. These, however, were never fully effective, largely because of continued support of Rhodesia by South Africa and Portugal. Sanctions did, however, put considerable strain on Zambia, whose main routes of communication with the outside world lay through Rhodesia and which was dependent on Rhodesia for coal and for manufactured goods. Nevertheless, attempts were made by President Kaunda to carry out sanctions and, more important, to find alternative outlets by constructing roads and a railway to Tanzania; the latter, the Tan-Zam Railway, was completed in 1974.

With Rhodesia's declaration of independence, many African nationalists fled across the Zambezi to mount guerrilla resistance. Crippled, however, by internal rivalries, this proved ineffective until Mozambique's independence transformed the situation. Until then, Britain's attempts to achieve a negotiated settlement had failed. With the realignment of forces after the Portuguese withdrawal, however, Ian Smith came under unrelenting pressure from South Africa to release and negotiate with imprisoned black nationalist leaders. They in turn were under pressure from Zambia and Tanzania to engage in talks with Smith, in an attempt to avoid war. At the end of 1975, despite divisions within African nationalist ranks, the veteran leader Joshua Nkomo and Ian Smith undertook to try to establish a basis for talks.

In the spring of 1976, after South Africa's invasion force had to withdraw from Angola (see below), the pressures were intensified. Mozambique opened its frontiers to training and base camps for Rhodesian guerrilla fighters, who intensified their war in Rhodesia (now being called Zimbabwe). Fears of open war and Communist intervention led the Western powers to the view that it was necessary to get rid of minority rule, at least in its extreme form as represented by the Smith regime, before the last chance of a gradualist compromise vanished. The U.S. secretary of state, Henry Kissinger, had two meetings in Europe with the South African prime minister, B.J. Vorster, who realized that he might have to sacrifice the Smith regime in the interests of his own. After meeting Kissinger in Pretoria on September 19, 1976, Smith told his electorate, though in somewhat ambiguous terms, that majority rule would have to come in two years' time. A conference under the chairmanship of a British diplomat assembled in Geneva at the end of October to plan the transfer of power; whether the conflicting demands of the nationalists and of the Smith regime were capable of peaceful resolution was doubtful.

Rhodesian guerrilla pressures

ANGOLA AND MOZAMBIQUE

In the Portuguese territories, developments since World War II have in some ways been more dramatic than elsewhere in the subcontinent, with more than a decade of warfare leading to an army coup in Portugal itself and the ultimate transfer of power in the African territories. In both Angola and Mozambique, economic progress and development lagged behind the rest of the subcontinent. The Portuguese dictator António de Oliveira Salazar blocked economic development in the colonies for years in the interests of "stability" and Portuguese advantage, and it was not until 1961 that the territories were opened to overseas investment. Nevertheless the coffee boom in Angola in the 1950s and the discovery there of minerals and petroleum largely stimulated immigration and outside interest in the territory. White immigration increased Angola's settler population by 400 percent between 1940 and 1960 and doubled that in Mozambique between 1950 and 1960. Though this im-

migration was mainly to the towns, the government also instituted large agricultural settlements for whites, especially in the coffee-growing areas of Angola and in the fertile river valleys of Mozambique. Despite Portuguese claims that their policies were based on racial harmony, the increase in white settlement led to greater demands for African land and labour, while economic development brought little benefit to the African population.

The general movement toward colonial independence also affected the Portuguese territories. With the Indian attack on Goa in 1961, world attention was drawn to Portuguese colonial policies. Salazar responded by making the territories overseas provinces of Portugal and by granting limited local autonomy and increased participation in elections to the Portuguese National Assembly to whites and the handful of *assimilados*.

In the face of these new developments, African nationalist movements revived among *assimilados*, secondary school students, and trade union members in the towns. In neither of the territories, however, were the nationalists equipped for a political or military struggle. The divisions between the *assimilado* and *mestiço* elite in the towns and the rural masses, especially in Angola, were probably greater than elsewhere in southern Africa, while the meagre industrial and urban development and educational facilities before the 1950s militated against any broad national consciousness. Apart from a few areas where Protestant missionaries provided the organizational example, there were few nationalist leaders outside the towns.

In Luanda, however, from the early 1950s political associations proliferated. From among these the Movimento Popular de Libertação de Angola (MPLA), with a strong Marxist strain, emerged as the most important group by 1956, though an abortive uprising in Luanda in 1961 led to its temporary suppression by the Portuguese secret police. From the mid-1960s, the fortunes of the MPLA revived under its poet–president Agostinho Neto; moving its headquarters from Brazzaville (in the Congo) to Lusaka (in Zambia), it extended guerrilla operations in eastern Angola and resuscitated urban political activity. Although it failed to build up its base in eastern Angola, where it was supplanted by Jonas Savimbi's União Nacional pela Independência Total de Angola (UNITA) in the late 1960s and early '70s, the MPLA retained its hold on the capital and among Mbundu speakers.

The MPLA in Angola

In March 1961 the Kongo people of northern Angola—an area suffering most acutely from land alienation and forced labour practices, and with a long anti-colonial tradition—revolted. With their favourable terrain and the support of their newly independent kinsmen in Zaire, the most militant of the Kongo political organizations, the União das Populacões de Angola (UPA), later the Frente Nacional de Libertação de Angola (FNLA), threatened the Portuguese hold in the north. Hampered by ethnic, ideological, religious, and personal rivalries, and the constant proliferation of Kongo exile political organizations in Zaire and the Central African Republic, the movement failed to spread beyond the Kongo area. Despite Portuguese military reprisals, however, a war of attrition continued, with neither side able to press home its advantage for more than a dozen years.

In Mozambique the nationalist organizations, though also initially plagued by divisions, were more successful in overcoming their disunity. In 1962 three exiled organizations based in Tanzania came together to form the Frente de Libertação de Moçambique (Frelimo) and began organizing a political and military underground movement. By building on pre-existing political networks, such as the cooperative movement in northern Mozambique, and by educating selected leaders, Frelimo carefully prepared the ground before moving its guerrilla fighters into the northern provinces of Mozambique in 1964. Within three years they claimed to have an army 8,000 strong and to have established their own administrative, educational, and marketing networks in Cabo Delgado and Niassa districts.

Though Portugal's initial response to the outbreak of revolt was savage military repression, and some 70,000 to 100,000 Portuguese troops were kept in each territory, the uprisings produced a number of reforms. It was, however, always a case of too little and too late, and ultimately the sheer cost of the wars led to the revolt of Portuguese army officers and the downfall of the regime in Europe. After a short transitional period, Mozambique became independent in June 1975 under a Frelimo government headed by Samora Machel. It faced a number of urgent political and economic problems, largely connected with the poverty of its resources, the need to create a new state, and the nature of its relationship with Rhodesia and especially with South Africa. During this difficult period, it found it necessary, at least in the short term, to establish a relationship with neighbouring South Africa.

Independent Mozambique

In Angola, unlike Mozambique, the transitional period found the three main liberation movements—MPLA in the centre, FNLA in the north, and UNITA in the south—vying for control of any future government. Their rivalries were greatly exacerbated by the involvement of the great powers, Portuguese settlers, Zaire, and South Africa in their struggles. When on November 11, 1975, the governor general withdrew from Luanda, the country was in the throes of a civil war, which threatened to expand far wider as the Soviet Union flew in arms in support of MPLA and the U.S. indirectly aided the FNLA–UNITA alliance through Zaire. Meanwhile South Africa, equally anxious to avoid an MPLA government, played a hazardous interventionist role which drew its troops from the Angola–Namibia frontier almost to the outskirts of Luanda in support of UNITA. Although the South Africans were forced to withdraw by MPLA, now assisted by Cuban troops, and eventually MPLA under the leadership of Agostinho Neto established its control, sporadic fighting, especially in the UNITA-dominated region in the south, continued.

South West Africa

South West Africa (Namibia) lies on the Atlantic coast of Africa between latitudes 17° and 29° south. In the north it is bounded by the Kunene and Okavango rivers, which separate it from Angola. Here a narrow strip of land—the Caprivi Strip (Caprivi Zipfel)—extends eastward for nearly 300 miles, bringing the territory to the borders of Zambia. In the south the Orange River marks the boundary with South Africa. In the east the territory adjoins both Botswana and South Africa. Extending inland some 600 miles (965 kilometres) in the north, without the Caprivi Strip, and about 220 miles in the south, its total area is estimated at 318,000 square miles (824,000 square kilometres).

For articles on associated physical features, see KALAHARI; NAMIB DESERT; OKAVANGO RIVER; and ORANGE RIVER. For history, in addition to that given below, see SOUTHERN AFRICA, HISTORY OF.

HISTORY

As a geographically defined area, South West Africa came into being during the last two decades of the 19th century. It was the result of agreements and boundary settlements between Britain, Portugal, and Germany following Germany's decision in 1884 to acquire a colony in southwestern Africa. One important enclave, however, did not become part of the German acquisition. The largest port, Walvis Bay, and a coastal strip comprising in all an enclave of 434 square miles (1,124 square kilometres) had already been annexed by Britain in 1878 and became a part of Cape Colony in 1884. At the time of the formation of the Union of South Africa in 1910, it became South African property.

Apart from this enclave, South West Africa remained under German rule until shortly after the outbreak of World War I, when it was successfully invaded by troops from South Africa. The colony was then placed under South African military administration until January 1, 1921, when it became a Class C mandated territory, administered by South Africa on behalf of the League of Nations.

The Class C mandates explicitly authorized the administering governments to exercise full powers over the territories as integral parts of their own states, subject to the international supervisory authority of the Council of the League of Nations. Upon the formal dissolution of the League in April 1946, South Africa, after unsuccessfully seeking United Nations approval for the incorporation of the territory, refused to place it under the UN trusteeship system. Since that time the status and future of South West Africa have been in dispute between South Africa and the United Nations. The position of successive South African governments has essentially been that, with the demise of the League and its supervisory machinery, all their international obligations in respect of the mandate save one have lapsed. The acknowledged exception is the clause providing that the territory should be administered as a "sacred trust of civilization," and establishing an obligation to rule in accordance with the spirit of the mandate. The initial position of the United Nations was that the mandate was still in force, that the supervisory authority of the League was to be exercised by the United Nations, and that, both by its refusal to sign a trusteeship agreement for South West Africa and by the conduct of its administration, South Africa had violated the mandate.

Dispute between South Africa and the UN

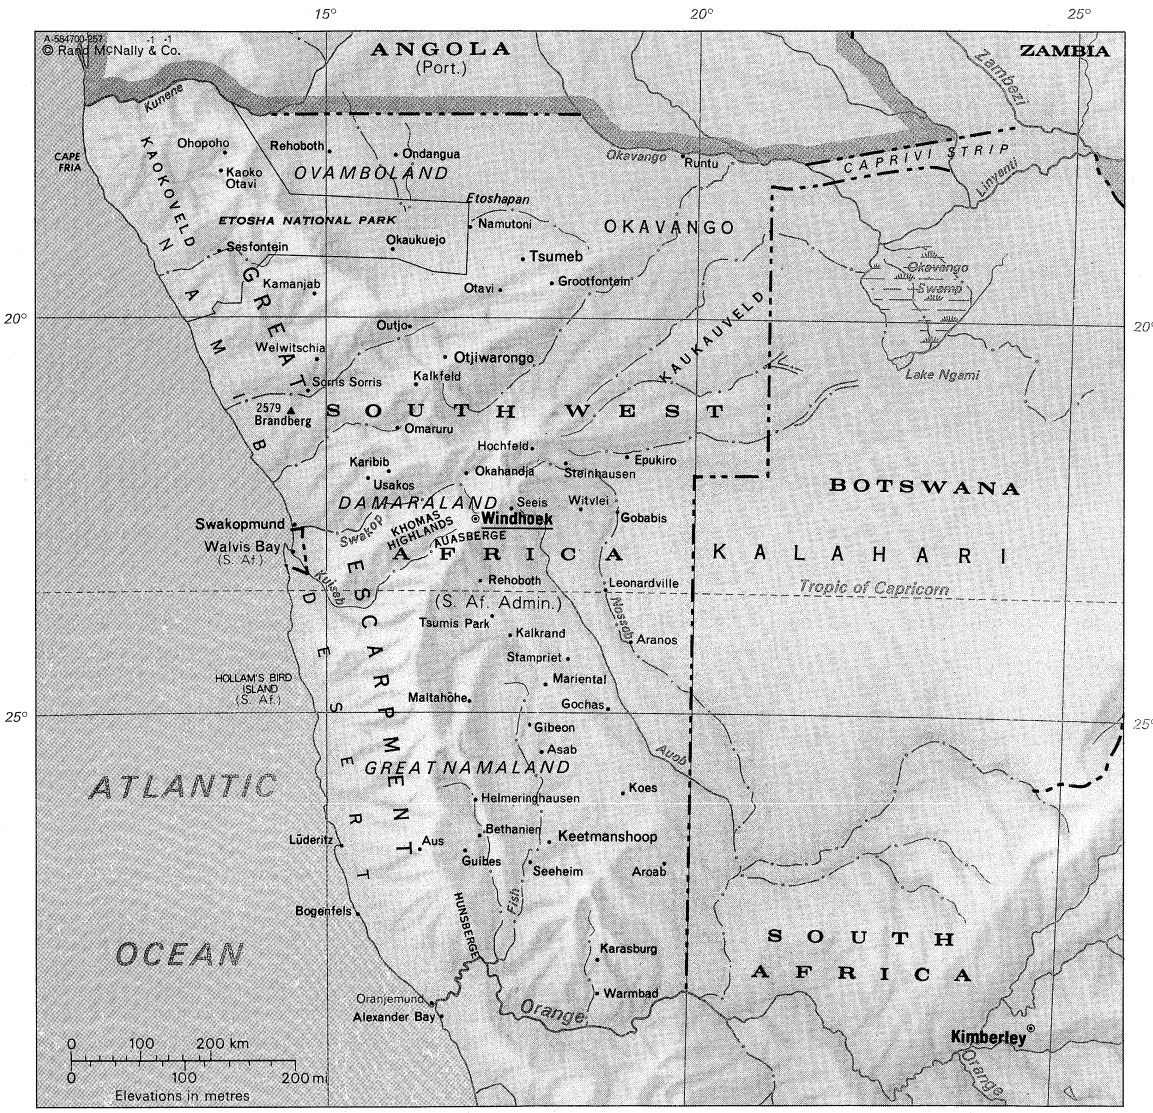
On July 18, 1966, the International Court of Justice handed down a judgment in the South West Africa Cases (1960–66) but without ruling on these issues. On October 27, 1966, the UN General Assembly adopted a resolution declaring that the mandate was terminated and that the UN assumed direct responsibility for the territory until it attained independence. In May 1967, to implement this decision, the assembly created an 11-member Council for South West Africa; on June 12, 1968, it renamed the territory Namibia.

The South African government condemned these actions as illegal and impractical. Thereafter the UN Security Council repeatedly called for South Africa's compliance with the assembly's decisions, but without result. Demands by South West African and other African nationalists for the independence of the territory led South Africa to convene the South West Africa Constitutional Convention, the first session of which was held in Windhoek in September 1975. By early 1977 it had produced a commitment that full independence should be achieved by December 31, 1978, and in January 1977 a draft constitution providing for an interim government until independence was published.

THE LANDSCAPE

Physiography. South West Africa may be described as a highland between two desert areas. Three main topographical regions may be distinguished—the Namib coastal belt, the Central Highland of the Central Plateau, and the northern and eastern parts of the plateau known as the Kalahari Belt. The Namib Desert extends from the Atlantic coast in the west until, at an altitude of 3,000–3,500 feet, it meets the foot of the plateau edge, or Great Escarpment, in the east. A desolate strip of sand desert, high shifting dunes, salt pans, and bare rock outcrops, it is bounded by the Kunene River in the north and by the Orange River in the south; for much of its length it is less than 100 miles wide. To the north it becomes more mountainous, with spectacular granite masses rising abruptly from the plain. The Brandberg, with an altitude of 8,461 feet (2,579 metres), is the highest point in the territory. The Namib constitutes about 15 percent of the total area of the territory.

East of the Great Escarpment lies the Central Plateau, which has two major surface divisions—the plateau hardveld (or rocky plain), known as the Central Highland, and the Kalahari sandveld (desert). The Central Highland extends from the southern to the northern frontier and varies in altitude from 3,200 to 6,500 feet. Its diverse surface characteristics include broken veld, rugged mountains, sand-filled valleys, gentle plains, and isolated peaks. A mountainous central part in the vicinity of Windhoek divides the Central Highland naturally into Damaraland to the north and Great Namaland to the south. Comprising such ranges as the Khomas Highland, the Auasberge (where the Moltkeblick at 8,153 feet is the second highest peak), and the Eros and Onyati to the east, it forms the territory's highest mountain tract, constituting a central watershed from which the various headwaters drain north, south, east, and west.



The Kalahari sandveld extends along the whole of the eastern frontier to the Okavango River. Its thick layers of terrestrial sands and limestone vary in depth from more than 1,000 feet to a mere covering at the hardveld edge. It varies in width from 50 miles in the south, where it covers most of the Nossob-Auob Basin, to 250 miles in the north, where it comprises part of the Etosha Basin and the middle Okavango Basin. It has a level, sandy surface, which may rise to as much as 300 feet. In the south it is crossed by long sand dunes and grass and is covered with thorn trees.

The scarcity of water

The water shortage, or the uncertainty of obtaining water, touches all aspects of life and of development. Of the larger rivers only the Orange, Kunene, and Okavango are perennial, and they constitute boundaries of the territory. All rise outside South West Africa and—as with the Okavango—the Cuando and the Zambezi in the north flow only through small sections of the territory. The potential of these rivers for irrigation, however vital, is thus limited to the southern and northern margins. The remaining rivers, whether the large westward-flowing deep-channel streams such as the Swakop and the Kuiseb or the eastward-flowing shallow watercourses (*omurambas*) such as the Epukiro and the Omuramba Omatako, usually run only intermittently. They rarely contain surface water, except after rains or floods, although they constitute storage places for groundwater. Surface water collects mainly in shallow clay or limestone pans, especially in the sandveld region—the most famous of which is the giant Etosha Pan measuring some 68 miles by 31—as well as in small lakes. There are also a number of springs.

The general scarcity of water thus makes the well and the borehole the basis for land utilization. The conservation of floodwater through the construction of dams is, however, also of importance. It is estimated that there are some 10,000 dams, with a total storage capacity of 670,000,000 cubic metres. The largest of these is the Hardap Dam on the southward flowing Fish River, just north of Mariental.

Climate. The climate is generally hot and dry. The territory is situated in the tropical high pressure belt of the Southern Hemisphere, located between latitudes 25° and 35° south, which governs the wind system of the plateau. The coast region, however, experiences the air circulation that occurs as a result of the interaction between the eastern sector of the South Atlantic High pressure system, and the upwelling of the cold Benguela Cur-

rent offshore. The mean temperature is, as a result, lower than the latitude might suggest. The temperature varies from 66° to 72° F in the Central Highland to about 60° F on the coast. During the summer months it may reach 100° F in the north and 120° F in the Namib and the south. In July, which is usually the coldest month of the year, frost may occur, although only lightly in the north. In the south, however, temperatures may drop to 20° F or lower.

Rainfall in the territory increases from south to north. In the arid Namib and the Orange River valley, the mean annual rainfall is less than four inches; in the north, and along the Caprivi Strip, the rainfall increases to between 24 and 26 inches. The mean annual rainfall for the territory as a whole is slightly above ten inches. Most rainfall occurs in the summer months (December to February). Only the extreme southwest receives as much as half an inch of rain in winter. The territory is occasionally subject not only to periods of flood, when the precipitation may be more than double the normal expectation, but also to periods of drought. The rains are the most reliable in the wet northeast, and the most variable in the dry south.

Vegetation and animal life. There are two categories of vegetation. In the west is found the desert and semi-desert type, with its desert grasses and shrub; in the east the woodland savanna type, with its grasses, bushes, and trees. In the Namib Desert region there is little vegetation except for succulents and the narra, the nut of a gourd-like plant. Further inland, and in the south, there are varieties of grasses, of succulents, such as the large aloe, of euphorbias, and of dwarf trees such as those belonging to the *Acacia* and *Boscia* genera. From south to north the veld changes to grass country, increasingly studded with thorn trees, of which most are acacia. Many others are also found, however, such as raffirboom, witgat, bush willow, and wild olive. Further north the annual grasses become more abundant, the "bush" vegetation and acacia scrub grows thicker, and the variety of thorn trees increases. This pattern is not, however, uniform. The areas to the east and west of the palm-tree belt in southern Ovamboland are, for example, sparsely wooded. In the north the growing density of the trees, the appearance of the palm-tree belt, and, to the west, the baobab tree, all are signs marking the proximity of the well-wooded northern forest region, which stretches from the Kaokoveld across Ovamboland in the west to the greater part of the Okavango and Caprivi Strip areas in the east. It is here that most of the indigenous timber trees of the territory are found—Rhodesian teak and mahogany, mopane, marula, manketti, and kiaat among others. In the west, however, as one approaches the dry steppe of the Kaokoveld, the trees and the bushes thin out, the grass spreads more abundantly, and the mopane trees and bushes diminish in size.

The northern forest region

Big game is relatively abundant and is found in many parts of the territory. The wildlife includes lion, elephant, rhinoceros, giraffe, leopard, buffalo, eland, oryx, hartebeest, kudu, and zebra, as well as many smaller species of game and of predatory animals. The most renowned of the game reserves is the Etosha National Park, which covers an area of 15,004 square miles and is one of the largest game parks in the world.

The landscape under human settlement. The ecological relationship between man and environment is a complex one. Among the elements affecting it are frequent drought, the low protein and low phosphorous content of grasses, and the high salt content and humus deficiency of the soil. The best grazing and the most groundwater are found in the plateau hardveld region, most of which—some 140,000 square miles—is now owned by European farmers. This region supports a white rural population of 19,000. The white-owned farm area amounts to 96,000,000 acres. Africans living in the Reserves occupy 54,000,000 (1960). The Reserves are now officially termed Home Areas or Homelands—of which there are 17 in the Southern Sector of the territory and four (in which there is no European settlement) in the Northern Sector. In 1960 the total estimated Home Areas population was 324,235 (of which only 38,648 persons were in the Southern Sector), with an average land area per capita of 168 acres.

The factors affecting the pattern of land settlement have primarily been the following: firstly, the uninhabitable character of the large desert regions; secondly, the original areas chosen for settlement; thirdly, changes caused by the German wars against the Herero and Nama; fourthly, the encouragement of white settlement, mostly Afrikaner, by South Africa since the mandate; fifthly, the setting aside of the Northern Sector for the Africans living there, and the allocation of additional scattered Reserves for Africans in the Southern Sector, when more are planned. The Southern Sector may be divided into urban areas, rural areas (comprising mostly surveyed white farms), and the Home Areas. According to the 1960 census, there were 59,100 Africans in the urban areas and 68,300 in the rural areas. The remaining 53,700 whites were in the urban areas, making a total population of approximately 526,000.

According to the *Report of the Commission of Enquiry into South West African Affairs* (1962–63)—the Odendaal Commission—there are 37 towns and township areas in the territory, all of which are situated in the Southern Sector. The largest is Windhoek, the administrative centre and principal town, with a population of 66,000 (1967 estimate). No other town has a population of half this size. The chief port for the territory is Walvis Bay, which has the only natural deep harbour. The other port is Lüderitz, but it is shallow and is used mainly by small coastal craft or lighters. Tsumeb is the principal copper- and lead-mining centre, some 250 miles to the north of Windhoek.

PEOPLE AND POPULATION

The total population of South West Africa was 746,000 at the 1970 census, giving the territory as a whole an average density of under 2.5 persons per square mile. Its composition was as follows: Europeans 91,000; Damara (Bergdama) 65,000; Herero 49,000; Nama 33,000; Coloureds 28,000; Rehoboth Basters 16,500; Bushmen 22,000; Tswana and others 18,500; Ovambo 342,500; Okavango 50,000; East Caprivians 25,000; Kaokovelders 6,500. The last four groups are settled in the Northern Sector, as also are 20 percent of the Bushmen. The remainder of the population is settled in the Southern Sector.

Of the white population approximately 67 percent are Afrikaans speaking, 23 percent German speaking, and 10 percent English speaking. The nonwhite population may be divided into two main types, the Southwestern Bantu and the Khoisan types. The Bushmen and the Nama belong to the Khoisan peoples and their language contains the characteristic Khoisan clicks. The Damara, a black African people of unknown origin, have adopted the Khoisan language. The Hereros, who speak their own language, belong to the Bantu language family, as do the Ovambo, the Okavango, and the Kaokovelders. The latter are closely related to the Hereros in origin, language, and culture. The East Caprivians also belong to the Bantu-speaking peoples but are related to the Lozi and Makololo groups of Barotseland (western Zambia), rather than to the Bantu of South West Africa. The Tswana and other groups include some 4,000 people from Angola. They are mostly Bantu speaking but are not related to the other ethnic groups in the territory. Apart from the established group of Tswana, who are related to the Tswana of Botswana, most of these peoples are dispersed throughout the rural and urban areas of the territory. The Basters of Rehoboth (or Rehobothers) are of mixed origin, being descended in part from unions between Afrikaner trekkers and Nama women. They moved from the Cape Colony in the 1860s and settled at Rehoboth. Their language, like that of the Coloured people, is predominantly Afrikaans, and their way of life is Western. The Coloured people, more recent immigrants, were originally a part of the Cape Coloured population of South Africa. According to official statistics all population groups have shown sustained growth. Figures for the Europeans and Col-

oureds have, however, been increased by recent immigration and are not, therefore, comparable to those for the other groups in terms of growth.

The distribution of population in urban, rural, and Home Areas (1960) for the Southern Sector was as follows: towns 47%; rural areas about 37%; Home Areas 16%. The most highly urbanized groups were the whites (73%), Coloureds (64%), and Damara (42%). Of the Bushmen, 86% are found in the white rural areas, as are 56% of the Nama, 46% of the Damara, 30% of the Herero, and 29% of the Coloureds. Of the Basters and Hereros, 79% and 44%, respectively, live in their Home Areas.

THE ECONOMY

South West Africa's economy is determined, in part, by the harsh and arid environment. Its three key industries —farming, mining, and fishing—together account for more than 60 percent of the gross domestic product. Its internal market is small; traditional subsistence farming persists over large areas, and its economic dependence upon South Africa is virtually complete. Apart from loans and subsidies, South Africa supplies a little less than half the capital investment, as well as 90 percent of the total imports, and receives over half of the exports. The estimated contribution of agricultural production to the gross domestic product (GDP) is approximately 17 percent. Cattle account for about 60 percent and sheep (mostly Karakul) for about 35 percent of the total gross output of commercial agriculture. The territory obtains its fruits and vegetables, as well as the bulk of its grains for the Southern Sector, from South Africa. The South African rand is the unit of currency. In bad seasons, the Northern Sector, too, must rely on South Africa for these commodities. Mining contributes about 45 percent of the GDP, with diamonds accounting for about 60 percent of mineral sales, and base metals for about 40 percent. Manufacturing is severely restricted by high costs, and by a low aggregate demand from a small, poor, and widely scattered population. For the foreseeable future, despite progress already made, and despite new water and power developments—such as the Ovamboland irrigation and the Kunene hydroelectric schemes—planned by the South African government, the territory is likely to continue to remain dependent upon a few primary products. Mineral products account for over half the total value of exports, fishery products for approximately a quarter, and agricultural products for most of the remainder.

TRANSPORTATION

The transportation network primarily serves the Southern Sector. Transport development in recent years has been aided by capital and loan funds from the South African government. In 1953 there was not a single mile of tarred road. By 1966, however, over 800 miles out of the 20,000-odd miles of principal roads had been tarred. The tarred roads link Windhoek to Tsumeb in the north, to Keetmanshoop in the south, and to Swakopmund and Walvis Bay in the west—all of which are in the Southern Sector. All but 200 or 300 of the 40,000 vehicles in the territory were registered in the Southern Sector. A road construction program for the Northern Sector has been announced but is still in a rudimentary phase.

The railroad system

The territory's railway system has been amalgamated with that of the South African Railways and Harbours Administration, which subsidizes it. The track and sidings are all in the Southern Sector. The railroad runs from South Africa to Windhoek, and then north to Tsumeb. This north–south central spine is linked, via east–west lines, with the two ports of Walvis Bay and Lüderitz. A line to the east links Windhoek with Gobabis.

The high cost of road building and the distances involved add to the importance of air services. Windhoek has an international airport, and there are a number of other airfields and landing strips. There are five return flights from Johannesburg to Windhoek and four from Cape Town each week—service that since 1948 has been subsidized by the South African Railways and Harbours Administration. South West Airways, a private airline, maintains internal services and is also subsidized.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of the government. If the juridical status of the territory remains in dispute, the structure of its de facto administration is quite clear. The territory has not been incorporated into the Republic of South Africa but is so closely connected with it as virtually to constitute a fifth province. According to South African law, an administrator is appointed by the South African government. He is assisted by a white Legislative Assembly

chosen by the white electorate. The Assembly has executive and legislative powers in all matters not expressly reserved to the South African government, and its ordinances have the effect of law, so long as they are not "repugnant" (in the legal sense) to acts of the South African Parliament. Subject to the approval of that Parliament, the state president of the republic may issue proclamations in regard to the reserved matters—which include defense, police, foreign affairs, native affairs, transport, information, immigration, customs and excise, and banking and audit. The South African minister of Bantu Administration and Development of Bantu Education is responsible for "Native Affairs"—*i.e.*, for the administration of the majority of the nonwhite peoples living in the territory. He is not, however, responsible for the administration of the Basters or of the Coloured population, who fall under the jurisdiction of South Africa's minister of Labour and Coloured Affairs.

The South West African whites, for their part, elect six members to the white South African Parliament and have four seats in its Senate, two chosen by the combined vote of the 6 members of Parliament and the 18 members of the Legislative Assembly and 2 nominated by the South African State President. The majority of the white voters supports the South African National Party and a minority supports the United National South West Party, which is allied to the official opposition in South Africa, the United Party. Government policy and administration is worked out, with the respective differences having been considered, within the framework of "separate development" or apartheid.

The military. The responsibility for military defense is assumed by the South African government and is undertaken by the South African Defense Force. The territory's police force has been amalgamated with that of South Africa since 1939, and some three-quarters of the costs are borne by the Republic. It musters about 400 whites, about 200 Africans, and a few Coloureds. It does not operate in the Northern Sector except in unusual circumstances.

Justice. For the administration of justice the territory is divided into 21 magisterial districts. The law applied is either customary law (where it does not conflict with principles of public policy or natural justice) or Roman-Dutch law. The High Court is a division of the Supreme Court of South Africa, and sits in Windhoek; appeals are heard by the Appellate Division of the South African Supreme Court at Bloemfontein. In the Northern Sector, except with regard to the most serious crimes, full civil and criminal jurisdiction is given to the tribal chiefs and to councils of headmen, to be exercised in accordance with customary law. The system includes provision for District Courts, for the Tribal Court, and for the Court of Appeal, which is attended by the government's Bantu Affairs Commissioner in an advisory capacity. In the Southern Sector the Bantu Affairs commissioner's courts have concurrent jurisdiction with the magistrates courts to hear disputes between members of the African communities in accordance with African law and custom. In such cases assessors may be appointed from those communities. The chiefs and headmen are responsible to the Bantu Affairs commissioner, or to the district magistrate, for the maintenance of law and order in their areas. They are paid by the Department of Bantu Administration.

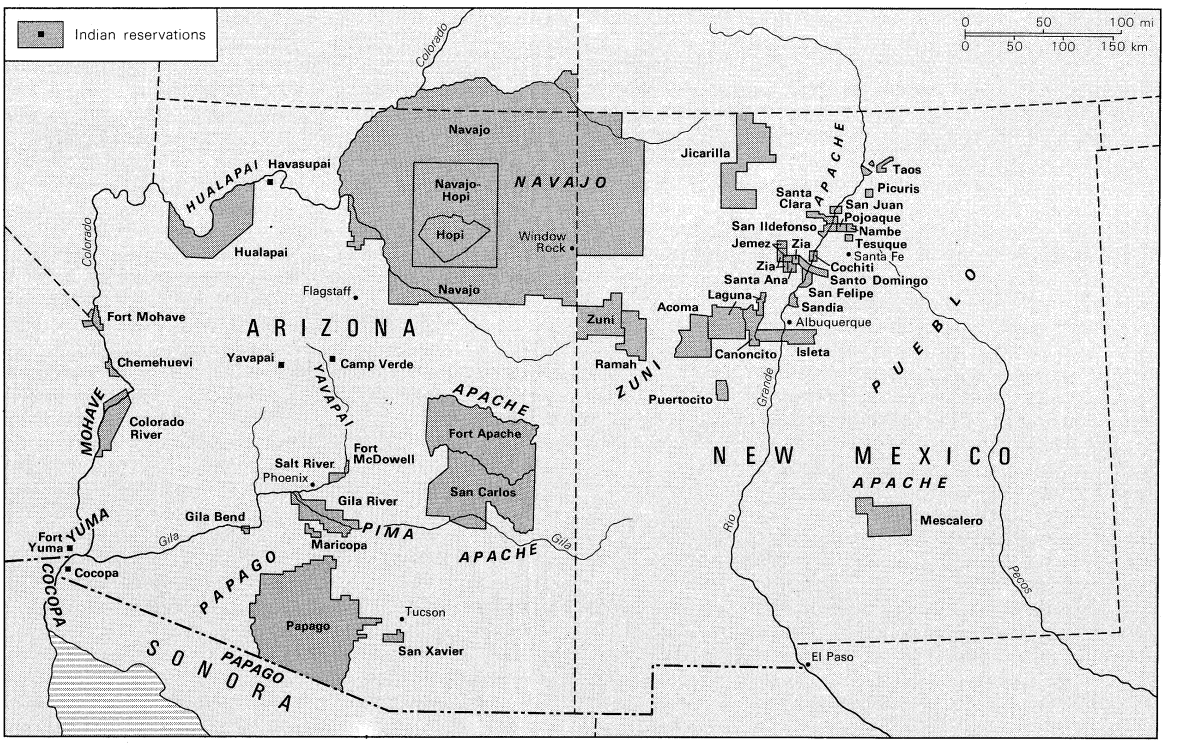
The "pass laws"

Racial policies. The system of "pass laws," so important a feature of the Republic's administration of its racial policies, is in force in the Southern Sector. With the exception of those included in certain exempted categories of office or profession, all African males over 18 years require permits or passes to move from one magisterial district to another, to visit urban areas, to leave or re-enter a Home Area, to leave the Northern Sector, or to purchase a railway ticket. They are also required to carry such other identification documents as the law may demand. Permits enabling Africans to seek work in towns are not issued to those who are not already qualified—by birth, residence, or long employment service—unless there is a temporary shortage of labour.

Africans are not required to pay general—or poll—taxes and are not subject to income, personal, or land taxes. The Coloured people and the Rehobothers, if they fall within the specified income brackets, pay the same income and personal taxes as the whites.

Education. Education is segregated and is compulsory only for white pupils, who number about 20,000. Most of the 66,000 African pupils enrolled are in the substandard or primary grades. There are about 10,000 Coloured children enrolled in school. There is no university in the territory; South West Africans who obtain university education usually do so in South Africa.

PROBLEMS AND PROSPECTS



The political activities of the Africans are not always easy to determine in a context in which the South African government and the South West African whites hold power and show themselves determined to maintain it. Radical reformers of all kinds are silenced, and apartheid laws are rigorously enforced. The South African government has, however, given the territory a measure of internal stability and has been responsible for economic and financial benefits for South West Africa in which—without threatening the living standards of whites—nonwhites have had some share, even if a disproportionate one. The disputes between the United Nations and the Republic of South Africa over the policies of apartheid, however, as well as over the status and future of the territory, have served as a focus for African frustration over the continued political, economic, and social dominance of the white minority. The mood of discontent increased awareness of old grievances. The Herero people, for example, still claim lands that Germans had taken from them after the 1903 rebellion; the Ovambos dispute some boundary settlements. Leading figures from the Herero, Damara, Nama, and Ovambo people, as well as from the Rehobothers, have, over the years, petitioned the United Nations to intervene.

Various political leaders inside the territory, as well as exiles abroad, have sought to unite the various opposition elements into an intertribal organization but as yet without success. At least four African nationalist organizations are in existence—the South West Africa People's Organisation, the South West Africa National Union, the South West Africa National Liberation Front (which the first two formed), and the South West Africa National United Front. Despite this, internal opposition remains fragmented and overawed. Such acts of violence as have occurred have been isolated and sporadic. The infiltration of armed African "freedom fighters" from the north has not as yet constituted any threat to the government, or any challenge to its security forces.

For some time to come the prospect is that the future of South West Africa is bound up with that of the Republic of South Africa.

(R.B.Ba.)

Distribution of Southwest American Indians and their reservations and lands.

Southwest American Indians

More than one-third of the rapidly growing population of American Indians live in the southwestern United States, mainly in or bordering Arizona and New Mexico. In this predominantly arid and climatically unstable region, located between the Rocky Mountains and the Mexican Sierra Madre, the Continental Divide separates the watersheds of two great river systems: the Colorado–Gila–San Juan, in the west, and the Rio Grande–Pecos, in the east.

Environment of the area

From the viewpoint of human habitation, the region's main geographic features are the two river systems, cyclical droughts, and arid lands, some low and hot, others high and cold. The hot deserts have sparse and irregularly occurring rainfall. Their long growing season supports a great variety of plant and animal communities adapted to desert conditions—creosote, sage, tarbush, and numerous cactus species, as well as such small, nocturnal, burrowing animals as the kangaroo rat. Along the river flood plains grow cottonwood, willow, mesquite, and sycamore. Basin and range landscape, from about 1,000 to 4,000 feet (300 to 1,200 metres) in elevation, predominates.

Despite its low moisture content, coarse texture, and occasional salty patches, the soil of most of the Southwest is relatively fertile.

The cold semideserts include the Colorado and other plateaus of northern Arizona. The frost-free growing season is relatively short. Much of this plateau area is covered with scrub or with piñon–juniper woodland, where rattlesnakes, rabbits, coyote, bobcat, and mule deer are found. Antelope, American elk, and mountain sheep were once plentiful. Bordering the plateau country are sheer cliffs, deep canyons, and forested mountains. Ponderosa pine, Douglas fir, blue spruce, and alpine meadows shelter weasel, deer mouse, porcupine, squirrel, and chipmunk, as well as the larger animals of the region.

In the past century most of the wild mammals have disappeared from the region. Domesticated species brought to America from Europe by the Spaniards during the 16th and 17th centuries, such as cattle, sheep, goats, horses, and burros have multiplied and destroyed delicate ecological balances, critically accelerating natural erosion processes, especially on the Colorado Plateau and in the basin and range country.

The Indian tribes that have gained a foothold in the Southwest are highly diversified culturally, linguistically, and psychologically. From a comparative viewpoint, however, they fall roughly into four groupings, each of which is characterized by living patterns designed to cope with the practical problems of communities attempting to survive and prosper in the diverse geographical zones of the region.

The peoples

The ancient Yuman tribes inhabit the floodplains on both sides of the Lower Colorado River (Yuma, Mohave) and the Middle Colorado highlands (Havasupai, Hualapai [Walapai]), as well as the lower Gila (Cocopa, Maricopa) and the Rio Verde (Yavapai). The Pima and Papago, constituting the second group, live along the middle Gila River and in the basin and range country west of the Santa Cruz River, as well as in Sonora across the Mexican border.

The Colorado Plateau and the Middle Rio Grande, with its tributaries, have long been the home of the third group, the Pueblo (village-dwelling) Indians, who, although highly diverse linguistically, share many basic cultural traits. These form three subgroups: the western Pueblos (Hopi, Hano, Zuni, Acoma, and Laguna); the central Pueblos (Jemez, Santa Ana, Zia, Cochiti, Santo Domingo, and San Felipe); and the eastern Pueblos (San Juan, Santa Clara, San Ildefonso, Nambe, Tesuque, Taos, Picuris, Isleta, and Sandia).

Finally, also on the Colorado Plateau, completely surrounding the Hopi villages and Hano and separating them from the other Pueblos, dwell the fast-growing Navajo, a branch of the Athabascan-speaking Apache who are relatively late comers to the Southwest. Their nearest linguistic relatives are found in parts of California, Canada, and Alaska. The Apache, inhabiting the mountains of the plateau rim, form a wedge between ancient Pueblo inhabitants of the region and the Pima–Papago. The major Apache tribes are the Western Apache, the Chiricahua, the Mescalero, the Jicarilla, the Lipan, and the Kiowa Apache.

TRADITIONAL CULTURAL PATTERNS

Differences among the four native groupings

General characteristics: ethos. Even though the four native groupings share some patterns of behaviour, they also evidence considerable variety in the ways in which they adapt to life and perceive life. Moreover, all of the distinctively Indian points of view differ radically from Euro-American patterns of thought. For example, River

Yuman tribes, who combined collecting edible fruits and seeds with farming rich bottomland, were relatively free of the food anxiety common to most desert dwellers. Yuma tended to focus attention on the acquisition of supernatural power by means of singing songs acquired through dreaming and illustrative of myth sequences. The individual's success in life, including leadership in warfare and curing rites, was considered to be entirely dependent on this unusual form of solitary dreaming.

On the other hand, the desert-dwelling Papago tempered their reliance on magical power achieved through singing, vision seeking, and intoxication, with concentration on such practical living problems as the defense of village communities dependent on flood farming, hunting, and collecting wild foods. Their wary approach toward any sort of personal commitment and their preference for perceiving the world in terms of flexible wholes and a continuous range of inductions, rather than the two-sided options characteristic of Euro-Americans, directly reflected a long-range, successful adjustment to an exceptionally inhospitable environment.

The Hopi Indians expressed an extreme variation of Pueblo culture developed in response to their unusually dry niche of the high, semiarid Colorado Plateau. The Hopi tribe's solution to the well-nigh insoluble living problem of village farmers without a permanent water supply was embodied in a flexibly balanced social system that stressed not only group self-defense, sobriety, and peaceful relations but also dry and arroyo flood-farming techniques developed to a high degree of skill. Their technological expertise was supplemented by formal ceremonial activities and reinforced by a conception of the world requiring, in order to keep the system in working order on behalf of the mutual welfare, active collaboration of each individual Hopi, with superhuman powers embodied in deities, animals, and plants. Consequently, a Hopi tended to develop a special type of planning mentality with a complex approach that took into consideration well-formulated whole problems with their effective parts in balance.

Another version of the Pueblo culture was found at Zuni, which differed from Hopiland in having sufficient water to meet the needs of the pueblo. From the time of its European discovery (1539–1540), Zuni was under strong pressures from Spanish explorers, soldiers, Franciscan missionaries, and governors to repudiate its indigenous customs, especially its religious beliefs and activities. The Zuni's solution to this persistent cultural harassment was figuratively to draw a magic circle around their innermost beliefs and ceremonies in order to keep them hidden from prying foreigners. Outside this sacred core they allowed certain changes to occur in behaviour and attitudes. Thus, the famous dances of kachina (masked impersonators of deities) functioned as a screen for the perpetuation of ancient rites. When the wholeness of their culture was destroyed by the intrusion of outside influences, the Zuni became preoccupied with a rote-perfect rendition of detailed ceremonial procedures, each fraught with magical efficacy. Zuni tended to perceive and emphasize tiny details rather than complex wholes, as among the Hopi, or global wholes, as among the Papago, but this tendency is giving way to a more integrated approach toward the external world.

In contrast to the Pueblos, the Navajo, who entered the southwestern region more recently than other Indian tribes and settled there by expropriating crops, herds, and rangelands, expressed an aggressive, mobile way of life. Their culture pattern, bolstered by an animistic conception of the world, fostered in the individual a matter-of-fact mental approach that singled out for attention large, discrete details with little interest in relationships between them. Such an approach relied both on adjusting to new situations by adapting segments from other cultures and on avoiding long-range planning. The Navajo were well able to make and carry out complex planning projects, however, if they believed such activities would enhance their welfare.

Social structures and economic systems. The most favourable habitation sites of the region, from the indigenous viewpoint, were probably the basins of permanent rivers, especially the floodplains of the Lower Colorado. Toward the end of the 18th century, the most desirable patches of bottomland were densely settled by village-dwelling Yuma Indians. Each village comprised a relatively stable and autonomous band composed of a number of large families living in brush shelters or rectangular, sand-covered houses. The male head of each family participated in an informal village council that settled disputes (often over land ownership) and made decisions on community problems. The wisest, ablest, and most powerful senior member of the band was its acknowledged leader. A number of bands constituted the loosely organized but strongly identified tribe, which fostered friendly relations and trade with neighbouring tribes (Mohave, Yavapai, Papago) and maintained a state of hostility or open warfare with others (Cocopa, Maricopa).

Yuma social and economic patterns

Unlike most other southwestern tribes, the Yuma did not suffer from a water problem, despite a minimum of rainfall and a hot desert climate, Although they collected edible fruits and seeds, fished, and hunted small game, the river was their lifeline. In small, irregular fields that were flooded and silted in spring when the Colorado overflowed its banks, they cultivated, with simple hand tools, several varieties of rapidly maturing maize, as well as beans, pumpkins, melons, and grasses (later, wheat and cowpeas acquired from the Spaniards). Such fields were privately owned and were inherited in the male line. Abundant harvests, supplemented by gathering and storage of food in large baskets, coupled with a simple inventory of material possessions, allowed the Yuma to concentrate on a rich world of dream and fantasy.

Pima–Papago social and economic patterns

Although the culture of the Pima–Papago showed a certain resemblance to that of the Yuma, it represented an alternate version of the ancient Southwestern desert tradition. In the Pima–Papago case this tradition was modified and enriched by a prehistoric influx of immigrants who built canals to irrigate larger areas of cropland than had been possible by flash flooding alone. After the first summer rains, fast-growing varieties of maize, as well as tepary and lima beans, pumpkins, and cotton, were planted to take advantage of the moisture before it evaporated. During this time (July and August) the Papago lived in several (perhaps 50 or 60) scattered *ranchería* villages near their fields. After the harvest, when water and food became scarce, each village community moved from its "fields" village to its "wells" village in the hills, where fresh water and game were obtainable.

Each Papago village was composed of several related extended families living in widely spaced wattle-and-daub houses and led by the oldest active man. A village council, attended by all the adult men of the community, met nightly to discuss and resolve local problems, such as land distribution and defense. Each village had its "keeper of the smoke," a religious leader (shaman) who presided over the village roundhouse and led its communal ceremonies. A number of villages formed a dialect group, and six or seven such groups constituted the tribe—a nonpolitical entity united by traditional, linguistic, and genetic bonds.

Western Pueblo social and economic patterns

Compared to the Pima–Papago and Yuman tribes, the Pueblo villages were more independent as well as more sedentary, spatially compact, and highly structured both socially and ceremonially. Although they shared a common theocratic life-style based on complex interweaving ties between kinship and religious groups and also a similar pattern of perceiving the world of nature, they differed considerably both in language and in the way the members of each village organized themselves to cope with the vicissitudes of their particular environment. Life for the western group of Pueblo farmers on the high, semiarid Colorado Plateau was particularly hazardous and nowhere more so than on the mesas of Hopiland. Here the well-being, even the survival, of whole communities long depended on what seemed to the casual observer to be minute, even insignificant variations in climate and topography—especially in the amount and seasonal rhythm of precipitation, the configuration of floodplains and ero-

sion of ephemeral stream beds, the presence and flow of freshwater springs, even the piling of sand into fixed dunes that conserved moisture.

In all of the western Pueblos the key social grouping was the maternal family line, or lineage. This was a kinship group centred in a core of blood-related women but conceived as timeless, extending backwards into the remote past and forward through generations yet unborn. Several related lineages formed a corporate clan with descent through the female line.

Among the Hopi, sets of linked clans, considered to be ceremonial "partners," formed what have been called phratries. Under this system a person was not allowed to marry into the lineage of his mother, his father, his mother's father, or into his own phratry or set of clans. The Hopi clan owned croplands and ritual paraphernalia, and its oldest active woman functioned as its "real" head, while her brother assumed the responsibilities of ceremonial leader. Although the ceremonial leader supervised the annual re-enactment of various ceremonies, the performance of a major ceremony was the responsibility not of a single clan but rather of a voluntary secret society that drew its predominantly male initiates from the entire pueblo. In each pueblo were several such societies. Their elaborate ritual activities were centred in a number of kivas (underground ceremonial chambers).

The kinship system was extended symbolically beyond the human community into the world of nature, linking clans with certain kinds of animals and plants as well as with other classes of natural and supernatural phenomena into a supersociety that included all aspects of the Pueblo world considered important to its well-being.

The basic local unit in the social organization of the western Pueblos was the extended family. This was a female-centred group occupying a common household of two or more adjoining rooms in a three-storied terraced communal structure. It was built of stone, faced the sun, and partially surrounded a central dance plaza. A household normally consisted of a core of women related through the female line, together with their husbands and unmarried sons (and unattached male relatives of the women), as well as their daughters, sons-in-law, and maternal grandchildren. In Hopiland the women of the household cared for the children, cultivated spring-irrigated gardens, produced baskets and pottery, and had charge of the cooking and storage of food as well as of certain clan fetishes. On the other hand, the men of the household raised field and dune crops of corn, squash, beans, and cotton (later apricots and peaches) and wove clothing. They were also the sheep herders. They "belonged ceremonially" to their mothers' households, however, to which they returned frequently to fulfill religious responsibilities.

The Hopi fired their painted clay pots and warmed their ceremonial chambers and homes with soft coal, which they mined by hand methods from open veins near their villages. Coal mining (the Hopi were the only American Indians to have discovered it) helped to create favourable wintertime conditions for building a surplus of skillfully fabricated craft goods—baskets, pottery, cloth woven of cotton (later of wool), and ceremonial paraphernalia. Such goods formed the basis of a trade network that supplied food and other necessities to the mesas.

Central and eastern Pueblo social and economic patterns

Except for Acoma and Laguna, the Keresan-speaking central Pueblos are located on the banks of the Rio Grande and its tributaries, with a permanent and dependable water supply that is used for household purposes and irrigation. In contrast to the pueblos in the west, the Keresans and their eastern-Pueblo neighbours inhabited adobe, rather than stone, houses and built circular, rather than rectangular, kivas. These villages also cooperated in interpueblo ceremonies, but each formed an economic unit engaged in agriculture, gathering, and hunting.

Except for the Tewa, knowledge of the social structure of the central and eastern Pueblos is incomplete and often conflicting, partly because, in reaction to the Spanish system of administration, they tended to disguise their native rites and beliefs (while still holding on to them strongly). It is known, however, that the Tewa-speaking eastern Pueblos exhibited a unique type of dual organization of social and ceremonial life—one division associated with summer and the other with winter and each, on the basis of solar observations, regulating various seasonal activities and interpersonal village rivalries. In general, they divided communal responsibilities.

Navajo and Apache social and economic patterns

The most aggressive Southwestern tribes were its most recent (about the 11th century) Indian settlers—the Athabascan-speaking Apache and Navajo. (The Navajo are generally believed to be descendants of a band of hunters and gatherers closely related to the Apache.) By the beginning of the 17th century the Navajo on the Colorado Plateau achieved a relatively settled way of life. From the neighbouring Pueblos, they had learned to grow corn, to weave, and to care for livestock. Toward the end of the 17th century, however, when the Spaniards and Pueblo Indians attempted to re-establish themselves in the area, the Navajo developed their propensity to spread into and prey upon settled communities to acquire food, sheep, horses, and cattle. The movement of Navajo groups westward into and around Hopi lands seriously threatened the precarious economic situation of that tribe.

The basic socio-economic unit of the Navajo was the extended family, which consisted of one or more related women, their husbands and unmarried sons, their daughters, sons-in-law, and grandchildren. Certain other unattached relatives might also reside with the group. Each "nuclear" family of husband, wife, and children—or each wife and her children, if a man had more than one wife—occupied a separate hogan (circular, earth-covered lodge), but the entire extended family cooperated in activities such as farming, sheepherding, and family ceremonies. Navajo extended families were grouped into about 60 clans, with descent reckoned through the female line; and marriage within one's clan was considered incestuous. Neighbouring extended families cooperated in solving land-use problems, such as range management, farmland development, and water use, under the direction of a noncoercive type of headman chosen for his leadership qualities. Such a community (which might occupy 12,000–80,000 acres [5,000–30,000 hectares]) was called an outfit. All the outfits together constituted the Navajo tribe, which was not a political unit but was unified by traditional, linguistic, and cultural bonds.

The Apache were probably the least understood of Southwestern Indians. Their culture ranged from that of the Western Apache group, who resembled Pueblos and Navajo in the practice of agriculture, in clan organization, and in the elaboration of mythology, to that of the Chiricahua Apache, who retained their mobile, war-geared organization and their hunting economy until the late 19th century. The Chiricahua consisted of three bands, which were associated respectively with the northern, central, and southern parts of their vast semiarid tribal territory ranging from the Rio Grande to southwestern Arizona and from northern Mexico to Zuni and Acoma. Within each band's hunting grounds, sites favourable for defense, hunting, and food collecting were used as temporary encampments and rallying points for smaller local groups the members of which cooperated in such undertakings as war and important ceremonies. Each local group consisted of a number of widely scattered extended families similar to the families of the Navajo, except that descent was reckoned through both parents. The Chiricahua family, however, was more mobile than that of the Navajo.

As among the Navajo, the family in all the Apache groups was centred in related women who cared for the children; gathered and processed edible seeds and other wild plants, such as yucca fruit and mescal; collected firewood and water; produced buckskin clothing, baskets, and pottery; and constructed the dome-shaped, branch-covered shelters that housed the group. The men of the family, on the other hand, hunted, fought, raided, and made weapons, such as arrows, slings, and shields. The most persuasive, strong, and successful family heads became Apache leaders whose authority depended primarily on their personal charisma and success in warfare.

Socialization and education. In all the Southwestern tribes, child training was a serious adult responsibility. The Indians were conscious of a maturation process, which was regarded in several tribes as a "path" along which the individual made his "journey through life."

Without exception in these tribes, a child was treated with warmth and permissiveness during the period of infancy (which might last from one to three or four years). He was given the breast whenever he cried. Weaning was gradual, and training in cleanliness was delayed until a child could walk or even longer. Care was taken not to agitate him unduly, and he was protected from harm (often by means of magical prophylactics) and accepted as an integral part of the family. In some tribes the infant spent much of his time laced onto a cradle board which, among the Navajo at least, was hung up in the hogan so that his head was level with the other members of a seated family circle. The effect of this treatment was apparently to augment the child's physical safety and to enhance his feeling of security. Among the Hopi the use of the cradle was viewed as an early conditioning to the restrictions of the difficult Hopi way.

Adolescence

After the infancy period, tribal socialization patterns began to diverge. From the beginning of childhood there was a strict sexual division of labour. Little boys were given chores appropriate to developing strength, such as collecting firewood or tending animals, while little girls early began to learn food processing and child care. But the child soon learned that every individual in the group was expected to pull his own weight, at every age grade, according to his sex, strength, and capacities.

When they were between five and seven years old, the boys in all the tribes began to associate almost exclusively with the men of their households, who from then on directed their education into masculine tasks and lore, while the girls remained with their mothers and aunts, taking on increasing responsibilities for the exacting tasks of the household. Among the warrior tribes the physical strength, stoicism, and skill needed for the warpath were stressed, and warrior training intensified as the youth grew to young manhood. Even among the peace-oriented Pueblos, however, boys learned agility, endurance, and speed in running. Racing was important ceremonially because it was considered to possess magical efficacy in helping plants, animals, and human beings to grow.

Among the Papago–Pima a child early learned the fundamental principles of family life: the precedence of males over females; seniority and respect for age, regardless of sex; solidarity among all family members under the leadership of the oldest active male; and respect for the role, function, and opinion of every member of the group. Within these limitations the Papago child, male or female, was allowed more freedom of action than was customary elsewhere among the Southwestern tribes.

By contrast, the Pueblo child, after infancy, was probably the most restricted, the degree of harshness in his training apparently depending on the severity of the living problem that the particular Pueblo community had to resolve. The transition from each phase of the Pueblo life cycle to the succeeding one was marked with a major ceremony. Any child who failed to move along the path of life at the culturally designated pace was pulled or pushed in formalized ways to meet the standard. For example, during the secret kachina ceremony, which marked the initiation of all Hopi children into the tribe at about seven years of age and their introduction to the Hopi gods (impersonated as masked dancers), it is reported that all the novices were ceremonially whipped to exorcise evil influences. "Bad" boys, however, were whipped more severely than the others.

Whereas the Pueblos stressed life-crisis ceremonies that offered symbolic solutions to the major problems faced by the entire community of humans, animals, and plants, the warrior groups in this region emphasized rites by which an individual might ward off sickness and acquire magical power for personal success in war and the hunt. In still another manner, the Papago youth was expected to go alone into the desert in quest of a power-giving vision to help him through life.

Belief and aesthetic systems. The life-crisis rites reflected the religious belief systems of the several tribal groups. The spectacular, communally centred Pueblo ceremonies for rain and growth reflected a conception of the universe in which every person, animal, plant, and supernatural being considered significant to the Pueblo lifestyle had its place and role. Without the active participation of every individual in the group, it was believed that the life-giving sun would not return from his "winter house" after the solstice; the rain would not fall nor could the crops grow. In fact, without human help in an annual cycle of ceremonies, the cosmic order would be in danger of breaking down.

Importance of rites and ceremonies

To the Yuma, on the other hand, the universe was pervaded by a single animating principle that was the source of all supernatural power. There was only one medium, namely dreaming, for the personal acquisition of power that was considered necessary for success in life. Sequences of traditional myths acquired through dreaming were converted into songs and acted out in ceremonies. So great was Yuman interest in this kind of dreaming and the power that it could bring to an individual religious or war leader that all other activities—farming, food collecting, and even hunting—were of secondary concern.

The religion of the Papago seems to reflect their position between the Yuman tribes and the Pueblos. Not only did they "sing for power" and go on individual vision quests, but they also held regular communal ceremonies to "bring down the clouds" and keep the world in order.

By contrast, the Apache conceived of the universe as composed of a great many different kinds of power entities, such as animals, plants, witches, superhuman beings, rocks, and mountains. Each power source could exert force in the world for good or ill, with reference to human beings, and each had to be separately propitiated. Each was personalized, talked to, sung to, scolded, or praised. Apache ceremonies were concerned mainly with the magical coercion of these power entities for the curing of disease and the acquisition of personal success in hunting and warfare.

Navajo ceremonial was apparently based on an elaboration of a similarly animistic view of the universe, with the power sources both diffused and specified. Power was localized in a great many autonomous personal beings who were dangerous and unpredictable. These were of two classes: Earth Surface People (human beings, ghosts, and witches) and Holy People (supernaturals who could aid or harm Earth Surface People by sending sickness).

With the acquisition of techniques of farming, herding, weaving, and silversmithing, and the abandonment of hunting and warfare, the Navajo turned their attention to elaborate and colourful ceremonies (called "sings") that aimed, by means of compulsive magic, to cure sickness and bring an individual into harmony with his family group, nature, and the supernatural.

CHANGES AND MODERNIZATION OF THE CULTURES

Heritage of integrating and disintegrating factors. Each local community tried to maintain a delicate balance between population and natural resources. If the population outgrew the capacities of its base within the limitations of the group's technology, a segment or faction might split off and form a colony in a favourable habitat resembling that of its parent group. Under normal conditions the daughter colony was so constituted to reproduce as far as possible the parent culture even in its most esoteric aspects. If prolonged drought (as in 1272–1299) dried up springs needed by Hopi villages for drinking water, an entire community might migrate.

Traditional adaptations to change

By contrast, human pressures from without, such as raids by marauding bands or aggressive missionary activity, caused some pueblos to consolidate or to move to less vulnerable mesa sites. In 1680, for instance, all the Pueblos united to kill or drive out the Spaniards (who, however, eventually re-established Catholic missions in all the pueblos except those of the Hopi). Papago settlements consolidated into large compact villages for defense against the Apache, but they spread out again after the raids ceased.

Religious reactions

Constant or intermittent efforts by missionaries, educators, and administrators to undermine native ceremonies and to change indigenous beliefs were resisted in various ways. The mobile Navajo–Apache tribes rejected all efforts of the Spaniards to reduce or convert them. The more accessible sedentary Pueblos employed various devices, under cover of practicing the outer forms of Catholicism, to hide their sacred religious paraphernalia and to perpetuate their essential beliefs and ceremonies. The Papago produced their own Christian sect, a blend of native and mission practices known as Sonoran Catholicism.

Unless totally destroyed, a pueblo of the western type, which was relatively decentralized, did not surrender structurally to foreign control. In fact, pueblo organization was characterized by a permanence and continuity that would not accommodate externally imposed social change. Alterations in socio-political or ceremonial patterns due to foreign intervention occurred only at superficial levels, while basic religious beliefs and practices tended to persist (even to the present day).

By contrast, pueblos of the eastern type, with more centralized control, proved more vulnerable to attack at both the socio-political and the ceremonial levels. If not utterly destroyed, most of them incorporated aspects of the foreign system into their own structures so that the result was a blend of the two.

The Navajo and the Western Apache adapted their mobile hunting cultures by borrowing from the Pueblos whole complexes of traits, such as agriculture, herding, weaving, and sand painting, and later from their industrialized neighbours, such traits as lumbering, mining, and commercial enterprises.

In virtually all the Southwestern tribes, however, the native languages are still spoken in the family groups, which continue to organize themselves according to traditional principles and values. Native ceremonies are still practiced, often secretly, in all the tribal groups, even those considered to be at least nominally Christian.

Effects of modernization

Current cultural conditions. Although the seeds of "modernization" probably were sown earlier, the process did not get under way until the end of the 19th century and the beginning of the 20th. The isolation of many of the tribes (the Havasupai at the bottom of the Grand Canyon are still the most isolated Indians in the United States), the vastness, aridity, and poor natural endowment of many of their lands, and, of course, the ferocity of the Athabascans all played a part in delaying modernization of the Southwestern tribes. Indeed, military defeat, the loss of traditional lands, and missionary efforts to change their religious beliefs and practices left a heritage of rejection and bitterness among these Indians.

Under the administration of the United States, many changes have been made on the reservations in the interests of Indian welfare. Tribal government has been developed and empowered with legal authority. Schools and hospitals have been constructed. Irrigation systems have been built and crops increased in quantity and quality. Roads and highways have been improved and communications by telephone and radio, bus and airplane inaugurated. Ranges have been protected and erosion controlled, while livestock has been upgraded by scientific breeding practices. Timber has been commercialized on a sustained yield basis, and sawmills have been constructed. Uranium and copper have been mined, oil and gas leases have been granted, and electronic as well as many other industries have been established.

Still there remains an "Indian problem." Indian incomes are generally low compared to those of the rest of the American population, especially among the Papago, Hopi, Fort Apache, and some of the highland Yuman tribes. Unemployment is high among Indians both on and off the reservations. Absenteeism and irregularity among those with jobs is high. Indifference and hostility to white ways, alcoholism, and crime are significantly present.

Biculturalism

In the opinion of some authorities, however, the Indian problem in this region is not poverty or lack of industriousness or even apathy. The primary problem rather is biculturalism. Today, the tribal reservations are the physical and spiritual homes of the several Indian groups, half of the members of which may reside outside their boundaries. All except a few who have identified with the surrounding American culture periodically return to their family households on the reservations for ceremonies and for deep religious and social nourishment. Contrary to what may appear on the surface, almost all these Indians —regardless of their degree of education and training, the work they do, and the measure of their integration with the surrounding industrialized civilization—remain Indians at heart, each according to the attitudes, values, conception of the universe, and socialization patterns of his tribe.

(L.Th.)

Sovereignty

Sovereignty may be defined as a theory of politics that deals with an ultimate overseer, or authority, in the decision-making process of the state and that explains the rules of maintaining order (internal or political sovereignty). In a more limited but related sense, sovereignty is the power to make or change the law. In the context of international law and relations, sovereignty is the freedom of a state from external control (external sovereignty).

Etymology of the term

If the etymology of the word—its derivation, through Old French *soverainеté*, from the medieval Latin *supremitas*, or *suprema potestas* ("supreme power")—indicates the meaning of the theory, it also reveals the difficulties inherent in it. Qualities such as "supremacy" or "absoluteness" that have been attached to sovereignty oversimplify and often obscure the issue. The problem is complicated by the many aspects of sovereignty that have emerged in political theory, including internal, external, legal, political, popular (in the sense of all power deriving from the people), and limited sovereignty.

THE THEORY OF SOVEREIGNTY

The locus of sovereignty. To speak of entities in which, according to various theories, sovereignty does or should reside, provides a shortcut to the ideas of particular thinkers. The locus of sovereignty may be the monarchy, the people, Parliament, parliamentary and judicial

institutions, or shifting pluralist groups. A commonly held position is that the locus of sovereignty is important because it determines the relationship of the individual to the state and government. In fact, sovereignty itself states that relationship. That is what sovereignty is about. Locating sovereignty in the people, the constitution, or the various institutions violates the logic of the concept: such plausibility as is possible is achieved by isolating concepts of "power" and "authority" from all other considerations. It is important to the concept of sovereignty that it not be given a locus. "Where ought the sovereign power of the state to reside?" asked Aristotle. "With the people? With the propertied classes? With the good? With one man, the best of all the good? With one man, the tyrant? There are objections to all these."

Limitations on the exercise of sovereignty. Perhaps the most misunderstood attribute of sovereignty concerns its so-called unlimited character. Among limiting factors, natural and positive law, constitutions and "practical" limitations are usually mentioned. Objections raised against sovereignty imply that they are limitations on sovereignty, whereas in fact they are denials of the latter. Instead of clarifying the subject, they explain the concept away. By being labelled unlimited, or omnipotent, sovereignty is transformed into a shibboleth, an old-fashioned, abandoned doctrine. Pronouncements by critics have obscured the original meaning: the definitions of the "classics" are often quoted, but neither their assumptions nor the implications of their ideas (or their relevance) are adequately considered. Thus, to dwell exclusively on an often-quoted definition by the French jurist Jean Bodin, "Majestas est summa in cives ac subditos legibusque soluta potestas" ("highest power over citizens and subjects, unrestrained by laws"), and to play down his qualifications (that the sovereign is limited by natural and divine laws and by the laws of the realm) is to miss the intent of the doctrine, which was to make the sovereign non absolute.

Bodin. According to Bodin, the definition of the state as "lawful government" is "the very end and scope of the matter propounded." This statement can be easily overlooked if one tries to separate sovereignty from the law that gave rise to it. On the other hand, the problem with juristic theories in general is the attempt to reconcile irreconcilables—government under law with the concept of the lawgiver who must be above and outside the law. Since Bodin, two types of reconciliation have been most popular: the identification of government and the governed (popular sovereignty), and the identification of government and law (constitutional sovereignty). Neither of these was Bodin's solution. He presupposed that human beings want to live under law; that the problem of government is to define authority so that desire can be fulfilled; that a lawmaker is necessary; and that the argument for the need of adherence to the law or will of the people serves no purpose when the law is being questioned. Logically, there can be only one supreme authority. If there were more than one, the emergence of more than one set of laws would be likely to ensue and conflict with the basic human desire to live under law. What emerges from this conception of sovereignty is that it implies two different views of law: law under which people want to live, and law as the command of the sovereign.

Although the necessity of obeying the second type of law logically derives from the desire to have the first, the two types are not equivalent. There is nothing in Bodin's doctrine either to compel the sovereign to observe the first or even to give him a clear idea of what it is. The problem with Bodin's theory is not that there is no legal restraint on the sovereign but that the sovereign has no way of knowing when he is fulfilling his function, whereas his subjects know—but cannot do anything about it.

Hobbes. In Hobbes's theory of sovereignty this difficulty does not arise because in his theory it is not the desire for law that leads to the acceptance of sovereignty but rather the desire for a particular type of lawmaking.

The natural law conceptions that underlie Bodin's theorizing—his concept of sovereignty was a part of natural law—play a different role in Hobbes, who detaches natural law from divine law. Hobbesian "natural laws" are laws of self-interest and their enforcement is made part of the self-interest of the sovereign. Hobbes's sovereign knows what he has to do to be a sovereign—he is in fact closer to being a function than an actual human being with a physical existence—whereas Bodin's sovereign is a supreme lawgiver who is in a curious position of having no clear notion of the type of laws he is supposed to proclaim. Little wonder that, subsequently, jurists have wanted to convert such a sovereign into the law itself. The assumption about the desire to live under law could then be reconciled with something approximating the rule of law.

Assumption of Hobbes's theory

Hobbes's theory of sovereignty, like Bodin's, emerged during a civil war, a fact that was conducive to an opinion that the theory is an argument for absolutism, for a power strong enough to impose a social order on those who, in Hobbes's own argument, lack a natural desire to live together in peace and harmony. For Hobbes, civil war is not an accident of circumstances but an ever-present threat; man is utterly egocentric and does not feel bound by any sense of obligation resulting from benefits conferred in the past; unless constrained by a superior force, he will keep no agreements nor observe any laws that are not to his advantage.

According to Hobbes, when men begin with the assumption of basic equality and egoism and reflect on the consequences of living together without imposed restraints, they recognize that life would be "nasty, brutish and short." To him, the social contract was not a legal fact of life in society but a personal—and essentially selfish—line of thought that each man follows when he raises the question of his relation to society. It is a continuous process rather than a hypothetic historical event the consequences of which have been imposed on later generations. In a world in which no one can be trusted to keep any agreement not to his advantage, each man agrees that mutual interests are so necessary to life in society that their requirements must be enforced. Because everyone is, or at least feels, equal in the state of nature and hence equally capable of violating agreements when personal advantage is at stake, an artificial inequality must be created—a sovereign superior in power to everyone else who can ensure that mutual interests are enforced.

There can only be one such supreme power, and it cannot be bound by any terms in the contract. Although the contract may seem to create a sovereign with unlimited powers, his power is not absolute but conditional. It exists only so long as expectations are fulfilled that the sovereign power can maintain law and order, so long as agreements be kept, and norms of the community be observed. No party to the contract has agreed that the will of the sovereign (as a private will) shall prevail over his private will; for a contract then would make the hypothetical state of nature an inescapable fact of life under sovereignty. If man desires power as a good in itself, however, there is a danger that granting of special powers to the sovereign may lead to their unlimited extension. Hobbes dealt with this aspect of absolutism when he said:

> I put for a general inclination of all mankind, a perpetual and restless desire of power after power, that ceaseth only in death. And the cause of this, is not always that a man hopes for a more intensive delight, than he has already attained to; or that he cannot be content with a more moderate power: but because he cannot assure the power and means to live well . . . without the acquisition of more.

This has been widely interpreted as a statement about an innate power drive. But to Hobbes power hunger is a product of circumstances—"because . . . [man] cannot assure the power and means to live well." The purpose of the contract was to ensure this and hence preclude "the general inclination of mankind" from being a component element in the sovereign power.

Rousseau. Rousseau's analysis, whereas it has fitted democratic concepts of popular sovereignty and has had political impact, has been less influential in political science than the Hobbesian view.

Unlike Hobbes, Rousseau's hypothetic natural man was not utterly self-centred: his sense of self included a capacity for sympathy. There was nothing in the state of nature impelling men to establish a power over themselves capable of limiting the injuries they inflicted on each other. Indeed, there was nothing in the state of nature that made it imperative for men to leave it, so that Rousseau either had to assume that man was still in a state of nature or that there was a capacity for corruption—either in man or in social orders—that led man away from the state of nature. Because it was impossible to believe that contemporary European societies represented the state of nature, Rousseau chose the second possibility; of the alternatives in the second possibility, he chose the view that the social order itself can corrupt. (If the capacity for corruption lies within man himself, there is no escape: man would be better off as a solitary animal, even though that would be contrary to his nature.) But not all social orders corrupt. Because of man's nature, some kind of social order is inevitable, and what needs to be done is to ensure the existence of the kind that does not corrupt.

Rousseau's concept of the general will

Rousseau's conception of man's nature comprises the idea that each man has within himself a knowledge of the good and a desire to act by it and that this good looms larger than self-interest because man is not purely egoistical. This idea is not the same as the will of all because it is only part of any man's will—each having selfish interests—and there is no reason to suppose that the mere counting of "ayes" will ensure that the will, which Rousseau calls the General Will, will prevail. The problem is to find a form of society in which this will shall be sovereign. Democracy alone will not secure it, unless selfish elements are eliminated from the individual will. Rousseau offers here no plausible solution, which provides the reason why interpretations of his theory have oscillated between two extremes epitomized in the title "Rousseau—totalitarian or liberal?" Indeed, a dictatorship is no impediment to the "reign" of the General Will because here again each man has the same impulses to act as have all of the others and purely selfish desires need not override the demands of the General Will. The weakness of this conception of sovereignty is that Rousseau has not been able to suggest a method whereby the General Will actually becomes sovereign.

Austin. To grasp the nature of Austin's argument on sovereignty it is necessary to understand why he discusses it in a book on the province of jurisprudence. Although the concept of sovereignty supplies a ready definition of law as the command of the sovereign, it is not a logical necessity to the jurist. Austin introduces the concept in order to distinguish positive law from other types of law. As he puts it, "In order to an explanation of the marks which distinguish positive laws, I shall analyze the expression *sovereignty*. . . ." Inevitably, this purpose colours his discussion. One should remember that Austin is not discussing a theory of government but a theory of law. Because of his interest in using sovereignty to define the fact of law, he has no need to begin with the concept of "contract" that played a central role in earlier discussions of sovereignty. He begins, instead, by distinguishing sovereignty from other powers. He argues: "The *generality* of the given society must be in the *habit* of obedience to a *determinate* and *common* superior: whilst that determinate person, or determinate body of persons must *not* be habitually obedient to a determinate person or body. It is the union of that positive, with this negative mark, which renders that certain superior sovereign or supreme. . . ." The terms he italicized are essential to his theory; significantly, not one of them is mentioned or implied by his predecessors. Austin alone feels that the number of people in a given community who acknowledge the sovereign power is significant. The "habit" of obedience is also a term peculiar to him; it has no function in the Hobbesian concept. It is important in Austin because it describes the essential nature of obedience, which —unlike Hobbesian obedience—is nonrational and (usually) non-motivated. An interesting feature of Austin's definition is that, whereas the attributes of the sovereign are correlatives of those of the subject, the sovereign is described as "not habitually obedient."

Austin's distinction between sovereignty and other powers

The problem implied by Austin's theory is: Are we to define sovereignty in terms of the state or international law? Is sovereignty being granted by the recognition of other states: is it always de jure? Or is it established irrespective of whether other states exist? With regard to the state in its international relations, the difference between Hobbes and Austin is that the former's sovereign is not dependent on whether he is recognized by other states. For Hobbes, de facto and de jure sovereignty are the same thing. Austin's sovereignty, however, has to be de jure, or it will cease to exist.

SOVEREIGNTY AND INTERNATIONAL LAW

Distinction between internal and external sovereignty. In international law sovereignty means autonomy or independence of a state. Either type of sovereignty (internal or external) implies that the state's claim to it is exclusive and that there is no agency higher than the state. But while a sovereign state is master of its acts, the mastery does not extend to all possible acts. The nature of external sovereignty is essentially negative in the sense that—except when it is "abrogated" by a treaty —it entails absence of subordination to a foreign authority. Internal sovereignty is more positive: it establishes the ultimate authority over individuals or groups within the state territory. It is possible for a state to have full external sovereignty but to lack internal sovereignty. Extraterritoriality in an otherwise sovereign state is an instance of this condition. The possession of internal (but not external) sovereignty is more common, as in protectorates and suzerainties. Apart from being an assertion of the supremacy of law internationally, the argument that all states are now bound by the law of nations has some basis in the logic of sovereignty. Internal sovereignty refers to a locus of power and authority such that only one power can assert supremacy and maintain its claim. In a world divided into sets of such powers, external sovereignty can refer only to such residual areas and mutual accommodations as result from the sovereign powers' consciousness of their mutual interdependence and inability to extend their claims to internal sovereignty over larger geographic areas.

Positive nature of internal sovereignty

Sovereign equality of states. Conventional legal theory considers the idea of sovereignty obsolete, "contrary to facts," and lacking in positive content (bereft of the power to give unconditional orders), and stresses the de jure equality of states and their de facto inequality. For the contention to be valid would mean that Hobbes did not succeed in producing an argument for sovereignty. Significantly, Hobbes began with just such assumptions about equality and inequality with regard to individuals. It would seem strange that, with respect to the relations between states, de jure and de facto equality or inequality are supposed to establish that sovereignty is contrary to fact. Clearly, there is a difference between the assumptions made by Hobbes and those of conventional modern jurists. Hobbes's principal argument derives from equality, but by leaving room for conquest as a possible method of achieving sovereignty—in addition to contract—he makes allowances for inequality. To him, equality without normative implications is the primitive condition—neither sought nor asserted, but simply existing as a fact. In Hobbes, equality is the condition that makes the normlessness of the state of nature intolerable, and it is the latter which is given up for the sake of normative order. Only when this has "happened" is the "second method" of establishing sovereignty—conquest (which sanctions inequality)—possible. The situation is reversed in international law. The "equality" of states is the primary condition, but it is pure fiction. States are, in fact, unequal. The equality of states has some other source: the law. The jurist sees that states in fact are unequal, yet has to begin with the fiction of equality in order to apply a law universally. In practice, advanced societies usually exempt certain classes—minors, idiots, madmen—from the full rigour of the law, but the basic meaning of justice demands that it be blind to inequalities—that "equality" be a juris-

tic fiction. Within the state, this fiction operating under sovereignty allows the law to be applied in all cases. In the absence of sovereign power, it makes the law itself a fiction between states. International law is not the result of an accommodation between equals.

As regards equality, it would seem that this concept, which law considers necessary with respect to internal sovereignty, has been uncritically applied to questions of law relating to external sovereignty. One authority has proposed the substitution of "independence" for equality. But it is also not true that states are in fact independent in any meaningful sense. In order to replace equality by independence, it would be necessary to supply an analysis of the new term that would show it capable of making international law applicable to all states.

Sovereignty and recognition. Sovereignty is related to the recognition or nonrecognition of sovereignty. According to one view, international law makes recognition of the state a precondition of its sovereignty. According to another, sovereignty and recognition are not related. In the latter view, claims that the assertion that states have no legal existence before recognition are not supported by practice; sovereignty is neither created by recognition nor destroyed by nonrecognition.

The problem arises when a nonsovereign state happens to assert its independence and demands recognition as a state. The matter is by no means academic. Thus, for many, it is at present an open question whether Rhodesia is an independent state with a legitimate government, or is not a state and therefore has a government that is illegitimate—an issue of special importance to anyone trading with this country, or trying to emigrate from it.

Limitation of sovereignty. War is so often viewed as an expression of power, and power as the essence of sovereignty, that a limitation on the right to war can be regarded as an instance of a voluntary limitation on sovereignty. But it comes closer to being "diplomacy carried on by other means" than it does to being an expression of power, and sovereignty is not to be equated with power.

Sovereignty and the League of Nations

It is often maintained that the Covenant of the League of Nations changed the foundations of law with reference to the place of war in international law. Before the establishment of the League of Nations, international law had no alternative but to accept war. The Covenant created express obligations to use peaceful means for settling disputes; it also established an organization whose task was to see that those obligations were observed by the states and to apply sanctions if necessary. It would appear that international law thus created a power capable of limiting the force of sovereign states in relation to war. This in fact, was not the case and little was changed by transferring the League's authority to the newer United Nations.

At present, "agreeing to abide by decisions of international bodies" is a special case of treaty limitation. No nation has as a rule agreed to submit to the jurisdiction of an international body, except in a restricted sense in particular cases. Thus, when nations agree to the jurisdiction of the International Court of Justice, they in effect make an agreement with each other and abide by the decisions of the Court for the same reason as they abide by treaties. Such reasons can be very complicated and quite unrelated to the problem of sovereignty.

Effect of treaties on sovereignty

It is plausible to examine the extent to which states limit their freedom of action and thereby limit their sovereignty. Nations normally plan to keep their treaty obligations despite the absence of an enforcing agency. The rationale behind treaties is the advantage obtained if both parties keep the agreement. Sovereignty, then, cannot be said to be limited or transferred—there is no one to transfer it to—unless it can be demonstrated that some element of coercion exists. There will always be some pressure—if only that of self-interest—behind all such arrangements, but on what premises one could erect the needed criteria of coercion is not clear. The only way in which a sovereign body can limit sovereignty is by an explicit decision. It cannot do so accidentally, and it would seem misleading to regard law—domestic or international—as being a limitation on sovereignty. Whether it derives from custom, natural law or treaties, law is the expression and evidence of sovereignty, rather than an infringement or limitation of sovereignty. The fact that, domestically, states do not expropriate property owners without compensation or that there is a system of independent judiciary is not regarded as a limitation on sovereignty. Whether voluntary limitations on action are undertaken on the national level or internationally, there is no reason for treating them as limitations on sovereignty.

Sovereignty and intervention. International organizations have limited powers as far as the right of intervention is concerned. Thus the competence of the UN is to "consider," "discuss" and "recommend" with reference to breaches of human rights. Any interference in internal sovereignty that may result is justified on the ground that the action is not enforceable and no intervention within the meaning of the UN Charter (Article 2:7) is involved. On a regional level, the Council of Europe in 1953 set up the European Convention for the Protection of Human Rights and Fundamental Freedoms. A list of basic rights and freedoms subject to protection was drafted and an institutional machinery was created in the form of a Commission and a Court of Human Rights. The most serious limitations on the Court's action stem from the fact that there is no obligation binding member-states to accept the Court's jurisdiction (as is the case with the International Court of Justice); nor, as a rule, can action be initiated by any party other than a state. Although it has been held that one case (*Lawless* v. *Ireland* [1961]) upheld the right of individual petition against a sovereign state before an international court, the known principles of international relations do not seem to confirm this. There is no legislative machinery to enact international law which would be binding on the states or their peoples. States often refrain from ratifying the decisions signed by their representatives at conventions and the reluctance of public opinion to give support to international legislation jeopardizes the process. One of the implications is that the rise of democracy, which has given public opinion more weight in decision making, has interfered with the development of international law.

The UN Charter contains numerous references to human rights, notably Article 1 (which describes the promotion of human rights and fundamental freedoms as one of the purposes of the United Nations), Article 55, and Article 56 (which refers to "joint and separate action" that individual members pledge to undertake in this respect in cooperation with the UN). The Charter does not define the rights and in its "domestic jurisdiction" clause, Article 2:7 states as a general principle that there is nothing in it to "authorize the United Nations to intervene in matters which are essentially within the domestic jurisdiction of any state." This provision raises the question of the extent to which the UN can investigate alleged violations of human rights. Although the Universal Declaration of Human Rights adopted in 1948 by the General Assembly of the UN (which defined some rights, such as rights to life and liberty and to a fair trial) remedies the lack of a definition of rights and freedoms, it is a declaration, not a treaty or legal instrument. If it were a treaty, it would have a major effect on international law. As a declaration, it is but a guide to rights and freedoms.

But it is usually held that even if the Charter is binding in the same way as any treaty, it does not bind the signatory states to recognize human rights as a legal obligation. Apparently, even if a country feels that human rights are being violated in another state, international law does not allow it to proceed against the violator either alone or jointly with other states. Indeed, an act designed to stop a violation of human rights would be an act of aggression according to international law. Human rights exist and are recognized, but their defense is hardly possible.

According to Article 24 of the UN Charter, the responsibility for the maintenance of international peace and security is conferred by its members on the Security Council, whose decisions—provided they accord with the Charter—the members agree to carry out. It is clear,

Effect of decisions of the UN Security Council on state sovereignty

however, that the Security Council can make decisions which member states, and even some members of the Security Council, may not accept. There have been several instances of this situation, such as the Korean War and the Suez Crisis. Great Powers have often refused to be bound by decisions with the formulation of which they did not concur. Technically, the sovereignty of Security Council members has not been limited but extended over states outside the Security Council. Members have a legal right to infringe on the sovereignty of other states for those purposes which they themselves define. Normally, there is no threat to their own sovereignty, or even interests, since they have veto power.

SOVEREIGNTY IN THE 20TH CENTURY

After World War I, some jurists held the view that, with the establishment of the League of Nations, the theory of sovereignty had become academic and impracticable and the sovereign state obsolete. The argument seemed to be that equality before the law—reflected in the expression "equal members"—eliminated the distinction between sovereign and nonsovereign states. The observation that a state bound by treaties was not sovereign was supposed to reinforce this position. The reasoning is unacceptable to many authorities, who argue that there cannot be such a thing as equality before the law in fact, unless there is a sovereign power to ensure it; that the League was not a suprasovereign power any more than is its successor, the United Nations. In this view, all that can be said is that, with regard to their relations with the League, all members were equal—which is not the same as saying that as regards their relations with each other all were equal. These relations were not markedly changed by the existence of the League. The League's task was to deal with relations between states as if there were no difference between a sovereign and a nonsovereign state. When this conflicted with the interests of the states concerned, the League collapsed. It, not sovereignty, proved obsolete.

The above argument is a special case of a commonly asserted view that sovereignty is limited in fact by the presence of treaties between states and hence that sovereignty—in the form required by theory—does not exist. The consequence of this view is that if a treaty diminishes sovereignty, it is conceivable that the conduct of foreign relations will eventually lead to the elimination of sovereignty. Yet the theory of sovereignty has not been affected by such views, although they may well have lain behind some forms of isolationism in the 1930s.

The question remains whether sovereignty can indeed become obsolete. The expression seems to imply that although a function is now performed by sovereignty, that function can be performed by a different agency, or that conditions can change and there will no longer be any need for fulfillment of the function. There is nothing inevitable, so far as one knows, in what human beings create, whether it is sovereignty or anything else. Indeed, the concept of sovereignty presupposes choice, and behind its classical Hobbesian form is the assumption that there have been times when there was no sovereignty and that there will be such times in the future; the possibility of a system without sovereignty is inherent in the argument for sovereignty. If one changed one of the basic assumptions or the system of values itself, sovereignty would become superfluous. Few people nowadays believe that man is as egoistic as Hobbes maintained: numerous Utopian communities have been set up on the premise that man is unselfish (their fate lends weight to Hobbes's view, although it does not necessarily prove he was right). One need only begin with a different, more sanguine assumption about man's nature in order to make sovereignty obsolete. But most authorities believe that few persons are willing to be so sanguine: presumably not because they are cynics by nature, but because they argue that no reasonable person would found a society or advocate change on the basis of mere hope. Sovereignty can probably be made "obsolete" in many ways, and it is the task of political theory to analyze them and to ask whether —in the light of their probable ultimate consequences— it is advisable to choose any of them.

Recent criticisms of the concept

Since World War II the concept of sovereignty has been under concerted attack from philosophers, social scientists, jurists, and students of international relations. Attempts have been made to discredit sovereignty on three grounds: semantic, empirical, and moral. Critics of the concept have dwelt on the diffuseness of sovereignty, the inability to indicate its locus with any precision, and the "anti-democratic" connotations of the concept. They have shown a tendency to take some of the statements of "classical" thinkers at face value, often missing the true intent of the doctrine as revealed not merely by the main body of the latter, but also by its attendant qualifications. They may have shown a utopian bias by projecting their dreams of human nature and international society into the world of contemporary power politics, the realities of which they often choose to ignore. Others argue that what has escaped the notice of such theorists is the logical function of the concept, and the ability of sovereignty as a theory to integrate a number of distinct concepts, such as power, authority, legitimacy, obligation, community, thus providing the foundation for a type of discourse without which political theorizing must come to an end.

BIBLIOGRAPHY. Classic statements of the theory of sovereignty may be found in JEAN BODIN, *Six livres de la Republique* (1576; Eng. trans., *Six Bookes of a Commonweale*); THOMAS HOBBES, *Leviathan* (1651); JEAN-JACQUES ROUSSEAU, *The Social Contract* (1762); JOHN AUSTIN, *The Province of Jurisprudence Determined* (1832); and ALBERT V. DICEY, *Introduction to the Study of the Law of the Constitution* (1885).

The following are general accounts: C.E. MERRIAM, *History of the Theory of Sovereignty Since Rousseau* (1900); S.C. CHEN, *Recent Theories of Sovereignty* (1929); and HYMAN EZRA COHEN, *Recent Theories of Sovereignty* (1937). The pluralist position emerges from the three works of HAROLD LASKI, *Studies in the Problem of Sovereignty* (1917), *Authority in the Modern State* (1919), and *The Foundations of Sovereignty and Other Essays* (1921); and FRANCIS G. WILSON, "A Relativistic View of Sovereignty," *Political Science Quarterly*, 49:386–410 (1934). For the juristic approach, see JOHANNES MATTERN, *Concepts of State, Sovereignty and International Law* (1928); and J.L. BRIERLY, *The Law of Nations*, 6th ed. rev. by C.H.M. WALDOCK (1963), a standard introduction to international law. Recent articles giving juristic views on sovereignty are K.W.B. MIDDLETON, "Sovereignty in Theory and Practice," *Juridical Review*, 64:135–162 (1952); H.W.R. WADE, "The Basis of Legal Sovereignty," *Cambridge Law Journal*, pp. 172–197 (1955); GEORG SCHWARZENBERGER, "The Forms of Sovereignty," *Current Legal Problems*, 10:246–295 (1957); and HANS KELSEN, "Sovereignty and International Law," *Georgetown Law Journal*, 48:627–639 (1960). A comprehensive discussion of the relationship between law and sovereignty, with reference to the legal thought of various traditions, is contained in A. LARSON *et al.*, *Sovereignty Within the Law* (1965). Perceptive, balanced modern statements on sovereignty are J. DICKINSON, "A Working Theory of Sovereignty," *Political Science Quarterly*, 2 pt., 42:524–548, 43:32–63 (1927–28); and W.J. REES, "The Theory of Sovereignty Restated," *Mind*, 59:495–521 (1950). YVES R. SIMON, under "Sovereignty in Democracy," in his *Philosophy of Democratic Government* (1961); and BERTRAND DE JOUVENEL, *De la souveraineté* (1955; Eng. trans., 1957), discuss sovereignty within the context of original political theories. A powerful defense of sovereignty is provided by F.H. HINSLEY in *Sovereignty* (1966), which offers a speculative reconstruction of relevant facts relating to different societies throughout history. See also Hinsley's subsequent article, "The Concept of Sovereignty and the Relations Between States," *Journal of International Affairs*, 21:242–252 (1967); and W.J. STANKIEWICZ, "In Defense of Sovereignty: A Critique and an Interpretation," and "The Validity of Sovereignty," in *In Defense of Sovereignty* (1969), a critical symposium that contains many of the articles mentioned in this bibliography. MAURICE KEENS-SOPER in "Sovereignty Revived?" *Political Studies*, 18:147–150 (1970), assesses the case for sovereignty advanced by the symposium. Among statements by the most outspoken opponents of the concept are JACQUES MARITAIN, "The Concept of Sovereignty," in his *Man and the State* (1951); and STANLEY I. BENN, "The Uses of 'Sovereignty,'" *Political Studies*, 3:109–122 (1955).

(W.J.St.)

Soviet and Socialist Legal Systems

Soviet and Socialist Law is a system of public order devised by Communist politicians after the Russian Revolu-

tion of 1917 and emulated subsequently in Asian and eastern European states where Communist parties became dominant. Although it was classified by some legal scholars as a subdivision of the Romanist, or civil-law, system, its adherents claim independent status for it. This claim was recognized in practice after World War II by election to the International Court of Justice of judges representative of the Soviet legal system in accordance with requirements of the International Court's statute (article 9) that it include judges who are representative of the main forms of civilization and of the principal legal systems.

HISTORY

Origin. Since Karl Marx and Friedrich Engels prescribed no pattern of law for a state organized to achieve the aims set by their *Communist Manifesto* of 1848, it was left for Lenin and his colleagues in the Russian Communist Party after the Bolshevik Revolution of 1917 to improvise a legal system. General guidelines provided by Marx and Engels were that law be regarded as an instrument of the state, not as a limitation upon those who make policy, and that it enunciate rules of public order facilitating the transition to Socialism and ultimately to Communism. Its major tasks were to be two: (1) elimination of the political power of the bourgeoisie (the property-owning middle class) by depriving them of their ownership of productive resources and (2) education of citizens in the disciplined pattern of life claimed by Communists to be requisite to the achievement of the social order they desired. Completion of these two tasks would, in the Communist view, assure both abundant production suitable to realize the Communist aim of distribution according to need and also the self-discipline of citizens necessary to make coercion unnecessary in preserving order. The police, the army, and courts would become unnecessary, and law would, in Marxist terminology, "wither away." Citizens would perform social obligations, expressed in morals and unsanctioned administrative regulations, out of conviction of their desirability rather than out of fear of punishment for their violation.

The new principles were embodied in the first constitution of the Russian Soviet Federated Socialist Republic (R.S.F.S.R.), promulgated July 10, 1918 (article 9), as follows:

> The basic task placed during the present transitional moment on the constitution of the R.S.F.S.R. is the establishment of the dictatorship of the city and village proletariat and of the poorest peasantry in the form of a powerful all-Russian Soviet authority with the objective of complete suppression of the *bourgeoisie*, the exploitation of man by man and the installation of socialism, under which there will be neither division into classes nor a State authority.

Early implementation. Lacking any precise pattern for a legal system designed to achieve the purposes stated in the first constitution, the new government issued only a few decrees designed to establish a framework for a new society and a primitive institutional structure to enforce it. The decrees deprived private individuals of the ownership of land, banks, insurance companies, merchant fleets, and large-scale industry in implementation of the policy of expropriation of the bourgeoisie, created restrictions on the employers of labour, and secularized marriage and divorce. The enforcement instruments, called "people's courts," operated without benefit of professional prosecutor or bar.

"Revolutionary conscience" as a guide

To permit regulation of the multitudinous social relationships for which no new law was prescribed, judges were directed at the start to apply Russian imperial laws, but only to the extent that they had not been revoked by the Revolution and were not contrary to the revolutionary conscience of the judges. Perhaps because Lenin and his colleagues were too busy to do otherwise, or perhaps because they preferred to let develop in practice a new legal order, no all-inclusive systematized body of law was prescribed until 1922. Local judges were guided during the first years, apart from the basic decrees indicated, only by suggestions issuing from the people's commissar of justice in the form of instructions, procedural manuals, and journal articles praising some court decisions as the proper application of revolutionary conscience and denouncing others as improper.

Political enemies of the Communists were not brought before the courts but were condemned by political bodies created at the same time as the people's courts and called revolutionary tribunals, or they were arrested and imprisoned without public hearings by the political police (Cheka). Lenin and his jurists professed only temporary resort to treatment of opponents outside the regular court system. Nevertheless, the conduct of revolutionary tribunals and of the Cheka greatly influenced the course of Soviet law long after their formal abolition in 1922, for they stimulated lack of respect for formality and strict adherence to law even among those charged with enforcing and administering the law.

New instrumentalities emerged after 1924 within the People's Commissariat of Internal Affairs (NKVD), now the Ministry of Internal Affairs (MVD), under the personal dictatorship of Lenin's successor, Joseph Stalin, to rid him of opponents. Following Stalin's death in March 1953 the Communist Party's first secretary, N.S. Khrushchev, disclosed that many innocent persons had been convicted and sentenced to long prison terms and even to death by special boards of the MVD. The Soviet method of preserving order was revealed officially to have been dual, with courts on one side dealing publicly with nonpolitical offenses and social disputes, and administrative boards and the security police punishing secretly on the other side those whom Stalin chose to call his enemies.

Codification. Reintroduction of private enterprise in limited areas and subject to strict controls followed the declaration, in 1921, of the New Economic Policy aimed to speed reconstruction to overcome the devastating effects of world and civil war. This reintroduction necessitated, in the Communist view, stabilization of law if capitalists were to be induced to invest. Lenin's commissar of justice, D.I. Kurskii, considered these measures retrogressive but necessary, while N.V. Krylenko, later to become federal commissar of justice, called them the natural evolution of five years of Soviet law. Whatever their origin, stabilization efforts took form in the first systematic codification, and a complex institutional framework of courts was constructed.

A judiciary act of October 31, 1922, established within the Russian republic a three-stepped system of general courts with civil and criminal jurisdiction.

1. The name "people's court" was retained for the lowest level, but the institution was less primitive than that of 1917. Its bench comprised a full-time judge appointed annually and two lay judges selected for service of a few days in rotation from a panel of intelligent and politically trustworthy citizens. Lay judges shared responsibility with the professional judge in deciding issues of law and fact.

2. Appeals from this court lay to a new provincial court evolved from the Congress of People's Judges, which, under the prior rules, had gathered periodically in each province to survey the work of the local courts. The provincial courts also received jurisdiction to try offenders against the security of the regime and other serious civil and criminal cases. As an appellate court the provincial court presented a bench of three professional judges. As a trial court it was composed like the people's court, except that the lay judges were selected from a panel of more experienced and politically sound citizens.

3. To coordinate policy in all provinces there was created the Supreme Court of the republic, evolving from a control department established earlier in the Commissariat of Justice. This court was authorized not only to hear appeals from cases tried in provincial courts but also to discipline lower courts, issue rulings interpreting the codes, and even to try cases of an unusually important character.

To provide specialized treatment of crimes relating to military matters and to the disruption of transport, then deemed critical to the success of the regime, special courts that had evolved earlier were continued by the judiciary act and subordinated to the Supreme Court. An office of public prosecutor and a college of defenders to perform

the functions of a bar were established to aid the judges, following experimentation with institutions designed to conduct prosecution and defense on a nonprofessional basis.

Substantive law and procedure to be applied by the new courts were established by codes enacted throughout 1922 and early in 1923, these being criminal, civil, family, land, and labour codes and also codes of criminal and civil procedure. Drafters of these codes followed patterns essentially similar to those of the Romanist states of the European continent, *i.e.*, all of the European states except the Scandinavian, to varying extents.

Patterns of legal institutions and substantive and procedural law enacted by the R.S.F.S.R. were copied with little variation in the other Soviet-type republics that had emerged in peripheral regions of what had been the Russian Empire. Federation of the Soviet republics into the Union of Soviet Socialist Republics on December 30, 1922, caused no change in the judicial system except the establishment, as a coordinator of all practice, of a Supreme Court of the U.S.S.R. The first federal constitution, adopted provisionally on July 6, 1923, and permanently on January 31, 1924, extended authority to the federal government to enact general principles of law to be followed by the republics in maintaining their codes. While this development might have caused a change in the Soviet legal system, it did not; the first federal judiciary act of October 29, 1924, confirmed the system of courts then existing in each of the republics, and no change was made in substantive or procedural law. The sole innovation was that the military and transport courts were placed under sole control of the Supreme Court; thus was created a self-contained system of federal courts, with lower branches functioning throughout the republics but beyond the reach of republic officials. A sharp line was thus drawn between courts dealing with matters vital to the security of the regime and those concerned with social disputes.

The pattern established for Soviet courts and codes of law in 1922 and 1923 continued until Stalin's death, although the second federal constitution of December 5, 1936, transferred authority to the federal level to enact codes of law to replace those of the republics. Although a second federal judiciary act was issued on August 16, 1938, new codes were not enacted. On February 11, 1957, the constitution was amended to restore the original relationship between republics and federation, namely that they enact their own codes but conform to general principles established federally. The first of the new general principles were enacted for criminal law and procedure on December 25, 1958; for civil law and procedure on December 8, 1961. Others were enacted at intervals thereafter, and republic codes were revised subsequently. The major innovation of the 1958 enactments was the requirement that punishment be ordered only by a court in accordance with the rules of the procedural code. This provision was heralded by Soviet jurists as preventing return to extralegal procedures such as those exercised by the MVD during Stalin's dictatorship.

APPLICATIONS OF SOVIET LAW IN PEOPLE'S DEMOCRACIES

Application of the pattern of law evolved within the U.S.S.R. to other areas began when Outer Mongolia declared establishment of its "people's government" on July 11, 1921. Mongolia was then a nomadic society without industry. Nationalization of productive resources had little effect on nomadic life, an exception to nationalization being made in the area of primary concern, namely the private ownership of cattle herds. Nevertheless, the base was laid for following Soviet legal patterns in the first constitution of the Mongolian People's Republic promulgated on November 26, 1924. Thereafter, state-owned industry was developed after Soviet patterns, and following adoption in the U.S.S.R. of the second federal constitution, a second Mongolian constitution was promulgated on June 30, 1940. Its provisions for courts and prosecutors were like those of the U.S.S.R., and the subsequently adopted law on land use of February 6, 1942, provided the same formula of state ownership of land allocated for use gratis and in perpetuity to the nomadic herdsmen for their privately owned cattle. A labour law of February 14, 1941, followed the Soviet pattern, as did a social insurance law of June 22, 1942.

The extension of Soviet law

The major opportunity to install the Soviet legal system outside the U.S.S.R. came only after World War II, when Soviet-type governments were created for European states occupied by the Soviet army in pursuit of retreating German forces. The system was also established in China, North Korea, and North Vietnam as military victories placed the Communists in power. In each country there was some variation, related to the degree of economic development, from the Soviet pattern evolved in the U.S.S.R.

Throughout all the states that became Communist, law was given the functions previously established in the U.S.S.R. Thus, the constitution of the Hungarian People's Republic of August 20, 1949, declared (article 41):

> Courts of the Hungarian People's Republic punish enemies of the working people, defend and secure the state, economic and social structure of the people's democracy, its offices and the rights of the toilers, educate the toilers in the spirit of observance of the rules of socialist intercourse.

Regulations governing the organization of the people's courts in the People's Republic of China, promulgated September 3, 1951, specified that courts were "to consolidate the people's democratic dictatorship, uphold the new democratic social order and safeguard the fruit of the people's revolution." The People's Republic of Bulgaria was even more outspoken than the U.S.S.R. in clarifying the function of law; in its constitution of December 4, 1947, it granted the right to citizens to create associations, but (article 87) only "if they are not directed against state and public order established by the present constitution," and then stated:

> It is forbidden and will be punished by law to form organizations having as their purpose taking from the Bulgarian people the rights and freedoms won by the people's uprising of September 9, 1944, and guaranteed by the present constitution, or to limit these rights and freedoms, to place under threat the national independence and state sovereignty of the country or to propagate open or concealed fascist or antidemocratic ideology, or to facilitate imperialist aggression, and also to participate in these organizations.

The Chinese Communist Party leader, Mao Tse-tung, in his 1949 speech "On People's Democratic Dictatorship," indicated that he had adopted in effect what had been Stalin's interpretation, enunciated in 1930, of the Marxist concept of the withering away of the state. Mao declared that there could be no withering in China as long as there was opposition to the state. The constitution of the People's Republic of China, promulgated on September 20, 1954, nearly five years after proclamation of the people's republic on October 1, 1949, fixed as final the system of courts evolved in emulation of the U.S.S.R. There were to be lay assessors, full-time professional judges, Soviet-type prosecutors, and three levels of courts; "judges were independent and subject only to the law," as they had been declared to be in the U.S.S.R. constitution.

Judicial patterns of the same type were established in the constitutions of the other people's democracies: the Democratic Republic of Vietnam (November 8, 1946), the People's Republic of Albania (March 14, 1946), Socialist Republic of Romania (April 13, 1948, and September 24, 1952), the Republic of Czechoslovakia (May 9, 1948), the Democratic People's Republic of Korea (September 8, 1948), the German Democratic Republic (October 7, 1949), and the Polish People's Republic (July 22, 1952).

The applicable law was stated in a small number of specific decrees in each republic, but otherwise determination of law was left to the judges. The Chinese government, among its first actions, abrogated all legal codes of the prior government. In October 1950 the Chinese premier, Chou En-lai, listing the documents to serve as guides to the judges, included not only specialized decrees of the government but also the Common Program of the Chinese Communist Party.

The provisional regulations on people's courts of 1951

(article 4) read, "Where no regulation is applicable, the policy of the Central People's Government will be adhered to." A law codification commission was established in the spring of 1950, but no basic codes emerged, only specialized statutes such as the land reform law of June 28, 1950; the law on marriage, April 13, 1950; the law on questions of employment, July 25, 1952; and the organic law for the court system, September 21, 1954.

The Soviet-type states in eastern Europe moved more rapidly toward codification than had China, and in contrast confirmed the existence of prewar civil codes, although with modifications. Poland adopted a General Statute on Civil Law with 119 articles on July 18, 1950. As in the Soviet Civil Code of 1922, the codifiers sought to avoid possible injury to working-class elements; article 3 provided: "It is forbidden to use one's rights to violate the fundamentals of social intercourse of the people's government." A Polish family code was adopted on June 27, 1950, and a decree on planned contracts on April 26, 1950.

Before the expulsion of the Yugoslav Communist Party from the Cominform on June 28, 1948, Yugoslavia, under the constitution of January 31, 1946, had followed the Soviet legal pattern. Under Tito, Yugoslavia accepted the concept of monopoly of power in a Communist Party and the necessity of state ownership of productive resources but refused to accept dictation from the Soviet Union on every detail, especially on centralization of industrial control and the speed of collectivization. The Yugoslav government experimented with bringing workmen into the managerial process of public corporations and in broadened autonomy for local government councils. Yugoslav legal philosophers rejected the view that the state could not begin to wither away until full achievement of Communism; they wanted to start relaxation of coercion immediately. Stalin's attempts to unseat Tito failed, and on Stalin's death his successors attempted reconciliation for a time, indicating acceptance of the idea that there could be many roads to Socialism.

Changes after the death of Stalin

Stalin's death in 1953 and his downgrading by the Communist Party of the Soviet Union at its 20th congress in 1956 opened a new era in the law of Communist-led states. The People's Democracies sought to be relieved of Soviet tutelage. Risings in Hungary and Poland forced the Soviet leaders to acquiesce in the evolution of divergent legal systems. Polish jurists, including Communists, demanded humanistic attitudes toward legal procedure with greater flexibility and an increased regard for the individual, and other east European states followed their lead. Even Soviet legal philosophers in 1958 endorsed a new humanism and declared it always to have been fundamental to Lenin's thought.

Only Chinese Communists resisted the trend toward strengthened legal procedures, denouncing Soviet policies of humanism and legality in an open letter published in 1963. After 1957 Chinese leaders abandoned their policy of copying Soviet legal patterns and ceased efforts to draft codes of law, declaring that they wanted flexibility in court. They evolved a legal system seemingly inspired by relics of traditional Chinese attitudes as modified by their own guerrilla experience before 1949 and by their study of Soviet practices during the period of War Communism before 1921.

Concurrently with revival of concern for humanistic values, Communist states other than China revised their constitutions and law codes to give formal support to their claim to have passed beyond capitalism to Socialism. Mongolia and Czechoslovakia declared themselves Socialist republics in constitutions adopted July 6 and 11, 1960, respectively. North Vietnam introduced its new constitution on December 31, 1959. Yugoslavia promulgated its revision on April 7, 1963; Romania on August 20, 1965; and the German Democratic Republic on April 9, 1968. New civil codes designed for Socialist economies were introduced in Poland and Czechoslovakia in 1964, the latter incorporating terminology that departed sharply from Romanist tradition.

Several features, however, remained unchanged in the law of these states even after the introduction of variations. Most notable was continuation of Lenin's principle that no basis remained after the Russian Revolution for the Romanist division of law into public and private spheres. To Lenin the Soviet state's concern with every detail of social intercourse required maintenance of the state's right and opportunity of intervention in any matter at any time. Consequently he held that in the Soviet system all law must be public, that is, reflect the state's vital concern in the social relationships governed by law. This attitude of state direction of all matters, sometimes called *dirigisme* by French scholars, remained characteristic of Soviet law.

CHARACTER OF SOVIET AND SOCIALIST LAW

Montesquieu's concept of separation of powers as embodied in the Constitution of the United States of America was rejected by the founders of the Soviet legal system. The legislature was made supreme over the executive and the judiciary. In principle only the legislature's enactments were a source of law.

Practice made the executive a source of law, however, for the Council of Ministers often acted without convening the legislature. The second federal U.S.S.R. constitution of 1936 attempted to stop this practice in violation of the constitution of 1924, but the executive soon again usurped legislative authority. The post-Stalin reforms again sought to restore monopoly lawmaking power to the legislature. In practice it was not the legislature in full assembly but its derivative body, the presidium, elected from its membership to legislate during intervals between full sessions, that created the day-to-day changes in law. Although subsequent ratification from the full body was sought, revocation of presidium action was virtually impossible because of the passage of time. The presidium thus became the most important source of law, except for the state economic plan, the budget, and enactment of general principles for republic codes.

Legislative domination

Communist Party orders were in the technical sense not a source of law, for to be binding on courts these had to be enacted by state agencies. Still, the party provided the initiative for legislative action. Some vital laws, such as those reforming agriculture or industry, were given preeminent status by signature by the party secretary as well as by the chairman of the presidium when they were published as law.

Having rejected judicial lawmaking with assertion of the legislature as the sole lawgiver, Soviet jurists accepted no concept of judicial precedent like that of the Anglo-U.S. common law. Nevertheless, the Supreme Court of the U.S.S.R., in exercise of its authority to enunciate principles of interpretation based upon examination by its full body of a course of judicial practice proclaimed such far-reaching principles as to make of these a source of law. Even individual decisions of the Supreme Court, although lacking the authoritative force of the general rulings, were given careful attention by lower courts, since they were published as guides. The Soviet legal system in practice adopted much the same approach to judicial decisions as have Romanist systems generally.

The Supreme Court of the U.S.S.R., being subordinate to the legislature, had no right to declare a law unconstitutional nor to create any limitation upon the legislature or the executive on the ground that some higher or general principles of law had been violated.

Control over the judiciary was preserved for the legislature at all levels above the people's court by giving it appointive and recall power, through the Soviet operating at the court's level. Only people's judges were elected by the people under provisions introduced by the 1936 constitution, although elections were not begun until after World War II. Elections followed the pattern established for all representative bodies in the U.S.S.R. by Stalin, namely the one-candidate ballot, the candidate being chosen by local professional groups with the guidance of the Communist Party members in the groups. In practice, judicial decisions had to accord generally with Communist Party policy or the judge risked recall.

In light of the foregoing, the constitutional provision that "judges are independent and subject only to the law"

(article 112) had to be understood as denying to local officials the right of intervention in the formation of an individual decision on personal grounds, but as not prohibiting Communist Party intervention when such intervention was properly formulated in criticism of a line of decisions out of keeping with party wishes.

Judges were not deprived entirely of initiative by the rule of legislative supremacy or by the leading role played by the Communist Party. In both the Civil and Criminal codes adopted in 1922 there was authorization to depart from the rigid provisions of the code under special circumstances. The Civil Code opened with article 1, reading, "Civil rights are protected by law except in cases where they are exercised contrary to their social and economic purpose." This rule permitted judges to apply their concept of state policy, when it was not specifically stated, to achieve an appropriate result in a given situation, but the decision created no rule of law for future cases. The article was used frequently to justify judicial refusal to protect the rights of capitalists during the period of reconstruction (1922–28), but after 1930 it fell into disuse. Soviet jurists argued for its deletion from the code as unrelated to a stable society from which all capitalist elements had been eradicated, but it was retained in the civil-law general principles of 1961 (article 5).

The Criminal Code of 1922, and as revised in 1926, permitted the judge to exercise discretion not only in withholding conviction where a crime had clearly been committed, provided that he found no social danger, but also in punishing a citizen who had committed no crime defined as such by the code. The formula for such judicial initiative was that the act be found socially dangerous in a manner analogous to another act specifically defined as a crime. This provision, which led to unpredictability, was eliminated from the criminal law by the general principles adopted in December 1958.

SUBSTANTIVE LEGAL PROVISIONS

Soviet jurists and their colleagues in eastern Europe and the Communist-led states of Asia claimed uniqueness for their system because of its constitutionally defined function of promoting Socialism. The end, in their view, transformed the means. While the novelty of the system was, therefore, primarily in its philosophical base, the substantive law was revised to introduce some novel institutions.

Property. The *Communist Manifesto*'s interpretation of property ownership as the source of political power was accepted by all Communist parties as the guiding principle to be followed in revision of law. Consequently, private ownership of productive wealth was everywhere abolished in some degree as soon as state officials felt competent to administer production efficiently. The second federal constitution of the U.S.S.R. (1936) set forth the ideal, denying to private individuals the right to employ labour in productive enterprise (article 9) and reaffirming Lenin's decree of February 19, 1918, nationalizing all land (article 6).

Lesser achievement of the goal was realized elsewhere. Polish and Yugoslav Communists continued to permit peasants to own farmlands and also allowed private citizens to conduct service trades, although under limitation on the number of employees. China alone permitted private ownership of factories to continue, but subject to the limitation that owners retain no financial link to foreign capitalists and share their ownership with the state as partner. Profits to such owners became a fixed return on investment, indicative more of loan capital than equity, and even this payment was often regained by the state on demand for various fund-raising campaigns for social organizations.

The various legal codes reflected the preponderant importance given state-owned productive property. For example, more severe penalties for theft of state property than of private property were prescribed by criminal codes. The U.S.S.R. labour codes were concerned solely with state employment. The provisions of civil codes relating to sales, contracts, property damage and inheritance governed only consumer goods in traditional Romanist legal fashion, while new forms were developed to govern transactions in state property. Title to state property was subject to restrictions: no sales or leases, with limited exceptions for land allocated to peasant households disrupted temporarily by military service or departure for temporary industrial employment.

The ownership of land and personal property

Land, although declared state property only in the U.S.S.R. and the Mongolian People's Republic (constitution of 1924), was brought increasingly, in all Marxian Socialist states except Poland and Yugoslavia, under the administration of cooperative-type associations structured on the Soviet collective farm model. Peasants were induced, often under strong pressure, to assign to these the use of plots originally owned by or assigned to them. The variation introduced in China (1958) was called a "commune" and united both local government and land administration in one administrative unit supervising "brigades" (groups of villages) and their subordinate "teams" (individual villages). By law, land ownership in China was placed not in the state as in the U.S.S.R. but in the "team" to stimulate peasant initiative in its development.

The Soviet model collective farm placed ownership of machinery, tools, commonly used farm buildings, and crops in the cooperative; but member families were declared owners of their family homestead, including hand tools and barnyard animals. Small plots of state-owned land were assigned each family for private use as a household garden. Farm government was carried on by a membership assembly that elected management, usually introduced to the members by central government authorities. Remuneration was in a share of the produce graduated according to value of work performed computed on an accounting unit called a "labour day."

Agricultural cooperatives were generally regarded as transitional forms designed to guide peasants toward a superior type of organization patterned on industry so that peasants would become farm employees receiving wages and social insurance benefits. Only China rejected this ultimate goal, preferring to perfect the "commune" as a model for rural productive units.

Nonproductive property was left to private ownership as were artisans' tools, all being labelled "personal property" to distinguish them from income-producing "private property." Early efforts to equalize ownership of consumer goods were abandoned by Stalin (1930), and egalitarianism was denounced as a petty bourgeois utopian idea. Shortage of goods forced a change in attitude. Wages differentiated according to work performed became the means of stimulating production, a differentiation that led progressively to weakening of restraints on inheritance and ownership of luxury items.

The second federal constitution of the U.S.S.R. (1936) entrenched the property incentive system by guaranteeing private ownership of savings accounts and inheritance. To hamper reversion to capitalist practices, various restrictions were placed on use of personal property. Thus, dwellings were limited in size to satisfy only family needs; sales of dwellings and apartments could occur only at long intervals; members of a family sharing a joint household might own only one dwelling and might lease excess space only temporarily and occasionally and at rentals not exceeding those charged for occupancy of state-owned premises. Sales of privately owned automobiles and motorcycles could be effected only through state commission stores at fixed prices. Property purchased with income gained illegally could be expropriated. Neglected property might be expropriated if repairs were not made following warning.

The determination to eliminate income from investment of private funds weakened under various paramount state pressures. Thus, interest was paid on state savings bank accounts to stimulate deposits as a means of accumulating funds for state investment and to reduce the threat of an inflation of currency. Investment in state bonds also was encouraged, but returns were paid not in conventional interest but as lottery winnings. Inheritance from abroad was paid to heirs within the U.S.S.R. Sums received through such channels were used to purchase dwellings, apartments in cooperatively constructed structures, expensive consumer goods, and tours.

Marxian Socialist states outside the U.S.S.R. established comparable restrictions: Czechoslovakia going furthest to require that the source of personal ownership be "honest," that is, derived mainly from work for the benefit of society. China, under Mao Tse-tung, took the strict position, opposing extensive use of property incentives among individuals and espousing asceticism.

Communal ownership was reserved in Marxian Socialist states, except China, for the distant future when abundance should have been achieved, money would no longer be used as a medium of exchange, and the state had "withered away," in accordance with the prophecy of Marx and Engels in the *Communist Manifesto*.

Meanwhile, the state represented the community and sought to enlarge its segment of productive property. Yugoslav Communists attempted to create a variation, rejecting the Soviet model of state ownership of industry to create in 1950 "social ownership" of factories, under which title to industrial property was conceived to be not in the state but in the plants' workmen, organized into a "workers' council." Management was appointed not by a central ministry, as elsewhere in the Marxian Socialist states, but by the "workers' council," acting in concert with local government and an industry-wide chamber representing all workers' councils in the republic in the same branch of industry. The aim was to overcome evils thought inherent in centralized bureaucracy.

Economic planning. Production was planned in all Marxian Socialist states, although in varying degree and through different types of institutions. Stalin favoured detailed planning and centrally made decisions by the Council of Ministers, advised by the State Planning Commission (Gosplan). The Yugoslav opposition to a centralized bureaucracy placed the emphasis on planning by local government and "workers' councils," subject to influences exerted by the central government through allocation of major capital investment and establishment of national goals.

Stalin's heirs experimented after 1957 with forms of decentralized decision making through regional economic councils (Sovnarkhoz) for industries not directly related to national defense, hoping to stimulate managerial initiative. Most central industrial ministries were abolished from 1957 to 1965, but Gosplan and specialized financial and technical institutions retained control over allocation of key resources. Return to centralization with abolition of the Sovnarkhoz and reconstitution of industrial ministries in 1965 was in a form differing from Stalin's model in that responsibility of republic authorities was heightened and plant managers were directed to search out local sources of supply and markets.

Encouragement of local initiative went farther in some Marxian Socialist states, Czechoslovak specialists even proposing to dramatize the change in emphasis by declaring the public corporations administering state-owned property as the "owners" of the buildings and tools rather than only the administrators. This extreme experimentation was terminated by Soviet intervention in 1968, although the Yugoslav Communists continued to rely on their system of local ownership and direction subject to indicative plans having no force of law.

Contracts as tools for economic planning

An interesting legal feature connected with production in all Marxian Socialist states was the contracts executed by plant managers for the implementation of production plans. These contracts prescribed quantity, design, technical specifications, price, and delivery date, using, as a basis for negotiation, plan requirements. Increasingly, after 1957, elements of consumer choice were considered. These contracts served also as the basis for dispute settlement by permanently functioning state tribunals called State Arbitration. These tribunals might also require execution of contracts to implement the plan if parties could not agree on terms. China alone provided a variation, establishing no permanent tribunal but preferring mediation through ad hoc committees established by local economic commissions linked to the planning apparatus.

Labour. While production and distribution occurred under compulsory orders, labour remained free to move as it wished, except during the emergency conditions of World War II in the U.S.S.R. Subsequently, the Soviet labour supply was again regulated by monetary and other inducements but subject always to centralized determination of job classification, hours and wages, and in China to vigorous political pressure designed to force urban dwellers back to the farms.

The role of collective labour agreements changed as the central authorities progressively prescribed details of employment. They fell into disuse in the mid-1930s but were restored after World War II to mobilize the labour force for production. Since job classification, wages, and hours were established by law, the agreements concentrated on betterment of local working conditions and indicated the labour union's preferences regarding the use of bonuses collectively earned as incentives for exceeding the plan. Collective bargaining was expected to reappear in the U.S.S.R. in more traditional form after the post-1965 reforms as plant managers exercised their new authority to reduce unneeded staffs and rearrange wage scales to reflect heightened productivity.

Strikes and grievances

Since production was planned and, therefore, was by definition rational, strikes were given no place in Marxian Socialist states. Remedies sought by management or labour unions against apparent injustice had to take the form of petitions to higher authority for legislative or administrative rectification. Strikes did occur in Poland and Hungary in 1956 when Communist influence weakened, and reforms became necessary to hold power. Collective agreements were enforced primarily through moral suasion, strengthened by penal code provisions applicable to state managers who violated the code, the collective agreement, or legal activity of labour unions, and to labour unions who disrupted production so severely as to commit the crime of "wrecking."

The "right to work" was established by all constitutions of Marxian Socialist states, but no system implemented it by court order on an employment office to provide a job. The concept came to require only elimination of discrimination on the basis of race, sex, age, or domicile in filling such jobs as might exist.

Individual employment contracts reflected statutory provisions governing the employment relationship and its termination. Since individual bargaining in establishing employment terms was eliminated, written contracts were often omitted in practice. A grievance procedure under labour union supervision was established by which aggrieved parties could appeal to courts for review of the reasonableness of managerial decisions on payment and dismissal controversies. Labour becoming redundant with automation's advance was to be retrained for other employment by state centres.

Yugoslavia's "workers' self-government" presented a variation in the theory of the employment relationship since workers were said to employ themselves, being both owners and workers. Their activity was regarded as a social duty rather than a labour relationship, but in practice standards of employment were established to which management was required to adhere, these being generally the same as in other Marxian Socialist states.

Accident insurance. Social insurance was introduced in all Marxian Socialist states to protect employees injured on the job or elsewhere. No coverage was offered collective farmers until 1966, nor to housewives and children, forcing them to rely for recovery on suits based on the Civil Code's provisions on obligations. These rules conformed to traditional Romanist legal models with some variation. Thus, the first Russian Civil Code (1922) required no fault for recovery, but this provision became conventional through court practice. Fault became necessary for liability except when the instrument causing injury was classified as extra hazardous. The list of such instruments included motor cars.

The social utility of negligence suits

Social insurance benefits were originally inadequate because of the impoverishment of the state treasury. Consequently, victims of accident were stimulated to sue for the difference between social insurance payments and total losses. Soviet policy makers finally concluded it desirable to continue this practice even when social insurance funds were increased, the argument being that state managers

would be prompted to exercise care because of the threat of suits, which would be likely to reduce the profit margin and their eventual chances for promotion. Social insurance benefits thus continued to be set at levels lower than damages suffered.

Damages were limited to loss of wages or anticipated wages for unemployed victims. Poland and Czechoslovakia continued ancient practice to allow recovery for pain and suffering additionally. No capitalization of damages was permitted, in part to avoid transfer to irresponsible individuals of large sums and in part to discourage accumulation of wealth likely to provoke speculation.

No personal liability insurance was made available to individuals in the U.S.S.R., except to foreigners, in the belief that its availability would reduce the deterrent effect created by civil suit for accident. Czechoslovak and Hungarian civil codes retained pre-World War II provisions, however, creating the opportunity of purchasing liability insurance. State insurance provides state enterprises in all Marxian Socialist states with protection from suit by employees injured by extra hazardous equipment, unless charges of fault are made. The burden of proving absence of fault is on the defendant.

Liability for injury was attached to state activity even when not of an economic character, as with ministries and local government, although until 1961 in the U.S.S.R. sovereign immunity for governmental functions had to be waived explicitly by statute to permit suit. Thereafter, liability was extended to all types of state administration unless immunity was claimed by specific law. The Czechoslovak Civil Code (1964) established a new approach by drawing no distinction between types of state activity in establishing a rule of liability to suit.

The Chinese penchant for mediation over litigation developed after 1957 to eliminate possibilities of suit for injury in accident, but in cases of reprehensible conduct the police were authorized to impose administrative sanctions for minor infringements of citizens' personal or property rights, or require payment of medical expenses and property damage under the Security Administration Punishment Act of 1957.

A duty to protect state property (article 131) and to observe rules of Socialist conduct (article 130) was created by the second U.S.S.R. federal constitution (1936). It initiated judicial practice establishing an obligation of a state enterprise whose property had been protected to pay damages to a victim injured while attempting to perform his duty. This principle was written into the U.S.S.R. Fundamentals of Civil Law in 1961. No implementation was provided, however, for failure to rescue another in performance of the obligation to observe the rules of social conduct. Soviet authors concluded that this duty was moral and not legal, and violation could create no civil liability in favour of a citizen or his heirs if no rescue was attempted.

The Yugoslav constitution (1963) likewise created a duty to rescue but no formal obligation to pay damages to persons injured as the result of another's failure to act in their protection. The Czechoslovak Civil Code (1964) was the first to establish not only the duty to rescue but also a right in the injured party to recover damages from an individual who failed to perform his duty. It also established the right of the rescuer to recover from the person in whose interest he acted such damages as he might have suffered.

Artistic creation and invention. The legal rights protecting authors, artists, and inventors presented problems in socialized economies unless such persons were state employed. Practice indicated that authors, artists, and inventors were most imaginative when unimpeded by state supervision. To provide the requisite freedom coupled with stimulation of initiative, Soviet codifiers created a status for innovators midway between Western concepts and those of the Socialist ideal of production for wages. This status was called "a law of personal relationships rather than of property relationships."

Inventors in the U.S.S.R. were offered two alternatives: (1) an "author's certificate" or (2) a patent. The first was granted after proof of novelty to the state patent office and qualified the inventor to receive payments computed on the saving to the state enterprise from use of the invention, the computation being based on the best of the first five years of use. Additional benefits were tax exemption on a portion of the receipts, priority in the allocation of scarce living space, and acceptance into a technical school. The patent form was traditional, except that restrictions on private enterprise limited its use to assignment to state enterprise. In practice only foreigners chose patents. The international convention protecting patents was ratified by the U.S.S.R. in 1965.

Although other Marxian Socialist states in Eastern Europe also offered a form similar to the "author's certificate," patents retained vitality until 1963 when the trend toward the Soviet model became marked. All states, however, retained the patent form for local inventions likely to have appeal abroad so as not to discourage potential foreign licensees unlikely to purchase a novel form of protection.

Protection of artists' rights

Authors and artists were provided more conventional protection than inventors, but they were deprived of some traditional rights of a copyright owner. They could not bargain for royalties nor sell their work to foreign publishers except through a state trading enterprise. Royalties were paid in accordance with a state tariff based on type and size of an edition. In addition to monetary rewards, payable for life and to heirs for a term of years, moral protection was offered in the form of a right to control editorial changes in a manuscript and its use. Exceptionally, community interests were exerted against an individual author's will if the work was regarded as a national treasure. Thus, it could be translated or published continuously after a first disclosure by the author. Royalties were paid, however, except when the language of translation was other than Russian on the ground that minority peoples needed culture for which they could not afford to pay.

The U.S.S.R. ratified no international copyright convention and has avoided the obligation to obtain consent and pay for publication of foreign authors within its boundaries. Other eastern European Marxian Socialist states, however, have accepted the Brussels Copyright Convention.

Nonmonetary inducements, including medals and honorific titles, were also utilized to stimulate innovation.

Domestic relations. Women's equality with man and secularization of marriage were the major aims of the Russian revolution in regard to the family. Other Marxian Socialist states, where these goals had not yet been achieved at the time of Communist assumption of power, had the same program. Before 1926 Soviet family law presented little variation from western European models, but the 1926 code introduced unregistered marriage and divorce. Marriage could be recognized as legally constituted if cohabitation as if in marriage were proved orally. Divorce would be registered on the request of one party on proof of termination of marital relationships.

A trend toward discouragement of promiscuity emerged in the mid–1930s on evidence of increasing juvenile delinquency resulting from the breakup of homes. A law of June 27, 1936, required both parties to appear for divorce if the care and maintenance of children was in issue and sought to discourage repeated divorces by establishing a system of graduated fees for each succeeding divorce. The 1926 provisions accepting proof of marriage or divorce other than by registration were finally revoked by law of July 8, 1944. Thereafter registration was compulsory to establish marriage, and courts were given sole jurisdiction over divorce. Judges were required, however, to attempt reconciliation and to grant divorce only when convinced that restoration of the family was impossible. Children born out of wedlock were denied the father's name and maintenance or inheritance. Unwed mothers were given state aid.

The compromise on marriage and family

Hostility to the 1944 system mounted with succeeding years. A compromise position was formulated and adopted by law of June 27, 1968. While registration of marriage remained a requirement, divorce might be registered without prior court decision if both parties consented and

there were no offspring. In other circumstances court proceedings were compulsory. The paternity suit was restored, but only to provide the father's name and maintenance rights if a child had been born from a union having all characteristics of marriage except registration. Offspring of casual unions remained under the regime established in 1944.

While other Marxian Socialist states generally followed the U.S.S.R. model, all introduced variation to preserve national cultural patterns. None but China adopted the U.S.S.R.'s early attitudes on unrestrained divorce, and even China discouraged resort to its simple procedure of granting divorce at the request of either party. All Marxian Socialist states sought to preserve the conjugal family against lighthearted decisions to separate. The formula was to establish no precise grounds for divorce but to authorize divorce only in the event of complete and permanent breakdown of the marital relationship. Yugoslav law prohibited suit for divorce by the spouse responsible for creating an unbearable situation, but in practice marriages were considered broken if cohabitation ceased. Generally children born out of wedlock were accorded the same rights as those born legitimately, with the exception indicated in the U.S.S.R.

The marital property regime established in the U.S.S.R. after early experimentation with individually owned property was established in 1926 as a system incorporating the concept of community of acquests; *i.e.*, property owned individually by the spouses before marriage remained their individual property, but that acquired during marriage was communally owned, unless received by one spouse as a gift from outside or by inheritance. The U.S.S.R. model was adopted elsewhere among the Marxian Socialist states.

Criminal law. Novel definitions of crime emerged in Marxian Socialist states to reflect Socialist principles. To the traditional crimes against the person and property retained from the definitions of pre-Socialist codes, in 1932 the U.S.S.R. added "economic crimes." This development coincided with the time when the private enterprise system, permitted during the period of the New Economic Policy, was terminated in favour of the system of state monopoly of large scale production and state planning. Under these altered priorities, merchandising became a crime. The 1936 U.S.S.R. constitutional prohibition of all private employment of labour for production purposes was reflected in the Criminal Code to penalize employers. Even artisans employing no labour were forbidden to engage in various production activities unless customers provided the raw materials. Later, leasing of unused space in small private dwellings at rates exceeding those established for tenants of state-owned apartment buildings became criminal.

Crimes against the state

Fear of opposition to Communist Party leadership caused the introduction by draftsmen in the Russian republic's Code of 1922 of a chapter on "counter-revolutionary" crime. It remained in the successor code of 1926 and was replaced by a chapter on "state crime" by a law of December 25, 1958. While all legal systems punish attempts to subvert state authority, the definitions and practice under Stalin exceeded the norms of liberal Western democracies in vagueness of expression and severity of penalties prescribed. Further, in keeping with the principle established by the Russian republic's constitution of 1918 and continued in subsequent constitutions that limited the exercise of civil rights to activities in the interest of Socialism, prosecutions for anti-Soviet agitation occurred under circumstances that elsewhere would not have constituted criminal sedition. After Stalin's death there was a decade of lessened severity, but a new epoch was initiated in 1966 when authors were prosecuted for publication abroad of allegorical manuscripts that had been rejected by Soviet censors. The ground given for this prosecution was that the authors should have anticipated the hostile use to be made of their writings by enemies of the U.S.S.R.

In implementation of Marxist attitudes toward religion as an intolerable superstition to be discouraged, the conduct of religious schools and of social activity unrelated to worship was prohibited in the U.S.S.R. Strong discouraging measures adopted during the 1920s when the religious hierarchies opposed Communist programs were relaxed during World War II to gain peasant support, but basic policies remained unchanged. An order of March 18, 1966, prescribed punishment for religious activity deemed harmful to health, and in practice was interpreted broadly to hamper worship by minority sects.

While other Marxian Socialist states introduced less restrictive laws, their leaders sought to discourage religion. Chinese Communists expressed belief in re-education of monks and priests. Eastern European leaders were initially militant in prosecuting clergy but relaxed their vigilance as religious institutions became more tractable, Yugoslavia even going so far as to sign a concordat with the Vatican in 1966.

Procedural law. Romanist influence was strong in the codes of criminal and civil procedure, which copied the main features of the French codes, although retaining more possibilities of control by the state.

Emphasis in criminal procedure was placed on investigation before trial, as in French practice. The examiner had to establish more than a prima facie case required of the grand jury in the traditional common-law system. The suspect had to be given an opportunity to testify and to produce witnesses and evidence in his defense. The examiner became a preliminary judge authorized to bring the case to trial only if he became convinced of guilt, so that the public trial consisted primarily of verifying the examiner's work rather than hearing the defendant's case for the first time. Contrast with the French model was provided by the fact that the examiner was not a magistrate but subordinate to the office of prosecutor, and until 1958 no attorney was permitted the defendant in the U.S.S.R. during the preliminary investigation. Even thereafter only juveniles were given an absolute right to an attorney.

The "inquisitorial" system

Trial procedure followed the French model closely in that the judges were instructed to establish their personal conviction of guilt. To do so they might go beyond evidence presented by the prosecution and defense. The court might call witnesses, seek its own experts, examine material evidence, and visit places connected with the crime. The judges did most of the interrogating in the courtroom, relying on the prosecutor and the defense only to bring out points overlooked. No rule of evidence of any kind bound the court, except the rule of relevance.

Civil procedure required observance of rules of evidence only for certain formalities established by the civil codes, such as those for such documents as contracts or wills. Otherwise, the judges were as free in civil as in criminal matters to seek or hear what they desired to establish their personal conviction. Soviet jurists claimed an innovation in the prosecutor's authority to intervene in a civil case at any stage when thought necessary for the interests of society. This power sometimes brought in the prosecutor to protect a party whose attorney appeared incompetent.

Appellate courts finding violation of procedural requirements of substantive law or unconvincing evidence were required to remand for new trial. Revision of a sentence or of a decision without retrial in a court of original jurisdiction was permitted only when the original court had no jurisdiction, where an amnesty had been improperly applied, or where there had been no basis for trial. A penalty could not be increased on defendant's appeal.

A singular feature of Soviet procedure was the authority given to Supreme Court presidents and to the prosecutors of the republics and of the U.S.S.R. to protest a decision, whether civil or criminal, after it had become final on appeal or in absence of appeal. This procedure permitted reopening of convictions or even of acquittals if the highest legal authorities found grave error in their periodic audit of inferior-court activities. Prosecutors frequently requested such reopenings, even of convictions obtained by inferior prosecutors. This created the opportunity of petition to superior prosecutors or to court presidents after all remedies as of right had been exhausted. At the same time it gave state authorities a second chance, not given the convict or the party to a civil suit, to change an otherwise final decision.

Soviet law in perspective. The industrialization characteristic of the 20th century required legal systems in all states to accept increasing state intervention in social relationships. Employers were no longer left free to execute labour contracts as they wished; property owners were subjected to increasing restraints on use and in some countries were subjected even to the loss of farms or dwellings if these were not used productively; nationalization in banking, industry, and transport was widespread; compulsory insurance against injury to third parties became commonplace, as did social insurance against industrial accidents; and secularization of marriage and divorce nearly everywhere prevented citizens from conducting their marital relationships solely within religious rules.

Soviet and Socialist law, in its reflection of the state's pervading presence in human relationships, appeared to be but an extreme extension of trends common to legal systems everywhere. Yet many legal philosophers concluded that Soviet law differed in more than degree from other systems. While its techniques were those of the Romanist system, its difference in degree was interpreted as a difference in kind, justifying the conclusion that Soviet law was a unique system requiring separate categorization.

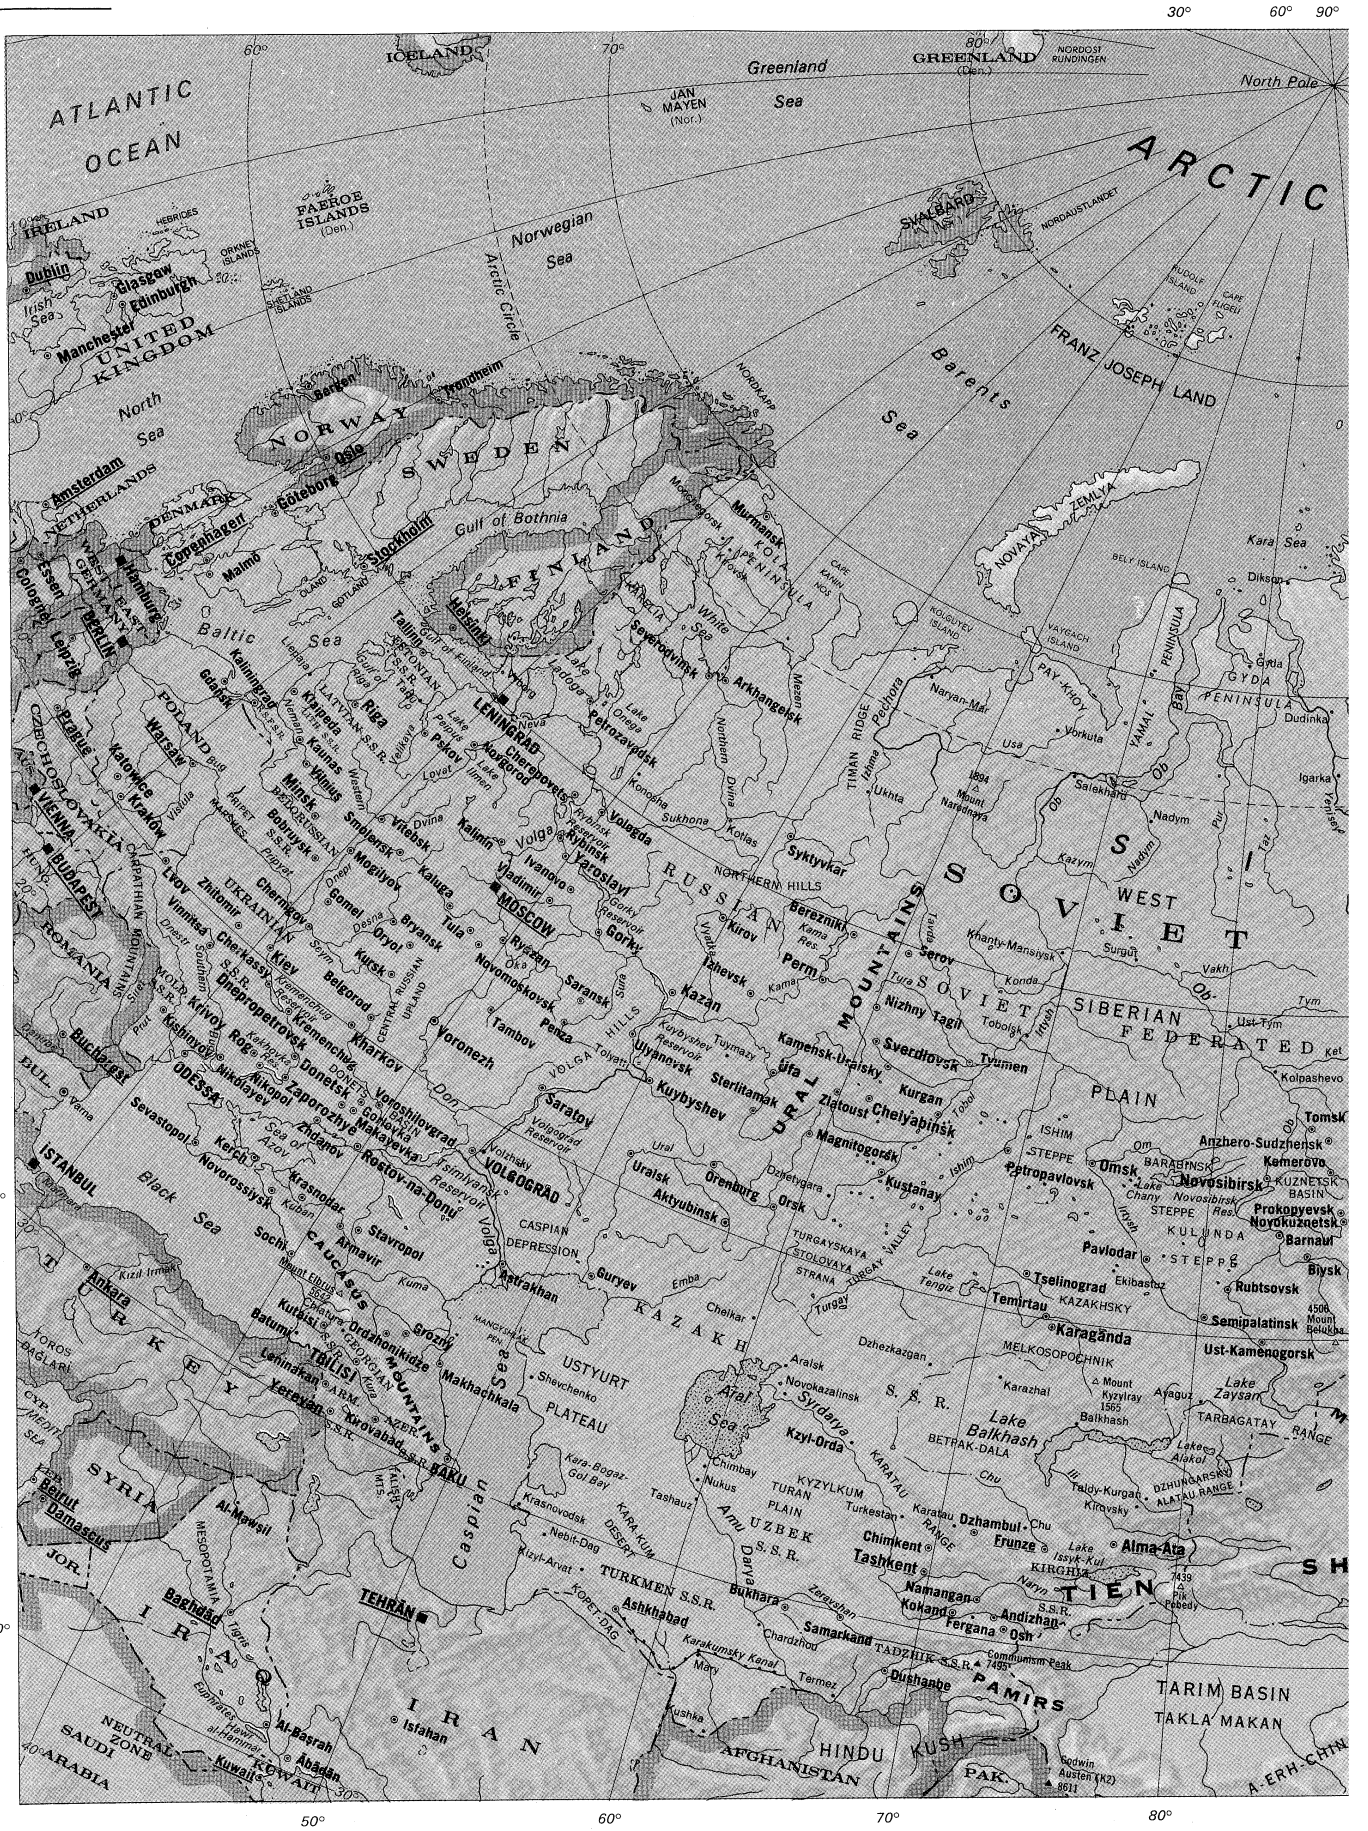
(J.N.H.)

Soviet Union

By area the world's largest country, the Union of Soviet Socialist Republics (U.S.S.R., or, popularly, the Soviet Union) covers a vast segment of the Northern Hemisphere: one-sixth of the world land surface and two-fifths of the Eurasian continent. Its 8,650,000 square miles (22,400,000 square kilometres) are seven times the area of India, two and one-half times that of the United States, and 60 times that of Japan. It covers 11 of the 24 world time zones; while citizens of the Soviet Far East are greeting the dawn, their fellows in Moscow, the capital, are sitting down to dinner. The total population reached an estimated 257,824,000 in 1977.

Neighbouring countries

The Soviet Union has the world's longest frontiers, and no other country is bounded by so many nations. Norway, Finland, Poland, Czechoslovakia, Hungary, and Romania lie to the west; Turkey, Iran, Afghanistan, China, Mongolia, and North Korea lie to the south; the eastern and northern frontiers are coastal. Conventional lines linking the Rybachy Peninsula and Big Diomede Island to the North Pole form the boundaries of the Soviet sector of the Arctic. Twelve seas, belonging to three oceans (Arctic, Atlantic, and Pacific), wash the country's coast.

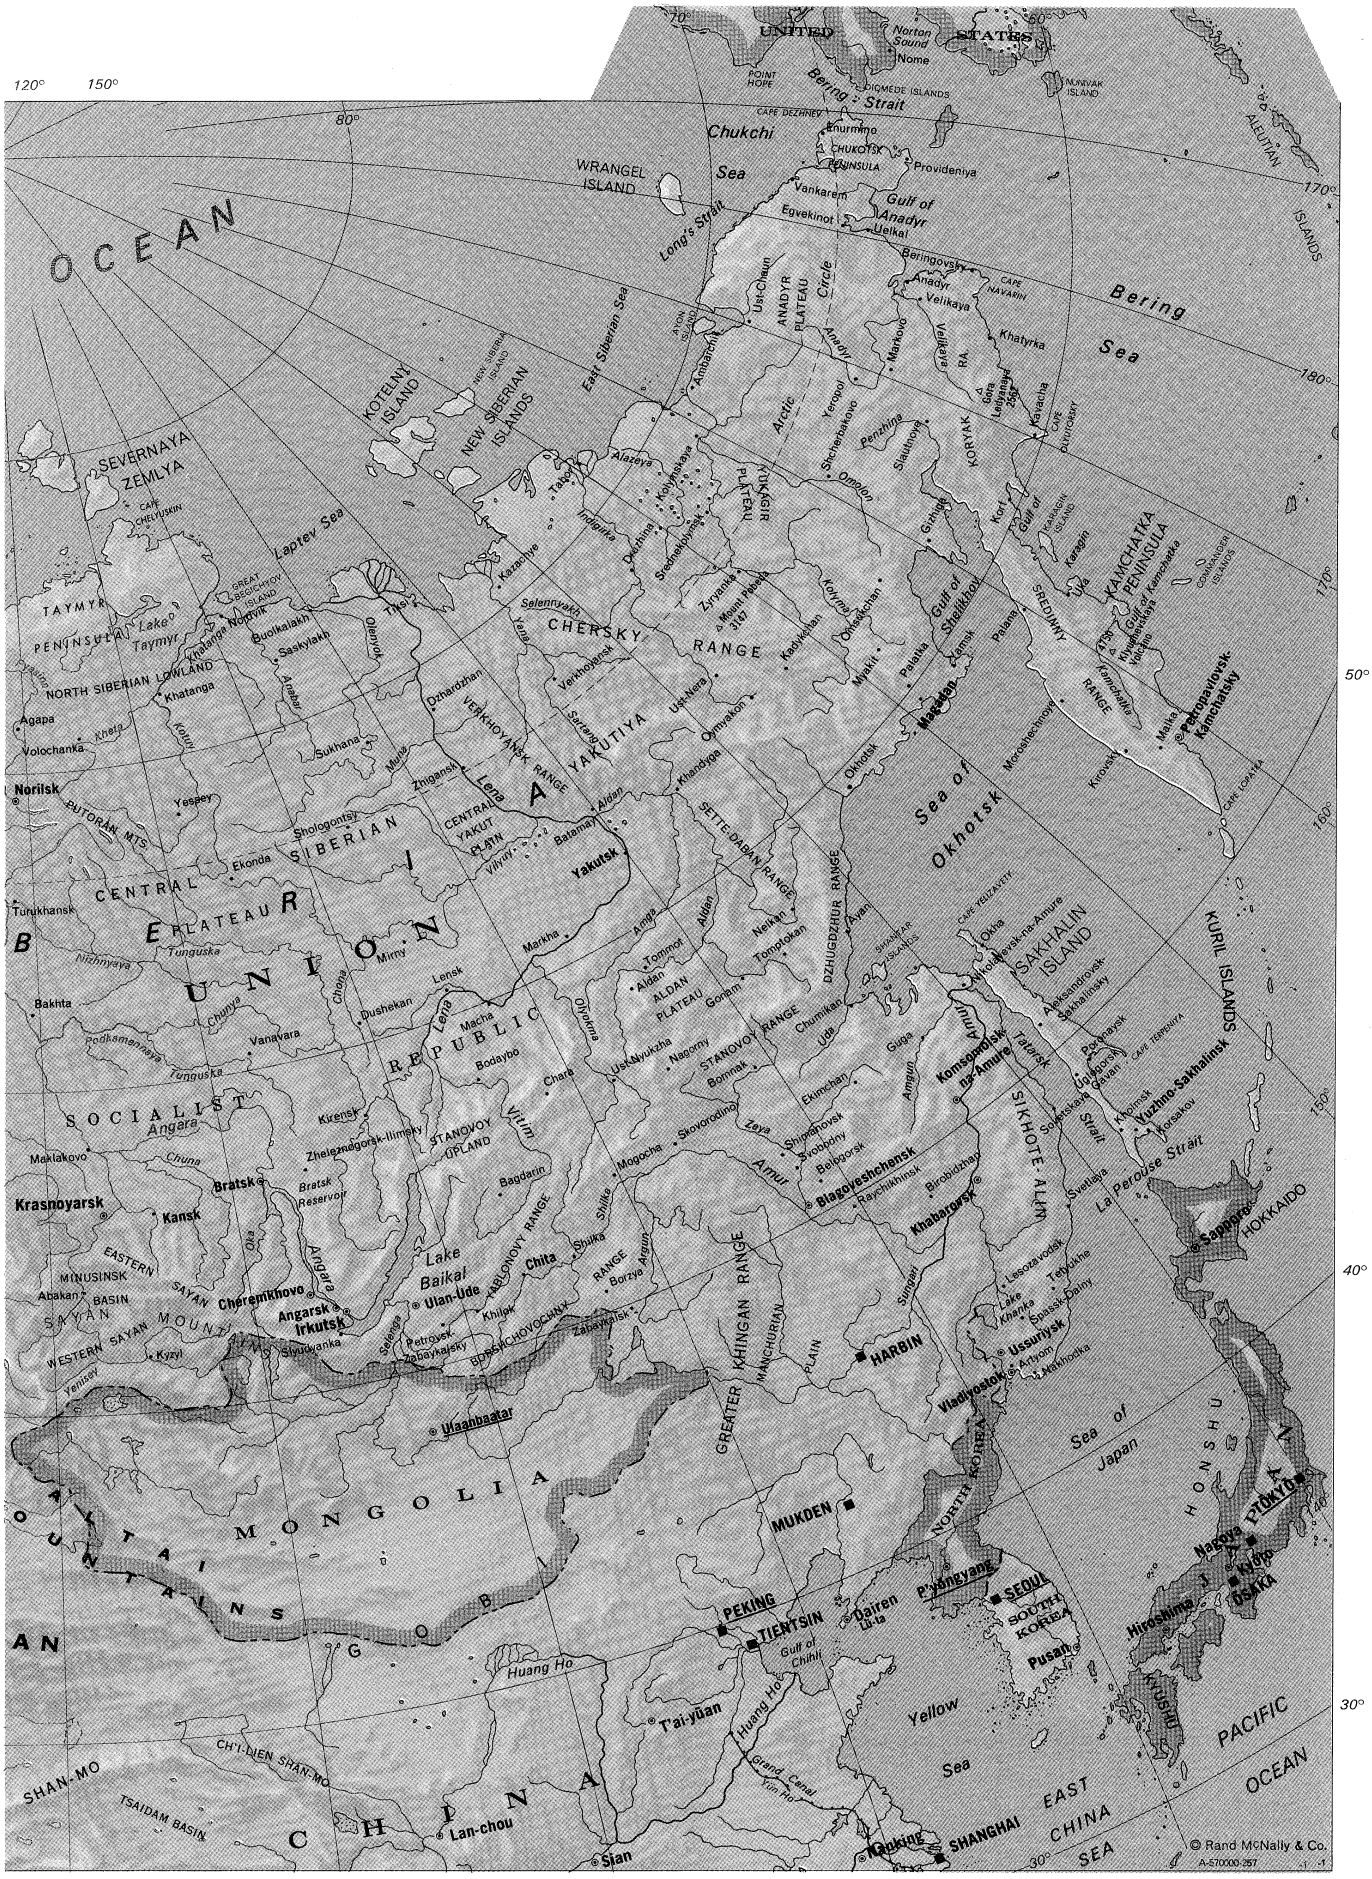


The Soviet Union was formed on December 30, 1922, and it now comprises, in addition to the 15 union republics, 20 autonomous republics, 8 autonomous regions, 10 autonomous districts, 6 territories, and 121 regions. Under the constitution adopted October 3, 1977, the political foundation of the Soviet Union is formed by the Soviets (Councils) of People's Deputies, with the Communist Party of the Soviet Union (CPSU) the "leading and guiding force of Soviet society and the nucleus of its political system." The economic foundation is "Socialist ownership of the means of production."

The varied terrain of the Soviet Union harbours a wealth of raw material, fuel, and power resources. The Soviet period has seen the accelerated development of these resources and the emergence of the country as an advanced industrial power. The proportion of the population living in cities has risen from 18 to more than 60 percent, and the population as a whole is growing at the rate of some 2,300,000 a year.

The following article offers a survey of the contemporary Soviet Union. It is divided into the following major sections and subsections:

I. The land
  The natural landscape
  The traditional regions
  Settlement patterns
II. The people
  National composition
  Social characteristics
  Demographic trends
III. The national economy
  The Soviet economy in world context
  The extent and distribution of resources
  Sources of national income
  Management of the economy
IV. Transportation
  The Soviet system in its national context
  The component systems
V. Administration and social conditions
  State and society
  The judiciary, armed forces, and public order
  The system of public organizations
  Social conditions and services
VI. Cultural life and institutions
  The cultural milieu
  The individual arts
  Cultural and educational institutions



Historical aspects are covered in the article RUSSIA AND THE SOVIET UNION, HISTORY OF; and additional historical information may be found in BALTIC STATES, HISTORY OF THE; EUROPEAN DIPLOMACY AND WARS (*c.* 1500–1914); INNER ASIA, HISTORY OF; MONGOLS; SCYTHIANS; and URARTU AND ARMENIA, HISTORY OF. Geological descriptions and information on the natural environment are also dealt with in the articles EUROPE and ASIA and in articles on the major physical features of the country (*e.g.*, VOLGA RIVER; BLACK SEA; URAL MOUNTAINS). Descriptions of the traditional cultures of the country are found in such articles as ARCTIC PEOPLES AND CULTURES and SIBERIAN CULTURES. The following article is also supplemented by separate articles on each of the union republics and on major Soviet cities. (I.V.Ko./Ed.)

I. The land

THE NATURAL LANDSCAPE

As a result of the country's enormous territorial extent, the complexity of its relief, and the wide range of climatic, drainage, and soil conditions, the natural landscapes of the Soviet Union exhibit exceptional variety.

Relief. Broad plains and depressions occupy the western half of the Soviet territory, while plateaus and mountain ranges prevail in the east; an almost continuous belt of high mountains runs along the southern border of the country. Altitudes range from the 24,590-foot (7,495-metre) Communism Peak in the Pamirs to the bottom of the Karagiye, a depression that lies 433 feet (132 metres) below sea level in the Mangyshlak Peninsula.

Range of altitudes

Plains and plateaus. The plains—subdivided into the enormous Russian (or East European), West Siberian, and Turan plains—stretch from the Baltic Sea in the west to the Yenisey River in the east and from the shores of the Arctic Ocean to the foothills of the southern Kopet-Dag Range.

The average altitude of the Russian Plain is about 560 feet, but elevations rising to 1,000–1,300 feet above sea level alternate with depressions. In the northern half of the plain, formerly covered by glaciers, the relief between the river valleys is strewn with lakes and swamps. In the south, however, watersheds are higher and cut into by valleys and ravines. The ancient wind-blown deposits known as loess are widespread and locally deep in the Ukraine and in the Don River Basin. In the northwest, near Scandinavia, the ancient uplands of Karelia and the mountains of the Kola Peninsula (maximum height 3,907 feet [1,191 metres]) abut on the Russian Plain, while in the south it is bounded by the moderately high (maximum 6,762 feet [2,061 metres]) mountain ranges of the Carpathians and the Crimea and the great barrier of the Caucasus. The last named, stretching from the Black Sea to the Caspian, rises to 18,510 feet (5,642 metres) at Mt. Elbrus. In the east, the moderate relief of the Ural Mountains extends for more than 1,200 miles (2,000 kilometres) from north to south, forming part of the traditional dividing line between Europe and Asia.

The Russian Plain

The upland ridges of the Urals also separate the Russian Plain from the West Siberian Plain, an area of monotonous, low relief and one of the largest lowlands in the world. In the south this is bounded by the Turgay Plateau and the Kazakh Uplands, which rise to a maximum of 5,134 feet (1,565 metres). South again, the Turan Plain occupies the greater part of Central Asia. Its relief is varied; troughs lying below sea level alternate with extensive low plateaus.

Between the Yenisey and Lena rivers lies the Central Siberian Plateau, mainly at heights of 1,500–3,000 feet (450–900 metres). This is bounded on the north by the North Siberian, or Khatanga, Lowland, beyond which the uplands of the Taymyr Peninsula rise to 3,760 feet (1,146 metres), while to the east, in the middle basin of the Lena, lies the Central Yakut Plain.

The mountainous belts. Regions with markedly dissected mountainous relief lie in the south and east of Soviet Asia. The highest ranges occur in the Uzbek, Tadzhik, Kirgiz, and Kazakh republics and in southwest Siberia, where the Pamir, Alai, Tien Shan, and Altai have crest lines well above 10,000 feet (3,000 metres). Numerous somewhat lower ranges, together with extensive plateaus and uplands, occupy a large area on either side of Lake Baikal. Farther east, the Stanovoy Range forms the watershed between the Aldan River, which flows toward the Arctic, and the Zeya, draining to the Pacific via the Amur. Southeast of the Stanovoy lie the mountain ranges of the South Primorye and the region around the Amur River. North from the Amur region, on the shores of the Sea of Okhotsk, stretches the Dzhugdzhur Range, and beyond it the mountains of northeast Siberia and the Chukchi Peninsula begin.

The Kamchatka Peninsula is also mountainous; it harbours a group of volcanoes, including the Klyuchevskaya Volcano, at 15,584 feet (4,750 metres) the highest summit in all Siberia and the Far East. The Kuril group of some 30 rather large and markedly rugged islands is part of the East Asian volcanic arc. In these islands are found more than 100 volcanoes, almost 30 of which are active. West of the Sea of Okhotsk, Sakhalin Island forms a major feature running north–south for more than 560 miles but with an average width of only about 60 miles.

Latitudinal climatic belts

Climate. *Regional distribution.* Latitudinal climatic belts are superimposed on the patterns of Soviet relief. The Far North, with most of its offshore islands, lies in the Arctic climatic belt; the northern European Soviet Union, Western Siberia above the Arctic Circle, and Central and Eastern Siberia between 70° and 60°–64° north latitude are in the sub-Arctic climatic belt; the remainder of Soviet Europe and Siberia, as well as Central Asia as far south as 40° north latitude, are in the temperate belt; and parts of Transcaucasia and southern Central Asia lie in the subtropics.

As most Soviet territory lies far from the oceans, the climate almost everywhere is markedly continental, with a clear division of the year into cold and warm periods. Continentality increases eastward and is especially pronounced in Central Asia and Eastern Siberia, where the average temperature difference between the warmest month (July) and coldest month (January) ranges from 45° C (81° F) to 65° C (117° F). The most westerly regions on the Black Sea coast and the south Crimean coast are much milder than the rest of the country. The southern Far East is subject to Pacific Ocean influences, having a monsoon climate.

Atmospheric circulation, temperature, and precipitation. Atmospheric circulation above Soviet territory depends upon the seasons. In winter, when there is a negative heat radiation balance (that is, the Earth's surface is losing heat), a region of high pressure known as the Asian anticyclone is formed in Inner Asia. West of it, a ridge of high pressure (the "Voyeykov axis") stretches over the northern edge of Central Asia and the southern Russian Plain. The northern half of Soviet Europe is then under the influence of recurrent Atlantic cyclones that bring west and southwest winds, relative warmth, and rain and snow. In the Far East, meanwhile—a region reached by air formed in the Asian anticyclone—the winter monsoon is under way, and cold, dry west or northwest winds prevail.

A cold continental air mass, formed as a result of the cooling of the land, nevertheless dominates the greater part of Soviet territory in winter; it is cold almost everywhere, and precipitation is relatively small. Average January temperatures along a line from the southwest to the northeast fall from 43° F (6° C) at Batumi, on the Black Sea coast, to a remarkable —58° F (—50° C) in the vicinity of Verkhoyansk, in the Far East region. The Murmansk coast, Kaluga, Volgograd, and Kyzyl-Orda, situated in widely different latitudes, have the same January mean of 14° F (—10° C). There are particularly severe January frosts (down to —85° F [—65° C] or below) in the Yakut A.S.S.R., while the absolute minimum of —90° F (—68° C) recorded at Verkhoyansk is the lowest temperature ever recorded on the Earth's surface outside Antarctica. Relief as well as anticyclonic conditions contributes to this "pole of cold" in the Verkhoyansk district; the heavier cold air lingers in hollows, which are much colder than the surrounding mountain slopes. The highest winter temperatures occur in southern Central Asia, but even here the January mean is only a few degrees above freezing.

Minimum temperatures at Verkhoyansk

In the cold half of the year up to eight to 12 inches (200 to 300 millimetres) of precipitation occurs in the Soviet west, but this decreases toward the east, falling to only two to four inches (50 to 100 millimetres) in Central Asia and Eastern Siberia. Winter precipitation falls mostly as snow, which lies for a few days in the Crimea, Transcaucasia, and Central Asia but covers the ground for 260 days or more in the Taymyr Peninsula and on the Arctic islands. The thickness of the snow cover is also uneven. In the steppes of the southern Ukraine and northern Caucasus and in the Central Asian deserts it is rarely as much as four inches. Snow cover is thin on the Baltic coast and in Belorussia, where there are frequent thaws, and also in the Volga region and Kazakhstan, where there is little winter precipitation. It generally thickens to the north and east to reach 40 inches or more on the east coast of Kamchatka.

In summer, because of the intense heating of the land surface (the radiation balance is now positive everywhere), a broad region of low pressure is formed over Asia and covers almost all Soviet territory except the southern Russian Plain, where pressure remains high. Westerly winds prevail in Soviet Europe, northerlies in Northern Siberia and in Central Asia; meanwhile, the east and southeast summer monsoon dominates the Far East. Summer air temperatures are above freezing everywhere (except in the mountains) and generally decrease toward the north; only on the northeast Pacific coast, under oceanic influence, is a fall in temperature observed from west to east. Average July temperatures in southern Central Asia are, in places, above 86° F (30° C). The absolute Soviet maximum temperature, recorded in the town of Termez in the Uzbek S.S.R., is 122° F (50° C). The central Soviet Union has considerably lower July temperatures—from 59° to 70° F (15° to 21° C)—while the Arctic coasts experience even lower readings. Conversely, the frost-free period increases from 45–60 days in the Siberian tundra to 270 days in Transcaucasia.

Maximum temperatures at Termez

Most precipitation falls in the warm half of the year; in the central Soviet Union, totals drop from 20 inches in the west to less than half that in Eastern Siberia. The heaviest rain (up to 47 inches, or about 1,200 millimetres) falls in the western Caucasus, the least (less than 4 percent of the 1,200 millimetres) in the southern Turan Plain.

Drainage. *River distribution patterns.* There are more than 150,000 rivers in the Soviet Union that are more than six miles long; their total length is about 2,000,000 miles (3,200,000 kilometres), one-sixth of which is suitable for navigation or floating logs. Soviet waterpower resources are the world's greatest. The density of the river system, however, ranges from 0.40–0.56 mile per square mile (0.25–0.35 kilometre per square kilometre) in the

European forest zone to a fraction of this amount in the deserts and semideserts of the Caspian Depression.

Arctic rivers

The majority of rivers drain to the Arctic Ocean. The largest of these northward-draining rivers are the Northern Dvina, Pechora, Ob and Irtysh, Yenisey, Khatanga, Lena, Indigirka, and Kolyma. The Pacific Ocean takes in all the Far Eastern rivers, including the Amur, Anadyr, Penzhina, and Kamchatka. The Atlantic Ocean ultimately receives the waters of the rivers that discharge into the Black Sea (the Danube, Dnestr, Dnepr, Kuban, and Rioni), the Sea of Azov (the Don), and the Baltic Sea (the Neva and the Western Dvina).

The eastern Caucasus, part of the Russian Plain, the Tien Shan, and the Pamirs, as well as the semideserts and deserts of Central Asia and Kazakhstan, comprise the extensive internal Aral–Caspian drainage region, more than 60 percent of which is drained by rivers flowing into the Caspian Sea. These are the Volga, Ural, Emba, Kura, and Kuma rivers. The Syrdarya and Amu Darya drain to the Aral Sea Basin, while many rivers in this region, such as the Ili, Chu, and Zeravshan, either end in lakes or vanish into the desert sands.

The river regimes. Climatic variety is reflected in river-flow characteristics, or regimes. The differing climatic zones offer varying sources of nourishment to the associated rivers and affect annual distribution of flow. Thus a distinction is made between rivers fed mainly by melted snow (the Volga, Don, Dnepr, Pechora, Ob, Yenisey, and Lena), by rain (the Amur), by glacier and snow melt (the high mountain rivers of the Caucasus, the Central Asian mountains, and the Altai), and by subterranean groundwaters (in the foothill regions of Central Asia).

Soviet rivers may be divided into three groups, depending on flow characteristics: those with spring high water (the most numerous); those with spring and summer high water (the rivers of the Far East, the Yana–Indigirka Basin, Transbaikalia, and the high mountains of the Caucasus and Central Asia); and those with a flood regime (the mountain rivers of the Crimea, the northern slope of the Great Caucasus, the Carpathians, and the Black Sea coast of the Caucasus). The rivers with the largest discharge are those in the Arctic Basin (three-fifths of the annual total Soviet river discharge), especially the Yenisey, which has an annual discharge of 150 cubic miles (624 cubic kilometres).

Most Soviet rivers are at times covered with ice; the period varies from eight to nine months in the Siberian north to one to two months in the extreme south.

Lakes and reservoirs. An abundance of lakes—they number about 270,000—includes five of the world's largest, each with an area exceeding 4,000 square miles (10,000 square kilometres): the Caspian and Aral seas, Lake Baikal (at 5,315 feet [1,620 metres] also the world's deepest), Lake Balkhash, and Lake Ladoga. An additional 14 lakes—including Onega and Issyk-Kul—have areas of more than 400 square miles (1,000 square kilometres). The lakes are very unevenly distributed, being particularly numerous in the regions of surplus moisture in the Soviet north and the Western Siberian steppes. In Karelia and the Lena–Vilyuy plain, they occupy more than 10 percent of the surface area, whereas in the forest–steppe of the Russian Plain they are almost nonexistent.

Largest lakes

As a rule, there is a flow of river water through the large northern lakes, while in some regions (notably Karelia and the Kola Peninsula) there are many rivers that start from lakes, run through lakes, and sometimes even end in lakes. Nonflowing lakes are scattered through the Soviet south; each lies in a hollow from which there is no water discharge, gathers atmospheric and groundwater from the whole region, and then expends it mainly by means of evaporation.

Soviet lakes also vary greatly in their content of mineral salts, and there are freshwater, brackish, and salt lakes. In Soviet Asia, especially in the Kulunda Steppe of Western Siberia, there are lakes whose water has a high sulfate content, from which chemicals are produced.

Lake temperatures are subject to sharp variations. In summer, the water in shallow lakes is intensely heated, while in the deep lakes the temperature falls with depth to a low of 39° F (4° C); in winter the water temperature rises with depth as the lower levels retain summer heat.

As a result of the construction of hydroelectric plants and navigation canals, there are many very large artificial lakes in the valleys of the major rivers. These include the Kakhovka, Kremenchug, and Kiev reservoirs on the Dnepr, Tsimlyansk on the Don, Rybinsk, Kuybyshev, and Volgograd on the Volga, Novosibirsk on the Ob, and Bratsk on the Angara. The Kayakkum, Chardzhou, and other lakes in Central Asia have been created by irrigation projects.

Groundwaters and marshes. The groundwaters of the Soviet Union are not homogeneous. In much of Soviet territory—from the tundra to the northern steppes—they have a relatively high content of calcium bicarbonate and dissolved silica and are also marked by abundant underground discharge, thus helping to feed rivers. In the dry steppes, semideserts, and deserts, groundwaters with high chloride and sulfate content are formed, which in places are unsuitable for drinking. In the loamy deserts of Central Asia the groundwaters lie at great depth and are usually bitterly salty. In the sand deserts the water lies nearer the surface and is not so mineralized. In the foothill zone of Central Asia, groundwaters are abundant and slightly mineralized.

Marshes occupy nearly 10 percent of Soviet territory, and they are an important element of the landscape in several regions. They are found mainly in the northern half of the country, in the forest and tundra zones, where precipitation exceeds evaporation. In central and northern Karelia they amount to 40–50 percent of the land surface, and they occupy nearly 80 percent in parts of the Western Siberian taiga. Farther south the marshland area falls off, and marshes are concentrated in such depressions as that called (in the West) the Pripet Marshes (in Belorussia and the Ukraine) and the Meshchera (near Moscow and Ryazan). In the forest-steppe zone, marshland diminishes sharply, and south of this zone it becomes quite insignificant; it covers about 1.5 percent of the Ukrainian steppes.

Soils. The Soviet plains are characterized by several distinct latitudinal (zonal) soil belts.

In the Arctic islands and on the Arctic coast, relatively infertile (and often permanently frozen) Arctic and tundra soils are dominant. The latter are thin, with a low organic content (1–2 percent) and coarse composition, and are boggy.

About a third of Soviet territory is covered by the soils of the forest zone. These include podzols and (in Eastern Siberia) frozen taiga soils (both developed under taiga-type forests), together with turf–podzol soils and huge areas of peat bog and gley–podzol soils, "gley" being a sticky clay formed in waterlogged soils. All varieties of podzols and podzolic soils are characterized by intense leaching, as a result of which easily soluble substances are washed out of the upper strata. The top stratum is gray or brown with 1–4 percent of humus, or organic matter. The underlying stratum is ashy ("podzol" comes from Russian *zola,* "ashes") and consists of the finest quartz sand grains; nutrient substances are completely washed out. Below this is a third layer, which in fully developed podzols has an accumulation of humus and leached mineral nutrients; in podzolic soils the humus is lacking, and in gley–podzols there is only an accumulation of clay minerals. In the extreme southwest (in Transcarpathia) and southeast (the central Amur and South Primorye) of the podzol soil zone, there appear brown forest soils, formed under broad-leaved and partially mixed forests. These are characterized by an accumulation of clay minerals and ferrous oxides, which impart the brown colour; a "clotty" structure; and a fairly well-developed humus stratum (3–7 percent).

Podzols

South of the zone of podzol and marshland soils stretches a narrow strip of gray forest soils, developed under leafy forests of the northern forest steppe. Gray forest soils have a distinctly formed stratum of humus, and there is no uninterrupted podzolic stratum.

Still farther south stretch the black-earth, or chernozem, lands, occupying 9 percent of Soviet territory and comprising almost half the world area of this soil type. Black-earth soil is formed under the grassy vegetation of the steppe and forest–steppe, in conditions of adequate warmth and a negative or near neutral balance of moisture. This prevents intense leaching and assists the accumulation of organic substances. In addition, meadow–black-earth soil is also widespread in the steppes. The greater part of the black-earth belt is now under the plow.

In the dry steppes and semideserts of the southeast Russian Plain and of Kazakhstan are found chestnut soils, marked by a rather low humus content, a tendency toward saltiness, and a feeble structure. The meadow–chestnut soils are formed in hollows and estuaries in conditions of heightened surface or ground moisture.

Continuing the southward succession, chestnut soils give way to other semidesert types and then, in the deserts themselves, to brownish-gray and gray-earth soils (sierozems). These are all very poor in humus and are often salty (solonetz and solonchak) and are broken by extensive salt marshes. A unique type of desert soil is the *takyr,* a clay soil found in depressions, which creates impassable mud during rain and a brick-hard crust in dry periods. These soils are so barren that they are often devoid of all vegetation except meagre lichens.

Red-earth soils

Red-earth soils in their typical form are found only on the lower mountain slopes of the Kolkhida plain (in the Caucasus). These, the most ancient of Soviet soils, are soils of humid subtropical forests, very thick, and rich in iron and aluminum oxides. Abkhaziya and the Talish Mountains are the sites of other humid subtropical forest soils, the yellow-earth soils, distinguished from the red-earth by their paler yellow tint and their inconsiderable depth. In addition to the typical gray-earth soils, brown soils are widespread in the dry subtropics, notably on the slopes of the mountains of Central Asia and the Caucasus, being found under low-growing, broad-leaved forests, sparse forests, and thickets.

Finally, in the mountain regions, comprising 31 percent of Soviet territory, the soils form a series of vertical belts. A particularly full selection of high-altitude soil belts is represented in the Caucasus, where the soils vary from black-earth to mountain pasture, subalpine, and alpine. The mountain soils are stony, well drained, and not very thick. The alluvial soils of the river floodplains also should be mentioned, because they are the youngest of Soviet soils, still being formed.

Vegetation. About 17,000 plant species and almost half of all the families of higher plants known in the world are found in the Soviet Union, which lies entirely in the area known to botanists as the Boreal kingdom. The vast Soviet plains are characterized (as in the case of soils) by clearly marked latitudinal vegetation zones. Successively, these are Arctic waste, tundra, forest–tundra, forest, forest–steppe, steppe, semidesert, and desert.

The latitudinal belts. The Arctic wastes include most of the Arctic islands and the north coast of the Taymyr Peninsula; mosses, lichens, and a variety of grasses cover scarcely half of the soil surface.

The tundra zone—divided into subzones of Arctic, moss–lichen, and scrub tundra—stretches in a continuous belt along the northern border of Eurasia, including some Arctic islands and the Commander Islands of the Pacific.

To the south lies the zone of forest–tundra, in which the barren tundra landscapes alternate with marshes and sparse forests of birch and fir (in the west) and larch (in the east).

The forest zone

Farther south stretches the broad belt of the forest zone, extending from the western borders of the country to the Pacific coast. Coniferous taiga forests of fir, pine, silver fir, cedar, and Siberian larch are most widespread to the west of the Yenisey River, while in Central and Eastern Siberia the forests are predominantly of larch. Marshes are very common, especially in the taiga of Western Siberia, and various types of meadows are also found.

Large areas of birch and aspen groves, growing on the site of former coniferous forests destroyed by felling or fire, are common in the southern taiga of the Russian Plain and in the West Siberian Plain; they do not last long, because shoots of conifers gradually appear under their canopy and choke the young trees. Mixed (coniferous and broad-leaved) and broad-leaved forests occur in the southern half of the Russian Plain forest zone. Unlike the conifers, the broad-leaved forests have many tiers, the uppermost usually consisting of crowns of oak, lime, ash, and maple. Below these come bird cherry and mountain ash, then a thick, shrubby undergrowth, perhaps of hazel; the whole is underlain by grass. Beech and hornbeam appear in broad-leaved forests in the southwest of the zone. Mixed forests are also widespread in the southern Far East, where most of the conifers are pine or whole-leaf silver fir, and common broad-leaved trees include oak, Amur linden, maple, and hazelnut. The depressions and lower mountain slopes are covered with broad-leaved forests of oak with a striking admixture of black birch.

The forest–steppe zone extends in a narrow latitudinal belt across the Russian Plain and the West Siberian Plain. Meadow steppe with various grasses alternates with small areas of oak (in Soviet Europe) or birch and aspen (in Western Siberia). Farther east, forest–steppe is encountered only as isolated islands in taiga forests.

To the south, forest–steppe gives way to mixed-grass and grassy steppe, and the forests remain only along river valleys and ravines. The herbaceous covering of the grassy steppes consists of needlegrass (*Stipa* sp.) and such other perennial turf grasses as fescue.

Farther south lies a semidesert zone extending in a continuous belt from the Yergeni hills (in the southeast of the Russian Plain) to the mountain systems of the Altai and Tien Shan. Grasses that like dryness (such as *Stipa rubens* and fescue) and semishrubs (such as saltwort and wormwood) predominate in the thin, patchy, vegetation covering.

The desert zone

Finally, the southernmost desert zone occupies the southern third of the Caspian Depression and the Central Asian plain. It is distinguished by a very sparse and poor covering of vegetation, composed of saltwort, wormwood, and grasses. Saltwort (*Salsola richteri*) and sand acacia are found in relatively light sandy soils and in river valleys. An abundance of ephemeral plants is typical of the southern part of the zone, where sand deserts, notably the Kara-Kum and Kyzylkum, predominate; in addition *Haloxylon* "forests" are common, alternating with salt-marsh wastes overgrown with saltwort.

The subtropical, Mediterranean, and mountain regions. The humid subtropics of the Kolkhida and Lenkoran depressions have a unique vegetation as well as soils; they are clothed in dense broad-leaved forests that include oak, beech, hornbeam, chestnut, and alder, with an undergrowth of evergreen plants and lianas.

Vegetation of the Mediterranean type makes a strong showing on the Black Sea coast. Forests of oak, juniper, and pine are common.

In mountainous regions, vegetation is distributed in altitudinal belts, particularly in the Caucasus, the Carpathians, and the mountains of the Primorye. Thus the steppes of the foothills of the northern Caucasus give way to mountain forest–steppe, broad-leaved forests of oak and beech, and then pine (in the west) and fir (in the east). Above the forest belt lie sparse high mountain forests, thickets of rhododendron, and subalpine and alpine meadows. In arid regions the middle mountain belt of vegetation is in some places composed of turf-grass steppes, related thickets, and sparse juniper forests. High mountain steppe and meadow are widespread in Central Asia, with turf-grass steppe giving way to areas of dark coniferous forests of spruce or to mixtures of steppe, meadow, shrub thickets, and sparse juniper forests. Coniferous taiga forests cover the Siberian mountains, with tundra above; the higher Altai, however, exhibits subalpine and alpine meadows.

Animal life. The Soviet Union lies entirely in what zoologists call the Palaearctic subregion of the Holarctic

faunal region, in which animal life is characterized by five distinct sectors of varying size and natural conditions.

The Arctic sector embraces both Arctic and tundra landscape zones. The Arctic zone (the islands and the mainland seacoasts) is poor in animal species; such mammals and birds connected with the sea as the polar bear, sea hare, seal, walrus, eider, gull, and loon are found. In summer the coastal rocks are covered with nesting colonies of seabirds. The tundra is inhabited by animals adapted to cold climate and open spaces that are under snow for long periods. They include the Arctic fox, reindeer, alpine hare, lemming, and—among its birds—ptarmigan and snowy owl. Geese, swans, and ducks migrate into the region in summer. Lizards, frogs, and other reptiles and amphibians are found only in the extreme southwest of the zone and in the forest–tundra.

The European–Siberian forest sector (covering the Russian Plain, Siberia, and much of the Far East) possesses a much richer and more varied animal life. The northern taiga harbours elk, brown bear, reindeer, lynx, sable, and alpine hare, with such birds as the crossbill, nutcracker, cuckoo, owl, and woodpecker. There are few reptiles or amphibians. Representative fauna of the broad-leaved forests are wild pig, deer, and mink, and the most typical birds are the hawfinch, oriole, owl, and nightingale. Various snakes, lizards, and tortoises are the common reptiles.

The steppe environment

In the steppes, the abundance of plant food allows such rodents as the marmot, jerboa, and hamster to predominate. Birds include the kestrel, crane, eagle, and lark; hooved animals include the occasional steppe antelope; the masked (or steppe) polecat and Tartar fox represent beasts of prey. There are few amphibians but more reptiles than in the north.

Animal life in the Mediterranean sector, found in the Caucasus and mountainous Crimea, is very varied as a result of the great landscape variety and also of the fact that the fauna was originally connected with that of the Mediterranean, Central Asia, and south and southeast Europe. The Caucasus harbours the wild goat, bison, chamois, bezoar goat, Caucasian deer, wild pig, porcupine, leopard, hyena, jackal, Persian squirrel, brown bear, and roe deer. Birds include species characteristic of both mountain (Caucasian black grouse, turkey, and stone partridge) and forest (nuthatch, jay, crossbill, woodpecker, and bullfinch). Reptiles and amphibians are numerous, ranging from cobra to tortoise.

The semideserts and deserts of Central Asia and Kazakhstan form the Central Asian sector, whose animals are specially adapted for existence in conditions of high summer and low winter temperatures, lack of water, and poor vegetation. Many of them are nocturnal. Typical desert dwellers are the Persian gazelle, sand cat, sand eel, and ground squirrel; birds include the bustard, pheasant, raven, and sparrow. Spiders, including tarantulas, are also present. Several northern forest species are widespread in the eastern part of the Tien Shan; the Kopet-Dag harbours fauna of the fore-Asian type (leopard, stone marten, partridge, and others); and the remaining part of the mountains is inhabited by animals of Central Asian and even (in insignificant measure) Indian origin: the argali (a wild sheep), snow leopard, wild goat, red wolf, bear, turkey, and others.

(V.M.St./J.C.D.)

THE TRADITIONAL REGIONS

Traditional names for large sections of the Soviet Union, such as the North, Western Siberia, and the Far East, are well established. Some of these names have been applied to the present-day official economic regions into which the country is divided for planning purposes, but the traditional regional divisions do not constitute natural or economic entities; it would be more correct to define them as natural historic regions, differing in both their geography and their economy and also in the density and composition of their populations. Their borders are quite arbitrary, following sometimes natural and sometimes administrative boundaries.

The traditional regions of the European Soviet Union are the North (or European North), Centre, Volga Lands, West, Southwest, and Urals. The Caucasus is a distinctive region abutting the European Soviet Union on the south. The Asian part includes Central Asia and Kazakhstan, which occupy the vast area south of Western Siberia and east of the Caspian Sea; the huge territory of Siberia, traditionally subdivided into Western Siberia and Eastern Siberia; and the Far East.

The North. The European North (also long known as the Russian North and equivalent to the present-day Northwestern economic region) corresponds closely to the ancient lands of Novgorod and covers a much greater area than the other European Soviet regions. Bordered by Finland on the west and the Urals on the east, it comprises the northern slopes of the Russian (or East European) Plain, running toward the Arctic Ocean and to the Gulf of Finland of the Baltic Sea. It also includes such major Arctic islands as Novaya Zemlya and the Arctic archipelago Franz Josef Land. Administratively, the North lies within the Russian Soviet Federated Socialist Republic and is composed of the Arkhangelsk, Leningrad, Murmansk, Novgorod, Pskov, and Vologda *oblasti* (regions) and the Karelian and Komi Autonomous Soviet Socialist republics. It covers some 640,000 square miles (1,660,000 square kilometres)—about one-third of Soviet Europe—and is the home of nearly 13,000,000 people, mainly Russians, with Komis (or Zyryans), Karelians, and Nenets (or Yuraks) leading the minority nationalities.

Regions of the North

The physical geography of such a huge area is naturally varied. The main overall character, however, is molded by forest and sea; the whole landscape is marked by a northern severity, and transitions are generally gradual.

A characteristic feature is the extremely uneven distribution of population and economic development. The east and north consist of taiga and swampy tundra and are thinly populated; settlement is concentrated principally in valleys of the main rivers, the Northern Dvina and Pechora. The most important resources here are timber, petroleum, and coal in the northeast and various minerals in the Kola Peninsula. The largest cities are Arkhangelsk, the country's oldest timber port and a centre of industry, and Murmansk, a major ice-free port and fishing centre.

In the southwest, conditions are less severe, and settlement was already quite dense in early times, for here such old Russian cities as Novgorod arose, as the economy developed. Here, too, is Leningrad, the second Soviet city in population and economic importance and one of the largest cultural and scientific centres.

The European North today is one of the Soviet Union's most important industrial regions and the main base of the timber industry.

The Centre. Central Russia (all of it within the Russian S.F.S.R.), with an area of 350,000 square miles (900,000 square kilometres) and a population of 44,500,000, occupies the whole central belt of the Russian Plain as far south as the Ukraine and from Belorussia eastward to the Volga Lands. Low hills alternate with broad lowlands, and the greater portion lies in a forest zone (taiga in the north, mixed and then broad-leaved forests farther south). The far south is in fact in the forest–steppe zone, noted for its black-earth soil; fields of wheat, sugar beets, and sunflowers occupy the open expanses.

The Russian nucleus

Ever since the formation of the Russian state in the 15th century, central Russia, as the nucleus of that state and the hearth of Russian national culture, has played a primary role in national growth. More than 17 percent of the Soviet population is concentrated here, in little more than 4 percent of the national area. Its proportionate share of industrial production, of scientific manpower, and of the training for the professions generally is even greater.

There are three distinct economic subregions: the Central Industrial region, the Black-Earth Belt, and the Volga–Vyatka region.

The Central Industrial region. This subregion (called the Central region in the official economic classifica-

tion and composed of Bryansk, Ivanov, Kalinin, Kaluga, Kostroma, Moscow, Oryol, Ryazan, Smolensk, Tula, Vladimir, and Yaroslavl *oblasti* and the city of Moscow) stands out sharply for its level of economic development; 28,400,000 persons (more than 11 percent of the Soviet total) make their homes here, in but 2 percent of the national territory. The region produces more than half the country's textiles and a large percentage of the total output of, among others, the products of engineering and chemistry. Among the urban centres (which contain 76 percent of the population), Moscow, the Soviet capital and leading political, industrial, scientific, and cultural centre, is of exceptional importance. Here the natural scenery has charm and variety deriving from its undulating expanses, the bright, neat birch groves, and the broad valleys of deep rivers on whose banks communities of various sizes lie amid meadows and copses.

The Black-Earth Belt. To the south, abutting the Ukraine, lies the Black-Earth Belt (officially the Central-Black Earth region and including the Belgorod, Kursk, Lipetsk, Tambov, and Voronezh *oblasti*), the home of 7,800,000 people and notable both for its extremely fertile black-earth (chernozem) soil and for the unique iron-ore deposits of the Kursk Magnetic Anomaly. The landscape has many features of the transition from northern forest to southern steppe; it is lent character by fields, oak groves, and villages strung out along river valleys and ravines or occupying flat watersheds. With only 0.75 percent of the country's area, this region nevertheless provides 6 percent of its agricultural produce and is of growing industrial significance. The largest town is Voronezh, and nearly half the population is urban.

The Volga–Vyatka region. This region (its name is the same in the official classification) occupies the eastern part of central Russia, covering the Gorky and Kirov *oblasti* and the Chuvash, Mari, and Mordvinian A.S.S.R.'s. It is the home of about 8,300,000 people. The regional landscape is given character by its great rivers, the Volga and its tributary the Vyatka. Steep river banks, wide bands of water, and water meadows lend variety to the plains. Here the Volga flows from west to east along the boundary of the forest and forest–steppe zones. On its precipitous right bank rise the "mountains," as the local people say, while on its left bank, beyond the water meadows, stretch forested lowlands. This area was often celebrated in the works of Aleksandr Herzen and Maksim Gorky, who were born there. The Volga–Vyatka region is known as the land of forests and factories. Timber is its principal natural wealth, but industry (particularly engineering) accounts for the greater part of economic output. More than 60 percent of the population is urban, and the largest industrial centre is Gorky.

The Upper Volga landscape

The Volga Lands. Near Kazan the Volga sharply changes direction to flow southward. Here the Tatar, Kalmyk, and Bashkir A.S.S.R.'s, together with six *oblasti* of the Russian S.F.S.R., form the Volga Lands, called the Povolzhye region officially. With an area of some 260,000 square miles (680,000 square kilometres) it is the home of about 19,100,000 people, approximately 7.5 percent of the Soviet total.

Stretching a thousand miles from north to south, the region extends across a series of natural landscape zones from the southern fringe of the forest zone to the semi-desert bordering the northern Caspian. Its principal natural resources are fertile land, pastures, the country's most important oil fields, and, not least, two rivers, the Volga and its tributary the Kama. As the largest waterway and the most important source of hydropower in Soviet Europe, the Volga is of enormous economic importance, and, with the building of hydroelectric stations at Kuybyshev, Saratov, and Volgograd, the Volga Lands have become the principal link in the Soviet unified power grid. After World War II the area became the country's main oil base and the main centre of the chemical industry. Agriculture, too, is important; the Volga Lands provide more grain than any other region of the Russian S.F.S.R., and Saratov wheat is among the best in the country. At the same time the region is one of the Soviet Union's main suppliers of meat, wool, vegetables, and melons. The curse of agriculture here is drought and dry winds, but the area of irrigated lands increases every year.

The Lower Volga landscape

More than two-thirds of the population is urbanized; the largest towns and industrial centres are Kazan, Kuybyshev, Saratov, and Volgograd (formerly Stalingrad).

The West. Composed of Belorussia, Moldavia, the three Baltic republics (Estonia, Latvia, and Lithuania), and the Kaliningrad *oblast* of the Russian S.F.S.R., the West occupies an area of more than 166,000 square miles (430,000 square kilometres) and contains more than 21,000,000 people (about 8 percent of the national total). Of these, about 7,500,000 are Belorussians, 2,300,000 Moldavians, 2,500,000 Lithuanians, 1,300,000 Latvians, and 900,000 Estonians. There are also about 3,200,000 Russians and nearly 700,000 Poles. The five union republics have vigorous national traditions.

The natural features here are lent character by the residual influence of ancient glaciers; the climate is relatively mild and humid, and many forests, especially pine forests, flourish on the sandy soil. Southwest Belorussia contains the world's oldest nature reserve, the Belovezhskaya (Belavezhskaya) Pushcha. The morainic ridges of residual glacial debris lend variety to the landscape, which changes imperceptibly every few miles from plain to hilly country, woods alternating with fields, meadows with marshes. Rivers connect hundreds of scattered lakes. In the Baltic republics a special element is introduced by the ruins of medieval castles that are often found on high ground, while the Baltic coastal resorts are very popular.

Effects of ancient glaciers on the landscape

The region as a whole embraces three major economic regions: the Baltic region (Estonia, Latvia, Lithuania, and the Kaliningrad *oblast*), Belorussia, and Moldavia. Fishing is highly developed (the Baltic republics provide more than 20 percent of the total national catch), as is engineering. Agriculture, specializing in raising livestock, is noted for its butter and bacon. The main type of fuel produced in Belorussia is peat, together with small quantities of oil, natural gas, and lignite. Belorussia also produces about 20 percent of Soviet flax and almost a third of its potassium fertilizers and is the main source of heavy trucks and tractors. Only about 54 percent of the population of the West is urban, figures for individual republics ranging from 37 percent in Moldavia to 66 percent in Latvia and 68 percent in Estonia. The biggest urban centres are the republic capitals—Minsk, Kishinyov, Riga, Vilnius, and Tallinn—and Kaunas and Kaliningrad (formerly Königsberg).

The Southwest. Covering an area of 233,000 square miles (604,000 square kilometres), the Southwest is coterminous with the Ukrainian S.S.R. (though in some classifications the region includes also Moldavia and the Rostov *oblast* of the R.S.F.S.R.). In the official Soviet pattern of economic regions, the Ukraine is divided into the Donets–Dnepr, Southwestern, and Southern regions. The Black Sea and the Sea of Azov are on the south, and it is through their ports that the Soviet Union maintains its trade with Asia, America, and southern Europe. The southern coast of the Crimean Peninsula and the area around Odessa are noted for their holiday resorts.

Forest–steppe and steppe occupy the greater part of the land area; both (but especially the latter) possess the fertile black-earth soil, which has attracted dense settlement from ancient times. The soils are almost entirely plowed to such crops as wheat, maize (corn), sugar beets, and sunflowers. There are also many orchards and vineyards there, especially in the Crimea, the southern coast of which forms the northern fringe of the subtropical zone.

Topographically, the Southwest is predominantly a plain (though the western Ukraine contains a portion of the Carpathians, and the Crimean Mountains rise in the south). The plain is divided into right bank and left bank regions by the Dnepr, the republic's largest river, as it flows south to the Black Sea.

Mineral resources of the Southwest

The Ukraine is rich in coal (the largest coalfield being the Donets Basin, or Donbass, which extends into the

adjacent Rostov *oblast* of the R.S.F.S.R.), iron ore (the Krivoy Rog and Kerch deposits), manganese (the largest deposit in the world is at Nikopol), natural gas, and other mineral resources. Hydropower is also significant, chiefly on the Dnepr.

Covering but 3 percent of Soviet territory, the Southwest contains more than 49,000,000 persons, or 19 percent of the national total. Of the region's population, 68 percent lives in urban areas, the proportion rising eastward from 35–40 percent in the western Ukraine to 67 percent in the eastern Ukraine. The largest Ukrainian cities are Kiev (the capital of the republic), Kharkov, Odessa, Dnepropetrovsk, and Donetsk. There are more than a dozen other cities with populations over 250,000, most of them in the Donets–Dnepr industrial zone.

The Urals. The Urals region contains the mountains that give it its name. These run southward from the Arctic shores to form the traditional boundary between Europe and Asia. The name is also given to the economic region. The region includes the Udmurt A.S.S.R. and five *oblasti* of the R.S.F.S.R., a total area of 260,000 square miles (680,000 square kilometres).

Divisions of the Urals

The Ural Mountains themselves consist of many medium ridges and rises, covered with forest. Customarily divided into the Polar, Nether-Polar, Northern, Central, and Southern Urals, they rise to a high point of 6,214 feet (1,894 metres). Natural features of the mountain region and the adjacent plains are unusually varied. The tundra and "alpine" peaks of the Polar and Nether-Polar Urals give way to the rolling taiga plains of the Northern Urals, while the fertile plowed steppes of the Central and Southern Urals are succeeded by the lake-dotted forest plains of the far (Siberian) side. The region is rich in minerals, notably metallic ores and precious and semiprecious stones. The Urals region has long played an outstanding role in the Russian economy because of its mineral wealth. In its industrial development it is surpassed only by central Russia and the Ukraine; it produces just under one-third of all Soviet iron, steel, and rolled steel. It is also a major petroleum-producing region and a base for the industrialization of the Soviet eastern regions.

The Central and Southern Urals are urbanized (65 percent of the total population) and contain such major industrial cities as Sverdlovsk and Chelyabinsk, metallurgical and chemical centres such as Magnitogorsk and Perm, and many settlements by mines, factories, and power stations. At the same time, old timber villages are to be found in the heart of the mountains. More than 15,000,000 persons, four-fifths of them Russians, live in the Urals, and there are many minority nationality groups, ranging from Tatars to the oldest inhabitants, the Komi-Permyaks.

The Caucasus. The Caucasus is the isthmus between the Black Sea and the Sea of Azov in the west and the Caspian Sea in the east. The northern boundary is the Kuma-Manych Depression, while the southern is the frontier with Turkey and Iran. The region is subdivided into the North Caucasus (predominantly plain), the Great Caucasus range, and Transcaucasia, containing the Kolkhida and Kura-Araks lowlands, the mountains of the Little Caucasus, and the Armenian Highland. The Caucasus is often alternatively divided (as it is in the formal Soviet classification of economic regions) into only two parts, the North Caucasus and Transcaucasia; the whole Caucasian sector of the Russian S.F.S.R. is included in the former, while Transcaucasia takes in the Georgian, Azerbaijan, and Armenian S.S.R.'s.

Extremes of the Caucasus landscape

The natural conditions of this comparatively small region (about 209,000 square miles [541,000 square kilometres]) are exceptionally varied, for it contains fertile steppe plains and high mountains covered with glaciers and snow (the highest point is Mt. Elbrus, at 18,510 feet [5,642 metres]); the hot and humid lowlands of Kolkhida and the dry steppes of the Kura-Araks; lava plateaus, alpine pastures, and forests on the mountain slopes of the humid west.

The Great Caucasus is an important natural boundary. North of it stretches the temperate zone of the Russian Plain, and to the south lie subtropical zones. A wide range of crops is cultivated.

The Caucasus has various minerals, notably petroleum, gas, copper, and manganese, which have contributed to the development of industry in several parts of the region. At the same time, the Caucasus is the main Soviet resort area, boasting a mild climate, warm seas, muds believed to be curative, and, most important of all, numerous mineral springs. The latter support such spas as Kavkazskiye and Mineralnye Vody in the northern foothills of the Great Caucasus, near which are the major resort towns of Kislovodsk, Yessentuki, Pyatigorsk, and Zheleznovodsk. On the Black Sea coast are numerous health and holiday resorts, of which Sochi is the largest in the Soviet Union. The Caucasus—especially around Mt. Elbrus—is also a major centre for hiking and mountaineering.

About 29,000,000 persons live in the Caucasus, and the region is unrivalled in the Soviet Union for the number of its nationalities; the Dagestan A.S.S.R. alone has at least 20 ethnic groups.

More than half the total population lives in cities, the largest of which are Baku, Tbilisi, and Yerevan, the capitals, respectively, of the Azerbaijan, Georgian, and Armenian S.S.R.'s. At the time of the 1970 census, there were 21 cities with populations of more than 100,000 and 19 with populations between 50,000 and 100,000.

The Caucasus is the home of the most ancient cultures in the Soviet Union. Numerous architectural monuments of past centuries are found, and the ruins of temples and fortresses witness to the distant past. As a consequence of this great age and the region's ethnic diversity, several distinctive local cultures may be distinguished.

Central Asia and Kazakhstan. In the heart of Eurasia, stretching from the Caspian eastward to the Altai and from the Urals and Western Siberia southward to the frontiers with Iran, Afghanistan, and China, the region known as Central Asia and Kazakhstan covers 1,550,000 square miles (4,000,000 square kilometres). This is the Soviet Union's hottest and driest region, full of striking contrasts: immense plains, with desert and semidesert depressions below sea level; very high mountains permanently covered with snow and ice; and thickly populated oases surrounded by empty deserts.

Desert and semidesert

All the Soviet deserts and almost all the semideserts (occupying in all about one-seventh of the national area) are found here. To the south and east, the desert expanses are bordered by mountain ranges, culminating in the Pamirs and the Tien Shan. To the north of the desert belt, low hills and isolated mountain ridges—the Kazakh Uplands—extend for hundreds of miles in central Kazakhstan. Many of the hills are covered with pine forests, while semideserts predominate in the depressions. North again stretches the West Siberian Plain; the north Kazakhstan portion is a zone of forest–steppe and steppe, with black-earth and dark chestnut soils.

Central Asia. In the political, administrative, and economic sense (and in terms of natural history), the term Central Asia embraces the four Central Asian republics—Uzbekistan (including the Kara-Kalpak A.S.S.R.), Turkmenistan, Tadzhikistan, and Kirgiziya. These republics cover almost 6 percent of the total Soviet area, and their 23,500,000 people represent 9 percent of the total population. Apart from the four nationalities for which the union republics are named, Central Asia is now the home of Russians, Ukrainians, Tatars, Kazakhs, Uighurs, and other people who have settled there at various times.

Settlement in the Central Asian republics is almost entirely concentrated where irrigation potential is high, in a narrow belt between the desert plains and the mountains and also in the valleys of the major rivers. The rivers of Central Asia not only irrigate the fields (the area contains more than half of all Soviet irrigated land) but also, with 15 percent of national hydroelectric resources, serve as an important source of power. Oasis agriculture specializes in fruit, grapes, silk, vegetables, rice, and cotton and other fibre crops. Central Asia provides nine-tenths of the cotton grown in the Soviet Union, 70 percent of its dried fruit, and 60 percent of its raw silk. The deserts and

mountains are areas of natural pasture for sheep and lesser numbers of cattle, horses, camels, and—in the Pamirs—yaks. Central Asia is of importance as a supplier of petroleum, natural gas, mercury, antimony, iodine, bromine, and gold and rare metals. Engineering is mainly directed to the production of cotton-picking and textile machinery and oil and chemical equipment.

Cities of the Central Asian region

The largest cities and industrial centres are the capitals of the union republics—Tashkent, Frunze, Dushanbe, and Ashkhabad—and also the oldest city of Central Asia, Samarkand, which was an important place in the 4th century BC. These ancient lands are replete with traces of the great civilizations of the past and cherish distinctive contemporary ways of life.

Kazakhstan. Lying to the north of the Central Asian republics, the Kazakh S.S.R., with an area of 1,050,000 square miles (2,700,000 square kilometres), is the second largest union republic and ranks third in population (14,300,000). Situated between the Urals, Siberia, and Central Asia, Kazakhstan finds much of its geographical and economic character molded by those of its neighbours; cold Siberia and hot Central Asia, forest and desert, broad plains and great mountain ranges meet, as it were, in Kazakhstan. It also contains important deposits of iron, copper, lead, zinc, and rarer minerals, as well as coal, oil, phosphorites, and rare metals. Industry dominates the republic's economy, but its agricultural importance increased greatly during the 1950s, when nearly 100,000,000 acres (40,000,000 hectares) were brought into cultivation in north Kazakhstan and southwest Siberia under the Virgin and Idle Lands Campaign. As a result, Kazakhstan now produces more cereals than the Ukraine, ranking second only to the R.S.F.S.R. in this respect.

The indigenous people, the Kazakhs, constitute only about a third of the republican total; Kazakhstan is also the home of representatives of almost all the major peoples of the Soviet Union, including Russians (42 percent of the republic's population), Ukrainians, Germans (deported from the Soviet west in 1941), Tatars, Uzbeks, Belorussians, Uighurs, Dungans, Koreans, and others. About 54 percent of the population lives in towns and cities, of which the largest are the capital, Alma-Ata, and the industrial centre of Karaganda.

Siberia. Siberia (all of which is part of the Russian S.F.S.R.), the giant among Soviet regions, stretches 4,300 miles (7,000 kilometres) from the Urals in the west to the mountain ranges of the Pacific watershed in the east; from north to south it extends 2,200 miles (3,500 kilometres) from the shores of the Arctic Ocean to the dry steppes of Kazakhstan and the Mongolian frontier. It occupies an area of 2,500,000 square miles (6,550,000 square kilometres), or 30 percent of all Soviet territory. Siberia lies in the Arctic, sub-Arctic, and temperate climatic belts, and its climate is sharply continental. The outlying northern parts of the region are covered by tundra and forest–tundra, with the taiga zone occupying the greater part. In the south there are zones of forest–steppe and steppe, and it is here that settlement is thickest.

Economic resources of Siberia

Siberia contains up to 90 percent of Soviet coal resources, petroleum, about half the natural gas, 70 percent of the peat, and deposits of iron and polymetallic ores and minerals. Siberia has more than 50 percent of all Soviet hydropower resources, more than two-thirds of its timber, and 230,000 square miles (600,000 square kilometres) of arable and pasture lands. Its forests contain a wealth of furbearing animals.

Just over 20,000,000 people live in this vast area, which accounts for about 8 percent of the Soviet Union's total industrial output, 15 percent of its electricity, and 25 percent of its timber. With each five-year plan the population increases, new towns are built, and production expands. The overwhelming majority of the people are Russians, who began to settle among the Ostyaks (Khants), Voguls (Mansis), Evenks, Buryats, Yakuts, Khakass, and other indigenous peoples in the late 16th century. There are several autonomous *oblasti* (regions) and autonomous (formerly national) *okruga* (districts) in which one of these peoples constitutes the chief element in the population.

Western Siberia. Western and Eastern Siberia—separated by the Yenisey River—may be differentiated (as they are in the official Soviet economic regional scheme) in respect of their physical geography and their degree of economic development. Three-fifths of Siberia's people live in the predominantly flat lands of Western Siberia (the West Siberian Plain), which cover 940,000 square miles (2,400,000 square kilometres). The greater part of Siberia's industrial and agricultural output comes from this region, the most important cities of which are Novosibirsk, Omsk, Novokuznetsk, and Barnaul.

Eastern Siberia. Eastern Siberia is predominantly plateau and mountain. It constitutes 18 percent of the Soviet total area, and only 8,000,000 people live there. It provides the country with diamonds, gold, aluminum, nickel, and other minerals, and its forests supply timber and furs. The world's largest hydropower stations are found on the Eastern Siberian rivers. The most important towns are Krasnoyarsk and Irkutsk.

The Far East. The Soviet Far East (which in some classifications is considered part of Siberia) stretches for 2,700 miles (4,300 kilometres) along the Pacific coast. It is composed of seven administrative entities: the Yakut A.S.S.R., the Primorye and Khabarovsk *kraya* (territories), and the Amur, Kamchatka, Magadan, and Sakhalin *oblasti*. Its area is 2,400,000 square miles (6,200,000 square kilometres), and its population is scarcely more than 6,500,000—a density of three persons per square mile (one person per square kilometre).

Low population density

The highest point—the Klyuchevskaya Volcano (15,584 feet [4,750 metres]—is less than 200 miles (300 kilometres) from the north end of the Kuril Trench, which at its lowest point is 34,586 feet (10,542 metres) deep. The Far East is mountainous: ridges, highlands, and plateaus are found in more than three-quarters of the region, and plains are found only between mountains and along the rivers and seacoasts. There are more than 250 volcanoes (almost 70 active) in the Kamchatka Peninsula and the Kuril Islands. The Far East is a source of gold, lead, tin, zinc, and other minerals. The customary power resources are here supplemented by the force of high ocean tides and heat generated by volcanoes and hot springs.

Most of the maritime region has a monsoon climate, with severe winters and cool summers. Because of abundant summer rainfall, the rivers, notably the Amur, are generally full. Landscapes are varied: in the north, tundra extends over large expanses; farther south lies taiga, giving way to broad-leaved forests. The Far East is second only to Siberia in its timber resources. In the south is a variety (and rare mingling) of southern and northern flora and fauna: lianas wind round the trunks of fir trees, and the northern deer meet the Siberian tigers.

Russians—who began to inhabit the region in the 17th century—constitute the majority of the population in the south. Next in numbers come Ukrainians, Belorussians, and Jews, and there is a great variety of very small indigenous population groups. Slightly more than three-quarters of the population lives in cities, the most important of which are Vladivostok, Khabarovsk, and Komsomolsk-na-Amure, the last named largely constructed by members of the All-Union Leninist Communist League of Youth, or Komsomol.

The Far East provides almost one-third of the total Soviet catch of fish and other seafoods and produces one-third of the canned fish. The region also takes a leading place in the extraction and smelting of ores, in the production of paper, and in the supply of timber. It is becoming of increasing importance as a base for Soviet exports.

SETTLEMENT PATTERNS

The basic trends. The population of the Soviet Union on January 1, 1977, numbered 257,824,000, giving an average density of about 28 persons per square mile (11 persons per square kilometre). Distribution, however, is very uneven.

Table 1: Soviet Union, Area and Population

	area		population (000)		growth (percent)
	000 sq mi	000 sq km	1959	1977	1959–77
Soviet Federated Socialist Republic					
Russian S.F.S.R.	6,591.1	17,075.4	117,534	135,600	15.4
Soviet Socialist Republics					
Armenian S.S.R.	11.5	29.8	1,763	2,893	64.1
Azerbaijan S.S.R.	33.4	86.6	3,698	5,776	56.2
Belorussian S.S.R.	80.1	207.6	8,056	9,414	16.9
Estonian S.S.R.	17.4	45.1	1,197	1,447	20.9
Georgian S.S.R.	26.9	69.7	4,044	4,999	23.6
Kazakh S.S.R.	1,048.9	2,717.3	9,295	14,498	56.0
Kirgiz S.S.R.	76.6	198.5	2,066	3,443	66.7
Latvian S.S.R.	24.6	63.7	2,093	2,512	20.1
Lithuanian S.S.R.	25.2	65.2	2,711	3,342	23.3
Moldavian S.S.R.	13.0	33.7	2,885	3,885	34.7
Tadzhik S.S.R.	55.2	143.1	1,981	3,591	81.3
Turkmen S.S.R.	188.4	488.1	1,516	2,650	74.8
Ukrainian S.S.R.	233.0	603.7	41,869	49,300	17.7
Uzbek S.S.R.	172.7	447.4	8,119	14,474	78.3
Total Soviet Union	8,598.1*	22,274.9*	208,827	257,824	23.5

*The total area of the Soviet Union is 8,647,250 sq mi (22,402,200 sq km), including the White Sea (34,750 sq mi [90,000 sq km]) and the Sea of Azov (14,400 sq mi [37,300 sq km]), which are excluded from the figures for the republics.
Source: Official government figures.

The mass of the Soviet population is concentrated in the so-called Main Belt of Settlement, which coincides with the main zone of grain production. Its base stretches along the western border from Leningrad to Moldavia; the northern edge of this belt passes through Cherepovets, Vologda, Kirov, and the north of the metallurgical and mining district of the Urals; the southern edge passes along the shores of the Black Sea and the Sea of Azov and then proceeds through Rostov-na-Donu, Volgograd, and Kuybyshev, to Chelyabinsk. Beyond the Urals the Main Belt of Settlement narrows, and to the east of Novosibirsk it becomes a narrow strip along the Trans-Siberian Railroad, spreading out only in a few places (in the Kuznetsk Basin, Minusinsk Basin, and elsewhere). This ribbon of denser population then stretches to the Pacific. To the south of this belt are important areas of denser population in Central Asia and the Caucasus.

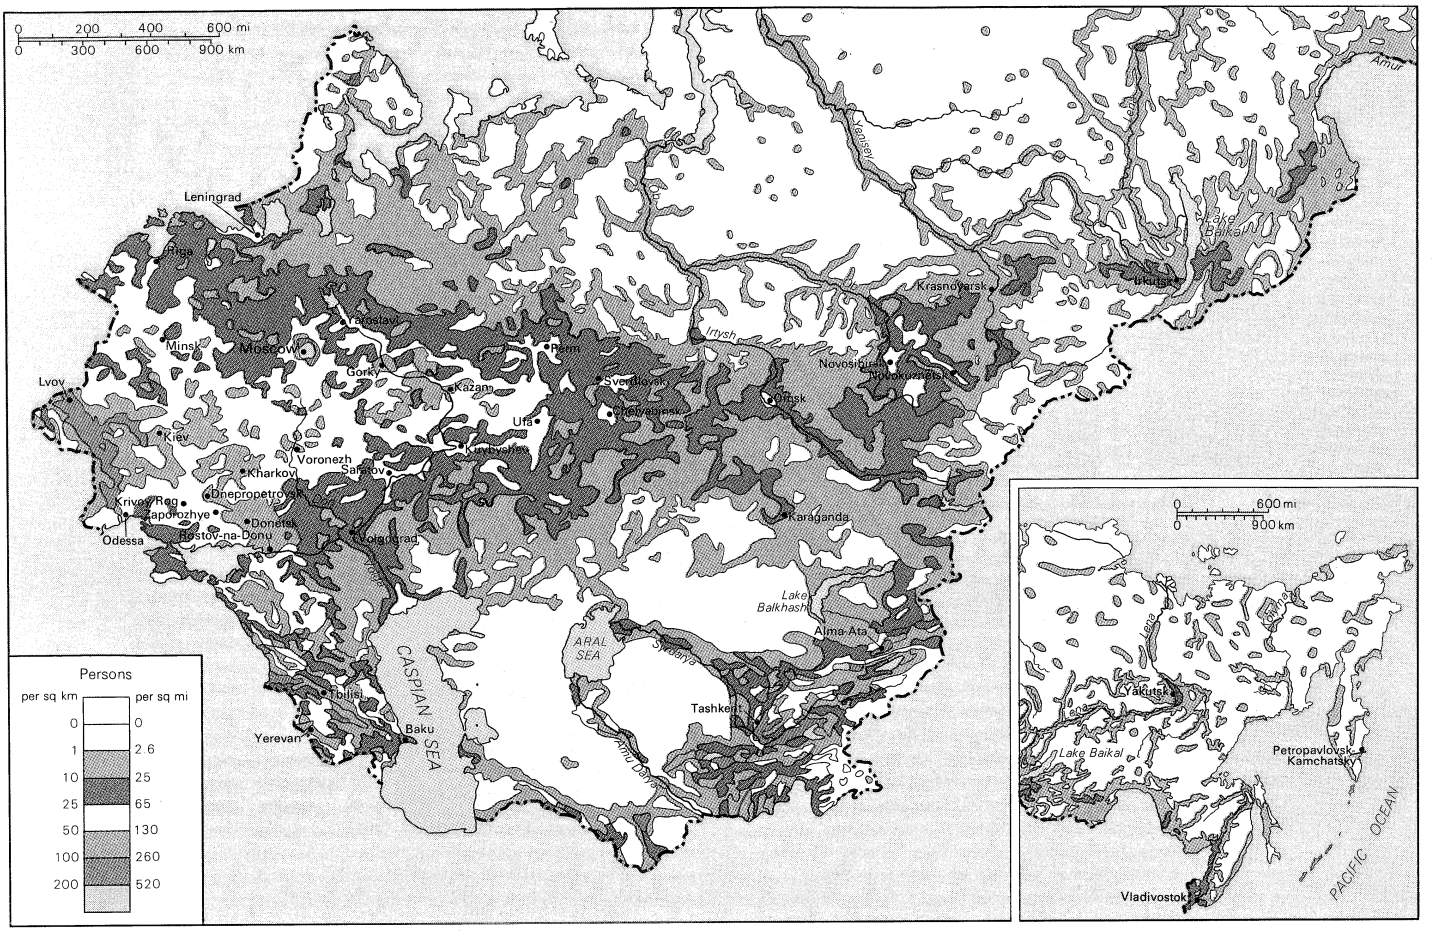
The overall rural landscape. Of the total Soviet population, 62 percent now lives in urban settlements. Before World War II more than two-thirds was still rural, but even then industrialization had brought about both a relative and an absolute reduction in the rural population. Rural dwellers were first outnumbered by urban in 1961, but, since urban settlements occupy only about 1 percent of the country's total area, it is rural forms of settlement that chiefly mold the character of the landscape visible to the transcontinental traveller.

It has been calculated that there are about 470,000 rural inhabited localities, with a population of about 100,000,000, in the Soviet Union. Most of these settlements are connected with agricultural production. The remainder include small settlements at railway stations, at individual small mines, at centres of timber felling, at small or medium-sized processing enterprises, and also at resort settlements, inhabited localities at sanatoriums and hospitals sited in rural areas, and so on. Agricultural settlements are either old, formerly separate hamlets and villages whose inhabitants now work on collective farms, or the communities of state farms.

Collective and state farm structure

As a rule, each collective and state farm (respectively, *kolkhoz* and *sovkhoz*) has a central principal farmstead with its own settlement. At collective farms this is usually the largest (or the most conveniently sited) village in the area; at state farms, the largest farm settlement is the centre that houses machinery, fuel, and produce. These central settlements contain the collective farm board or the state farm directorate and such services as a club, one or more shops, a secondary school, clinics, and so on. Peripheral settlements contain primary schools, simple shopping facilities, and medical posts (without permanent staff) and the individual collective farm brigade (or state farm section) leadership.

Regional variations in rural population. *Soviet Europe.* In the Far North of Soviet Europe the rural population is very sparse, a reflection of the unfavourable environment. Tundra is used only as pasture for reindeer and as hunting and trapping grounds; fishing settlements are found along the rivers and the Arctic coast. The habitations (*stanovishcha*) are small in size. Several clusters of mining and port settlements have nevertheless sprung up, and railways (with their station settlements) have consequently reached these remote parts.



Farther south, in the northern taiga, the population is somewhat denser; agriculture acquires significance, and small villages of perhaps 100 inhabitants, centres of cleared patches of land, are strung along the fertile river valleys. Timber felling and occasionally timber processing are still the economic mainstays and have caused the creation of a great number of small settlements (populations 100–500) surrounded by felled areas; some of these lie along rivers (floating timber by raft to processing centres is common), others along railway lines and their timber-hauling (sometimes narrow-gauge) branch lines, or at ports.

In the middle belt of the European Russian S.F.S.R. (home of up to a quarter of the total Soviet rural population) settlement is still denser, and the landscape becomes one of continuous cultivation, with arable land comprising 30–60 percent of the total area; southward are fewer and fewer forests, and at about the latitude of Kuybyshev they survive as mere islets or strips of pine forest. Overlying the comparatively dense village network are strings of settlements at railway stations and also whole clusters of settlements at industrial enterprises situated outside the towns. Fairly evenly distributed medium and occasionally large villages nevertheless continue as the basic structure. From northwest to southeast there is a marked regularity in the increasing size of rural settlements, reflecting the growth in general density of the agricultural population and the associated fall in the proportion of uncultivable land. Historical circumstances—the widespread earlier distribution of large farms—were also important in the south. The predominant rural building material in this region (and also to the north of it) continues to be wood. From this, one-family houses and the necessary auxiliary structures are constructed. Apartment buildings of the modern urban type, however, are gradually appearing. The systematic enlargement of rural settlements—especially in the northwest, where villages average only 10–20 households—is an important precondition for spreading urban amenities and for raising the level of services, a process that, it is thought, requires an average settlement population of 1,500 to 3,000.

Taken together, the Ukraine, southern Belorussia, and Moldavia contain nearly 30 percent of the total Soviet rural population. The forms of population distribution—a close village network—are similar to those that have arisen in the middle belt of the R.S.F.S.R., but, reflecting greater densities, villages are generally larger and closer together. They are especially dense in the western Ukraine and in Moldavia. Nonagricultural rural settlements are mainly connected with processing agricultural raw materials, occasionally with mining, and also (on the seacoast, especially in the Crimea) with resort functions. In Belorussia and the northern Ukraine wood is still the major building material, but bricks, clay, and stone are used elsewhere; multifamily structures are spreading very rapidly.

Stanitsy and *auly*

Especially large rural settlements—Cossack villages, or *stanitsy*, numbering several thousand and sometimes 10,000–15,000 inhabitants—are typical of the plains of the North Caucasus; in the past these were Cossack communities guarding the southern frontiers. Villages are also large in the neighbouring Lower Volga region. The *auly*, settlements of the indigenous peoples in the foothills and mountains of the North Caucasus, are also quite large, their size depending on the economic capacity of the valleys in which they are situated. While the popu-

Population density of the Soviet Union.

lation distribution in the plains is fairly even, in the foothills and mountains it is in ribbons following the rivers flowing from the mountains. Population distribution has also been affected by the plowing up of steppe and by the building of irrigation systems linked to, for example, the Nevinnomyssky Kanal and the Volgo–Donskoy Kanal reservoirs.

In Transcaucasia, too, the rural population is distributed in generally large villages; their siting is largely determined by the terrain, and stone is widely used in construction. In the plains, villages are evenly distributed, locally reflecting aridity and irrigation patterns, while in areas characterized by ravines the villages keep to the valley roads, and surrounding valley land is intensively utilized for vineyards, tea plantations, and other crops. The Black Sea coast is marked by a string of health resorts.

Urals and Siberia. In the Urals and Siberia, including the Far East, where only one-eighth of the total rural population is to be found, population distribution in the Far North differs substantially from that in the more settled part of the Main Belt of Settlement adjoining the Trans-Siberian Railroad. In the Far North the population distribution is similar to that referred to above in the description of the European North, and the rural settlements are even smaller and more widely dispersed (mainly following the rivers). A greater proportion of settlements is connected with mines. Ordinary villages of the same type as those in the middle zone of the R.S.F.S.R. predominate within the boundaries of the Main Belt of Settlement; but they are more widely separated and, within them, houses are spaced farther apart, reflecting the large Siberian expanses. There are more young settlements here (particularly in the state farm communities of the steppes), and settlements connected with industry and transport are common. Farmsteads are virtually nonexistent; in the recent past small groups of farmsteads were traditional for the Yakuts, but in the Soviet period rural dwellers have been concentrated in settlements of medium size, where it is easier to provide public services and to direct the collective economy. Although the rural population is denser near the railways and large towns, only a fraction of the whole territory is intensively utilized, and cultivated areas are separated by large areas of taiga and forest–steppe.

The young rural settlements of Siberia

Central Asia and Kazakhstan. In Central Asia and in southern and central Kazakhstan (rural settlement in north Kazakhstan is similar to that of southern Siberia) live about one-seventh of the Soviet rural population. The size and disposition of rural settlements are determined by the configuration and size of the areas used for agriculture, which are mainly irrigated. In the thickly populated oases, where water makes intensive farming possible, rural settlements (*qishlaq*s and *auly*) often are composed of several hundred households. The *qishlaq*s whose population is engaged in unirrigated agriculture or who specialize in livestock (raising Karakul sheep in the semideserts or raising free-ranging livestock in alpine and dry plain pastures) are much smaller. The appearance of *qishlaq*s is unique. The flat-roofed houses are built of raw bricks (occasionally of packed clay or reeds and clay); many of them have no windows onto the street, but the inner courtyard, which gives way to the orchard, usually has an open platform with an awning that is a place for dining, welcoming guests, and so on. There is often a small pond in the courtyard. The walls surrounding the house are thick. Because of the packed clay construction and the absence of windows, a village street in this region looks like a narrow clay corridor. New building, however, is in the main made to follow standard plans, with single-family dwelling houses of European type. Public buildings are new, meeting modern technical requirements but taking note of national architectural motifs.

*Qishlaq*s and *auly*

Urban population distribution. According to official data, town dwellers constituted 18 percent of the total population in 1926, 33 percent in 1939, 48 percent in

1959, and 62 percent in 1977, reflecting an absolute increase in urban population from 26,300,000 to 160,800,000. Apart from natural growth, the increase in the urban population was determined partly by migration from the villages to the towns and cities and partly by the transformation of some rural inhabited localities into towns and cities.

In most republics an inhabited locality will not be granted city status until its population reaches 10,000–12,000, and the population must be at least 3,000 before town status is conferred. A further requirement in both instances is that the overwhelming majority of the population not be engaged in agriculture. Since the criteria are not inflexible, there are about a thousand towns and several dozen cities with populations of less than 3,000.

In the mid-1970s there were about 2,000 cities and 3,700 towns, compared with 1,679 and 2,940, respectively, at the 1959 census. Between 1959 and 1975, the total urban population rose from 100,000,000 to 153,110,000, an increase of about 53 percent. The most rapid increase was in the number of people living in the larger cities. In 1975 some 87,700,000 people (57 percent of the total urban population) lived in cities with more than 100,000 inhabitants, as against 48,600,000 (49 percent) in 1959. Over the same period, the number of such cities rose from 148 to 240. The proportion of people living in small towns is declining, although their absolute number (as well as the number of small towns) continues to rise, reflecting new development of natural resources and the transformation of rural inhabited localities into urban settlements. Between 1959 and 1975 the number of urban centres with fewer than 10,000 inhabitants rose from 3,043 to 3,674 and their combined population from 14,400,000 to 16,800,000, but their share of total urban dwellers fell from 14 to 11 percent. Medium-sized towns and cities, with populations between 10,000 and 100,000, increased in number from 1,428 in 1959 to 1,838 in 1975, and their population rose from 37,000,000 to 48,600,000 over the same period. Their share of the urban total, however, declined from 37 to 32 percent.

Between 1959 and 1970 an increase of 36,000,000 in the urban population was made up of: urban natural increase, 14,600,000; migration from rural areas to urban centres, more than 16,000,000; transformation of rural inhabited localities into towns and cities, about 5,000,000.

Major cities

By the late 1970s, 15 Soviet cities had passed the 1,000,000 population mark. Moscow had a population of 7,819,000 (or 12,000,000 if the satellite towns of the Moscow region were added); Leningrad had 4,425,000, Kiev 2,079,000, and Tashkent 1,689,000 citizens; Baku, with its suburbs, had about 1,435,000; Kharkov, Gorky, and Novosibirsk had about 1,300,000 each; Kuybyshev, Sverdlovsk, and Minsk had about 1,200,000 each; and Odessa, Omsk, Chelyabinsk, and Tbilisi had just over 1,000,000. Another 26 cities had populations between 500,000 and 1,000,000, the largest of these being Omsk, Dnepropetrovsk, Donetsk, Perm, Kazan, Yerevan, Ufa, Volgograd, Rostov-na-Donu, Alma-Ata, and Saratov. More than three-quarters of the total urban population is to be found in the half dozen highly urbanized zones listed below, and the great bulk of the cities and towns fall within the Main Belt of Settlement and the outlying population concentrations of Central Asia and Transcaucasia. Quite a few urban nuclei, however, including some of considerable size (*e.g.,* Murmansk, Arkhangelsk, Norilsk, Bratsk, and Komsomolsk-na-Amure in the north and Karaganda, Astrakhan, Orsk, and Semipalatinsk in the south), lie in isolated situations outside these zones.

There are six major zones of urban concentration: (1) the Moscow region together with the adjacent cities on the Upper Volga from Kalinin through Yaroslavl and Kostroma to Gorky; (2) the zone stretching from Leningrad southwestward across the Baltic republics and into northern Belorussia, including Riga, Vilnius, Tallinn, Klaipėda, Kaliningrad, and the Belorussian cities of Minsk, Vitebsk, and Mogilyov; (3) the cluster of cities on the Donbass coalfield, where the urban population of two *oblasti*—Donetsk and Voroshilovgrad—totals nearly 7,000,000; (4) the cluster of cities around the Dnepr bend, with a total population of 4,000,000; (5) the Urals group of metallurgical and mining cities, notably Sverdlovsk, Chelyabinsk, Perm, Ufa, Nizhny Tagil, and Magnitogorsk; and (6) the cities of the Kuznetsk basin, including those in the Kemerovo *oblast* together with nearby Novosibirsk.

Role of administrative centres

The administrative centre of the *oblast* or the capital of the union or autonomous republic is nearly always the largest city—there are only isolated exceptions in the entire country. The fact that they are administrative centres attracts to these cities institutions of higher education, public bodies, associations, and so on, all of which contribute to increasing their population. Thus most of the largest cities combine many functions—productive, administrative, and social. Cities with only one predominant function rarely grow to considerable size. Smaller urban settlements may serve only one function (sometimes connected with a single enterprise—a mine or a fish-processing plant, for example). There are also smaller settlements that act as the centres of subordinate administrative units; they have several functions, housing the bodies concerned with administration and communications within the district and also serving the surrounding rural area, processing local raw material and producing consumer goods.

Restrictions on city growth

Although the largest cities as a group grew most rapidly between 1959 and 1975, some of the largest and oldest centres grew relatively slowly. Compared with an overall urban increase of 53 percent, the population of Moscow rose by only 26 percent, that of Leningrad by 29 percent, and that of Gorky by 36 percent. This was attributable to a specific policy of restricting their growth for ecological and social reasons. The concept of "central city—green zone for recreation—peripheral satellite towns" is regarded by the authorities as much more suitable for promoting economic growth than the piling of an ever-growing number of industrial enterprises into a central city. Some of the highest growth rates in the period since 1959 have been seen in medium-sized cities, especially those in which big industrial centres are being established, and sometimes the city itself (*e.g.,* Bratsk, Volzhsky, Tolyatti) is virtually built anew. Along with these recently founded cities, several old cities have greatly expanded or changed their productive functions and have thus also grown twofold or more. They include Balakovo, Belgorod, Kirovakan, and Novgorod.

II. The people

NATIONAL COMPOSITION

The Soviet population is composed of more than 100 distinct national groups. Soviet ethnographers and demographers generally consider it inaccurate to assign national-ethnic affiliation on the basis of mother tongue, since cases of persons using as their basic everyday language the language not of their own people but of the people among whom they live, though at the same time preserving awareness of their own national identity, are fairly common; according to the 1970 census, 6.1 percent of the Soviet people indicated the language of another nationality as their mother tongue. Accordingly, Soviet censuses establish nationality and mother tongue as separate and independent indexes (according to the awareness of the person interviewed, as he declares it). Provision is also made for the recording of any second language spoken fluently.

On the basis of ethnic territories occupied (and in most cases occupied since ancient times), the Soviet Union is composed of one Soviet Federated Socialist Republic (the Russian), which includes 16 Autonomous Soviet Socialist republics, five autonomous *oblasti,* and 10 autonomous *okruga* (districts); and 14 Soviet Socialist republics, which include four A.S.S.R.'s and five A.O.'s. Yet the total of such entities does not coincide with the total number of Soviet nationalities; there is much overlap of one kind or another. The Dagestan A.S.S.R., for example, in the R.S.F.S.R., is inhabited by no fewer than 20 nationalities, within which are consolidated many smaller national groups. The ethnic diversity of the Soviet popu-

lation is, however, officially recognized in the composition of these political entities.

The eponymous nationalities of (*i.e.*, those that give their name to) the union republics comprise 90 percent of the total Soviet population. The most numerous are Russians (53.4 percent of the 1970 total), followed by Ukrainians (16.9 percent), Uzbeks (3.8), Belorussians (3.7), Tatars (2.5), Kazakhs (2.2), and numerous other smaller groups of less than 2 percent. Even smaller but still administratively distinct nationalities include the Nenets, who number only 29,000 but, being scattered over huge tundra areas, are grouped in three autonomous districts. Nationalities without a distinct ethnic area and hence without administrative status include Koreans, Poles, Bulgarians, Greeks, and Gypsies.

Table 2: The Eponymous Nationalities of the Union Republics, 1970

nationality	numbers in Soviet Union (in 000)	percentage of population in their republic	percentage of total nationals in Soviet Union living in their republic
Russians	129,015	82.8	83.5
Ukrainians	40,753	74.9	86.6
Uzbeks	9,195	64.7	84.1
Belorussians	9,052	81.0	80.5
Kazakhs	5,299	32.6	78.5
Azerbaijanis	4,380	73.8	86.2
Armenians	3,559	88.6	62.0
Georgians	3,245	66.8	96.5
Moldavians	2,698	64.6	85.4
Lithuanians	2,665	80.1	94.1
Tadzhiks	2,136	56.2	76.3
Turkmens	1,525	65.6	92.9
Kirgiz	1,452	43.8	88.5
Latvians	1,430	56.8	93.8
Estonians	1,007	68.2	91.9

A comparison of the figures in the two right-hand columns of Table 2 shows that the bulk of each nationality is concentrated in its corresponding republic. The Armenians are something of an exception: although the proportion of Armenians in the Armenian S.S.R. (88.6 percent) is the highest of all, fewer than two-thirds of all Soviet Armenians actually live in the union republic.

A cause for disquiet in some of the non-Russian Soviet Socialist republics is immigration of Russians and, furthermore, their concentration in the cities. At the time of the census of 1970, for example, Kazakhs constituted only 32.6 percent of the population of Kazakhstan and Russians made up 42 percent. Of the population of Kirgiziya, 44 percent was Kirgiz, 29 percent Russian.

Language families and groups

It is Soviet practice to classify nationalities according to their affinity with language families and groups within families. Soviet nationalities speak tongues related to seven language families; in addition, because of their isolation, the languages of Koreans (360,000) and Kets (altogether about 1,000) may be treated as linguistic families, while Paleosiberian languages fairly remote from one another are brought together formally at the family level (see Table 3); some authorities consider Ket to be a Paleosiberian language also.

The Slavic language group predominates: about three-quarters of the population speaks Slavic languages (not counting those who speak one of these languages fluently as a second language). Russian was named as their mother tongue by 141,800,000 persons in the 1970 census, and a further 41,900,000 named it as a second language; thus, taking second languages into account, Russian is the language of cultural intercourse for 183,700,000 people, or more than three-quarters of the total population. Ability to speak Russian is necessary for career advancement for non-Russians. The Turkic language group, spoken by about one-eighth of the total population, ranks next in number of speakers.

SOCIAL CHARACTERISTICS

Religion. It is, and has been since 1918, official Soviet policy to eradicate religion, viewed by doctrinal Communism as the "opiate of the people." In that year, by decree, church and state were separated and all church property was confiscated. A church has no legal status, and believers who wish to have a place to worship must sign a contract with the local soviet, which has discretionary power to permit such use of a building. Private instruction in religion is hemmed round with restrictions.

Church membership

No official statistics on church membership or religious belief are published, but Western scholars have estimated that believers make up about 40 percent of the population of the Soviet Union; many of them, however, because of the official attitude, never attend services. The number of Russian Orthodox is estimated at 50,000,000, Muslims (mainly Turkic peoples and some in the North Caucasus) at 30,000,000. Roman Catholics (chiefly Lithuanian), Eastern-rite Catholics (Ukrainians and Belorussians), Lutherans (Latvians and Estonians), and Baptists also number several million, and there are about 2,100,000 Jews and about 500,000 Buddhists. The supreme catholicos of the worldwide Armenian Church resides in Echmiadzin, in the Armenian S.S.R.

Nationality and education. It is stated in Soviet law that all nationalities enjoy equal rights in terms of participation in the country's economic, cultural, and public life. An important precondition for the attainment of such a condition is an equalizing of cultural levels, a major objective of Soviet policy since the 1920s. Literacy is virtually universal, except among some older people (in 1970, 99.7 percent of those aged nine to 49 were classified as literate). Among the working population almost two-thirds have completed secondary or higher education. The non-Slav nationalities, however, continue to be at a disadvantage in terms of education. In 1970, for example, Kazakhs constituted more than 4 percent of the total Soviet population but less than 2 percent of graduate students. Among the Kirgiz, 98.3 percent over the age of 60, 91.8 percent between age 55 and 59, and 79.5 percent between age 50 and 54 had had no secondary education. Within the overall context of Soviet education (see below *Administration and social conditions*), the widespread training of specialists is assisted by the many territorial branches of the national education system. An increasing number of scientific and other centres—including the internationally famous Akademgorodok (Academic Community) of Novosibirsk—are sited far from the European heartland of the country.

Employed and pensioned

Economic categories. The 1970 census established that a total of 115,500,000 persons, or 47.8 percent of the total population, were actually employed (not counting those working only in the household or in personal ancillary agriculture). For 33,100,000 persons (13.7 percent) the main source of income was a pension paid by the state. The total number of pensioners at the beginning of 1970 was 40,100,000, but some of these continued to work and were receiving both a pension and wages. More than 3,500,000 students (1.5 percent) were receiving scholarships from the state. The remainder of the population (89,100,000 persons, or 36.8 percent) was composed of persons who were not employed in the national economy but were engaged in housework and bringing up children, or were children themselves; and of members of the families of collective farmers, workers, and employees, engaged in personal agriculture.

The distribution of the employed population by nature of work is estimated as follows: 75.4 percent in branches of material production (including personal ancillary agriculture); more specifically, about 60.8 percent are workers and employees, 12.7 percent collective farmers, and about 1.9 percent members of the families of collective farmers, workers, and employees, engaged in personal ancillary agriculture. The remaining 24.6 percent or so work in nonproductive branches (services, education, health, the arts, science, and literature, administrative bodies, and so on). In terms of specific branches of the economy (and not taking account of persons studying and doing military service), industry and construction account for 43.7 percent of the total; agriculture and forestry, 10.8 percent; transport and communications, 10.5 percent; trade and related activities, 8.6 percent; health, education, culture and the arts, science, social security,

and sport, 18.7 percent; state administrative apparatus (including financial operations) and public organizations, 2.7 percent; and the remainder—housing and other municipal and public services—some 5 percent.

DEMOGRAPHY

In the absence of large-scale immigration or emigration, the rate of growth of the Soviet population as a whole is attributable almost entirely to natural increase (*i.e.*, the excess of births over deaths). Regional population growth rates, however, are influenced not only by regional variations in the rate of natural increase but also by inter-regional migrations, which occur on a large scale.

Natural rates of increase. Social factors have had a considerable influence on the natural increase of the Soviet population. The most important factors have been a substantial decline in the average birth rate as a result of rapid urbanization (fertility is appreciably lower in the towns than among the rural population); the widespread employment of women, on the same terms as men, in nearly all branches of economic activity, including a rise in the percentage of trained female professional workers, which has also contributed to a fall in the birth rate; provision of state aid for mothers to assist them in the raising of children, which has tended to check birth rate decline; and, not least, a progressive rise in standards of health. This last factor has influenced the natural rate of increase in a number of ways: the decline in infant mortality has not only reduced the overall death rate but has also reduced the psychological "insurance" attained by giving birth to additional children and thus has tended to reduce the birth rate; in addition, reduced mortality at all ages and a subsequent increase in life expectancy have increased the proportion of the older, non-childbearing element in the population. The net result has been a long-term decline in both birth and death rates.

Birth rate

In the 1960s, birth rate decline was particularly marked, while the death rate stabilized at a low level and then rose slightly as the average age of the population increased. This contrasts with the situation at the beginning of the 20th century, when the demographic model of the country involved a very high birth rate and a fairly high death rate, producing a rate of natural increase much higher than that of most European populations; moreover, the change of generations was relatively rapid. The present model is based on a modest birth rate and a very low death rate, giving a rate of natural increase about half the world average but still significantly higher than that in the advanced countries of Europe.

The Soviet demographic model was greatly distorted by the enormous population losses incurred during World War II. Direct losses, both in the ranks of the military forces and among the civilian population (especially in the Nazi-occupied territories), exceeded 20,000,000. If the indirect losses—fewer births than usual as well as greatly increased mortality associated with poor living conditions—are taken into account, then the total population deficit resulting from World War II may be put at approximately 50,000,000. These war losses greatly deformed the age and sex structure (see below), with results still visible in the 1970s. In addition, the accelerated decline in the birth rate that occurred during the 1960s was in part caused by the arrival at marriageable age of the small wartime generation.

In 1976 the annual average number of births per 1,000 population was 18.4 (as against 47 in 1913) and that of deaths was 9.5 (30.2 in 1913), giving a natural increase rate of 8.9 per 1,000 (16.8 in 1913), little more than half the level of the early 1960s. The birth rate in towns, at about 17.2, was notably lower than that in rural areas (20.3), though the gap had been greatly reduced. Another major long-term trend has been the decline in infant mortality; the number of children dying in their first year was 273 per 1,000 live births in 1913, 182 in 1940, and only 28 in 1974.

The rate of natural increase varies greatly between republics, mainly as a result of variations in the birth rate. In 1976 natural growth in the R.S.F.S.R. was only 5.9 per 1,000 population (with 15.9 births and 10 deaths) and even lower in Estonia and Latvia (natural increase 3.1 and 1.7, respectively). In several southern republics, however, it was very high; in Tadzhikistan it reached 29.7 (with 38.2 births and 8.5 deaths), and it was also above 20 per 1,000 in Uzbekistan, Kirgiziya, and Turkmenistan. These territorial differences reflect ethnic differences. While many groups are increasing their numbers, however, others are declining as a result of assimilation; this is particularly true in the case of peoples who do not have their own ethnic territories and are dispersed in close contact with peoples of other cultures.

Age and sex structure. The demographic trends described above have determined the sex and age structure of the Soviet population. At the time of the census of 1970, there were 130,500,000 persons (54 percent of the total population) of working age (defined as 16–59 for men and 16–54 for women, as persons above these ages receive pensions). In the overall population, 46.1 percent were men and 53.9 percent women (the ratio was 46.3:53.7 in towns and cities and 45.8:54.2 in rural areas). The preponderance of women was attributable to their predominance in the older age groups, especially those that suffered most in the war; among those aged 45 or older there were only 547 men per 1,000 women. In the young groups, there was a higher percentage of married women than married men: in the 20–24 age group, 55.9 percent of the women and only 28.9 percent of the men were married, compared with 37.1 percent and 92 percent, respectively, in the 60–69 age group.

Marriage rates

The role of migration. Some of the results of the movement of population from rural areas to towns and cities are considered above in connection with the marked trend of urbanization (see above *Settlement patterns: Urban population distribution*). Further demographic aspects of this process may also be seen in a comparison of movement in the three intercensal periods 1927–38, 1939–58, and 1959–70.

Taking into account that the first period covered 12 years, the second 20, and the third 11 and that total population grew over the whole period, it may be concluded that migration from country to town is somewhat slackening. In the early 1970s the natural growth of the urban population was already approximating the net in-migration; the natural growth was to a considerable degree maintained precisely by that migration, for it is mostly young people who move to the towns, where they create their families.

The largest and most rapidly growing towns, including those at the sites of new construction projects, have attracted people not only from localities nearby but also from remote regions. Thus country-to-town movement is accompanied by inter-region and even inter-republican migration. The motive force in such a widespread redistribution of population is the creation of new jobs in economically developing regions; the state offers incentives (particularly in the Far North) to draw potential migrants to areas with manpower shortages. The regions that most attracted settlers in the 1959 to 1970 period were, above all, Kazakhstan and Central Asia, where, although the natural local population growth is already high, several million migrants (mainly from the R.S.F.S.R.) settled. On the other hand, the movement of population to Siberia from the European regions was much less than in previous periods and affected only certain areas. The 20 percent growth experienced in the Far East (as against 11 percent for the R.S.F.S.R. as a whole) was attributable largely to migration, as was the 29 percent growth in the Tyumen *oblast* of Western Siberia, where there was intensive development of newly discovered oil and gas resources. Migration also took place to the Baltic republics, where high economic potential brought about a shortage of manpower. The regions providing settlers were mainly the Volga–Vyatka region (where the numbers of emigrants almost reached the amount of the natural growth), the Black-Earth and Central Industrial regions, and Belorussia. In the Ukraine, internal movement was from the Southwest to

the Donets–Dnepr area and to the South. The characteristic link between migratory influx and a higher level of natural growth and between efflux and a lower level of natural growth is explained by the fact that it is mainly young persons that migrate.

Population density. Among the economic regions of the R.S.F.S.R. the Central Industrial region is the most populous (28,136,000) and has the highest population density; the proportion of urban population there is only slightly less than in the northwest, where it is highest of all (73 percent). The urban population also reaches a very high 71 percent in the Far East. In the Ukraine, the most densely populated areas are the industrial regions of the Donets–Dnepr area—the 5,000,000 people of the Donetsk *oblast* are 89 percent urban, and the figures for the Dnepropetrovsk and Voroshilovgrad *oblasti* are only very slightly lower (see Table 4 for corresponding data for the union republics).

The demographic outlook. Soviet scientists expect the population to reach 333,000,000 (± 25,000,000) by the year 2000. The overall natural reproduction will probably be marked by a not very high birth rate, a very low death rate, and a moderate net growth. Life expectancy will rise to 80–85 years, and three-quarters of the population may be urban. According to published Soviet forecasts, by the time the total population rises to 300,000,000 there will be 205,000,000 town dwellers (almost 70 percent); moreover, almost one-quarter of the population will be concentrated in the largest cities (those with more than 500,000 inhabitants) and almost one-third in large cities (100,000–500,000 inhabitants). The most rapid growth is forecast for this last category. A redistribution of the population in certain regions—specifically, a growth in the share of the eastern and southern regions—may also be anticipated. In rural areas, the size of inhabited localities will continue to increase, while their numbers will be reduced; by the year 2000 the bulk of the remaining rural population will probably be concentrated in well-equipped settlements with populations of at least 1,500 to 3,000 and with living conditions close to those in towns. Such an abolition of the substantial differences between urban and rural settlements is, at least, one of the major long-term Soviet goals.

(V.V.P./J.C.D.)

Moderate net growth

III. The national economy

THE SOVIET ECONOMY IN WORLD CONTEXT

Although considerable economic development took place between the 1860s and World War I, the economy of tsarist Russia lagged behind those of the western European industrialized nations and the United States. Since the early 1920s, the economy of the Soviet Union has

developed into the most powerful in the world after that of the United States. Since 1928 the course of economic development has been guided by a series of ambitious five-year plans.

The agricultural sector has become one of the world's principal sources of cereals and of a number of other farm, forestry, and fisheries products. Western specialists nevertheless regard the sector as relatively inefficient and underdeveloped, and Soviet authorities admit that they are far from satisfied with the level of some farms and some branches of agriculture, although they would doubtless emphasize that, by the 1970s, some others compared favourably with the best in the world.

Minerals and industry

In the world economy, however, the Soviet Union is more important for its mineral resources and industrial production. The country produces a very wide range of minerals and boasts huge reserves of coal, iron ore, copper, petroleum, and natural gas. Geography and climate make many of these reserves difficult to work, but the development of several new fields has placed the nation among the leading producers of iron ore, coal, oil, natural gas, and manganese. By 1975 the value of Soviet industrial production was estimated to be second only to that of the United States. The country manufactures an immense range of products, although large quantities of technologically advanced equipment are imported from capitalist countries. The nation is also among the world's three top manufacturers of a large number of basic and heavy industrial products. As a result of historical factors that made emphasis on consumer industries a relatively recent development, however, it tends to lag behind in the output of light industrial products and consumer durables. One result of this has been that consumer demand is only partially satisfied and that the quality of the goods available is, in some cases, poor when judged by Western standards.

Despite a rapid increase in industrial investment in the past, productivity and industrial technology are still judged to be below the level of the most advanced capitalist countries.

Role in world trade

Judged in Western terms, the role played by the Soviet Union in world trade is considerably smaller than its economic strength would justify. It has been estimated that it exports only some 3 percent of its national production and accounts for about 4 percent of total world trade—figures that would be more than halved if its trade with other Communist countries were excluded. Although the country has extensive influence—heightened by its foreign-aid program—in some developing countries, the principal international effects of Soviet economic power are felt in the Communist world. The eastern European economies in particular are closely

*Detail may not add to total given because of rounding.

integrated with that of the Soviet Union, which is the source of more than two-thirds of their imports and accounts for an even larger share of their raw material purchases.

In spite of rapid economic development in the past—a process carried out against a scarcely propitious internal and external background—Soviet living standards in the mid-1970s were lower than in some capitalist and certain Communist countries. Western economists estimate that the Soviet per capita national income puts the country somewhere between 20th and 30th place in the world. Soviet authorities aver that such a reckoning is somewhat misleading as it does not take into account the low rate of income tax, the low rents (generally about 5 percent of family income), and the provision of such free services as medicine and education.

THE EXTENT AND DISTRIBUTION OF RESOURCES

Mineral resources. *Coal reserves.* One of the most important of Soviet mineral resources is coal. Estimates of workable reserves vary; one frequently quoted official figure is 7,800,000,000,000 metric tons, of which about 5 percent is proved and 15 percent probable. A quarter of the output is accounted for by brown coal and lignite. Anthracite production has become more or less static. The country's coal output—which was scheduled to increase during the 10th Five-Year Plan—is more than enough to meet domestic requirements, and large quantities are exported, mainly to nations of eastern Europe. Reserves are widely scattered, but about a third of total output comes from three main producing areas. The most important is the Donets Basin (Donbass) region, where the seams are thin and difficult to work but the coal is of high quality. The region is also well situated in relation to a number of industrial centres. In second place is the Kuznetsk Basin region, with thicker seams and some coking coal. It is followed by the scattered fields of the Urals, which are easy to work but produce large quantities of lignite. Considerable amounts of lignite are also derived from the Moscow Basin. Other important coal-producing areas include Eastern Siberia, Karaganda and Ekibastuz in Kazakhstan (producing large quantities of coking coal), and the Pechora field in the Arctic, centred on the town of Vorkuta. Small quantities are also mined in Central Asia, Georgia, and a number of other places. There are huge and virtually unworked reserves in the Tunguska and Lena basins of the Central Siberian Plateau.

Donbass

Petroleum and natural gas reserves. According to official Soviet figures, known petroleum reserves total almost 70,000,000,000 metric tons—enough for about 200 years of domestic consumption at the current rate of extraction—and there are indications of a further 300,000,000,000 metric tons beneath land and sea. Annual output doubled between 1965 and 1975; it is more than adequate to meet domestic requirements, and large quantities are exported. The largest producing area is the Volga–Urals region, which accounts for 55–60 percent of total production. Other important fields are situated at Baku in Azerbaijan, in the North Caucasus, and in Western Siberia. Baku has lost much of its previous importance, but Western Siberia, where deposits were discovered as recently as the 1960s, has been developing rapidly. Lesser producing areas include the Emba River district, the Mangyshlak Peninsula of Kazakhstan, and western Turkmenistan (all on the Caspian Sea), the Fergana Basin in Central Asia, the Pacific island of Sakhalin, the Pechora Basin, the western Ukraine, and the Rechitsa district of southern Belorussia. Large untouched reserves lie in Eastern Siberia, mainly in the Lena Basin of Yakutiya.

Production of natural gas has increased even more rapidly than that of oil. Output increased more than sixfold from 1960 to the mid-1970s, and the 10th Five-Year Plan called for further increase. The principal gas fields are situated in the Volga–Urals region, the Ukraine, Central Asia, and the North Caucasus. A major new source was under development in the northern part of the West Siberian Plain in the mid-1970s. Shale oil is produced in relatively small quantities around Lake Peipus in Estonia and is also found in the Volga Valley and eastern Kazakhstan.

Metals. Soviet reserves of iron are estimated to account for about 40 percent of the world's total. Between 1960 and 1975, annual output more than doubled, to make the country the world's largest producer. Iron ore is mined in a number of different places, but some 70 percent of total output comes from two areas, the Ukraine (especially the fields at Krivoy Rog) and the Urals. Small quantities of ore are also derived from scattered sites elsewhere. Most ores are of fairly high quality; according to the United Nations, the average metal content of total Soviet output is approximately 60 percent. Intensive development of lower grade ores, notably those of the Kursk Magnetic Anomaly (in the Black-Earth Belt) and the Kustanay *oblast* of northwestern Kazakhstan, began in 1975.

Ores for iron and steel

The Soviet Union is also the world's leading producer of manganese. This is mined in two principal areas, Nikopol in the Ukraine—which yields relatively poor-quality ore but accounts for more than 50 percent of total output—and Chiatura in Transcaucasia, which produces a higher grade ore. Output (with an estimated manganese content of about half) is more than adequate to meet domestic demand, and large quantities are exported, especially to eastern Europe but also to some Western countries. The Soviet Union has large reserves of ores of several other important components of steels, including nickel, cobalt, molybdenum, vanadium, tungsten, and, in the Urals, chromium (sufficient to allow substantial exports).

Ores for nonferrous metallurgy

There are also large copper resources in several parts of the country. The principal producer is Kazakhstan, but there are also important mines in parts of the Urals as well as in Uzbekistan and Armenia. Monchegorsk, in the Kola Peninsula region, and Norilsk also yield quantities of copper ore, and there are huge unworked reserves—estimated to be capable of producing 90,000 tons of ore a day—around Udokan in Siberia. Output of copper is second only to that of the United States. The most important zinc and lead deposits are situated in the Altai Mountains of eastern Kazakhstan, where they occur in association with copper, and at several sites in the mountains of Central Asia and the Caucasus.

The Soviet Union is not particularly rich in bauxite; there are several rather low-grade deposits in Asia (mainly in Kazakhstan) and in the European northwest, where a major new source was under development in the Onega Valley in the mid-1970s. Aluminum production, while relying to some extent on imported bauxite (from the Balkans) and alumina (from Hungary), is chiefly supported by the use of alternative ores—nephelite from the Kola Peninsula, nephelite and alunite from Transcaucasia, and kaolinite from Central Asia. Titanium is produced in the Ukraine and in the Urals; and uranium is derived from Uzbekistan, Tadzhikistan, and Kirgiziya.

The rarer metals and minerals

The country is thought to be the world's second largest producer of gold, and a large number of other metals—including, among others, platinum, beryllium, columbium (niobium), and mercury—are also produced on a significant scale.

Nonmetallic minerals. There are large phosphate deposits at Kirovsk in the Kola Peninsula, at Karatau in Kazakhstan, in the Donbass, and around Moscow. Potash is mined in the Urals, and there are also a number of pyrite deposits. The Urals area also yields large quantities of asbestos (especially north of Sverdlovsk) and some graphite. Other important nonmetallic minerals include kaolin, mica, fluorspar, and salt.

Biological resources. Taking the vast expanse of Soviet territory as a whole, much of the soil is unsuitable for agriculture, and the climate—characterized by long, cold winters, poor water distribution, and much unpredictability in most parts of the country—is also adverse. The northernmost belt, stretching from the Kola Peninsula eastward toward Kamchatka, consists of economically unimportant barren tundra, where the subsoil is permanently frozen.

Timber resources

The northern part of European Russia, much of Western Siberia, and most of the area east of the Yenisey River is covered with forests (see above *The land: The natural landscape: Vegetation*). All in all, about 40 percent of the country's total land area is covered by forests. Total timber resources are estimated at 2,800,000,000,000 cubic feet (80,000,000,000 cubic metres), of which approximately four-fifths are coniferous. The Soviet Union is the world's leading timber producer, with Siberia and the Far East accounting for about one-third of the total output.

Agricultural activities are concentrated in an irregular and narrowing belt stretching from the Ukraine, Belorussia, and the Baltic lands toward Omsk, Karaganda, Novosibirsk, and Barnaul, and extending into Eastern Siberia. All in all, agricultural land accounts for 27 percent of Soviet land territory. Approximately 40 percent of the agricultural area consists of arable land; the remainder is made up of meadows and pastures.

SOURCES OF NATIONAL INCOME

Agriculture and fisheries. The agricultural sector (see also above *The land: Settlement patterns*) provides just over 14 percent of the country's net material product and employs some 23 percent of the economically active population. Contrary to the practice in several other Communist countries, farming in the Soviet Union is fully socialized, the two basic agricultural units being the collective and the state farm (*kolkhoz* and *sovkhoz,* respectively).

The only obligation that the collective farm has is to meet a delivery quota. It makes its own decisions on profit sharing. Weak and unprofitable collectives are being amalgamated into larger collectives or turned into state farms. As a result, their numbers have shown some decline; thus in 1976 there were 27,700 collectives compared with 36,900 in 1965. They accounted for some 13,300,000 farm households—an average of about 486 per collective—and their agricultural land area represented nearly 35 percent of the total. Just over 50 percent of this was arable land; the rest was meadows and pastures. The average collective of 16,300 acres (6,600 hectares) owned 39 tractors, 1,715 cattle, 1,837 sheep and goats, and about 957 pigs. Some 14,700,000 acres (5,900,000 hectares) of the collectives' land area is distributed in the form of small private plots among members, who are also allowed to own some livestock. Although these plots account for little more than 3 percent of all Soviet agricultural land, they account for a significant proportion of the output of a number of agricultural products (*e.g.,* over half the eggs, a third or more of total meat and milk). The collectives as a whole (which provide pasture and feed for the individual plots) concentrate, Soviet sources emphasize, on the production of grain and cotton, sugar beets, and related industrial crops.

State farms are owned and operated by the state, and their employees are paid a regular wage which is not usually significantly affected by their performance. Since the mid-1950s, the number and importance of state farms have progressively increased. By the mid-1970s, there were more than 19,600, and their agricultural area (one-third of it arable) made up more than 60 percent of the Soviet total. Their size varies considerably, but on average they employ some 550 workers and have about three times as much farmland as the average for the collectives. State farms account for rather less than 50 percent of the output of most agricultural products, and in a number of cases (notably cotton, sugar beets, and sunflower seeds) their share is very much smaller than that of the collectives.

As in most other countries of the Communist bloc, agriculture, in the opinion of Western experts, has been the Achilles' heel of the Soviet economy. Growth in agriculture has not kept up with that of the rest of the economy; gross agricultural production in the 1966–70 plan period was 22 percent above that of 1961–65, but output in 1971–75 was only about 14 percent above the 1966–70 level. Among agriculture's principal problems have been the lack of adequate resources, the absence of effective material incentives, and the low level of earnings; there has been some improvement in the situation, however.

Material incentives in agriculture

After much discussion, efforts have been made to give greater independence and responsibility to both collective and state farms and to provide some material incentives; bonus payments for target overfulfillment are widespread, and there are experiments to create within the state farms and the collectives small units that are given a degree of independence and are paid according to their own achievements as opposed to those of the collective or the state farm. The ninth and 10th Five-Year plans put considerable emphasis on agriculture. Investments were planned to continue at a high level, resulting in a good increase in the supply of agricultural machinery; further steps were to be taken to encourage initiative and to provide incentives for target overfulfillment.

Despite undoubted improvements, the farming sector is still relatively underdeveloped if compared with those of many other—including some Communist—countries. Soviet use of mineral fertilizers is still one of the lowest among the members of Comecon (the east European trade group), and agricultural machinery is still in short supply and, in some areas, relatively poor in quality. Notwithstanding a spectacular rise in productivity, labour is still inefficiently used, especially in the collectives. As a result, and as a consequence of poor climatic conditions, yields tend to be low. Productivity in livestock also leaves much to be desired; the difficulties here are aggravated by an almost permanent shortage of high-grade fodder.

Of the total crop area, about 60 percent is devoted to grain, nearly half of it sown to wheat. Fodder crops occupy another 30 percent, and the area devoted to industrial crops—mainly cotton, sugar beets, and sunflower seeds—constitutes only about 7 percent of the total. Most forms of agricultural production expanded more rapidly in the late 1960s and early '70s than in most earlier periods; there was a 37 percent increase in the total average annual value of agricultural output between 1961–65 and 1971–75. In terms of volume, the largest increases were achieved in cotton, grain, meat, and eggs, the smallest in sunflower seeds, potatoes, wool, and flax. The number of livestock also increased markedly. More than a fifth of all livestock was owned by individuals as opposed to collective and state farms.

The Soviet Union accounts for about 14 percent of the world fish catch.

Industry. Because of its wealth of mineral resources and its long-standing policy of giving priority to industrial development, the Soviet Union is among the world's foremost industrial powers. Although international comparisons of industrial production are always subject to qualifications, it is estimated that, in absolute terms, Soviet total industrial output is second only to that of the United States, and it exceeds that nation in production of

some individual items. The country's industrial strength is also illustrated by its ranking as the second or third world producer of a wide range of important industrial products.

The status of technology

Although Soviet industry can claim a number of spectacular technical achievements in certain fields, including space exploration, it is still well behind the leading capitalist countries in terms of productivity and overall industrial technology; for example, early in the 1970s the Soviet computer industry was still turning out second-generation machines while the advanced Western countries were producing third-generation computers. Similar examples can be found in several other industries—including metallurgy, chemicals, and engineering—many of which rely on relatively unsophisticated and outdated equipment and are incapable of producing sufficient quantities of the more advanced products. While imports of advanced machinery account for a large share of total Soviet purchases from the West, sales of such products are insignificant in relative terms. As a result, the five-year plans for 1971–75 and 1976–80 placed heavy emphasis on measures to increase labour productivity and to narrow the technological gap between the Soviet Union and the United States.

The industrial sector (including mining) contributes nearly two-thirds of the country's net material product and employs more than a third of the economically active population. Growth in this sector has been extremely rapid; the index of industrial production rose by 114 percent in the decade 1965–75—an increase that was considerably larger than the average for developed market economies and for the world as a whole. In fact, among the developed countries only Japan recorded a better performance during this period.

Capital and consumer goods output. As in most other centrally planned economies, the main emphasis has been on the development of the capital goods industries. In successive five-year plans since World War II, this sector received 30–35 percent of the country's total expenditure on investment, whereas only about 5 percent was directed into consumer goods industries. As a result, between 1950 and 1970 (according to official Soviet sources, which have been criticized by Western economists as exaggerating industrial growth rates) the output of capital goods was multiplied by about 7.7, whereas consumer goods production was multiplied by only about 5.4, a ratio of about 1.4:1. These figures, however, represent a considerable acceleration in the relative as well as the absolute growth rate for consumer goods production; in prewar five-year plan periods (1928–40) the ratio between the two sectors was about 4:1. Investment in the consumer goods industries has been given progressively greater emphasis in plans since World War II, and by the early 1970s the two sectors were growing at approximately equal rates.

In spite of this change of priorities, the funds devoted to the consumer goods sector remained rather small in relation to its role in the economy; it received only about one-sixth of total industrial investment, although it accounted for more than a quarter of gross industrial production and employed about a quarter of all workers occupied in industry.

As a result of the past emphasis on heavy industry, production facilities in consumer goods are generally outdated and inadequate, and labour productivity is considerably lower than in most other branches of industry. In consequence, output is not large enough to meet domestic demand, and there are also frequent complaints about quality and variety. It was hoped, however, that the 1971–75 and 1976–80 five-year plans—which devoted considerable attention to this sector—would see a significant improvement in the situation. The main objective was to double capital investment during the 1970s in comparison with the previous decade and to achieve a production increase of 95–100 percent. In the 1971–75 plan, the output of consumer goods was scheduled to grow faster than that of heavy industry (44–48 as against 41–45 percent), but in the 1976–80 plan the order of priority was reversed, to 38–42 percent growth in heavy industry and 30–32 percent in consumer goods. This indicated the failure of the plan for 1971–75 to raise the standard of living as it was meant to do. The plans also stressed the need to adopt better management techniques and to speed up the absorption of new technology.

The main branches. Within the capital goods sector, which makes up approximately three-quarters of total industrial production, the principal emphasis has been on the development of machinery building (defined as producing the means of production), metalworking (*i.e.*, using a semi-finished metal product such as plate or tube to make a component or finished product), metallurgy, and the chemical industry. Collectively these branches form the backbone of Soviet industry, accounting for about half the total industrial production.

Table 5: Soviet Output of Selected Industrial Commodities

	1960	1977	% increase
Crude steel (000,000 metric tons)	75.3	147.0	95
Rolled steel (000,000 metric tons)	43.7	118.0	170
Sulfuric acid (000,000 metric tons)	5.3	21.1	298
Caustic soda (000,000 metric tons)	0.7	2.7	286
Mineral fertilizers (000,000 metric tons)	13.9	96.7	596
Plastics (000,000 metric tons)	0.3	3.3	1,000
Machine tools (000)	155.9	236.0	51
Trucks (000)	362.0	734.0	103
Automobiles (000)	138.8	1,280.0	822
Tractors (000)	238.5	569.0	139
Grain combines (000)	59.0	106.0	80
Paper (000,000 metric tons)	2.3	5.5	139
Cement (000,000 metric tons)	45.5	127.0	179
Cotton fabrics (000,000 metres)	6,387.0	6,800.0	6
Woollen fabrics (000,000 metres)	342.0	800.0	134
Linen fabrics (000,000 metres)	559.0	805.0	44
Silk and synthetic fabrics (000,000 metres)	810.0	1,600.0	98
Leather shoes (000,000 pairs)	419.0	735.0	75
Clocks and watches (000,000)	26.0	60.7	133
Radio receivers (000,000)	4.2	8.7	107
Television sets (000,000)	1.7	7.1	318
Domestic refrigerators (000,000)	0.5	5.8	1,060
Domestic washing machines (000,000)	0.9	3.6	300
Dairy products (000,000 metric tons)	8.3	24.3	193

Between 1965 and 1975, the metalworking and machinery-building sector trebled its output and more than doubled its labour productivity—a better performance than could be seen in any other branch of manufacturing.

Chemicals

In the pre- and early post-World War II periods, the chemical industry was one of the less well-developed branches of Soviet manufacturing industry. From the late 1950s onward, however, helped by the rapid growth in the production of oil and natural gas, particular attention was paid to this sector of manufacturing, and in the early 1960s it was the most rapidly expanding branch. During the late 1960s and early '70s, there was a noticeable slowdown in the growth of the chemical industry, attributable partly to a slight decline in the rate of overall industrial growth but mainly to a change in planning priorities. During the phase of most rapid expansion, the main emphasis was on ensuring an adequate supply of such basic chemicals as soda ash, sulfuric acid, caustic soda, and chemical fertilizers and on the establishment of large-scale artificial fibres and plastics industries. This growth was aided by heavy imports of Western equipment and technology, including a large number of complete plants. Now that a chemicals industry more commensurate in scale with that of the Soviet industrial economy as a whole has been established, it is not surprising that annual growth rates should have slowed down. Nevertheless, expansion continues—between 1965 and 1975 the output of all chemical products rose by 178 percent, a rate of increase about half that of the decade 1955–65.

Metallurgy

Since the beginning of the Soviet era, a strong metallurgical industry has been looked upon as one of the main preconditions of industrial growth and has, on the whole, been given priority in the allocation of investment funds. Its share of total capital spending, although subject to some recent limitations, has been significantly higher

than its share of industrial output. Although the increase in both productivity and production has fallen well below the average for industry as a whole, output has managed to keep up with the growth of domestic demand, and steel, manganese, and a number of other metals are exported in substantial quantities.

Other important manufacturing branches include the building materials, timber, woodworking, and paper industries; at the start of the 1970s these absorbed about 14 percent of total industrial investment. Over the 1960s they saw a rapid growth in output, but, in common with most other capital goods industries, there was a marked slowdown in the period 1966–75.

The bulk of the country's industrial output comes from relatively large production units, and the average size of industrial plants is steadily increasing. In the mid-1970s about 35 percent of all enterprises employed 100 or fewer people but accounted for only 6 percent of gross production (compared with 44 percent and 7 percent, respectively, in 1960). Enterprises with a labour force between 101 and 1,000 accounted for 53 percent of the total number and for some 26 percent of output (49 percent and 40 percent in 1960). At the top end of the scale, enterprises employing more than 1,000 workers, while making up only 12 percent of the total number, provided no less than 68 percent of gross industrial production (7 percent and 53 percent in 1960).

Energy. Throughout the Soviet period, the energy sector has been given high priority by economic planners; partly in response to Lenin's dictum that "Communism equals Soviet power, plus the electrification of the whole country," particular attention has been paid to the development of the electric power industry, which in the early 1970s took 11–12 percent of all capital investment in the industrial sector. Between 1965 and 1975, total installed capacity increased by 90 percent and output doubled. The five-year plan for 1976–80 envisaged a 30–33 percent further rise. Although hydroelectricity production has also seen a rapid increase, its share of the total has declined from a peak of nearly 20 percent in the late 1950s. This change marks a realization of the greater returns obtainable from coal-, oil-, and gas-fired thermal stations in consuming areas and some lessening of the emphasis on grandiose hydroelectric projects in remote districts (though these continue to be built). The Soviet Union's first nuclear power plant came into operation in the mid-1960s, and several others have been built, but their combined output remains a minor proportion of the total.

Oil and natural gas fuels

A major development in the energy sector since the mid-1950s has been a rapid growth in the production of oil and natural gas (see above *Mineral resources*), which are now the leading fuels. Whereas in 1955 oil and gas accounted for only about a quarter and coal for some two-thirds of the country's energy supplies, by the mid-1970s the contribution of coal was down to about 33 percent and that of oil and gas had reached 65 percent (the small balance came from such minor sources as peat, oil shale, and firewood).

The development of Soviet energy resources, particularly oil, gas, and hydroelectricity, has involved problems resulting from their highly uneven distribution and the great distances that separate resources from consuming areas. These difficulties are being attacked by a large program of oil and gas pipeline construction (see below *Transportation*) and the creation of an integrated electric power grid and by bringing the geographical pattern of demand nearer to that of supply.

Finance. As in other Socialist countries, the banking sector is owned and controlled by the state. This control

Gosbank

is exercised through the powerful Gosbank (Gosudarstvenny Bank S.S.S.R., or State Bank of the U.S.S.R.), which not only fulfills most of the functions of a Western central bank but also acts as a clearing bank and is used as one of the principal instruments of control over state enterprises. It is responsible for note issue, for controlling the currency circulation, for foreign trade and other overseas transactions, and for executing the government's financial and credit policy. It administers tax receipts, pays out much of the state's current expenditure, monitors the performance of state enterprises, holds their accounts, handles their receipts and payments, and provides them with short-term credit.

A number of specialist transactions, however, are handled by other banking institutions, notably the Bank for Foreign Trade (called Vneshtorgbank, from Bank Dlya Vneshney Torgovli) and the Stroybank (Vesesoyuzny Bank Finansirovaniya Kapitalnykh Vlozheny, or All-Union Bank for the Financing of Capital Investments; the common name is derived from *stroytelstva,* "construction," which the bank finances), which is the source of much long-term credit to state enterprises and organizations. The most widely spread banking institution is the State Savings Bank (Sberegatelnye Kassy). It has about 79,500 branches distributed all over the country and provides a wide range of banking services to the general public, collectives, and other organizations. Savings deposits have been growing at a rate of just under 20 percent annually. The Soviet Union also maintains a number of banks in the West.

Foreign trade. Although the Soviet Union's foreign trade nearly tripled between 1965 and 1975, the country is still a very small foreign trader in relation to its size and economic power. In value terms its exports and imports are slightly larger than the combined foreign trade of Belgium and Luxembourg but smaller than that of Italy, the population of which is only some 22 percent of the Soviet total. The figure is also small when compared with that of other Communist countries. The country's rather poor showing in world trade is attributable in part to its wealth of mineral resources, which obviate the need for large purchases of raw materials, and in part to a marked lack of interest in specialization.

In effect, Soviet policy appears to be to attain virtual self-sufficiency in as many fields as possible and to use foreign trade as a means of making good some gaps that cannot otherwise be filled by domestic producers and to mitigate occasional shortages. As is the case in most other countries of the Communist bloc, great care is taken to maintain a balance between exports and imports or to earn a surplus.

Trading partners

Although the bulk of the Soviet Union's foreign trade since World War II has been with fellow Communist countries, their share of the total declined from nearly 75 percent to about 56 percent during 1960–75; the Comecon group accounted for 44 percent. This change was partly accounted for by reduction of trade with the People's Republic of China, but the chief cause of it was the Soviet Union's expanding trade relations with the West. By the mid-1970s trade with the non-Communist world had reached the same level as that with the Comecon group. The largest component of this was trade with developed capitalist countries, which had grown rapidly over the preceding decade. Though the Soviet Union's largest single trading partner was still the German Democratic Republic, followed by Poland, Bulgaria, and Czechoslovakia, leading capitalist partners were the Federal Republic of Germany, Japan, Finland, the U.S., Italy, France, and the United Kingdom. Trade with developing countries has also been increasing at a rapid rate, though by the mid-1970s it still represented only 12.5 percent of the total. The most important partners in this group were India, Iraq, Iran, Egypt, and Brazil.

In contrast to the healthy surplus maintained in most years in the Soviet Union's trade with Communist and developing countries, trade with several of the developed capitalist countries (*e.g.,* West Germany and the United States) has often yielded a deficit. This is covered by exports of gold, of which the Soviet Union is one of the world's leading producers.

Imports

In view of the country's abundant mineral resources, it is not surprising, as noted above, that raw material imports make up a relatively small part of its purchases abroad. About a third of these purchases are accounted for by a wide and growing range of machinery and equipment. The second largest import group is consumer products, followed by foodstuffs and ores, concentrates,

and metal products. The composition of Soviet imports from the developed Western world is more than half accounted for by machinery and transport equipment items, while a further quarter is taken up by shipments of manufactures, especially iron and steel and textile yarns.

Principal exports

Nearly a quarter of the Soviet Union's export earnings is derived from sales of machinery and allied products, mainly to fellow Communist and some developing countries. The advanced Western world takes only a minute portion of the total. Approximately 8 percent of Soviet machinery sales is made up of complete plants. Vehicles and transport equipment, communications equipment, lifting machinery, agricultural equipment, and a wide range of electrical machinery are also important. In second place come sales of metallic ores and concentrates, and fuel and electricity sales—mostly of oil and petroleum products—rank third.

The structure of Soviet sales to the West, however, differs sharply from the overall pattern. A large proportion of these is made up of inedible crude materials (hides and skins, textile fibres, metallic ores) and oil. Manufactured products account for about a quarter.

Overall, the Soviet Union is a net importer of machinery, consumer goods, and chemical products and a net exporter of fuels, ores and metals, and timber products. Exports and imports of foodstuffs are usually small and in most years cancel each other out. On a number of occasions in the 1960s and early and mid-'70s, however, large imports of grain were necessary to offset poor harvests at home.

MANAGEMENT OF THE ECONOMY

The role of government. In this, the prototype Communist economy, the government's role is all-important. Industry and most service trades are owned and controlled by the state, and agriculture is in the hands of the collective and state farms. In effect, there is no private sector; in the countryside, private enterprise is tolerated only in respect of farmers' small individual plots, while in other sectors of the economy only artists, a few artisans, etc., can earn a living without being formally employed by the state.

This means that the government is in full control of the economy. It formulates economic policy, prepares long- and short-term plans, lays down a large number of detailed targets, controls investment, determines wages and incomes, and fixes the prices of most commodities and products. It is in control of foreign and internal trade, banking, and almost every other branch and sector of the economy.

The structure of state planning

The mechanism by which such control is operated underwent extensive reform—accompanied by considerable discussion—in the late 1960s. Under the system that had evolved by the early 1970s the top planning position is occupied by Gosplan (Gosudarstvenny Planovy Komitet, or State Planning Committee), the authority of which extends right down the line through a number of regional Gosplans. Detailed control over industrial activities is exercised by all-union ministries and ministries of the union republics, which look after industries of national significance. There are also some republican ministries that control local industries and certain construction activities. In addition, there are a number of state committees, the most important of which are the State Committee for Science and Technology and the State Committee for Material and Technical Supplies. The latter works through regional supply authorities and shares the task of material and resource allocation with Gosplan. There is also a State Committee for Prices, but this comes under Gosplan rather than under the Council of Ministers. Agriculture is the responsibility of the Ministry of Agriculture, while credit, finance, banking, and foreign exchange are under the control of the Ministry of Finance and the Gosbank.

At the top of the planning mechanism is the Council of Ministers, determining the broad lines of economic policy and the principal plan priorities. These guidelines are passed down to Gosplan, which is charged with incorporating them into a fairly detailed draft plan, setting out the principal tasks for the various sectors and branches of the economy. The plan is then passed on to the appropriate ministries, the local Gosplans, and other regional authorities, where—after extensive consultations with individual enterprises—more detail is added. The draft plan, suitably embellished, then goes back to Gosplan, which—after the necessary checking, coordination, and balancing—works out a detailed program. This is then submitted to the Council of Ministers and thence, after amendments, to the Supreme Soviet. After any further amendments, it becomes the all-important official current plan.

Taxation. The two most important taxes are the turnover tax and the tax or levy handed over to the government by state enterprises. The latter is made up of the difference between the enterprises' profits and the amount they are allowed to keep, as well as a charge on their capital assets. Receipts from enterprises became increasingly important during the 1960s, when they rose from less than a quarter to more than a third of total budgetary revenue. The percentage of net earnings deducted varies from firm to firm, but in the late 1960s probably averaged from 76 to 80 percent. Subsequent moves toward a greater degree of self-financing (as opposed to reliance on budgetary grants) have diminished the importance of receipts from enterprises to less than a third of revenue. Turnover tax is collected at the factory or the wholesale distribution centre and is levied on a wide range of consumer goods. The rates vary considerably, but since the late 1960s the relative yield of this tax has seen a decline to a third or less of total revenue.

Turnover tax

Among other taxes, the most important group covers direct levies on the general public. Most of the amount raised in this way is derived from income tax, which is payable on incomes in excess of roughly two-thirds of the average wage. It is slightly progressive; on wages it rises from 5 percent to 13 percent, but the rate is doubled on incomes from self-employment, and in a few cases it is fixed even higher. Another direct levy is the tax imposed on collective farmers in respect of the area of their private plots. The rate of this tax is fairly low but is increased by a significant margin if the farmer fails to reach a stated work-day quota in the collective. This regulation is designed to ensure that farmers do not neglect their work in the collective in favour of their private activities.

Contemporary policies and the economic outlook. Since the mid-1960s, the Soviet Union has been engaged in the gradual implementation of a far-reaching program of economic reform. Seen from the Western standpoint, the aim of the program—the need for which was widely recognized for several years—appears to be to mitigate the rigidity, the inconsistency, the complexity, and the inefficiency of detailed central planning by placing greater reliance on incentives, individual initiative, and a rather restricted use of some of the economic instruments that are operating in non-centrally planned economies. Soviet authorities view the flexible methods of the reforms as stemming from the growth and complexity of the economy—a situation that has rendered the historically necessary highly centralized system obsolete.

Economic reform

The most important change concerns the control, the responsibilities, and the independence of the state enterprises. Before the introduction of the reforms, these were given a large number of centrally determined targets, including physical output figures, which left practically nothing to the management's discretion and provided no incentives for producing goods of the right type and quality and for using resources of labour and capital efficiently. Under the reform program, however, the number of targets or indicators was reduced from 40 to eight, the most important of which are concerned with sales and profits. Although these changes gave enterprises only a limited freedom of action, they nevertheless had the effect of encouraging the enterprises to pay greater attention to improving quality, increasing efficiency, and thereby raising profits.

Coupled with these changes were some reforms that related to the system of employee remuneration and the

financial responsibilities and independence of state enterprises. The principal development in this field was the creation of three new incentive funds: for material incentives, cultural and social welfare and housing, and the development of production. The size of the material incentive and cultural and social funds determines the amounts available for bonus payments and social expenditure and is dependent on the fulfillment of sales and profit indicators. The production development fund is a function of profits, depreciation allowances, and proceeds from the sale of existing capital assets and is designed to allow a much greater degree of self-financing than previously for those enterprises that reach their profit targets and are efficiently managed. The aim of these changes, combined with the strong link between profits and the size of the incentive funds, is to encourage a more efficient use of capital resources.

Industrial prices revision

An equally important part of the reform program was a general revision of industrial prices, which, of course, are not determined by market forces as in a capitalist economy. In 1966 and 1967 new prices were fixed on the basis of production costs, although, in the case of coal, electricity, and oil, allowance was made for the wide regional cost differences. Some basic raw materials prices saw a very large jump—coal went up by 78 percent, gas by 51 percent, electricity by 22 percent, zinc by 64 percent, and heavy chemicals by 61 percent. Since the 1967 price revision, much thought has been given to the problem of increasing the flexibility of the price-fixing mechanism.

Although not part of the economic reforms announced in 1965, the slow trend toward the creation of associations of enterprises also deserves mention. The aim is to create larger units in order to take advantage of the economies of scale, to reduce the duplication of certain facilities, to encourage centralized supply of equipment and materials and of such services as research, which smaller units would not be able to finance without substantial assistance. Although there have been some ill-conceived amalgamations, there is evidence that, on the whole, the program has had a positive effect, and current policy is to encourage further mergers, especially among smaller enterprises.

Further reform

The evidence available to Western specialists at the time of the introduction of the 1976–80 plan indicated that the economic reforms have, on the whole, had a positive effect on industrial efficiency. Although there is much discussion in Soviet circles, it is generally recognized that reforms need to be deepened and developed, and it is thought likely that further changes in the system of economic management will evolve. Among the problems that are receiving considerable attention are some reforms to the procedure for fixing prices; the form and content of planning; and a further increase in the independence of the state enterprises. It is often admitted that the current system is inflexible, which makes it difficult to ensure that costs and market conditions are fully taken into account and that scarce resources are allocated in the most efficient way. There are plans for more frequent price revisions and for the development of techniques that will allow economic factors to play a greater role than hitherto. Some tentative steps have already been taken in this direction, but there is still a long way to go. In the field of planning, the emphasis is on reducing the number of binding output targets. Much progress has already been made in this field—the number of mandatory output targets was lower in the 1971–75 plan than ever before and was reduced still further in the plan for 1976–80—but further changes are likely. The discussion relating to the degree of independence of the state enterprises concerns their right to choose their suppliers and to take a more active part in procurement of raw materials. Although some steps have been taken along these lines, contact between most producing and consuming enterprises is still fairly weak.

In sum, it appears that the enormous development of the Soviet economy since World War II has generated a whole new set of problems and challenges, which—not least in the realm of technology—will occupy Soviet economists, planners, and politicians for several decades ahead. (E.I.U./J.C.D.)

IV. Transportation

THE SOVIET SYSTEM IN ITS NATIONAL CONTEXT

In a country the size of the Soviet Union—where great distances separate industrial resources from manufacturing centres and manufacturing centres from markets—transport costs, both capital and recurrent, assume a much greater scale and significance than they do in smaller geographic entities. This is particularly so where heavy industry has received priority and requires the movement of enormous quantities of bulky materials over long distances; in addition, long-distance movement of foodstuffs, particularly grain, takes place on a very large scale. It is not surprising, therefore, that the development of the Soviet economy has involved a vast increase in the volume of freight movement and, to a lesser extent, of passenger travel. The various transport media have been developed as a single coordinated system, avoiding the competition between various modes of transport that occurs in the capitalist world.

The transportation system employs about one in 10 Soviet workers and receives about 10 percent of all capital investment.

The expansion of the economy is reflected in the growth of transport operations, with railways accounting for about 60 percent of freight turnover in the mid-1970s. The growth rates of freight handling by other forms of transport—pipeline, sea, and road—are even higher, and the railways' share is slowly diminishing. The 1976–80 five-year plan provided for a 30 percent increase in total freight turnover and continued to emphasize sea, pipeline, and road transport.

For historical, economic, and geographical reasons, the transport network is very unevenly distributed. The densest road and rail networks are in the Baltic republics, the Ukraine, and Moldavia; intermediate densities occur in the Central Industrial region and Belorussia; and very low densities are characteristic of the Asiatic regions.

THE COMPONENT SYSTEMS

Rail transport. Though it is declining, first place in volume of operations is still taken by rail transport; the explanation for this is the country's immense overland expanses and the spread of the principal production zone over several thousand miles from west to east. Only rail transport can effect long-distance mass carriage of freight and passengers all the year and this despite the severe climatic conditions of the eastern and northern regions.

Railway freight movement

The railways account for around 60 percent of the country's internal freight turnover, which amounts to more than half the freight turnover of all the world's railways. Rail transport handles most of such regular mass deliveries as coal, ore, timber, metal, and grain.

The total length of the rail network has roughly doubled during the Soviet period. Railway construction in the European sector has been mainly confined to rebuilding old lines and building shortcuts to reduce the length of many of the more circuitous routes between the cities of the European plain; the only completely new route is the Vorkuta–Kotlas line, constructed in the 1940s to provide an outlet for the Pechora coalfield. Most of the new routes built since the Revolution are to be found in the economically expanding middle zone of the country, embracing the Volga, Urals, West Siberian Plain, Kazakhstan, and Central Asian regions. In this zone, the Novosibirsk–Novokuznetsk main line linked the main Trans-Siberian line with the Kuzbass; the Artyshta–Barnaul–Tselinograd–Magnitogorsk line linked the Kuzbass with the Urals via north Kazakhstan; the Petropavlovsk–Karaganda–Chu line linked the Trans-Siberian with the Central Asian system, while the latter was drawn together by the completion of the Turkistan–Siberia (Turksib) route from Krasnovodsk on the Caspian via Tashkent, Alma-Ata, and Semipalatinsk to Barnaul. The busiest and most important main lines have been reconstructed, notably the Moscow–Donbass, Moscow–Sverdlovsk, Yaroslavl–Arkhangelsk, and Che-

lyabinsk–Vladivostok sections. Until the early 1970s there was little new building east of Lake Baikal. The largest single project under construction in the middle of the decade, however, was the Baikal–Amur Mainline, linking existing railheads at Bratsk and Komsomolsk-na-Amure. Running about 250 miles (400 kilometres) north of the Trans-Siberian line for a distance of some 2,000 miles (3,200 kilometres), this line, due for completion by 1985, is designed to tap a variety of new industrial resources in Eastern Siberia and the Far East. It will also lessen reliance on the Trans-Siberian line, which, over much of its length, runs very close to the border with China.

Railway modernization

Traffic on many sections of the Soviet railway system is the heaviest in the world, and the growth of traffic during the 1960s necessitated the replacement of steam by diesel and electric traction, along with other technological improvements. Several major routes have been electrified, notably those from Moscow to Leningrad, the Donbass, northern Ukraine, Caucasus, and Urals, together with the Trans-Siberian as far as Irkutsk. Virtually all other lines are now operated by diesel locomotives.

Sea transport. Sea transport plays an increasingly important role, accounting for about 14 percent of total freight traffic (but only about 3 percent of passenger movement), and has a high growth rate. In addition to its dominance in Soviet foreign trade, sea traffic is of considerable importance in freight movement between the various regions, particularly where, as in northern Siberia and much of the Far East, no alternative form of communication is available. The great length (30,000 miles) of the Soviet coastline favours this, though the winter freeze in northern regions limits its growth potential.

First place in internal traffic volume is taken by the Caspian and Black Sea–Sea of Azov basins, followed by the Far Eastern, Baltic, and Arctic basins. The northern sea route, through the seas of the Arctic and Pacific oceans, has, since 1935, played an important role in ensuring regular communications between regions of the European North and Siberia and the Far East.

Foreign traffic nevertheless predominates; the well-equipped Soviet merchant fleet holds sixth place in the world and carries about 7.5 percent of world sea freight traffic. The main emphasis in technological development in the Soviet fleet is toward containerization of freight and expansion of regular freight and passenger line services.

Under the 1971–75 plan, seagoing freight more than doubled in volume, and the merchant fleet is being augmented by ships with automatic control systems.

Transport by inland waterways. Inland waterways are an important component part of the unified system, accounting for 4.3 percent of total freight traffic. The majority of waterways (of which about a fifth are artificial) lie off the main lines of communication, a factor that helps to explain the relatively small percentage of river freight traffic. But wherever the river networks coincide with the main transport routes, or other forms of transport are insufficiently developed, the proportion of inland waterways traffic increases. The Volga area, the northwest of Soviet Europe, the Far East, and Eastern Siberia are such regions.

Some 70 percent of the freight carried is oil, timber, and bulk materials such as stone, gravel, ores, coal, and grain. More than half the freight is carried on the rivers of the Volga–Kama Basin. Other important areas are the Northern Dvina, Dnepr, and Don in the European part of the country; the Ob and Irtysh, Yenisey and Angara, Lena, and Amur and its tributaries in Siberia and the Far East, and the Amu Darya in Central Asia.

The most important navigation canals are the Moskovsky Kanal (a short but vital link between the Moskva and Volga rivers), the Volgo–Donskoy Kanal, the White Sea–Baltic Waterway, and the Volga–Baltic Waterway (a system of canals linking the Baltic Basin and the Volga).

Pipeline transport. One of the most economic forms of transport, pipelines, became of major importance only after World War II. By the mid-1970s pipelines accounted for about 13 percent of total freight turnover, and pipeline traffic more than tripled between 1965 and 1975.

Oil pipelines

The oil pipeline network is most highly developed in the European Soviet Union and the Caucasus. Oil is carried from the Volga–Urals field to the major cities of the European plain, to exporting ports on the Baltic and Black seas, and, via the Druzhba (Friendship) pipeline, to the Communist countries of eastern Europe as well as to West Germany, France, and Italy. A major oil pipeline from the Volga–Urals region (Tuymazy–Omsk–Angarsk) traverses Siberia; in the 1970s lines from the Tyumen oil field of Western Siberia were connected to the trans-Siberian pipeline, which then began pumping Siberian oil westward as well as eastward. Oil pipelines also connect the Mangyshlak field of eastern Kazakhstan with the European system and carry oil from Sakhalin to Komsomolsk-na-Amure.

The first big gas pipeline, running 524 miles (843 kilometres) from Saratov on the Volga to Moscow, began to function in 1947. Since then an extensive system has been laid in the western part of the Soviet Union carrying gas from the Ukraine, Caucasus, and Central Asia to the Central Industrial region, the Urals, and other industrial zones.

Road transport. Road transport, second only to that of the railways, accounts for about 6.5 percent of the total freight traffic and 40.6 percent of the total passenger traffic by public transport. Most of this movement is over relatively short distances.

The densest network of improved roads is in the Baltic region, the western Ukraine, the Crimea, Transcaucasia, and the region around Moscow. The oil field areas of Tatariya and Bashkiriya are also well provided with hard-surfaced roads. On the whole, the European part of the country is better provided with roads than the east. In Siberia and the Far East, roads are the main means of communication in a number of areas remote from railways.

Bus services

About three-quarters of road freight is carried in the European part of the Soviet Union, and four-fifths of the urban and suburban bus traffic is found there, with around 2,000 communities served by bus routes. In the towns, buses account for about 40 percent of all passenger transport. The greatest use of buses is in the suburban zones of Moscow and Leningrad. The freight turnover of public road transport more than doubled between 1965 and 1975.

Air transport. Air transport is most widely used for passenger movement. By the mid-1970s, internal airline routes reached more than 3,500 towns and inhabited localities. Air travel is very popular as the fastest form of transport over the country's immense distances, and more than 40 percent of all passenger flights are over distances of more than 300 miles. The high proportion (about 60 percent) of flights of less than 300 miles is to some extent due to the growth of air communication in regions in which it is the sole form of transport.

Aviation is used on a lesser scale for freight transport. Sixty percent of the freight traffic of local airlines is in the trackless northern and eastern regions.

Soviet international air routes link the nation with some 60 states in Europe, Asia, Africa, and America; Soviet air transport, by volume of traffic, accounts for more than 25 percent of the world total.

Urban electric passenger transport. Electric systems for the conveyance of passengers in urban areas are of major importance. By the middle of the 1970s there were tram services in well over 100 towns and trolleybus services in about 100. Trams and trolleybuses together carried 16,200,000,000 passengers a year. Five great cities—Moscow, Leningrad, Kiev, Tbilisi, and Baku—have underground railway systems. (V.N.D./J.C.D.)

V. Administration and social conditions

Differing national and international perspectives on the evolution of the Soviet political system may be found in the articles RUSSIA AND THE SOVIET UNION, HISTORY OF; COMMUNISM; and SOCIALISM. The following description

of the Soviet system can be supplemented by appropriate sections of the articles on the Soviet constituent republics.

STATE AND SOCIETY

The constitutional framework. In view of the domination exercised over political, economic, social, and cultural life in the Soviet Union by the ruling, monopolistic Communist Party, constitutions and other legal documents are subordinate to the policies of the party and its leadership, centred in the Politburo. The party, however, desires to project an aura of constitutional legitimacy. Hence, it is important that finally, after many years of a somewhat shadowy existence, the Constitutional Commission, appointed in 1962, produced in May 1977 a draft of a new constitution, which, after several months of well-organized discussion in the controlled press, was enacted unanimously into law by the Supreme Soviet in October 1977.

Comparison of the Stalin Constitution—as the "fundamental law" enacted in 1936 was usually called by the Soviet communications media—and the constitution of 1977 reveals no essential changes. The new document is far longer than the old one and in some ways more candid. It much more openly proclaims the ruling and all-penetrating role of the Communist Party of the Soviet Union (CPSU; Kommunisticheskaya Partiya Sovetskogo Soyuza), for example, describing it (Article 6) as "the nucleus of [the] political system." It describes more fully the various legal rights of citizens than did its predecessor. In emphasizing that all rights are accorded by the authorities in return for exemplary performance of duties, however, it in effect limits the rights of citizens more severely than did even the Stalin Constitution.

The fundamental point, however, is that, to a far greater extent than is the case in Western democracies, the Soviet constitution of 1977, like that of 1936, will have meaning only to the extent that the leadership desires and allows it.

The economic foundations. The economic life of the Soviet Union and all other aspects of social activity are dominated by the CPSU. Its Politburo determines economic policy and sees to it that its decisions are enforced by the Soviet government. The CPSU penetrates and guides the government by a system of interlocking membership of party and governmental executive bodies and by many other means. The Soviet economy is held to be "socialist" because its basic principle is state ownership, established by Lenin in 1918 insofar as the main elements (industry, transport, finance, etc.) were concerned and extended by Stalin to agriculture, which Lenin had for pragmatic reasons left largely in the hands of smallholder peasants. Despite state domination of the Soviet economy, not all property is directly administered by state agencies. The state owns and administers land, minerals, water resources, forests, industrial enterprises, banks, large state agricultural enterprises (known as *sovkhozy,* or state farms), means of transport and communication, municipal enterprises, and basic housing funds. In addition to state property, there are two other kinds of property in the Soviet Union, namely cooperative property, predominant in agriculture, and personal property. Most farmers are members of cooperative, or collective, farms, known as *kolkhozy*. Nominally, the land farmed by the collective farmers is assigned to them in perpetuity, but, as is indicated by government-ordered consolidations of collective farms into larger units since the late 1950s, the collective farms in fact exercise whatever control they have over their land within a framework of policies determined by the political authorities. See further above *The national economy: Management of the economy*.

Ownership of property

As for personal property, it includes articles of clothing, household objects, electronic goods, automobiles (in the case of citizens who can afford them, at prices several times higher than in the West, and only after waiting several years), and many other types of goods, including (again for upper-income persons) country cottages, or dachas. Soviet inheritance law with respect to personal property is fairly liberal. (See further SOVIET AND SOCIALIST LEGAL SYSTEMS.)

Social and political aspects. According to official doctrine, there are two "friendly" classes in Soviet society, the working class and the collective farm peasantry. There is also a rapidly growing "stratum," the intelligentsia, which, Western observers agree, is by far the most privileged of the three. This does not mean that all members of the intelligentsia are better off than the workers or even, perhaps, than the peasants. Highly skilled workers earn considerably more than the more poorly paid members of the intelligentsia, which roughly corresponds to the professional classes in Great Britain or America. However, the highest ranking writers, scientists, and other professionals are, next to highly placed party and state bureaucrats, the most privileged of Soviet citizens.

As implied by the official slogan, "From each according to his ability, to each according to his work," Soviet society is not egalitarian. However, there is a considerable degree of equality of opportunity. Generally, life is very competitive, and the unofficial guiding principle of distribution of rewards might be described as that of the career open to talents. This is modified by the requirement that to achieve success a person must be not only professionally competent but also politically reliable.

The CPSU, which as of late 1977 had about 16,200,000 members, dominates the political life of the country. The party rules through the formal structures of government, which include the pyramid of soviets ("councils") extending down from the Supreme Soviet of the U.S.S.R. to village soviets, and the system of ministries, headed by the Moscow-centred Council of Ministers and extending down to local representatives of ministries. Nominally, the deputies and presiding officers of the soviets at all levels are elected, but there is only one candidate for any office in those elections, and the selection of candidates is controlled by the CPSU. Party, soviet, and ministerial posts—as well as other positions of influence and power—are allocated in accordance with a "nomenclature" (*nomenklatura*) system, which is operated by the central authorities of the CPSU.

Soviets

The federal structure. The Soviet Union, in fact a highly centralized state, is nominally a federal republic. Its federal aspect derives from the fact that it consists of 15 theoretically equal republics, each of which has equal representation in the Soviet of Nationalities, the upper chamber of the bicameral Supreme Soviet, the national legislature. The republics, as well as lower ranking autonomous republics, autonomous regions, and autonomous (formerly national) districts, constitute a means by which symbolic political representation is granted to the numerous ethnic groups of which the Soviet Union is composed. All of the people of the Soviet Union, however, share common federal citizenship. Federal laws have equal force in the territories of the union republics. The federal legislature, under the guidance of the CPSU and the State Planning Committee (Gosplan), determines the federal budget, which includes the budgets of the union republics. (See also above *The national economy: Management of the economy.*) Thus the central government in Moscow dominates the economics of the union republics.

This dominance by Moscow is fortified by features of the Soviet system more fundamental than constitutional provisions. Perhaps the most important instrument of central control is the hierarchical, centralized structure of the CPSU. Party headquarters in Moscow, through its centralized control over personnel assignments, can appoint, promote, demote, or transfer even the heads of the party organizations of republics.

The tight control exercised by the Moscow leadership over local economic, political, and cultural life engenders keen resentment among many members of the non-Russian minority nationalities residing in the republics that are named for them. Resistance to Moscow's control has been manifested in a variety of ways; at its mildest it takes the form of anti-Russian jokes and other innocuous verbal behaviour (though even these have at

Resistance to Moscow

times been punished harshly) or—as after Soviet conquest of the western Ukraine as a consequence of the Nazi–Soviet pact of 1939 and Soviet victory over Germany in 1945—it may be manifested in sanguinary guerrilla warfare. Needless to say, the right of secession from the Soviet Union granted by the constitution (both that of 1936 and that of 1977) has never been exercised. Indeed, any suggestion of dissatisfaction with Moscow's rule on the part of members of non-Russian nationalities is usually regarded as grounds for the imposition of draconian penalties. Of all of the many forms of dissent or opposition to Soviet rule with which the Soviet authorities have had to contend over the years, nationality dissent has aroused the deepest anger and has been punished most severely.

Organs of state power and government. *The Supreme Soviet.* Formally, the Supreme Soviet is the highest organ of state power in the Soviet Union. In keeping with this status, affirmed in the constitution, only the Supreme Soviet can make laws for the entire country. In practice, however, the Supreme Soviet enacts only such legislation as has already been initiated by the CPSU; this is indicated by the fact that the CPSU Central Committee meets before the Supreme Soviet does and lays down the policies that are subsequently endorsed by the latter. It is also clear that the Council of Ministers, nominally appointed by the Supreme Soviet, is in fact a more powerful body than the latter. Despite its limitations, however, the Supreme Soviet is an important body. Its legislative commissions, each of which specializes in a given field of legislation, have been playing an increasingly larger role in bringing to bear on the legislative process the expert knowledge of lawyers, economists, and other kinds of specialists. Thus the competence of the Supreme Soviet to perform its legislative functions has increased. Certainly the Supreme Soviet is not the mere rubber stamp it was in the Stalin era, as is indicated by the increased regularity with which it has met since Stalin's death and by the increased length of its sessions, which, however, are still extremely short by Western standards.

Role of the CPSU

Nonetheless, the Supreme Soviet is far from being a parliament of the Western democratic type. Among the many striking differences, for example, is the fact that in the Supreme Soviet all legislation, including crucially important budgetary legislation, passes unanimously. Quite apart from this, and from the unfailing correspondence between CPSU directives and Supreme Soviet legislation, much law is made, despite the apparent lack of constitutionality, by governmental bodies other than the Supreme Soviet, such as the Council of Ministers. There are even many secret laws, not passed by and unknown to the Supreme Soviet.

In form, the Supreme Soviet is bicameral. Members of both chambers are elected (in one-party, one-candidate elections) for four-year terms. One chamber, called the Soviet of the Union, represents, with one deputy for every 300,000 inhabitants, constituents regardless of national origin. The other chamber, the Soviet of Nationalities, is so organized as to take at least symbolic account of the multinational composition of the Soviet population; it has 32 deputies from each of the 15 union republics and for the lower units, designated in descending order as autonomous republics, autonomous regions (*oblasti*), and autonomous districts (*okruga*), respectively 11, five, and one each. The Supreme Soviet normally assembles for regular sessions twice a year. It passes all legislation introduced by its leading members (who are also leading members of the CPSU) unanimously and expeditiously. It sometimes holds special sessions.

The two chambers

The Presidium of the Supreme Soviet. The Presidium of the Supreme Soviet has 37 members, elected by the Supreme Soviet itself and, like the parent body, serving for four years. Between sessions of the Supreme Soviet, which last for only about a week, the Presidium acts for it, performing such functions as convening and dissolving the Supreme Soviet, receiving ambassadors of foreign states, selecting and recalling Soviet diplomats, removing and appointing ministers, instituting and awarding honorary titles, etc. It may also order mobilization of the armed forces and may declare war.

It is obvious that the Presidium is a more powerful body than the Supreme Soviet, although probably somewhat less powerful than the Council of Ministers, which it appoints, and vastly less powerful than the Politburo and Central Committee of the CPSU. Of the 37 members of the Presidium, only its chairman is normally a major party leader and a significant national political figure. Fifteen vice chairmen, one from each of the union republics, serve under the chairman of the Presidium, symbolizing the nominally federal structure of the Soviet state. There are 20 additional members and a secretary.

Both the Supreme Soviet and its Presidium symbolize but do not really exercise power. They legitimize the power of the real ruling force in the Soviet polity, the CPSU. The Presidium also provides an instrument through which the CPSU can deal with foreign states in a manner more understandable and acceptable to the latter than direct transactions with the party would be. With regard to very important business, however—such as negotiations in the area of arms control—the general secretary of the CPSU has dealt with presidents of the United States, dramatically displaying the superordination of party to state in the Soviet Union.

The Council of Ministers. Nominally subordinate to the Supreme Soviet and, between Supreme Soviet sessions, to its Presidium, the Council of Ministers is in fact the most important governmental and administrative agency in the country; in fact, it is designated in the constitution as the "government" of the Soviet Union. According to the constitution, the decrees and ordinances issued by the Council of Ministers must conform to law as promulgated by the Supreme Soviet, but the Supreme Soviet has never overruled any decree of the Council of Ministers. This is not really surprising, since both bodies are dominated by the most powerful leaders of the CPSU.

Working under the direction of the council are ministries of two kinds, the extremely centralized all-union ministries (somewhat equivalent to departments of the U.S. federal government) and slightly less centralized union republican ministries, so-called because in addition to their Moscow headquarters they have local headquarters in the capitals of the union republics. In addition, there are under the council various state committees and special agencies, some of which wield enormous power; one of these is the Committee of State Security (KGB), which controls the Soviet political police and is probably, with the exception of the CPSU itself and perhaps the regular armed forces, the most powerful organization in the country. Both the state committees and the special agencies have ministerial status.

Ministries

Republican and local state organs. The political structure of republics and autonomous republics is almost identical to that of the country. To a somewhat lesser degree this is also true in the local administrative subdivisions, which are called, respectively, *kraya* (territories, very large in area), *oblasti* (variously translated into English as regions, provinces, etc.), *okruga,* and *rayony;* the last two subdivisions (both translated as districts) may be either rural or urban in character.

The essential element in this system of units is its hierarchical, pyramidal character; the whole constitutes a unified structure. There is no counterpart in the Soviet system to the independent unit of local government such as the American state, county, or city government, each with lawmaking and taxing powers.

The union republics have their own supreme soviets, but they are unicameral rather than bicameral like the Supreme Soviet. Like the federal Supreme Soviet, the supreme soviets of the republics (both union and autonomous) are elected for five-year terms; *oblast* and *rayon* soviets are elected for two and a half years. The soviets elect executive committees, in whose hands most of their power is concentrated. As at all levels of the system, CPSU groups in the local soviets see to it that these bodies carry out party policy.

It is possible that the highly developed "mass participa-

tion" in the working of this vast machine affords some satisfaction to some citizens. Official sources, such as speeches by party leaders, and a steady stream of articles on socialist democracy in the controlled press assert that the participation of citizens in local government constitutes a special advantage of the Soviet political system. It is impossible, because of official secrecy, either to confirm or refute such claims by direct investigation, but enough is known about the reality of political life in the Soviet Union to cast doubt on them. It is clear that participation is so hedged about with controls and limits that for most of its alleged beneficiaries it must be more a burden than a privilege.

The electoral system. Little needs to be said about Soviet one-party, one-candidate elections. They are so carefully managed that the official candidates—who are said to represent the bloc of party and nonparty voters—invariably receive virtually 100 percent of all possible votes. All citizens 18 years of age or older may vote, except for the certified insane and criminals confined by court sentence. In fact, voting, though not formally compulsory, is obviously regarded by the authorities as the duty of all citizens; enormous pressure and great fanfare are resorted to in getting people to vote.

THE JUDICIARY, ARMED FORCES, AND PUBLIC ORDER

The judicial system. The Soviet judicial system is highly centralized, hierarchical, and subject to supervision and control by the CPSU. Although far less arbitrary and coercive than it was under Stalin (whose police officials arrested, deported, and did to death millions of persons without anything remotely resembling due process of law), today's system is, by Western and especially by Anglo-American standards, exceedingly defective. There is no equivalent of habeas corpus, no trial by jury, no presumption of innocence, no real independence of the judiciary from ideological and political pressures. Indeed, judges, prosecutors, attorneys, and all others involved in dispensing justice are required to propagate CPSU policy in the judicial field. (See further SOVIET AND SOCIALIST LEGAL SYSTEMS.)

Political crimes

Moreover, although the Soviet authorities deny the existence of political crimes in the Soviet Union, they obviously do exist and are dealt with by very special, severe methods. The criminal code of the Russian Soviet Federated Socialist Republic, largest of the 15 union republics, contains provisions for prosecuting "especially dangerous state crimes" that are clearly political in nature; there are parallel provisions in the codes of the other republics. Loosely drafted, catchall statutes in effect make any publicly expressed criticism of official policy or ideology a crime. Thus, circulating or even having in one's possession written statements that "slander" the state or social system is punishable by long terms in concentration camps, euphemistically described as corrective labour camps. In several important categories of cases, judicial investigation is carried out not by the regular prosecutors but by officials of the security police (KGB). Outside the political sphere there is a system of courts, prosecutors, and attorneys that functions fairly well, subject to the limitations referred to above. In evaluating this system, however, it is necessary to bear in mind that it is subject to CPSU policies, which can change arbitrarily from time to time.

At the apex of the system is the Supreme Court of the U.S.S.R., whose judges are appointed by the Supreme Soviet. Below the Supreme Court (the only national court, apart from military tribunals) stand supreme courts of the union and autonomous republics, provincial, territorial, and city courts, courts of autonomous regions and national areas, and, at the lowest level, the people's courts, the last of which try the overwhelming bulk of all cases. The members of people's courts include a professional judge, who is elected, and two lay "assessors," who theoretically represent the people in the administration of justice at this level. Another so-called popular feature of the people's courts is the openness of their proceedings, though this is restricted in cases involving state security or intimate personal or family matters. Judges at the levels higher than the people's courts are legally trained professionals, appointed rather than elected. There is no institution of judicial review in the Soviet Union, though there is a well-developed system of appealing the verdicts of lower to higher courts.

An important role is played in Soviet justice by the institution of the procuracy. The procurator general of the U.S.S.R. is appointed for a seven-year, renewable term. He in turn appoints lower level procurators for five-year terms. The system of procurators has two main functions. The most unusual of these, in terms of U.S. practice, is supervision of the actions of government officials, with a view to preventing and if necessary prosecuting illegal actions taken by officials. The procurators also conduct criminal investigation and prosecute accused thieves, embezzlers, counterfeiters, and other violators of law. To be sure, prosecution of violators of certain Soviet laws (for example, that of "speculators" for engaging in private trade or other types of prohibited economic activity) is unfamiliar to Westerners.

The armed forces. In the Soviet Union military service is compulsory for all male citizens: two years for the army, three for the navy. There are a very large professional Soviet Army, Soviet Navy, Long Range Air Force, Air Defense Command (established 1955), and Strategic Rocket Force (1960). Most of the armed forces are under the direction of the Ministry of Defense, but the KGB also has several hundred thousand men under arms in such services as the Border Troops, which are equipped with patrol boats, helicopters, aircraft, trained dogs, etc. There is also a vast paramilitary organization known as DOSAAF (Vsesoyuznoye Dobrovolnoye Obshchestvo Sodeystviya Armii, Aviatsii i Flotu S.S.R., or All-Union Voluntary Society for Assistance to the Army, Air Force and Navy of the U.S.S.R.), which, among other functions, provides military training and patriotic indoctrination for schoolchildren. Of great importance also is the GlavPU SA i VMF (Glavnoye Politicheskoye Upravleniye Sovetskoy Armii i Voyenno-Morskogo Flota, or Main Political Directorate of the Soviet Army and Navy), an agency of the CPSU Central Committee, whose task is political supervision and indoctrination of the military forces.

DOSAAF

In the late 1970s it was estimated that the Soviet Union was spending 11–13 percent of its gross national product annually on its military forces, compared with 6 percent in the U.S., 5.1 in the U.K., and 3.7 in France. Its army strength was estimated at 1,825,000, its navy at 450,000 (including marines), and its air force at 1,025,000.

Public order. As in the administration of justice, two administrative systems maintain public order. The rough Soviet equivalent of Western police systems is the Ministry of Internal Affairs (Ministerstvo Vnutrennikh Del, or MVD), which controls the militia, or ordinary police, as well as prisons, labour camps, fire prevention services, road safety services, registration of births, marriages, and deaths, etc. The more political aspects of order maintenance are administered by the KGB (Komitet Gosudarstvennoy Bezopasnosti, or Committee of State Security), which performs espionage and counterespionage, guards high officials and state frontiers, and also exercises surveillance over foreign diplomats and press correspondents and in general safeguards the power of the regime.

MVD and KGB

There is an auxiliary police system known as the *druzhina,* whose more than 5,000,000 members, called *druzhinniki,* normally serve a few hours once a month. Wearing red arm bands, they patrol streets and other public places; they may apprehend violators of public order and turn them over to the militia.

THE SYSTEM OF PUBLIC ORGANIZATIONS

The Communist Party of the Soviet Union. The CPSU is the driving and integrating force and the main control mechanism of state and society in the Soviet Union. This fact is registered in article 6 of the constitution (1977), which states that the party is the "leading and guiding force of Soviet society . . . , of all state organizations and public organizations." Article 100 of the constitution also mentions the CPSU first in a list of organiza-

tions having the right to nominate candidates for election to the soviets. Of course these articles suggest only feebly the overwhelming initiatory, mobilizing, and penetrating capacities of the CPSU. Although official doctrine characterizes the party as a public organization, it is in fact the collective ruler of the country, containing within its ranks the men and women who make and enforce national policy. It, not the state through which it rules, dominates all Soviet life.

As of late 1977 its membership numbered more than 16,000,000. Perhaps 100,000 of those members enjoyed some measure of executive authority, but only a few hundred had much power. These were the people who headed the republic and main *oblast* party organizations and the party organizations of major economic and other enterprises and institutions, those who edited leading newspapers, and those who held high military or police positions or headed Central Committee departments and on the basis of such status were full members of the Central Committee or full or alternate members of the party's Politburo (Political Bureau).

Nomenclature system

The dominance of the party's central headquarters over the rank and file is effected by many means and methods. One of the most important is the nomenclature (*nomenklatura*) system of centralized personnel selection, according to which only party members who pass the screening tests imposed from above by appropriate levels of the party leadership can be promoted to a given post. There are lists of positions for which only Moscow headquarters can clear aspirants; lower levels of the party hierarchy screen candidates for positions at their levels, and so on down the line. Another important principle of party organization that enhances centralized control is known as democratic centralism, the most important components of which are strict party discipline and subordination of the minority to the majority (in practice, of lower to higher ranking organizations) and the obligatory nature of the decisions of higher organs for lower. In addition, Moscow headquarters dominates the Soviet mass media of communication. The CPSU Central Committee's newspaper, *Pravda,* and other Central Committee organs such as the magazine *Kommunist,* set the tone of the national press. Central control is also strengthened by the ladderlike system of political schools (in their role as hurdles for promotion somewhat similar to military academies in the United States armed forces), through which party leaders must pass in order to get to the top.

Komsomol and Pioneers. The All-Union Leninist Communist League of Youth (Vsesoyuzny Leninsky Kommunistichesky Soyuz Molodyozhi, or VLKSM), better known as the Komsomol, according to Soviet sources had nearly 35,000,000 members, between the ages of 14 and 28, in 1976. The Komsomol has grown very rapidly, a growth that reflects in large part the continuing urbanization and industrialization of the country, since Komsomol recruitment is far more successful in the cities than in rural areas. The Komsomol's organizational structure is modelled on that of the CPSU, and many former Komsomol leaders have risen to high posts as executives of the party. The Komsomol is regarded by the party as its reserve and helper, terms that convey some sense of the organization's role as an agency of indoctrination in the official ideology and as a channel for dissemination of CPSU propaganda on domestic and international issues. The Komsomol issues a number of publications, the best known of which is the mass circulation newspaper *Komsomolskaya Pravda* ("Komsomol Truth").

There is general agreement among Western experts on the Komsomol that it has by no means achieved its officially imposed objective of creating a "new Soviet man," imbued with Leninist zeal and self-sacrificing devotion to the ruling party's goals. This verdict is based, in part, on frequent Soviet press reports indicating political apathy, cynicism, and even widespread delinquency among Komsomol members. On the other hand, the Komsomol is a useful device for mobilizing Soviet youth for such drives as the Virgin and Idle Lands Campaign of 1954–56, to settle virgin lands especially in Siberia and Central Asia.

Pioneers

The Komsomol also performs other functions for the party, such as assistance in the work of the Pioneers (All-Union Lenin Pioneer Organization, or Vsesoyuznaya Pionerskaya Organizatsiya Imeni V.I. Lenina), an organization the membership of which embraces Soviet schoolchildren between the ages of nine and 14. Vastly larger in membership than the Boy Scouts and Girl Scouts in the U.S., and, unlike them, an organ of the state, the Pioneers assist the schools in ideological and patriotic indoctrination of children. Pioneers wear a three-cornered red scarf, which according to Soviet sources symbolizes the unity of the Communist, Komsomol, and Pioneer generations. Under the guidance of the CPSU and the Komsomol, the Pioneers seek to instill in children disciplined work habits, love of learning, and identification with Soviet ideology and the social and political system. Children's summer camps and educational and recreational centres aid in the pursuit of these goals.

The trade unions. Soviet trade unions are organized according to broad branches of the economy, covering employees of all ranks within a particular branch, such as medicine or engineering. Collective farmers are not covered. Membership is not compulsory but appears highly advisable on both economic and political grounds. By the later 1970s, total union membership exceeded 113,500,000, accounting for all but a small percentage of the total number of eligible employees. Among the largest unions are those for state farm and allied employees and educational institutions.

The basic units are the enterprise and factory unions, most of which are run by small committees. The activities of the enterprise and factory unions are coordinated by town, provincial, or republican union councils, which are elected at the conferences of the basic unit representatives. At the top is the All-Union Trade Union Congress, which is supposed to be convened every four years. The principal task of the congress is to elect the All-Union Central Council of Trade Unions (or VTsSPS; Vsesoyuzny Tsentralny Sovet Professionalnykh Soyuzov), the Presidium of which is responsible for broad policy and activities. Detailed administrative work is handled by the Secretariat. Individual unions, the structure of which follows this pattern, are closely controlled by the central union authorities.

Union function

Unlike the situation in Western countries with market economics, where the function of trade unions is to advance the economic and other interest of workers in relation to employers, labour unions in the Soviet Union are agents of the state. Strikes are forbidden, if not in law certainly in practice. Worker protests and even brief spontaneous labour stoppages occur now and then, but the outside world learns of these only by word of mouth reports that reach foreigners; they are not reported in the controlled Soviet press. From such reports as have reached the West, it appears that military force has been used to put down labour disturbances and that very severe measures were taken against some of their participants.

In 1977 a number of workers founded a trade union independent of the state. The authorities reacted with repressive measures, but this effort to break the official monopoly of organization of labour was thought by many to be a harbinger of highly significant future developments.

The main function of the trade unions is to stimulate workers to increase their productivity. Among the methods used to achieve this, perhaps the best known is "socialist emulation," in which factory is pitted against factory, industry against industry, in nationwide production contests; winning enterprises are awarded banners and receive much praise in the press. Another important function of the unions is the administration of the social insurance system. They also operate an extensive system of rest homes and sanatoriums and generally play an important role in providing services to workers who are in good standing. Like the other Soviet mass organizations, the unions operate an extensive publications net-

work, which of course functions within the framework of overall directives laid down by the CPSU Central Committee but focusses on matters of special interest to employees, including teachers and other professionals as well as industrial workers. The most important trade union publication is the newspaper *Trud* ("Labour").

SOCIAL CONDITIONS AND SERVICES

The basic principle of distribution of goods and services in the Soviet Union is stated in the constitution as "From each according to his ability, to each according to his work." The interpretation and application of this slogan is of course determined by the supreme leadership of the CPSU and is not subject to public discussion. There is abundant evidence, even in Soviet official sources—guarded though they are on such matters as the existence of pronounced inequality and privilege—that this constitutional principle is interpreted so as to permit very wide differences in income, perquisites, opportunities for domestic and foreign travel, access to quality education, and status and power. The existence of such differences is emphasized in statements by dissidents and by many former Soviet citizens now émigrés. In terms especially of power, but also in access to the best vacation and medical facilities, foreign travel, and many other values, high-ranking party and police executives, military officers, and government officials are at the upper end of the scale, while office workers, unskilled labourers, and collective farmers are at the bottom. Also exceptionally well off, in comparison with ordinary citizens, are writers and performing artists in good standing with the political authorities. Favoured novelists and playwrights receive enormous royalties. Scientists who rise to the coveted status of membership in the Academy of Sciences of the U.S.S.R. are perhaps the most honoured citizens of the Soviet Union. Not only do they enjoy, by Soviet standards, very comfortable incomes, superior recreational and medical facilities, and preferential access for their children to the best institutions of higher education, but they also receive substantial additional emoluments by virtue of their academy membership, in addition to their salaries as directors of scientific laboratories. Individual party officials who abuse their positions—for example, by building for their personal use excessively luxurious private homes, using materials illegally obtained at bargain prices—are from time to time sharply criticized or even severely punished, but, according to statements by leading Soviet dissidents, the traditional practice of regularly distributing special pay envelopes to party officials persists.

Privileged persons

Soviet society is thus far from being egalitarian. The people are also, by the standards of advanced Western industrial nations, rather poor. The average wage of industrial workers, even at the most generous estimate, is about $200 a month U.S. Though rents are low, and housing, though still of very poor quality, is increasingly abundant, the prices of food and clothing are far higher, in proportion to income, than they are in the West. Both husband and wife usually must work in order to make ends meet, though it should also be said that the overwhelming majority of women apparently want to work at paying jobs. In certain respects, women have achieved much in the Soviet economy, as is exemplified by the dominant role of women in the medical profession. Most of the best jobs in all fields, however, and particularly in industry, politics, and public administration, are occupied by men.

Standard of living

Since Stalin's death, the Soviet authorities have made great efforts to raise the standard of living above the very low level of the Stalin era. Perhaps even more important is the program, begun under N.S. Khrushchev, to raise the incomes of the lowest paid categories of workers and in general to improve the economic situation of the workers and collective farmers. This has involved, among other measures, the extension of social security coverage to the collective farm peasantry, who until the mid-1960s remained outside the social security system. Since the mid-1950s there has been a fairly steady rise in Soviet living standards, though this has not necessarily increased the contentment of the mass of the population and has been interrupted by bad harvests, such as those of 1972 and 1975. There has been substantial improvement in a previously dire housing and very poor food situation. There has also been rapid progress in availability of basic consumer goods—excellent in terms of refrigerators, quite good in terms of washing machines and even of television sets, but still very poor in terms of private automobiles. The Soviet population by the later 1970s, however, was still at a standard of life far below that of all of the developed capitalist countries and of several of the eastern European Communist nations.

Health services. Public health and education are perhaps the areas in which Soviet achievements have been greatest, especially in quantitative terms. The official Soviet claim is that medical services are "free and accessible." It is also asserted in Soviet sources that the Soviet Union has about a quarter of all the physicians in the world and that it has more than 3,000,000 hospital beds. Even if these claims are somewhat exaggerated, and in any case say nothing about the quality of medical care, there is no doubt that the Soviet Union's record in this field has been impressive, particularly in view of the backward conditions that prevailed in the tsarist period and the difficulties that had to be overcome along the way. It is also apparent, however, that Soviet medical services—which are administered centrally by the Ministry of Health—suffer from the evils common to overcentralized, bureaucratically administered programs: excessive time is spent by both doctor and patient in record keeping and patients often experience long delays in getting treatment. Nor can it be said that the Soviet Union has a record of innovation in medical research and development even remotely comparable to that of the United States and other advanced Western nations, and the quality of care available to Soviet citizens (so far as it can be judged on the limited information to which foreign students have access) is not equal to the best offered by Western medicine. There is no doubt, however, that death rates have been substantially reduced (though beginning in the 1970s the infant mortality rate rose substantially and life expectancy fell slightly), and the health of the population compares well with that of citizens of other industrial countries.

Education. An objective Western observer cannot fail to be impressed by the achievements of the Soviet Union in the field of education, especially quantitatively. At the same time, he will also be struck by the peculiarities of the vast Soviet program as it is viewed from the perspective of Western traditions. According to Soviet statistics, 46,468,000 pupils were enrolled in "general educational" schools of all kinds in 1976–77 (a drop from six years previously, when the figure exceeded 49,000,000). At the level of higher education, with a reported 4,950,000 students in 1976–77, the Soviet educational effort was surpassed quantitatively only by that of the United States, which had about 8,000,000 students in four-year colleges and universities (and another 3,000,000 in two-year institutions).

Politics and education

The Soviet educational system is characterized by extreme centralization and uniformity in structure and curriculum and by heavy-handed political control and political indoctrination. Especially (but not only) in the humanities and social sciences, textbooks and classroom instruction are permeated by Marxist–Leninist propaganda. Applicants for higher education must pass examinations in political subjects and must continue to devote several hours a week to the study of political subjects even after admission to medical or other professional schools.

Even in quantitative terms, however, Soviet education has thus far by no means achieved the goals set by the CPSU leadership. Universal secondary education (10 years of schooling) has not been attained, despite many years of predictions in the official press that it was imminent. Certainly the country is far from having made education equally available to all of its youth. Rural, as

contrasted to urban, youth are still at a great disadvantage in access to secondary and still more to higher education. As for access to the best universities, such as the state universities of Moscow and Leningrad, or to the best specialized scientific, economic, and other institutes, children of workers and peasants are at an almost hopeless disadvantage in comparison with children of professional people, administrators, and officials. The advantages of the intelligentsia in this respect are apparently so great that many students of the Soviet Union believe that a hereditary class, or caste, system may be forming, if indeed it has not already taken shape. Great efforts are made to provide opportunities to work toward higher education, by evening or correspondence study, etc., for young people who have chosen or have been forced to take jobs in industry upon graduation from primary or secondary school. It is generally agreed, however, that, useful though such efforts may be to the economy, they come nowhere near to equalizing opportunities for higher education.

Education in the Soviet Union is a formidable instrument of national policy. It provides the national economy, the armed forces, science and engineering, and the communications media with an abundance of reasonably well-trained man- and womanpower. These young people have acquired basic skills in a highly organized setting, in which discipline and conformity to authority are stressed. Also, though almost half of the Soviet population belongs to non-Russian national minorities, an apparently successful effort is made to teach all graduates (at least of the secondary schools and of course of higher educational institutions) to read and speak Russian effectively. Indeed, for non-Russians, mastering Russian—in addition to a "sound" political outlook—is a prerequisite for career advancement. Certainly the educational system is one of the sinews of the Soviet state. It is possible, however, that its successes, by providing for some individuals at least a basis for critical thought, may cause trouble for Soviet rulers in the future.

(F.C.B.)

VI. Cultural life and institutions

THE CULTURAL MILIEU

The roots of Soviet literature and arts lie deep in folk traditions. The vast extent, multinational nature, and varied history of the area that was to become the Soviet Union produced an exceptionally rich and diverse folk culture that continues to manifest itself in oral poetic forms, songs, dances, folk instrumental music, and various forms of decorative and applied art. The Russian Revolution and the establishment of the Soviet Union introduced fundamental changes into the cultural milieu. The process of change has been helped by the reduction of illiteracy and by expansion of education; by an immense growth in the output of printed matter; and by increasing the number of cultural institutions of all kinds, especially in the rural areas.

Multinational culture

One of the distinguishing features of creative life in the Soviet Union is its multinational character. Russian literature, music, and art had achieved international significance in the 19th century and were not without influence on the cultural life of all the peoples of the Russian Empire. Despite their somewhat lower overall level of economic and cultural evolution, many of the minority peoples—from the Baltic to Armenia, from the Ukraine to Central Asia—also had highly distinctive cultures and art forms. During the Soviet period, these have, in the majority of cases, been preserved and developed, within the official Soviet policy that all art should be "national in form and Socialist in content." The annual festivals of the arts and literature of the union republics (held in Moscow), together with republican festivals of the arts of other republics, help to assist the understanding of the cultures of the many different peoples of the Soviet Union. Annual competitions in the various arts further the same aim. All these events enjoy great popularity, as attested by large attendance figures.

Specifically Soviet culture, as distinct from Russian or any other national culture, is characterized by what is known as "Socialist Realism," and all national cultures are expected to conform to this approved artistic style. It consists of an emphasis on a Communist approach; "revolutionary humanism"; a popular spirit and appeal; an optimistic vision of the future; and a close connection with what is viewed as actual life. The characters portrayed are to embody what is conceived as the reality of contemporary Soviet life and the ideals of Soviet society, both nationally and internationally.

Socialist Realism

Soviet culture has also become known internationally (often through exhibitions, film distribution, and performances by leading individuals and cultural bodies) and has had a considerable influence, particularly in the other Communist countries. Internally, the highest recognition of creative work is indicated by award of the Lenin and State prizes and by republican prizes. Soviet cultural work is under the direction of the all-union Ministry of Culture; related union and autonomous republican bodies; and the cultural organs of the local soviets. Many mass organizations are also involved in cultural life.

(The following descriptive account of the main aspects of Soviet cultural life may be supplemented by reference to the articles on the union republics. Additional perspectives are offered in the articles LITERATURE, WESTERN; VISUAL ARTS, WESTERN; MOTION PICTURES, HISTORY OF; MUSIC, WESTERN; DANCE, WESTERN; and ARCHITECTURE, ART OF. See also ARCTIC PEOPLES AND CULTURES; CENTRAL ASIAN PEOPLES, ARTS OF. There are also biographies of the major figures of Russian and Soviet culture.)

THE INDIVIDUAL ARTS

Literature. Belles lettres occupy a leading place in Soviet cultural life, drawing on a multinational tradition that has produced acknowledged world masterpieces. The great poets of Central Asia—Neẓāmī, Fuzûlî, and ʿAlī Shīr Navāʾī—were writing in the Middle Ages. Shota Rustaveli's 12th-century Georgian poem *The Knight in the Tiger's Skin* is another landmark in world literature, and the major Transcaucasian poets of the 18th century, Sayat-Nova and Vagif, together with their contemporary the Ukrainian poet and philosopher Hryhoriy Skovoroda, also contributed much to this tradition.

But it was 19th-century Russian literature that acquired the greatest world standing. Giants of this period include Aleksandr Pushkin, the "father of Russian literature," whose masterpiece, *Eugene Onegin,* is a verse novel that achieved an encyclopaedic portrayal of Russian life; Mikhail Lermontov, whose *Hero of Our Time* is a brilliant novel in a Caucasian setting; Nikolay Gogol, whose unfinished masterpiece, *Dead Souls,* was a remarkable portrayal of the ruling class of the time; Aleksandr Herzen, whose memoirs, *My Past and Thoughts,* offered a penetrating commentary on Russian society; Ivan Turgenev, whose major novel *Fathers and Sons* produced much discussion among Russian youth and their parents alike; Ivan Goncharov, whose *Oblomov* is an acknowledged triumph of psychological portrayal; and, perhaps most famous of all, the great novelists Leo Tolstoy (*War and Peace*) and Fyodor Dostoyevsky (*Crime and Punishment*). There were also many other figures of major status active at the time, ranging from the dramatist Anton Chekhov to the poet and novelist Ivan Bunin, who in 1933 became the first Russian recipient of the Nobel Prize.

19th-century Russian achievements

Their ranks also included figures in what became the union republics. Among them were Taras Shevchenko and Ivan Franko (the Ukraine); Yanka Kupala and Yakub Kolas (Belorussia); Akaki Tsereteli and Ilia Chavchavadze (Georgia); Jānis Rainis and Andreijs Upīts (Latvia); Julija Žymantienė-Žemaitė (Lithuania); Eduard Vilde (Estonia); Khachatur Abovyan and Ovanes Tumanyan (Armenia); and many others.

The foundations of Soviet literature were laid by the great working class writer Maksim Gorky, whose *Mother* (1906) initiated a series of the first classics of Socialist Realism; and by the major early Soviet poet Vladimir Mayakovsky. Contemporary Soviet literature is marked by a wealth of forms and genres, which, although multi-

20th-century achievements

lingual and multinational, are integrated by the common Communist ideological content. In prose fiction, Soviet opinion ascribes major significance to the work of Aleksey N. Tolstoy (*The Road to Calvary, Peter the Great,* and other novels), whose attitude to life may be indicated by the statement in his autobiography that he loved life and opposed every kind of abstraction with all the power of his temperament. Mikhail Sholokhov, a Nobel Prize winner, created in his novels *The Silent Don* and *Virgin Soil Upturned* epic accounts of the struggle to construct the new society. Aleksandr Fadeyev was the author of *The Rout* and *The Young Guard,* novels that deal realistically with partisan and guerrilla activities in the Civil War and World War II; he was for three decades head of the Union of Soviet Writers. Aleksandr Serafimovich's *Iron Flood,* completed in 1923 when the author was 60, was one of the first significant novels about the Revolution. Dmitry Furmanov's novels *Chapayev* and *Mutiny* were among the first and best on the Civil War. Nikolay Ostrovsky, who died in 1936 at the age of 32, yet produced, in *How the Steel Was Tempered,* a classic autobiographical statement of the revolutionary generation. There are many other major figures, including Aleksandr Blok, the great poet of the Revolution; Ilya Ehrenburg; Boris Pasternak, a Nobel Prize winner, lyric poet, and translator of Georgian, German, and English poets; Konstantin Fedin; and Leonid Leonov. The great poet Anna Akhmatova incurred the displeasure of the authorities but was "rehabilitated" in 1959. Another major poet, Osip Mandelstam, perished in the Great Purge of the 1930s. The Tadzhik author Sadriddin Ayni; the Uzbek poet and dramatist Niyazy; the Tatar poet and writer Musa Dzhalil; the Kazakh author Mukhtar Auezov; and writers from the Baltic republics also have achieved national and in some cases international fame.

Oral folk traditions are continued in the work of such outstanding bards as Jambil Jabayev (called Jambil) in Kazakhstan, Suleyman Stalsky in Dagestan, and Toktogul in Kirgiziya.

Contemporary literature

In contemporary Soviet literature, Soviet opinion ascribes significance to such authors as Galina Nikolayeva, Mikhail Bubennov, and Sergey Sartakov, whose novels have described post-World War II agricultural and industrial life; Konstantin Simonov (*The Living and the Dead, They Were Not Born as Soldiers, The Last Summer,* and other works), Aleksandr Chakovsky (*Blockade*), and Vadim Kozhevnikov (*Shield and Sword*), who, with many others, have written of the war years; the Kirgiz author Chingiz Aytmatov, whose novel *Dzhamilya* is about a young woman who breaks away from traditional ways of life; and a host of others. The Nobel Prize-winning novelist Aleksandr Solzhenitsyn was exiled in 1974. The poets Yevgeny Yevtushenko, Andrey Voznesensky, Stepan Shchipachov, Nikolay Tikhonov, Rasul Gamzatov (of Dagestan), Vsevolod Rozhdestvensky, Leonid Martynov, Bella Akhmadulina, among many others, have achieved great contemporary popularity. Soviet children's literature—prominent writers of which include Korney Chukovsky, Agniya Barto, and Sergey Mikhalkov—is well-known at home and abroad.

Visual arts. Paleolithic and Neolithic art has been discovered in the Caucasus, in Central Asia, in Siberia, and on the northern Black Sea coast. In the Middle Ages the most notable work was done by the great icon painters of the Novgorod and Moscow schools, among whom the finest were Theophanes the Greek, Andrey Rublyov, and Dionisy. In the 19th century the modern realistic schools of Ivan Kramskoy, Ilya Repin, and Isaak Levitan were founded.

Major works of the revolutionary art of the Soviet period include the scenes from Revolutionary history associated with Isaak Brodsky, Valentin Serov, and Kuzma Petrov-Vodkin; the genre painting of Nikolay Kasatkin and Yury Pimenov; and the portraits of Mikhail Nesterov and Aleksandr Gerasimov. Artists from minority nationalities, including Ural Tansykbayev of Uzbekistan, Martiros Saryan of Armenia, and others, have recorded the varying scenery of the country. Yevgeny Lansere and Aleksandr Deyneka have produced monumental works, while the graphic arts, represented by Viktor Deni, Dmitry Moor, and "Kukryniksy" (a nickname of Mikhail Kupriyanov, Porfiry Krylov, and Nikolay Sokolov) are marked by great variety. Vera Mukhina's group "Worker and Collective Farm Woman" and the memorial ensembles created under the direction of Yevgeny Vuchetich in East Berlin and at Volgograd, as well as works by Sergey Konenkov and Sergey Merkurov, are regarded as masterpieces of monumental sculpture.

Monumental and decorative art

In the decorative and applied arts field, there is great demand for the products of factory and folk industries, which include pottery, glassware, and carpets; carving on wood, stone, bone, and horn; silverware; and delicate lacquer miniatures.

Persons working in the fine arts, as well as theatre designers, film cartoonists, and art scholars, are members of the Union of Artists and the Academy of Arts.

Music. The works of the classics—including those of Mikhail Glinka, Modest Mussorgsky, Aleksandr Borodin, Nikolay Rimsky-Korsakov, Peter Ilich Tchaikovsky, and Sergey Rachmaninoff—remain very popular. Soviet music is regarded as embodying important modern themes as well as those of the past: an example is provided by the symphonies of Dmitry Shostakovich, particularly his *Seventh* (*Leningrad*), *11th* (dedicated to the Revolution of 1905), and *12th* (dedicated to the October Revolution of 1917). Soviet opera reflects both national epics (as in Uzeir Hajjibekov's *Ker-Ogly*) and historical and modern themes, respectively illustrated by Sergey Prokofiev's *War and Peace* and *Semyon Kotko.* Soviet ballet music ranges from Prokofiev's *Romeo and Juliet* to Aram Khachaturian's *Gayane.* There is a union of Soviet composers.

Soviet performing artists have traditionally won international recognition, and to such well-known names as those of the pianist Emil Gilels and the violinist David Oistrakh have been added those of a brilliant new group including, among many others, the pianist Svyatoslav Richter, the cellist Mstislav Rostropovich (who, however, while serving as conductor of the National Symphony Orchestra in Washington, D.C., was deprived of Soviet citizenship), and the conductor Kiril Kondrashin.

Large folk-song choirs from differing national backgrounds have also won fame at home and abroad, and professional musical activities generally blend into and enrich amateur and folk music of all sorts, from balalaika orchestras to brass bands. Each summer, song festivals are held in public parks and squares, with individual performers and choirs participating. The international P.I. Tchaikovsky Competition for pianists, violinists, cellists, singers, and ballet dancers is held every four years in Moscow. At the first competition, in 1958, the young American pianist Van Cliburn won first prize.

Music festivals

Theatre and ballet. Soviet theatre, embodying the principles of Socialist Realism, has inherited much from the past, notably the tradition of Russian Realist theatre. By the second half of the 19th century and the turn of the 20th, this tradition included the Maly Theatre of Moscow (founded in 1824) and the renowned Moscow Art Theatre, founded in 1898 by the theatrical innovator Konstantin Stanislavsky, often characterized as the founder of modern acting, and his colleague V.I. Nemirovich-Danchenko.

Soviet theatrical growth was marked by the interaction of the old-established Bolshoi ("Large"), Maly ("Small"), and Art theatres in Moscow and the Aleksandrinsky, Mariinsky, and Mikhaylovsky theatres in St. Petersburg (now Leningrad), with the new Soviet theatres. Major Soviet drama producers have used a variety of forms and methods, often based on those of Stanislavsky. In similar fashion, the great traditional Russian actors passed on their skill to the newer generations of the Soviet period.

Of particular interest are the developments outside the leading centres, Moscow and Leningrad; such peoples as the Uzbeks, Kazakhs, Turkmens, and Kirgiz, who had no professional theatre before the Revolution, have

created vigorous national theatre based on traditional performing arts forms.

In addition to Soviet drama, the country's theatres put on many plays from the world and Russian literary traditions, from Chekhov to Shakespeare, Molière to Schiller. Modern foreign playwrights—Bertolt Brecht, Jean Anouilh, and Arthur Miller among them—are also often performed. These contemporary developments have been associated with the emergence of a young school of producers and actors.

Ballet stars

Contemporary Soviet ballet theatres strive to preserve all that is regarded as the best of the great pre-Revolutionary era while creating a repertory that conforms to Soviet reality and the interests of new audiences. Thus, new, heroic qualities appeared in the dancing of such stars as Yekaterina Geltser, A.N. Yermolayev, and S.M. Messerer, and the 1930s saw the development of many-act ballets with highly developed plots. That decade also saw the flowering of the talents of Galina Ulanova, the first Soviet prima ballerina *assoluta*. Ballet companies were also organized with striking results in the constituent republics. In later decades a new generation of performers—including Maya Plisetskaya, Yekaterina Maksimova, Vladimir Vasilyev, and many more—has emerged. Ballet in the West has been enriched by the emigration of several Soviet-trained dancers, among them the great Rudolf Nureyev and Mikhail Baryshnikov. Russian ballet has of course had a major influence on world dance, and Soviet companies continue to give many well-received performances abroad. There are almost 20 ballet schools, the best known being located in Moscow and Leningrad. Amateur ballet is also well developed.

The major Soviet theatres include the Gorky Moscow Art Theatre (MKhAT), whose curtain bears a sea-gull emblem as a symbol of the theatre's close links with Chekhov; the Maly Theatre in Moscow, one of the country's oldest; the Pushkin Academic Drama Theatre in Leningrad (the Aleksandrinsky Theatre from 1832 to 1920), after the Maly the great centre of Russian Realism; and the Academic Gorky Bolshoy State Drama Theatre in Leningrad, founded in 1919. In Kiev are found the Leslya Ukrainka and Ivan Franko theatres.

Opera and ballet theatres, in addition to the renowned Bolshoi Theatre (formally, the State Academic Bolshoy Theatre of the U.S.S.R., or GABT; founded in 1772), include the Kirov State Academic Theatre of Opera and Ballet in Leningrad (formerly the Mariinsky Theatre, founded 1836) and the same city's Maly Theatre (formally, Leningrad Academic Maly Theatre of Opera and Ballet), as well as the Academic Musical Theatre in Moscow, named after Stanislavsky and Nemirovich-Danchenko. The Shevchenko Theatre of Opera and Ballet is in Kiev. The Moscow Operetta Theatre is the major musical comedy stage.

Children's theatre

Almost all the country's theatres present special performances for children, and there are more than 150 theatres for children and young people, including puppet theatres. The most important include the Moscow Central Children's Theatre, the Moscow Young Spectators Theatre and its equivalent in Leningrad, and youth theatres in the major cities. The unique State Central Puppet Theatre in Moscow, founded and directed by Sergey Obraztsov, has delighted patrons of all ages in many countries.

Actors and producers are trained at the Lunacharsky Theatre Art Institute (GITIS), the Shchepkin and Shchukin theatre schools, the Moscow Art Theatre School, and many other institutions. Actors belong to the All-Russian Theatrical Society and analogous republic organizations.

Variety and circus. Both the variety stage and the circus are extremely popular in the Soviet Union, and the Soviet Folk Dance Ensemble, the Red Army Song and Dance Ensemble, and national groups have achieved world fame. Illusionists, acrobats, jugglers, and others appear in variety performances and also in circuses, which are well known for the variety of their performances and their high level of technique. Entertainments range from performances by the animals trained by V.L. Durov, noted for his scientific approach, to the clowning of Oleg K. Popov and others, much of which has a satirical, topical character.

Motion pictures. The cinema is undoubtedly the most popular form of Soviet art, the first Russian film having appeared in 1907. Historical themes and the developing Soviet experience provided the major subject matter of earlier films, and landmark productions of international renown include *The Battleship Potemkin* (1925; director Sergey Eisenstein), regarded as one of the world's great films; *Mother* (1926; director Vsevolod I. Pudovkin), from Gorky's novel, with Nikolay Batalov in the main role; *Earth* (1930; director Aleksandr P. Dovzhenko); and *Peter the Great* (1937–38; director Vladimir M. Petrov), from A.N. Tolstoy's novel.

Postwar films

Later years were characterized by a change of artistic emphasis to contemporary themes, notably the upheavals of World War II. Films include *The Cranes Are Flying* (1957; director Mikhail K. Kalatozov), *Ballad of a Soldier* (1961; director Grigory N. Chukhray), and *The Fate of a Man* (1959; director and leading actor Sergey F. Bondarchuk). There has also been a considerable output of biographical, documentary, and semidocumentary films. Films based on Russian and world classics include the *Hamlet* and *King Lear* of Grigory Kozintsev, several dramatizations of the novels of Dostoyevsky, and epics in several parts based on Tolstoy's *War and Peace* and Sholokhov's *Silent Don*. Other works popular with Soviet audiences include *The Living and the Dead, Soldier's Father,* the five-part epic *Liberation, The Belorussian Terminal,* and many others. International film festivals, held biennially in Moscow and Tashkent, are also very popular. There is a union of film workers (founded 1957).

Amateur activities. Folk art and mass nonprofessional art are widely developed. They include the production and performance of artistic works by dancers, ballad singers, singers of *chastushki* (rhymed couplets), and instrumentalists. There are many crafts workers. Clubs, palaces of culture, houses of folk art, and similar centres are the main base for a host of amateur organizations. Professionals may take part in amateur activities, and vice versa. Regular festivals, reviews, and competitions help raise the level of skill, and many professional groups and performers were originally amateur.

CULTURAL AND EDUCATIONAL INSTITUTIONS

Cultural and educational institutions include clubs, the institutions known as people's universities, libraries, lecture halls, museums, and parks of rest and culture. The stated basic object of these bodies is to spread political and scientific knowledge; to propagate the achievements of science and technology, of the arts, and of literature; and to organize the cultural leisure of the population. The Soviet authorities favour communal rather than individual leisure activity.

Clubs. There are some 135,000 clubs, all but 20,700 of them in rural areas. These are attached to and organized by individual state economic enterprises and collective farms, which are obliged to devote part of their income to the cultural and recreational functions carried out by the clubs. Membership is voluntary, but there are often strong social pressures on the individual to join, given the Soviet ethos. The clubs organize recreational evenings, concerts, lectures, and so on and provide facilities for amateur organizations such as dramatic, choral, dance, and musical societies.

Lecture halls and people's universities of culture. Lecture halls are to be found at many factories, farms, and other enterprises. They are important centres for the propagation of the state ideology as well as for the dissemination of cultural and scientific knowledge. A leading role is played by the all-union Znaniye (Knowledge) society, which organizes lectures, often providing travelling lecturers on particular topics in science and culture. The voluntary people's universities of culture have the aim of broadening people's political and cultural horizons through part-time courses of one to three years'

duration on such topics as Soviet and foreign literature, aesthetics, and the sciences.

Libraries. A considerable portion of the output of books, magazines, and newspapers enters the state library system. The Lenin State Library in Moscow is the country's largest, housing about 27,000,000 volumes in 173 languages. Other leading libraries are found in Leningrad at the Saltykov-Shchedrin Public Library (17,000,000 volumes) and at the U.S.S.R. Academy of Sciences; in Kiev at the Ukrainian S.S.R. Academy of Sciences; and in Moscow at the Moscow State University (MGU), whose Gorky Scientific Library houses 6,000,000 volumes.

Museums and galleries. Museum attendance in the Soviet Union is high. Most museums and galleries of art are state institutions, administered by the Ministry of Culture, but there are also museums established by volunteer enthusiasts, often found in small towns and rural areas. Famous museums include (in Moscow) the Central Lenin Museum, the Central Museum of the Revolution, the Armoury Museum in the Kremlin, the State Historical Museum, the Polytechnic Museum, the State Pushkin Museum of Fine Arts, and the State Tretyakov Gallery. Leningrad has the Hermitage and the State Russian Museum, while Kiev is the home of a historical museum, the Kiev State Museum of Ukrainian Art, and the Kiev State Museum of Russian Art. A unique place is occupied by the permanent Exhibition of National Economic Achievements, in Moscow; founded in 1959, it attracts 10,000,000 visitors annually.

Parks of rest and culture. Parks are administered by the state and by trade unions. The largest include the Gorky Central Park of Culture and the Sokolniki and Izmaylovsky parks in Moscow and the Kirov Central Park of Culture and Rest in Leningrad. Parks are the scene of many cultural events and lectures, including open-air Chess matches in the spring and summer.

COMMUNICATIONS MEDIA

The press. Soviet citizens are noted for their devotion to reading, and the Soviet Union produces more printed material than any other country. It takes first place internationally both in the number of books published and in the number of translations, producing works in 89 Soviet and more than 50 foreign languages. About a quarter of the total output deals with political, economic, and social matters, and one-tenth of the titles (and one-third of the copies) are belles lettres. About 30 percent of the books printed are educational literature, and books for children have become increasingly important. There are more than 200 book and some 15 newspaper and magazine publishing houses attached to a variety of state bodies.

The CPSU and the press

Newspapers include universally available Russian-language dailies, regional dailies in the languages of the constituent republics, and papers of smaller circulation published by individual ministries, economic enterprises, collective farms, and other organizations. Newspapers are owned and published by the Communist Party organization of the area or enterprise within which they circulate. The main all-union dailies are *Pravda* ("Truth"), the organ of the Central Committee of the CPSU; *Izvestiya* ("News"), the government newspaper, published by the Presidium of the Supreme Soviet; *Komsomolskaya Pravda,* published by the Central Committee of the Komsomol; and *Trud* ("Labour"), the organ of the All-Union Central Council of Trade Unions. *Pionerskaya Pravda,* the children's newspaper, is published thrice weekly, also by the Central Committee of the Komsomol. *Krasnaya Zvezda* ("Red Star"), the organ of the Ministry of Defense, is published six times a week. Other papers published two or three times a week are owned by the appropriate industrial ministry or trade union or by both jointly; these include, among others, special newspapers for workers in the railway, timber, and construction industries and for cultural workers, teachers, the medical profession, and athletes.

Content of all newspapers is closely scrutinized by party officials, and deviations from official policy are either eliminated by the editorial board or vigorously criticized after publication. On the other hand, newspapers often publish and investigate complaints by individual citizens and in this sense do provide a medium for the expression of public opinion. Criticism of the political and economic system as such, however, does not appear in the Soviet press. While content of individual newspapers varies according to the special interests of their readers, there is much common material supplied by official press agencies, of which by far the largest are TASS (the Soviet Telegraph Agency, founded in 1925) and APN (the Novosti Press Agency, founded in 1961).

Magazines

The number and circulation of weekly and monthly magazines increased greatly during the 1960s, though all are subject to the same restraints as the newspapers and are controlled by party organizations. Among the weeklies, two of the most important are *Literaturnaya Gazeta* ("Literary Gazette"), published by the Union of Soviet Writers, and *Ekonomicheskaya Gazeta* ("Economic Gazette"), published by the Central Committee of the CPSU, which deals particularly with problems of industrial organization. There are about 20 monthly publications for teachers, a dozen literary monthlies, and a variety of scholarly journals.

Radio and television. Soviet radio and television, like the press, are closely controlled by the state and party, and transmissions on ideological, political, economic, and social affairs, to which much time is devoted, reflect official policies. In addition to such aspects there is an increasing volume of light entertainment and special programs directed at, for example, preschool children, collective farmers, and the armed forces. Internal broadcasts are conducted in 70 languages, external broadcasts in 57 languages.

Although the first Soviet television transmissions began in 1931, it was not until the 1960s that a nation-wide system was developed. By the mid-1970s, television was accessible to about 80 percent of the total population. By use of communications satellites, the peoples of Central Asia, Siberia, the Far North, and the Far East receive programs originating in Moscow as well as the transmissions of their local stations. The Moscow television centre is the nerve centre of the Soviet system, from which the great majority of programs, whether live or filmed, originate, and the 1,758-foot (536-metre) tower at Ostankino is a striking feature of the city skyline, transmitting one colour and five black and white channels.

(I.V.Ko./J.C.D.)

BIBLIOGRAPHY

The land and people of the Soviet Union: Important works in Russian include AKADEMIYA NAUK SSSR, BOTANICHESKY INSTITUT, *Растительный покров СССР,* 2 vol. (1956), a detailed description of vegetation types; AKADEMIYA NAUK SSSR, ZOOLOGICHESKY INSTITUT, *Животный мир СССР; обзор фауны территории Союза и отчасти прилежащих стран на эколого-фаунистической и зоогеографической основе,* 5 vol. (1937–58), an excellent account of animal life; N.A. BOBRINSKOY, *Животный мир и природа СССР,* 2nd ed. (1960), a semipopular work providing a description of animal life; V.V. ALEKHIN, *Растительность СССР в основных зонах* (1951), a detailed description of the zonal vegetation types written by a major Soviet geobotanist; B.P. ALISOV, *Климат СССР* (1956), a comprehensive study of climate; A.A. BORISOV, *Климаты СССР,* 3rd ed. (1967; Eng. trans., *Climates of the U.S.S.R.,* 1965), dealing in detail with regional climates; L.S. BERG, *Географические зоны Советского Союза,* 2nd–3rd ed., 2 vol. (1947–52), detailed information on the natural landscapes according to geographical zones; L.K. DAVYDOV, *Гидрография СССР (воды и суши),* 2 vol. (1953–55), an authoritative work on hydrology; S.V. KALESNIK *et al.* (eds.), *Советский Союз, географическое описание в 22 томах* (1966–72), a 22-vol. geography of the republics and regions; N.I. MIKHAYLOV and N.A. GVOZDETSKY, *Физическая география СССР: Азиатская часть,* 2nd ed. (1970), a comprehensive study of the physical geography of the Asiatic regions, a continuation of F.N. MILKOV and N.A. GOVOZDETSKY, *Физическая география СССР,* 3rd ed. (1969), a general survey of the physical geography of the Soviet Union as a whole; F.N. MILKOV, *Природные зоны СССР* (1964), a detailed yet readable account of the natural regions; V.V. POKSHISHEVSKY, *География Населения СССР*

(1971), the standard work on population geography. English-language studies of the land and people include L.S. BERG, *Natural Regions of the U.S.S.R.* (1950; Eng. trans. from 2nd Russian ed., 1938); VIKTOR BUNAK *et al.*, *Contributions to the Physical Anthropology of the Soviet Union* (1960); JOHN P. COLE and FRANK C. GERMAN, *A Geography of the U.S.S.R.*, 2nd. ed. (1970); JOHN C. DEWDNEY, *A Geography of the Soviet Union*, 2nd ed. (1971); INNOKENTY P. Space Exploration

Space exploration may be defined as the investigation, by means of spacecraft, of all the reaches of the universe beyond the atmosphere of the Earth. Spacecraft, vehicles that operate above the Earth's atmosphere, include sounding rockets, Earth satellites, and lunar, planetary, and deep space probes.

Covered in this article are the basic elements of space flight, space programs, both manned and unmanned, space launch vehicles, the kinds of knowledge gained from space exploration, and proposed future missions (see also ROCKETS AND MISSILE SYSTEMS and LIFE-SUPPORT SYSTEMS).

On October 4, 1957, the Soviet Union launched the world's first artificial satellite, Sputnik 1, and set in motion a series of programs of space exploration by the United States and the Soviet Union. The first U.S. satellite, Explorer 1, was launched on January 31, 1958, not quite four months after Sputnik 1. Both nations participated during the next two decades in a space race, with nearly 1,700 successful launches of satellites and space probes of all varieties: scientific research, communications, meteorological, photographic reconnaissance, and navigation satellites, lunar and planetary probes, and manned space flights. The Soviet Union launched the first man into orbit around the Earth on April 12, 1961. On July 20, 1969, the U.S. landed two men on the surface of the Moon.

The cost

The cost of such programs was high. During the first 20 years of the space age, the United States spent more than $90,000,000,000 on its combined civilian and military space programs. More than half a million people have been employed directly in U.S. space endeavours. Corresponding data are not available from the Soviet Union, but from the physical evidence it is judged that Soviet expenditures and resources committed have been comparable, if not greater.

Many of the spacecraft, such as manned and reconnaissance vehicles, are designed for recovery. Most operational satellites become inert after a few months or years of operation. The North American Air Defense Command (Norad) keeps a constant watch on the thousands of objects of human origin circling the Earth in a variety of orbital paths. Both radar and optical telescopes are used. In addition to satellite payloads (active or inert) is a much larger number of objects classified as debris—spent upper stages of launch vehicles, bolts, tether cables, etc., that go into orbit along with functioning satellites, as well as fragments that result from in-space explosions. Eventually low-altitude debris re-enters the Earth's atmosphere and usually burns up. By mid-1977 Norad had tracked the decay of 5,700 payloads and debris. At that time there were still 888 payloads and 3,359 items of debris catalogued and being tracked in orbit. In size they ranged from the U.S. Skylab space station to bits of debris as small as a golf ball.

It is not yet possible to judge the value of the new knowledge of the Earth, planets, and solar system that has been gained through space endeavours. A wealth of new understanding and of new scientific puzzles has resulted. Many questions concerning the nature and origin of the cosmos have been answered, and many more have been raised. Until 1957, human beings were passive observers of the solar system. Now they have entered the realm of space and gathered firsthand knowledge of their planetary environment. Twelve men have been landed on the Moon, set up data-gathering experiments on the lunar surface, and brought back lunar rocks and soil for study and analysis. The hidden side of the Moon and the planets Mercury, Venus, Mars, and Jupiter have been photographed and studied, and probes have been sent on six-year journeys to Saturn. From the vantage point of Earth orbit, the Earth and its weather have been studied and communications relays and navigation aids have been established. Space stations have been placed in orbit with crews to observe and perform experiments for nearly three months.

Doing these things required new materials and a major expansion of technology and manufacturing techniques. Reliability goals far greater than ever before were set and exceeded. The functional reliability demanded in launch vehicles having 6,000,000 component parts—a reliability greater than 99.9999+—had never before been required. Whole new industries based on these new technologies have become established; *e.g.*, high-speed digital computers and inertial guidance systems. A new standard of technical ability has resulted from space exploration and space utilization. The sociological and long-term effects of space technology are difficult to assess from a limited perspective. Historical analogy suggests that the effects may well be as far-reaching as those of the Industrial Revolution.

Functional reliability of craft

The article is outlined as follows:

I. Prehistory to Sputnik 1
II. Elements of space flight
  The environment of space
  Basic considerations in spacecraft design
  Launching into space
  Flight trajectories
  Navigation, docking, recovery
III. Space programs
  Space launch vehicles
  Unmanned programs
  Manned programs
  Applications satellites
IV. Contributions to the physical sciences
V. Proposed future missions

I. Prehistory to Sputnik 1

The dream of flight into space is as old as astronomy. Once people learned that the lights in the night sky were actual bodies, a long way off, they felt an urge to travel to them. Tales of fanciful flight to the Earth's nearest celestial neighbour, the Moon, may be traced back to the 2nd century AD, when the Greek rhetorician Lucian wrote a satirical account of such a fantastic journey.

But hundreds of years were to pass before the motions of the planets about the Sun and the immense distances to be travelled were appreciated. Awareness of the universe evolved slowly until tools of observation were developed. In the 17th century Galileo's use of the telescope to study the Moon added greatly to contemporary knowledge. Within a few weeks he had mapped the major visible mountains and valleys of the Moon and concluded that it was a solid world. Turning his telescope to the planet Jupiter, he discovered four tiny specks that passed slowly across its face. Galileo deduced that these moving dots were moons of the planet. He postulated further that their small apparent size in comparison to that of the Earth's Moon was explained by the great distance to Jupiter. Thus for the first time a scale of magnitude was established. Further observation with the telescope confirmed the pattern of the solar system described by Copernicus a hundred years earlier. Johannes Kepler calculated the elliptical orbits of the planets. Later in the 17th century, Isaac Newton formulated his "laws of motion," which at last placed physics and astronomy on a firm theoretical foundation. Not until nearly a hundred years later were the first free balloon ascents made and the journey upward and away from Earth began (see also FLIGHT, HISTORY OF).

Fictional accounts of flight to the Moon appeared sporadically in the 17th and 18th centuries but were mostly based upon fantasy rather than upon any extrapolation of technology. In 1865 Jules Verne published *From the Earth to the Moon,* which made use of many still correct assumptions concerning space flight. A few years later, Edward Everett Hale's "Brick Moon" appeared, an account of an artificial satellite that was also designed to be used by seamen for navigational purposes. By the turn of the century the science fiction writings of H.G. Wells (*The First Men in the Moon* [1901] and *The War of the Worlds* [1898]) attracted much attention. The engineering achievements of the 19th and early 20th centuries led many to believe that flight to the Moon could be possible.

Fictional accounts of space flight

Three brilliant men, destined to be called rocket pioneers, were the first scientists to conceive pragmatically of space flight: the Russian Konstantin Eduardovich

Tsiolkovsky, the American Robert Hutchings Goddard, and the German Hermann Oberth.

Technology in the early 20th century was a long way from the level required for rocket-powered flight, but the theory and dynamics of such flights had been rigorously studied. By the end of World War II, the German development of rocket propulsion for aircraft and guided missiles (notably the V-2) had reached a high level.

Thus, with the German surrender in 1945, the United States as well as its Allies—Great Britain, France, and the Soviet Union—fell heir to the technical knowledge of rocket power developed by the Germans. The technical director of the German missile effort, Wernher von Braun, and some 150 of his top aides surrendered to U.S. troops. Most emigrated to the U.S., where they assembled and launched V-2 missiles that had been captured and shipped to the U.S. The Soviet Union carried out an unpublicized but extensive program that must have been very similar; Great Britain and France conducted smaller programs.

Missile technology and satellites

In both the United States and the Soviet Union the development of military missile technology was essential to the achievement of satellite flight. Preparations for the International Geophysical Year (an 18-month period devoted to a worldwide program of geophysical research) stimulated discussion of the possibility of launching artificial Earth satellites for scientific investigations. As a result, the planning committee for the IGY in 1954 passed a formal resolution calling attention to the desirability of using artificial satellites in the IGY program. The IGY extended from July 1957 through December 1958. Both the United States and the Soviet Union responded with announcements that they would prepare scientific satellites for launching during the IGY. While the United States was still developing a satellite launch vehicle the Soviet Union startled the world by placing Sputnik 1 in orbit.

The launching of Sputnik 1, followed a month later by Sputnik 2 carrying a live dog, caught millions by surprise. The failure by the U.S. to launch its small (two kilograms) payload on December 6, 1957, heightened that nation's political discomfiture in view of its supposed advanced status in science. Following debates in Congress on the necessity to achieve parity, the U.S. established the National Aeronautics and Space Administration (NASA) in October 1958. NASA conducts the U.S. national space program, making public all plans and scientific data obtained, with the exception of the military space program. The Soviet Union space program is, with few exceptions, clothed in secrecy.

II. Elements of space flight

THE ENVIRONMENT OF SPACE

Space, as considered here, may be defined as all the reaches of the universe beyond the atmosphere of the Earth. There is no definitive boundary of the atmosphere of the Earth. For convenience it may be considered to extend to an altitude of 100 miles (160 kilometres) above the Earth's surface (see also ATMOSPHERE). Such a distance is infinitesimal in comparison with the immensity of the universe. Even within the solar system, distances between planets are measured in tens of millions of miles. The distance to Pluto, the Sun's outermost planet, is more than 3,000,000,000 miles. While the planets and their moons all travel at different speeds about the Sun, the solar system itself is travelling through our galaxy, the Milky Way. The Earth's nearest neighbouring stars lie more than four light-years (about 25,000,000,000,000 miles) away.

Contents of space

This apparent unimaginable void of space, however, is not empty. Throughout these vast reaches, matter (largely hydrogen) is scattered at the extremely low density of perhaps 100 particles per cubic centimetre in interplanetary space and 10 particles per cubic centimetre in interstellar space. This is, however, a much greater vacuum than has been achieved on Earth. Additionally, space is permeated by gravitational fields and a wide spectrum of electromagnetic radiation, by cosmic rays and magnetic fields of unknown intensities and distributions. Until 1946, all deductions about space had been made from observations through the distorting atmosphere of the Earth. With the advent of high-altitude sounding rockets after World War II and the instrumented satellites and probes of the space age, it has been possible to discover at first hand the great complexities of space phenomena.

BASIC CONSIDERATIONS IN SPACECRAFT DESIGN

Types of spacecraft

Spacecraft is a general term that includes sounding rockets, artificial satellites, and space probes. They are considered separately from the rocket-powered space launch vehicle, which gives satellite or escape velocity to the craft. A space probe is a spacecraft that is launched at higher than Earth orbital velocity and escapes the Earth's gravitational attraction.

Space probes may be classed as lunar, planetary, or deep space. Other classifications of spacecraft are manned or unmanned, active or passive. A passive satellite transmits no radio signals. It may be tracked optically or with radar, and radio communications signals may be "bounced" off its surface. Active satellites send out radio signals to make tracking easier and to transmit data from their instruments to ground stations or other craft.

One other general differentiation of satellites is by function: scientific or applications. A scientific satellite carries instruments to obtain scientific data on magnetic fields, space radiation, the Sun or other stars, etc. Applications satellites have utilitarian tasks; examples are Earth survey, communications, and navigation satellites.

Spacecraft thus differ greatly in size, shape, complexity, and purpose. Since some 2,500 successful launchings of satellites and space probes were made between 1957 and 1978, it is convenient to group them into program families; for example, the Soviet Sputnik, Vostok, Molniya, Venera, etc., and the U.S. Explorer, Mercury, Intelsat, Apollo, Mariner, etc.

Lightness of weight and functional reliability are primary features of spacecraft design. Depending upon their mission, spacecraft may spend minutes, days, months, or years in the environment of space. Mission functions must be performed while exposed to high vacuum, extreme variations in temperature, and radiation.

There are nine general categories of subsystems found on most spacecraft: power supply, on-board propulsion, communication, attitude control, environmental control, guidance, computer, structure, and engineering instrument.

Power-supply subsystem. The power supply furnishes energy to all other subsystems. All active satellites need electrical power. It may be provided by batteries or by solar cells, fuel cells, or nuclear isotope devices. The amount of power supply required varies widely.

On-board propulsion subsystems. Many spacecraft missions require a source of rocket power to change spacecraft velocity for a variety of reasons. The rocket motors may use liquid, storable bipropellants, a monopropellant, or a solid propellant. Such on-board propulsion systems are used to change satellite orbits, to reduce velocity (retrorocket) for re-entry, or to slow down a spacecraft.

Communication subsystem. Radio communications link spacecraft with receivers on the Earth. Spacecraft transmitting and receiving antennas must be precisely pointed toward the Earth-based antenna "dishes" for maximum signal strength. Very high frequencies are used for spacecraft communication to penetrate the Earth's ionosphere. Frequencies in the range of 100 to 3,000 megahertz (millions of cycles per second) are common. Spacecraft do not transmit continuously, although tracking beacons often do to ensure against loss of contact, particularly in deep space (planetary) probes.

Attitude-control subsystem. There are two main functions of a spacecraft's attitude-control subsystem: stabilization and pointing. Stabilization is the act of maintaining a spacecraft oriented in a specific direction despite the contrary effects of various natural forces. "Pointing" refers to a requirement to point precisely at selected targets. Balanced in a weightless condition in satellite orbit or in free-fall on an Earth-escape trajectory, a spacecraft is subject to rotation about any, or all, of its three axes

(pitch, yaw, and roll). Various stabilization techniques have been studied and tried. The pressure of sunlight itself can cause a spacecraft to twist into undesired orientation. The pressure of sunlight acting on paddles has been used for attitude control on planetary space probes.

Pointing requires most satellites and space probes to aim their sensors at a target, be it the Sun, portions of the Earth, a planet, or a star. Similarly, the transmitter must be aimed at the Earth during transmission.

Environment-control subsystem. Anticipating and understanding the environmental conditions of space in a planned mission, a spacecraft designer provides for control of these conditions within desired limitations. The high vacuum, extreme temperatures of the Sun, ultraviolet, cosmic, and X-radiation, and other space conditions can affect instrumentation and communications equipment. Lest one side of a sunlit spacecraft be always in shadow, rotation may be employed to distribute solar temperature effects evenly. On the Moon, surface experiments must survive the very low temperature during the two-week-long lunar nights. Heating is sometimes provided and reflective insulation used. The interior of a spacecraft may become hot because of electric power thermal effects. Some spacecraft have louvres that open on the shaded side of the spacecraft to cool the interior.

To be habitable, manned spacecraft require a reasonable approximation of Earthly conditions. Fresh oxygen to breathe is necessary. Air-conditioning systems circulate the weightless air, remove toxic substances, and control temperature and pressure (see LIFE-SUPPORT SYSTEMS).

Guidance and control subsystems. The function of the guidance and control subsystem is to steer a spacecraft to its target and control its velocity. In the case of a spacecraft whose mission is to land softly on the Moon, on approach trajectory the attitude-control subsystem will rotate the spacecraft so that its retrorocket and landing radar are pointed toward the lunar surface; radar signals will tell the spacecraft guidance system the rate of descent and the distance to the surface, and this information will be compared continuously with on-board data that tell the spacecraft when to fire its retrorockets, which fire until radar data indicate that touchdown will occur at near-zero velocity and then shut off. Concurrently, the attitude control rocket thrusters will maintain precisely vertical trajectory to the surface.

Use of radar

Computer subsystem. Early satellites transmitted orientation data to the ground control, where digital computers calculated corrective changes. Increasingly, miniature computers are placed in the spacecraft.

Structure subsystem. The structure subsystem is the skeleton framework of the spacecraft, which physically supports and protects all other subsystems. Many spacecraft have a central core and deployable appendages such as antennas, solar cell paddles, and gravity-stabilization booms. The structure is usually made of aluminum or magnesium for lightness. Spacecraft shape is always symmetrical about at least one axis, to prevent wobbling while rotating; but since most spacecraft are not designed for recovery but operate in space only, their appearance is often unusual and angular, without concern for aerodynamic streamlining. Structural stiffness is required to withstand the stresses of launch accelerations. Thermal protective shields are provided for spacecraft that reenter the Earth's atmosphere and are recovered.

Engineering instrument subsystem. This subsystem is composed of all the "housekeeping" sensors. Included are voltmeters, ammeters, thermometers, and other instruments whose measurements provide data on the status of the spacecraft. In a manned spacecraft these status sensors telemeter to Earth as well as to display panels for monitoring by the astronauts. Also, the astronauts themselves are monitored by bio-instruments to keep watch on their physical well-being.

LAUNCHING INTO SPACE

Gravity. The gravitational attraction of the Earth was one of the major obstacles to space flight. Rocket pioneers understood the principles of space flight based upon the observations and calculations of Copernicus, Galileo, and Kepler, and on Newton's universal laws of motion; but the use of these principles had to await the development of rocket power to project a spacecraft to the required altitude above the Earth and to give it the velocity necessary to accomplish its mission.

The spacecraft at the forward end of a multistaged launch vehicle is projected upward by reaction to the high-speed jet of combustion gases produced in the rocket motor. If the lifting force, or thrust, of a rocket-powered launch vehicle is twice the weight of the vehicle at lift-off, then the spacecraft assembly will rise at an initial acceleration of one *g*, or 32.2 feet (9.8 metres) per second, each second. Because the propellant mass is being consumed and ejected from the rocket motor, the vehicle is continually lightened and acceleration increases.

The gravitational pull of the Earth upon the upward (and outward) travelling spacecraft subsides slowly. At an altitude of 100 miles (160 kilometres), the gravitational attraction is just 1 percent less than at the Earth's surface. At 1,700 miles (2,700 kilometres) it is halved (16.1 feet per second per second), and at 60,000 miles (97,000 kilometres) it is one-twentieth. For the purposes of space flight, the gravitational pull of the Earth becomes negligible only at distances of several million miles, except when a spacecraft approaches the Moon and lunar gravity (one-sixth that of Earth) exerts effect.

Decrease of gravitational pull

Staging. This term is used to describe a technique by which several rocket propulsion systems are mounted one on top of the other. The lowest, or first, stage ignites and lifts the vehicle at increasing velocity until its propellants are exhausted. At that point the stage drops off and a second stage is ignited. In this technique the empty propellant tankage and vehicle structure are cast off, thus lightening the weight of the launch vehicle. The second stage of lower thrust then begins to accelerate the launch vehicle and spacecraft, commencing at the velocity reached under first-stage power. Most space launch vehicles have three stages. Tsiolkovsky, Goddard, and Oberth all investigated this technique independently.

Acceleration rates. In general, the longer it takes a space vehicle to leave the Earth's atmosphere and achieve required velocity, the less economical the procedure becomes. At low accelerations the launch vehicle wastes great quantities of rocket propellant because it is losing, in effect, about 32 feet per second of velocity each second of travel. An upper limit of acceleration is governed by the maximums of accelerative stress permissible upon the vehicle structure and the spacecraft payload. In manned flight a gravity pull of six *g* is considered the maximum tolerable when the human body is positioned transversely with respect to the acceleration force (*g*-loading); *i.e.*, with the head and heart at the same level.

FLIGHT TRAJECTORIES

There are four general types of trajectories: sounding rocket, Earth orbit, Earth escape, and planetary.

Sounding rockets. The sounding rockets first launched for upper atmosphere studies in 1945 were fired nearly vertically. Generally single-staged, they reached speeds of 3,000–5,000 miles (4,800–8,000 kilometres) per hour. Burnout, the completion of rocket motor firing, usually occurred at altitudes of 10 to 20 miles (16 to 32 kilometres), at which point the rocket coasted upward, slowly losing speed because of gravity. Velocity upward dropped to zero at peak altitude, and the rocket began its fall, picking up speed until it crashed into desert or ocean. Instrumentation carried aboard for data gathering was sometimes ejected to descend by parachute, but increasingly the data were radioed (telemetered) to a tracking station at the launch site. Altitudes of 100 miles were reached with single-stage rockets.

Earth orbit. Earth orbital flight is achieved by launching vertically and then tilting the trajectory so that flight is parallel to the Earth's surface at the time that orbital velocity at the desired altitude is reached. At this precise point, the rocket engine is cut off. A spacecraft attached to the final-stage rocket is then in free fall about the Earth, the centrifugal pull on the spacecraft being equal to the Earth's pull of gravity. At an altitude of 125 miles

(200 kilometres), Earth orbital velocity is about 18,000 miles (29,000 kilometres) per hour. Since this 125-mile altitude is above most of the atmosphere, aerodynamic drag is not great, and the spacecraft will continue to orbit for an extended time.

The length of time required for the satellite to make one complete revolution is known as the period of orbit. At 125 miles this is about 90 minutes. At higher altitudes than this above the Earth, the velocity of a satellite decreases and the orbital period increases.

For example, at an altitude of 1,075 miles (1,730 kilometres) the orbital velocity is 15,800 miles (25,400 kilometres) per hour and the period is two hours. At 22,300 miles the velocity is 7,000 miles (11,300 kilometres) per hour and the period 24 hours. Since this particular period is equal to the time the Earth rotates once, such a satellite travels at the same angular velocity as the surface of the Earth and appears to be stationary in the sky. This particular orbit, called geostationary (or geosynchronous), has special value to communications and meteorological satellites. Finally, the Moon travels in an orbit of about 240,000 miles (386,000 kilometres). Lunar velocity about the Earth is about 2,300 miles (3,700 kilometres) per hour, with a period of about 28 days.

The geostationary orbit

The above applies only to circular orbit, often ideal, but difficult to achieve. Usually a satellite's orbit is an ellipse with a perigee altitude and an apogee altitude. Perigee and apogee are defined, respectively, as the points of the orbit

By courtesy of National Aeronautics and Space Administration

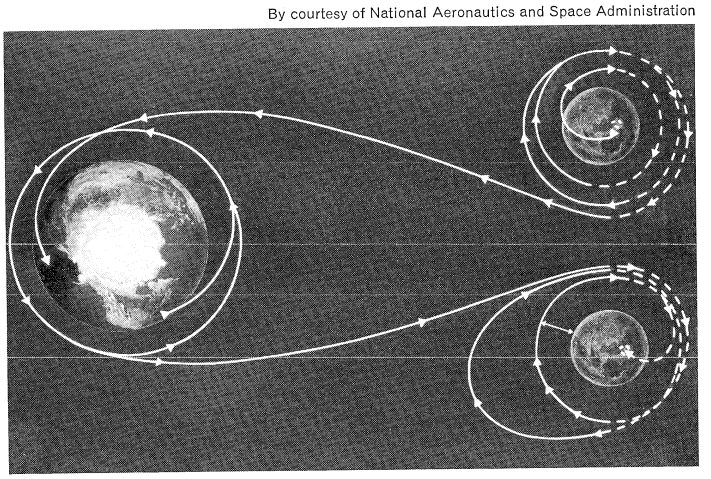

Figure 1: Apollo 11 lunar landing mission profile.

nearest and farthest from the body orbited. Orbits may be circularized if thrust is available by reducing the velocity at perigee (apogee is lowered) or by increasing the velocity at apogee (perigee is raised). Rocket power in such instances is applied along the axis of flight paths.

In projecting a satellite into Earth orbit, the launch vehicle is tilted after liftoff in an easterly direction. Launching to the east is done to take advantage of the Earth's eastward surface velocity. This rotational surface velocity is about 1,500 feet (450 metres) per second at the equator and 1,370 feet (400 metres) per second at the latitude of Cape Canaveral. It would be perfectly possible to launch a satellite on a westerly orbit, but an additional 2,000 feet (600 metres) per second would be required for an orbit of the same altitude compared with an easterly orbit.

If the satellite is launched in a northerly or southerly direction, a polar orbit is obtained. The easterly surface velocity launch advantage is lost, but there are other advantages. As the Earth turns on its polar axis, the satellite travels over all parts of the globe every few revolutions. This ground track, the path around the Earth directly under the satellite, thus varies according to the orbit, which is chosen according to the desired characteristics of a particular mission. Ground-tracking and data-receiving stations must be on or near the ground track.

Earth escape. In order to escape completely from the Earth's gravity, a spacecraft launch velocity of about 25,000 miles (40,000 kilometres) per hour is required. At that speed the spacecraft is able to reach distances beyond the Earth's gravitational field. If the spacecraft does not come under the gravitational influence of other celestial bodies, it will go into an orbit about the Sun like a tiny planetoid. With precise timing it is possible for the spacecraft to enter a trajectory that will carry it near the Moon. In the case of eight Apollo flights, the spacecraft was placed in a trajectory calculated to pass ahead of the Moon and, under the influence of lunar gravity, to swing around the far side. If no manoeuvre was made the spacecraft would loop around the Moon and return on a trajectory toward the Earth. By reducing flight speed on the far side of the Moon, the spacecraft was placed in lunar orbit held by lunar gravity.

Consideration of the actual dynamics of the Apollo trajectory will illuminate the statements made above (see Figure 1). The Apollo 11 spacecraft had been in an Earth orbit of 115–117 miles altitude, travelling at 17,427 miles per hour. By firing the rocket motor at the exact moment when the spacecraft was precisely aligned along the proper trajectory, the velocity was increased to 24,200 miles per hour. Because the Earth's gravitational pull continued to act upon the spacecraft during its 64-hour journey toward the Moon, the spacecraft velocity, with respect to the Earth, dwindled to 2,040 miles per hour at a distance of 39,000 miles from the Moon. At this point lunar gravitational attraction became greater than the Earth's, and the spacecraft began accelerating as it swung toward and around the far side of the Moon, reaching a speed of 5,600 miles per hour. By firing the rocket propulsion system, the velocity was reduced to 3,680 miles per hour and the spacecraft entered an elliptical orbit about the Moon. This orbit was later circularized preparatory to the actual lunar landing operations.

Apollo 11

The so-called three-body problem of mechanics (the relative motions of the Earth, the spacecraft, and the Moon) is extremely complex (see MECHANICS, CELESTIAL). Although equations expressing the relative motions can be written, no general solution was possible before the development of the high-speed digital computer, for ballistics calculations for long-range missile trajectories. The computer integrates the complicated equations of motion numerically upon command, provides direct readout of the complete translational motions of the spacecraft, and compares the actual to the preplanned flight path at any point in time.

Planetary flights. Because of the elliptical nature of the planetary orbits, distances to Earth's nearest neighbouring planets, Venus and Mars, vary. A so-called favourable launch opportunity occurs about every two years. Flights can be made at other times, but the velocity required is greater and length of time is longer, or, for the same launch vehicle, a lighter payload is necessary. Figures 2 and 3 show flight paths to Venus and Mars, respectively.

The trajectory from the Earth to Venus or Mars may be planned to take advantage of the changing orbital relationships of the planets for the most economical flight. Such advantageous paths were calculated in the late 1920s. Although these transfer trajectories require the least velocity, they are of long duration, as long as 260 days to Mars. Thus a compromise trajectory is used, as in the case of Mariners 6 and 7 in 1969. Launched on February 25, 1969, Mariner 6 passed within 2,131 miles of the planet 157 days later, when Mars was 58,000,000 miles distant from the Earth.

Changing orbital relationships of planets

NAVIGATION, DOCKING, RECOVERY

Navigation. Travelling from point A to point B in space is almost never in a straight line or at constant velocity because of the many influences on the body in motion.

The basis for space navigation is inertial guidance; that is, guidance based on the inertia of a spinning gyroscope, irrespective of any external forces and without reference to the Sun or stars. By the use of three gyroscopes and accelerometers, precise measurements may be made of any change of velocity (acceleration), either positive or

negative, along any or all of the three axes. By use of a memory system in the computer it is possible to determine where the vehicle is at any time along a trajectory.

Trajectory correction

By changing attitude (rotation about one or more axes) and firing a small jet or rocket motor, corrections may be made to the trajectory. Preprogrammed digital computers, both on the ground and in larger spacecraft, automatically or on command "keep an eye on" where the spacecraft is, where it was, and where it is supposed to be going. Direct readouts of such data from the computers are displayed to the crew in manned spacecraft.

During the launch phase, corrections to deviations in planned flight path are usually made at once by special small thrust motors, by deflection of the rocket exhaust jet, or by swinging one or more of the rocket engines in a gimbal mount.

In the case of rendezvous between two spacecraft, radar sightings fed to the computer tell the crew the corrections required along each of the three axes in feet per second (plus or minus). In the case of a lunar mission, deviations encountered are stored in a computer memory system until requested. One or more midcourse manoeuvres may be made. During Apollo lunar flights an optical sighting on three stars by means of a sextant was used as a backup system and check on the spacecraft position.

The above description of navigation techniques is oversimplified; the systems used are complex, powerful tools without which manned or unmanned spacecraft would not be feasible.

Rendezvous and docking. Rendezvous is the action of one spacecraft approaching another spacecraft. Rendezvous in space operations refers to a match of orbital trajectories and the action of one spacecraft arriving in proximity to another. Ideally, the orbit planes should be the same. The term is relative but, generally speaking, rendezvous distance should be within 100 yards or metres. To achieve rendezvous, the launch of the second spacecraft is timed within a fraction of a second. Since the orbiting spacecraft already has a high velocity and the second spacecraft is at rest (zero velocity) before launch, the second spacecraft is launched well before the first spacecraft passes overhead. Aim is for a co-planar orbit just below the first spacecraft. When this is done, the first spacecraft is travelling at a slower speed, being at a higher orbit; thus the second spacecraft will overtake the first. When slightly ahead of the first spacecraft, application of rocket thrust causes the second spacecraft to rise in orbit and thus to slow down, matching the first spacecraft's orbital altitude and velocity. Radar systems and on-board computers are necessary for such operations.

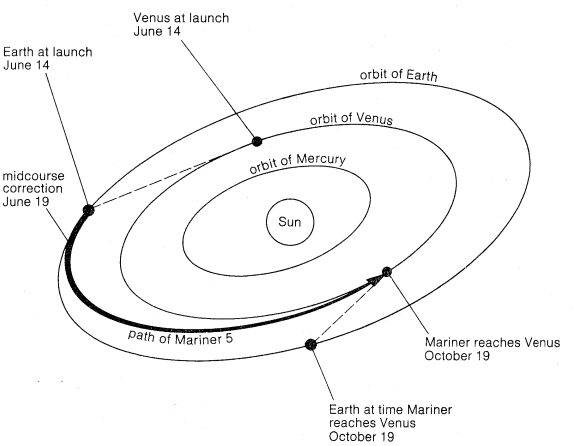

Figure 2: Flight path of Mariner 5 from Earth to Venus, 1967.

First spacecraft rendezvous

Gemini 6 and 7 were the first spacecraft to rendezvous with each other. In Apollo lunar landing flights the ascent stage of the Lunar Module rose from the surface of the Moon to rendezvous and dock with the orbiting Command Module.

Docking, the term for meeting and mating of two spacecraft, was an essential element of the Apollo lunar landing (lunar-orbital rendezvous) technique and is essential for many plans for future manned space exploration, such as a permanent Earth-orbiting space station. Significant in docking manoeuvres, from the starting point of rendezvous, are precise radar data (distance and closing velocity rate), attitude control, and computer subsystems. Whereas the United States has relied upon on-board crew guidance for close rendezvous and docking, the Soviet Union has demonstrated the ability to perform this task automatically (1967).

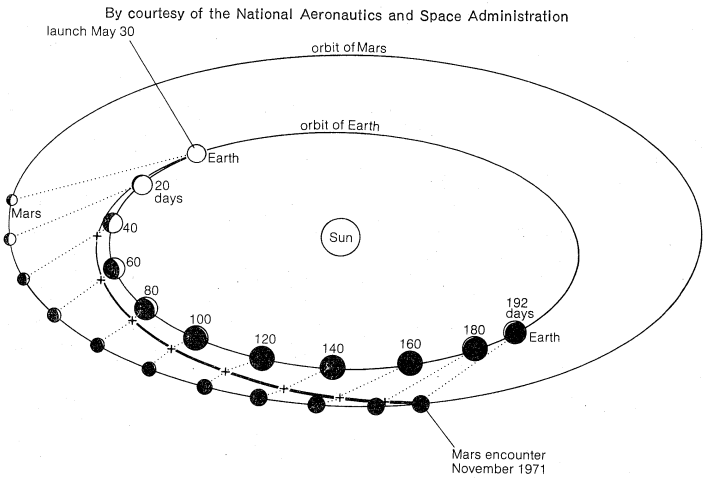

Figure 3: Flight path of Mariner 9 from Earth to Mars, 1971.

The concept of building a large space station out of component parts brought to orbit in successive stages or, similarly, assembling a deep space mission as for a manned trip to Mars, requires a reliable rendezvous and docking technique. The entire vehicle and propellants cannot be launched into Earth orbit at one time because of limitations on space launch vehicle payload. Further, rotation of space crews and emergency rescue missions require rendezvous and docking capability.

Re-entry and recovery. Re-entry means the return of a spacecraft into the Earth's atmosphere. This blanket of relatively dense gas surrounding Earth is useful as a braking, or retarding, force resulting from aerodynamic drag. A concomitant effect, however, is rapid and severe frictional heating caused by rapid flow of nitrogen and oxygen molecules along the blunt forward profile of the spacecraft. By use of an ablative heat shield, specially formulated plastic materials melt, vaporize, and carry away boundary layer heat. Insulation behind the heat shield keeps the spacecraft interior at a constant tolerable temperature.

Angle of re-entry

Inherent in safe re-entry of a spacecraft is precise control of the angle of re-entry. This angle of trajectory with respect to the Earth's horizon is —6.2° and is held within limits of ±1°. A returning Apollo Command Module approached the Earth at nearly 25,000 miles (40,000 kilometres) per hour. If the angle is too shallow, the spacecraft will skip or bounce off the atmosphere out into space probe trajectory. If the angle of re-entry is too great, the heat shield will not survive the extreme heating rates nor the crew and spacecraft the high *g*-forces. Even so, the heat shield of the Apollo Command Module was subjected to temperatures approaching 5,000° F (3,000° C).

The Apollo spacecraft under atmospheric drag slowed to the speed of sound (Mach 1) at 30,000 feet (9,000 metres). Shortly thereafter, three closed parachutes were deployed, then opened fully at about 10,000 feet (3,000 metres). The Command Module struck the ocean at about 22 miles (35 kilometres) per hour. Recovery helicopters and surface ships reached the spacecraft usually within minutes.

The Soviet Union recovers manned spacecraft on the plains of Siberia. Soviet cosmonauts, at least on early flights, could elect to parachute separately from the spacecraft in final stages of descent.

The United States Air Force recovers small spacecraft by aircraft while the spacecraft is still descending by parachute. This air-snatch technique eliminates the problem of search and recovery of spacecraft after landing and minimizes the time before study can be made of data obtained.

III. Space programs

Considering the two categories of space programs, manned and unmanned, a few generalizations may be made. Spacecraft without a human being aboard have invariably pioneered explorations. They are smaller, can operate for months or years, and offer no hazard to human life. Experiments and measurements, however, are limited by the need for preplanning. In manned flights, the range of experiments is greater because judgment can be exercised in observations, instrumentation can be adjusted, and, perhaps, repairs can be made and equipment maintained.

Manned space flight is much more expensive because of the added weight of vehicle and equipment required to provide a habitable atmosphere and controls. This extra weight requires a much larger space launch vehicle. Often, redundant or backup systems are provided in manned spacecraft to provide for high reliability and safety of personnel.

Thus, both categories of spacecraft have advantages and disadvantages.

SPACE LAUNCH VEHICLES

Although sounding rockets may reach altitudes above the atmosphere of the Earth, the term space launch vehicles is applied usually to those rocket boosters designed to place satellites in orbit or to impart Earth-escape velocity to spacecraft.

About 1950 the technology of rocket propulsion had reached a level at which consideration of a project to launch an artificial Earth satellite became feasible. Although space travel—flight to the Moon and planets—had been dreamed about for centuries, it was only now that the critical element, a rocket-powered space launch vehicle, could be constructed. Worldwide scientific studies during the International Geophysical Year (IGY), 1957–58, provided the basis for funding. In 1955 both the United States and the Soviet Union announced satellite programs as part of their national effort in the IGY.

First satellite programs

When Sputnik 1 and 2 were launched in 1957 the Soviet Union released no details of their launch vehicles. In May 1958 Sputnik 3, weighing nearly 3,000 pounds (1,360 kilograms), was launched.

It was not until 1967 that the basic Soviet launch vehicle was displayed. It was a 2½-stage vehicle: two stages with four drop-away booster pods. Each booster pod contained four rocket engines (totalling 16) with propellant tankage, and the central core had four engines. Propellants were conventional liquid oxygen and kerosine. Lift-off thrust of this vehicle was estimated at about 1,000,000 pounds (450,000 kilograms); it was a conversion of the Soviet intercontinental ballistic missile Sapwood.

The United States launched its early small satellites with two different vehicles, the Jupiter-C and Vanguard. Jupiter-C was a modified Redstone liquid-propellant ballistic weapon of medium range to which were added additional tankage length and three upper stages of clustered solid-propellant rockets. The modification was originally designed to achieve a velocity of 20,000 feet (6 kilometres) per second to test a nose cone (re-entry vehicle). The desired velocity was obtained with two upper stages, one a cluster of four solid-propellant rockets and the other a single rocket. Each rocket developed 1,800 pounds (800 kilograms) of thrust for 6.5 seconds. It was obvious that by increasing the final velocity 5,000 feet per second to the required 25,000 feet per second, Earth satellite velocity could be obtained for a small scientific payload. The additional velocity was obtained by adding another stage with a cluster of solid-propellant rockets so that the upper stages consisted of 11, three, and finally one rocket carrying a payload weighing 18.1 pounds (8.2 kilograms). Late in 1954 the Army Ballistic Missile Agency and the Office of Naval Research jointly proposed this scheme, known as Project Orbiter, but a newly designed Vanguard launch vehicle was selected. Failures in early attempts to launch Vanguard, however, resulted (two and one-half years later) in eventual approval of the Project Orbiter approach. Thus the first U.S. satellite was launched by a Jupiter-C on January 31, 1958.

The Vanguard launch vehicle was a three-stage booster approximately equal in length (about 72 feet) to the Jupiter-C but much lighter in takeoff weight (22,600 pounds compared to 64,000 pounds). Vanguard launched its first satellite (3 pounds) into high orbit on March 17, 1958. After a few more flights, the Jupiter-C was retired in 1958 and the Vanguard in 1959.

Vanguard

During the 1960s the United States developed a series of standard launch vehicles. The Air Force modified a Titan II intercontinental ballistic missile (ICBM) for space launch purposes by strapping two solid-propellant booster rockets, 10 feet in diameter, to the liquid-propellant core vehicle. The Titan IIIC is used for large military satellites. Then NASA increased performance of the obsolete Thor intermediate-range ballistic missile (IRBM) by adding solid-propellant boosters. A liquid oxygen/liquid hydrogen upper stage, Centaur, is used on obsolete Atlas ICBM's and Titan III ICBM's to launch large planetary space probes.

The Saturn series of NASA launch vehicles was developed specifically for the Apollo lunar mission program. The two operational Saturn models were the two-stage Saturn IB and three-stage Saturn V. The Saturn IB was used for Earth orbital developmental missions of Apollo, while the Saturn V, largest of all known space boosters, was used for lunar missions. Saturn V stood 363 feet (110.6 metres) high and weighed more than 6,000,000 pounds (2,700,000 kilograms) at launch. It was capable of placing 230,000 pounds in orbit and sending 95,000 pounds (4,300 kilograms) to escape velocity.

At the conclusion of the Apollo program in 1972, excess Apollo spacecraft and Saturn launch vehicles were used for the Skylab missions and the Apollo–Soyuz Test Project. The development of these great space boosters with the safety and reliability standards required for launch of manned missions to the Moon was a major challenge to the aerospace industry.

In the Soviet Union all space launch vehicle developments, as well as launch operations, are controlled by the military forces. Knowledge of details of design and performance of all vehicles is limited.

For some years the launching of spacecraft was limited to the U.S. and Soviet Union. The reason was that the rocket-powered launch vehicles were based upon long-range ballistic missiles, which only these countries had developed. France was the third nation to launch a satellite (1965), followed by Japan (1970), the People's Republic of China (1970), and the United Kingdom (1971). Both the United States and the Soviet Union have launched satellites or carried scientific payloads for other nations. The United States regularly launches communications satellites for U.S. industrial organizations and other nations, the cost being reimbursed. Eleven of a total of 15 NASA launches in 1977, for example, were for other nations, the North Atlantic Treaty Organization (NATO), the International Telecommunications Satellite Organization (Intelsat), and the European Space Agency (ESA).

Cooperative launchings

UNMANNED PROGRAMS

The unmanned space exploration program includes sounding rockets, scientific satellites and probes, and lunar and planetary programs (Table 2).

Sounding rockets. At the conclusion of World War II the Allies fell heir to the great advances in rocket technology made by the Germans in connection with guided missile development (see also ROCKETS AND MISSILE SYSTEMS).

The first program to use sounding rockets in exploration of the upper atmosphere was carried out from 1946 to 1951, when the United States Army fired about 60 V-2s in

near-vertical trajectories in New Mexico. The one-ton warhead was replaced by a payload of scientific instruments. The highest altitude obtained in these firings was 133 miles (214 kilometres).

The Aerobee and Viking sounding rocket programs were similar projects conducted at White Sands by the United States Navy, reaching altitudes of about 200 miles (320 kilometres).

During the decade following the war, rocket engine technology, supersonic design, flight controls, tracking, instrumentation, and other essential elements of sounding rockets were under development while high-altitude data were being obtained. Typical instrumentation carried aboard Viking rockets included Geiger (particle) counters, ionization chambers, photomultiplier tubes, and cameras.

The development of the Nike series of surface-to-air guided missiles provided a new family of relatively low-cost sounding rockets. With the exception of those sounding rockets based on the liquid-propellant Aerobee design, all U.S. sounding rockets by 1971 used solid propellants. During the 18-month International Geophysical Year (1957–58), there were many cooperative programs around the world in which sounding rockets were fired for scientific purposes. The U.S. launched 210 rockets from widely separated locations, including the Arctic, California, and Guam in the Pacific Ocean.

IGY programs

Meanwhile the Soviet Union and many other countries developed and launched sounding rockets. The Soviet Union launched 125 rockets during the IGY from locations in the Arctic, Antarctica, and Central Asia. It also has a variety of sounding rockets called simply Geophysical Rockets. In 1957 one of these carried a large payload of 4,850 pounds (2,200 kilograms) to an altitude of 132 miles (212 kilometres). In the payload was a capsule containing two dogs, which were parachuted safely to Earth. Later in the IGY a large Soviet payload soared to 294 miles (473 kilometres). Measurements were made of the Earth's magnetic field, physical and chemical nature of the Earth's upper atmosphere, cosmic and solar radiation, X-rays and ultraviolet radiation, and micrometeoroids.

Other countries having sounding rocket programs include Argentina, Australia, Canada, France, Germany, Great Britain, India, Italy, Japan, Norway, Poland, and Sweden. Often these programs are cooperative.

Less glamorous than their larger cousins that launch satellites and space probes, sounding rockets are workhorses valuable to continuing scientific studies. Although the period of their measurements is brief, usually five to 10 minutes, they provide the only feasible way of taking such measurements between 25 and 100 miles (40 and 160 kilometres) altitude above the Earth—above the range of aircraft and balloons and below minimum continuous satellite orbital height. Additionally, by using miniaturized payloads of sophisticated design, the U.S. has employed sounding rockets to perform experiments in materials processing under brief weightless conditions and conducted observations of stars emitting gamma rays.

Scientific satellites and space probes. This category of programs includes those spacecraft whose purpose is to make measurements of natural phenomena in space environment. Generally, these measurements are of solar and other cosmic radiation, magnetic fields and observation of stars. Such data are important in developing and verifying theories of the evolution of the solar system and the fundamental natural processes and forces that affect Earth and people. These natural processes directly affect living conditions, agriculture, and economy. This is the underlying logic behind space research.

The United States has a number of programs in this category. The Orbiting Solar Observatory (OSO), first launched in 1962, was the first of a series of these observatories that point toward the Sun and record and transmit a variety of data such as the frequency and energy of solar electromagnetic radiation in ultraviolet, X-ray, and gamma ray regions of the spectrum. An OSO carries instruments for eight to 10 experiments. The spacecraft consists of two major parts, a spinning base and a fan-shaped panel of solar cells that points continuously at the Sun. Altitude above the Earth is about 350 miles (560 kilometres).

Orbiting Solar Observatory

A Pioneer series of small spacecraft operates in deep space in solar orbit, typically carrying out experiments involving measurement of magnetic fields, plasma analysis, and cosmic-ray and solar-wind studies. Data are stored on recording tape and played back rapidly upon command from Earth.

An Explorer family of spacecraft collects a widely variant series of data. Explorer 1, the first United States satellite, was launched by the U.S. Army. The program was taken over by NASA after its organization in 1958. Explorer satellites have made measurements of the magnetosphere, Van Allen radiation belts, micrometeoroids, energetic particles, cosmic radiation, solar wind, and ionosphere. Some Explorer satellites, called Interplanetary Monitoring Platforms, are placed in eccentric orbits to take measurements at maximum altitudes. Another subseries of Explorer satellites is the Small Astronomy

Sputnik 3	U.S.S.R.	May 15, 1958	*	133–1,178	2,926	first instrumented multipurpose space laboratory (atmospheric pressure, composition; positive ion concentration, primary cosmic ray data, etc.)
SCORE	U.S.	Dec. 18, 1958	Atlas	115–915	8,800	first transmission of voice messages from space
Luna 1	U.S.S.R.	Jan. 2, 1959	*	91.5–214.7	796	first space probe to achieve Earth-escape velocity; radio contact to 371,000 mi
Vanguard 2	U.S.	Feb. 17, 1959	Vanguard	347–2,064	22	first cloud-cover photos transmitted by television
Luna 2	U.S.S.R.	Sept. 12, 1959	*	(Moon impact)	860	first spacecraft on Moon
Luna 3	U.S.S.R.	Oct. 4, 1959	*	25,500–294,250	959	first circumnavigation of Moon; first pictures of far side of Moon
TIROS 1	U.S.	April 1, 1960	Thor-Able	428.7–465.9	280	first weather satellite; television view of cloud cover; 22,952 photos transmitted
Transit 1B	U.S.	April 13, 1960	Thor-Able-Star	430–468	265	first navigation satellite
Discoverer 13	U.S.	Aug. 10, 1960	Thor-Agena A	161–436	300	first successful recovery of capsule from orbit
Echo 1	U.S.	Aug. 12, 1960	Thor-Delta	945–1,049	132	passive communication satellite; first successful voice and picture transmission by reflection
Sputnik 5	U.S.S.R.	Aug. 19, 1960	*	190–211	10,143	recovery of orbited animals (two dogs, six mice)
Sputnik 8–Venera 1	U.S.S.R.	Feb. 12, 1961	*	123–198	1,420	first hyperbolic escape of probe to measure interplanetary magnetic fields and solar radiation in space and near Venus; first launch from Earth orbit
Midas 2	U.S.	May 22, 1961	Atlas-Agena 2	298–301	5,000	first missile-launch detection satellite
Transit 4A	U.S.	June 29, 1961	Thor-Able-Star	543–623	175	all-weather global navigation satellite; first spacecraft to use nuclear isotope power system
OSO 1	U.S.	March 7, 1962	Delta	344–370	458	first Orbiting Solar Observatory, transmitting solar flare, radiation data
Ariel 1	U.K.–U.S.	April 26, 1962	Delta	242–754	132	first international cooperative satellite (U.S.–U.K.); ionospheric, X-ray, and cosmic ray data
Telstar 1	U.S.	July 10, 1962	Delta	593.4–3,501.8	170	first transatlantic relay of television signals; first colour television relay
Mariner 2	U.S.	Aug. 27, 1962	Atlas-Agena B		448	Venus flyby (21,594 mi); measurements of atmospheric and surface temperatures, magnetic field; radio contact to 54,300,000 mi
ANNA 1B	U.S.	Oct. 31, 1962	Thor-Able-Star	670–728	355	first geodetic satellite; transmitter, flashing lights
Mars 1	U.S.S.R.	Nov. 1, 1962	*	(solar orbit)	1,971	Mars flyby; transmissions ceased after 66,000,000 mi
Syncom 2	U.S.	July 26, 1963	Delta	22,132–22,823	79	first communications satellite in synchronous orbit
Vela	U.S.	Oct. 17, 1963	Atlas-Agena D	63,000–70,000	485 each	first nuclear explosion detection satellites; two orbited
Ranger 7	U.S.	July 28, 1964	Atlas-Agena B	(Moon impact)	807	transmitted 4,316 television photos of Moon's surface in last 13 min before impact
OGO 1	U.S.	Sept. 5, 1964	Atlas-Agena B	173–92,271	1,000	carries 20 coordinated geophysical experiments
Pegasus 1	U.S.	Feb. 16, 1965	Saturn I	308–462	3,080	micrometeoroid data; 2,300-sq-ft detection panels
Intelsat 1 (Early Bird)	U.S.	April 6, 1965	Thrust-augmented Delta	22,251–22,270	86	first communications satellite launched for commercial use
Venera 3	U.S.S.R.	Nov. 16, 1965	*	(Venus impact)	2,117	first spacecraft to land on another planet (Venus); no data
A-1 Asterix	France	Nov. 26, 1965	Diamant	328–1,099	93	first French satellite; third nation to achieve space launch
Luna 9	U.S.S.R.	Jan. 31, 1966	*	(Moon landing)	3,491	first successful lunar "soft landing"; photos of lunar surface televised
Luna 10	U.S.S.R.	March 31, 1966	*	(Moon orbit)	3,528	first spacecraft placed in lunar orbit
Surveyor 1	U.S.	May 30, 1966	Atlas-Centaur	(Moon landing)	2,194	first U.S. soft landing on Moon; televised photos of itself and lunar surface
Lunar Orbiter 1	U.S.	Aug. 10, 1966	Atlas-Agena D	(Moon orbit)	853	first lunar orbiting surface survey spacecraft; studied potential Apollo landing sites
Surveyor 3	U.S.	April 17, 1967	Atlas-Centaur	(Moon landing)	2,282	soft landing; surface sampler claw dug trenches; surface bearing strength data

Satellite (SAS), the first of which was launched in late 1970 and was designed to scan the celestial sphere and catalog stellar X-ray sources.

The Orbiting Astronomical Observatory is a large satellite equipped with a precisely stabilized guidance platform. Its purpose is to map the entire electromagnetic spectrum that Earthbound astronomers cannot see because of the absorptive and distorting features of the atmosphere.

One such device, launched in 1968, carried 11 star telescopes and studied ultraviolet, gamma ray, X-ray, and infrared radiation emissions from precise locations in the celestial sphere. Another, launched in 1972, carried a single large (32-inch) telescope. In 1982, according to plan, a 10-ton Space Telescope will be launched aboard a Space Shuttle. With a 95-inch aperture, the Space Telescope is expected to detect objects that are 50 times fainter than anything visible from Earth.

Pegasus was the name of a series of three satellites flown as a secondary experiment in 1965. The purpose was micrometeoroid detection. Fitted to its service module were wide, extendable wings carrying three layers of aluminum foil to measure penetration by small, medium, and large meteoritic particles.

Orbiting Geophysical Observatory

Orbiting Geophysical observatories are a class of large Earth-orbiting satellites weighing more than 1,000 pounds (450 kilograms) and carrying instrumentation for 20 to 30 experiments designed to study the relationship between Sun, Earth, and space environment. Areas of investigation include cosmic rays, energetic particles, magnetic fields, solar radiation, solar plasma, very-low-frequency radiation, aurora, airglow, micrometeoroids, atmospheric composition, and solar flares. Some of these satellites are placed into a low polar orbit, others into very eccentric orbits ranging out to nearly 100,000 miles.

Biosatellites

Biosatellite was the name of a family of recoverable scientific satellites flown to test the effects of weightlessness, radiation, and absence of the Earth's 24-hour day–night rhythm on biological specimens. The period of test was three days. Experiment specimens included bacteria, mold, seedlings, frog eggs, and amoebas. Retrieval in mid-air was by aircraft. In 1969 a pigtailed monkey was instrumented, orbited, and recovered. Data were inconclusive, however, and the program ceased.

Although the Soviet Union has also conducted a large number of scientific experiments in space, its programs have not been widely publicized. The Cosmos (Kosmos) series of satellites is said to be conducted for research purposes.

The United Kingdom built two Ariel satellites, which were launched by NASA to carry out experiments focussed on ionosphere and atmosphere research. In 1971 was launched Prospero, a technology satellite, using the British Black Arrow. The European Space Research Organization (now European Space Agency), a cooperative enterprise, in 1968 had two satellites called Iris and Heos launched by the U.S. Iris carried seven experiments to study solar and cosmic radiation in the lower Van Allen radiation belt. Heos carried experiments to measure radiation and magnetic fields.

Table 2: Space Exploration by Selected Unmanned Artificial Satellites and Space Probes (cont'd)

name	nation	launched	launch vehicle	perigee–apogee (mi)	spacecraft weight (lb)	remarks
Venera 4	U.S.S.R.	June 12, 1967	*	(Venus landing)	2,439	transmitted data on temperature and pressure of Venusian atmosphere; ceased transmitting before reaching surface
DODGE	U.S.	July 1, 1967	Titan III C	(lunar orbit) 20,661–20,884	430	took first colour photo of full Earth surface
Bios 2	U.S.	Sept. 7, 1967	Thor-Delta	180–188	440	studied effects of weightlessness on various plants and organisms during 47 orbits; capsule recovered
Surveyor 5	U.S.	Sept. 8, 1967	Atlas-Centaur	(Moon landing)	2,216	soft landed on Moon; transmitted 19,000 photos of lunar surface; chemical analysis of lunar soil
Cosmos 186	U.S.S.R.	Oct. 27, 1967	*	130–146	14,398(?)	first automatic rendezvous and docking; ejected capsules recovered
Cosmos 188		Oct. 30, 1967	*	119–158	14,398(?)	
Zond 5	U.S.S.R.	Sept. 14, 1968	*	(Moon orbiting)	12,789(?)	first recovery of circumlunar payload; carried biological experiments, turtles
OAO 2	U.S.	Dec. 7, 1968	Atlas-Centaur	479–485	4,400	first point-stabilized Orbiting Astronomical Observatory; hundreds of stars mapped and measured daily
Mariner 6	U.S.	Feb. 24, 1969	Atlas-Centaur	(Mars probe)	838	photos of Martian surface reveal Moonlike craters
Osumi	Japan	Feb. 11, 1970	Lambda 4S	218–3,188	53	first Japanese satellite; fourth nation to achieve space launch
China 1	China	April 24, 1970	*	237–1,287	382	first Chinese satellite; fifth nation to achieve space launch
Venera 7	U.S.S.R.	Aug. 17, 1970	*	(Venus landing)	2,602	first transmission of data from surface of Venus (Dec. 15)
Luna 16	U.S.S.R.	Sept. 12, 1970	*	(Moon landing)	12,789(?)	soft landed; remotely controlled vehicle bored into lunar surface, placed 101 grams soil into sealed container, launched payload to Earth and successful recovery
Luna 17	U.S.S.R.	Nov. 10, 1970	*	(Moon landing)	12,789(?)	soft landed; remotely controlled vehicle travelled 6.5 mi during 10 lunar days, relaying television pictures and obtaining scientific data
Mars 2	U.S.S.R.	May 19, 1971	Proton	(Mars probe)	10,253	orbited Mars, relayed data, ejected Mars lander (Nov. 27), brief transmission from surface of planet
Mars 3	U.S.S.R.	May 28, 1971	Proton	(Mars probe)	10,253	orbited Mars, relayed data, ejected Mars lander (Dec. 2), brief transmission from surface of planet
Mariner 9	U.S.	May 30, 1971	Atlas-Centaur	(Mars probe)	2,271	inserted into Mars orbit Nov. 13, relayed hundreds of photos and obtained extensive data
Apollo subsatellite	U.S.	Aug. 4, 1971	Apollo 15 service module	62–87 (lunar orbit)	80	released during Apollo 15 postlanding orbit of Moon; lunar magnetometer and charged particle measurements
Prospero	U.K.	Oct. 28, 1971	Black Arrow	915–2,640	146	first all-British satellite; micrometeorite and technology experiments
Pioneer 10	U.S.	March 2, 1972	Atlas-Centaur	(Jupiter probe)	569	first spacecraft to explore asteroid belt, fly by Jupiter, and leave solar system
ERTS 1 (Landsat 1)	U.S.	July 23, 1972	Delta	569–559	1,965	continuous global, multispectral Earth survey
Anik 1 (Telesat A)	Canada	Nov. 9, 1972	Delta	2,262–117	1,250	first domestic Comsat
Pioneer 11 (Pioneer Saturn)	U.S.	April 5, 1973	Atlas-Centaur	(Saturn probe)	571	will be first spacecraft to obtain close photos of Saturn
Mariner 10	U.S.	Nov. 3, 1973	Atlas-Centaur	(Mercury probe)	1,111	first flyby of Mercury
SMS 1	U.S.	May 17, 1974	Delta	22,026–19,331	1,379	first synchronous meteorological satellite
ATS 6	U.S.	May 30, 1974	Titan IIIC	synchronous	3,090	demonstrates new potential for satellite communication broadcast
Helios 1	U.S.–W.Ger.	Dec. 10, 1974	Titan IIIE-Centaur	(Sun probe)	816	closest approach to the Sun
Venera 9	U.S.S.R.	June 8, 1975	D-1	(Venus probe)	10,884	photos from surface of Venus
Viking 1	U.S.	Aug. 20, 1975	Titan III-Centaur	(Mars probe)	7,497	first photos from Mars surface
Aryabhata	India–U.S.S.R.	April 19, 1975	*	*	*	first Indian satellite
Lageos	U.S.	May 4, 1976	Delta	3,694–3,626	906	laser geodetic satellite

Other countries that have developed scientific satellites include France, whose spacecraft have been launched both with a French space booster and by the United States; Canada, whose International Satellite for Ionospheric Studies was launched in 1969 by NASA; and Italy, using a United States launch vehicle to launch the San Marco satellite. Japan and the People's Republic of China have launched experimental satellites using their own launch vehicles, as indicated in Tables 1 and 2.

Lunar programs. An early target for space exploration was the Moon, man's nearest extraterrestrial neighbour. By 1978 the Soviet Union and the United States were still the only countries with space launch vehicles capable of sending payloads to the Moon.

Luna series

The Soviet Luna 3 first photographed the far side of the Moon in 1959. Other Luna-series vehicles orbited the Moon or soft landed, transmitted television photographs of the surface, and tested the load-bearing characteristics of the lunar soil. Luna 16, in September 1970, soft landed, obtained a core sample of soil, and returned it to Earth in a sealed capsule.

A significant development was Luna 17, which in November 1970 landed an automated roving vehicle. Remotely controlled from the Earth, this television-equipped craft ranged several miles and survived nine lunar nights in robot exploration of the lunar surface.

Another Soviet series of lunar probes used the so-called Zond vehicles. A number of these made circumlunar flights carrying biological specimens and returned photographs to Earth.

Three U.S. programs studied the Moon with spacecraft: Ranger, Surveyor, and Lunar Orbiter. Ranger spacecraft transmitted television pictures of the Moon from as close as 10,000 feet before crashing on the surface. The Surveyor spacecraft was a soft lander, using retrorockets to reduce trajectory velocity to zero. Safely landed, Surveyor transmitted to Earth thousands of television pictures of the lunar surface and data on lunar soil characteristics and chemical composition. Lunar Orbiter was designed to obtain high-quality television photos of the Moon's surface in selected areas in preparation for Project Apollo manned landings.

Planetary programs. Both the United States and the Soviet Union have sent spacecraft to Mars and Venus, the Soviet Union concentrating most effort on Venus and the United States on Mars. In addition, the U.S. has sent spacecraft to Jupiter, Mercury, and Saturn.

Venera series

The Soviet Union made numerous attempts to launch spacecraft to Mars and Venus and achieved success, beginning with Venera 4 in 1967, and subsequently. In each of these flights an instrumented capsule was dropped by parachute into the hot, dense Venusian atmosphere. In each case, data were incomplete, though Venera 7 (1970) and 8 (1972) survived the landing and returned significant data from the surface. Venera 9 and 10 (1975) provided further surface data and the first photographs taken on the surface of another planet.

In May 1971 the Soviet Union launched two spacecraft to Mars. Arriving six months later, both spacecraft ejected landing capsules. The capsules had been

Table 3: Manned Space Flights

spacecraft	launch date	crew	duration (hr:min)	remarks
Vostok 1	April 12, 1961	Y.A. Gagarin	1:48	first manned flight
Mercury–Redstone 3	May 5, 1961	A.B. Shepard, Jr.	0:15	first U.S. flight; suborbital
Mercury–Redstone 4	July 21, 1961	V.I. Grissom	0:16	suborbital; capsule sank after landing
Vostok 2	Aug. 6, 1961	G.S. Titov	25:18	first flight exceeding 24 hr
Mercury–Atlas 6	Feb. 20, 1962	J.H. Glenn, Jr.	4:55	first American to orbit
Mercury–Atlas 7	May 24, 1962	M.S. Carpenter	4:56	landed 400 km from target
Vostok 3	Aug. 11, 1962	A.G. Nikolayev	94:22	first dual mission (with Vostok 4)
Vostok 4	Aug. 12, 1962	P.R. Popovich	70:57	came within 6 km of Vostok 3
Mercury–Atlas 8	Oct. 3, 1962	W.M. Schirra, Jr.	9:13	landed 8 km from target
Mercury–Atlas 9	May 15, 1963	L.G. Cooper, Jr.	34:20	first long U.S. flight
Vostok 5	June 14, 1963	V.F. Bykovsky	119: 6	second dual mission (with Vostok 6)
Vostok 6	June 16, 1963	V.V. Tereshkova	70:50	first woman in space
Voskhod 1	Oct. 12, 1964	V.M. Komarov K.P. Feoktistov B.G. Yegorov	24:17	first 3-man crew
Voskhod 2	March 18, 1965	A.A. Leonov P.I. Belyayev	26: 2	first extravehicular activity (Leonov, 10 min)
Gemini 3	March 23, 1965	V.I. Grissom J.W. Young	4:53	first U.S. 2-man flight; first manual manoeuvres in orbit
Gemini 4	June 3, 1965	J.A. McDivitt E.H. White II	97:56	21-min extravehicular activity (White)
Gemini 5	Aug. 21, 1965	L.G. Cooper, Jr. C. Conrad, Jr.	190:55	duration record
Gemini 7	Dec. 4, 1965	F. Borman J.A. Lovell, Jr.	330:35	duration record
Gemini 6-A	Dec. 15, 1965	W.M. Schirra, Jr. T.P. Stafford	25:51	rendezvous within 3 m of Gemini 7
Gemini 8	March 16, 1966	N.A. Armstrong D.R. Scott	10:41	first docking of 2 orbiting spacecraft
Gemini 9-A	June 3, 1966	T.P. Stafford E.A. Cernan	72:21	extravehicular activity; rendezvous
Gemini 10	July 18, 1966	J.W. Young M. Collins	70:47	first dual rendezvous (Gemini 10 with Agena 10, then Agena 8)
Gemini 11	Sept. 12, 1966	C. Conrad, Jr. R.F. Gordon, Jr.	71:17	highest Earth-orbit altitude (1,372 km)
Gemini 12	Nov. 11, 1966	J.A. Lovell, Jr. E.E. Aldrin, Jr.	94:35	longest extravehicular activity to date (Aldrin, 5:37)
Soyuz 1	April 23, 1967	V.M. Komarov	26:37	cosmonaut killed in re-entry accident
Apollo 7	Oct. 11, 1968	W.M. Schirra, Jr. D.F. Eisele R.W. Cunningham	260: 9	first U.S. 3-man mission
Soyuz 3	Oct. 26, 1968	G. Beregovoy	94:51	manoeuvred near unmanned Soyuz 2
Apollo 8	Dec. 21, 1968	F. Borman J.A. Lovell, Jr. W.A. Anders	147: 1	first manned orbit(s) of Moon; first manned departure from Earth's sphere of influence; highest speed ever attained in manned flight
Soyuz 4	Jan. 14, 1969	V. Shatalov	71:23	Soyuz 4 and 5 docked and transferred 2 cosmonauts from Soyuz 5 to Soyuz 4
Soyuz 5	Jan. 15, 1969	B. Volynov A. Yeliseyev Y. Khrunov	72:56	
Apollo 9	March 3, 1969	J.A. McDivitt D.R. Scott R.L. Schweickart	241: 1	simulation of lunar operations in Earth orbit
Apollo 10	May 18, 1969	T.P. Stafford J.W. Young E.A. Cernan	192: 3	successfully demonstrated Lunar Module descent to 14,300 m from the lunar surface
Apollo 11	July 16, 1969	N.A. Armstrong M. Collins E.E. Aldrin, Jr.	195:19	first landing of human being on lunar surface and safe return to Earth; first return of rock and soil samples to Earth, and manned deployment of experiments on lunar surface
Soyuz 6	Oct. 11, 1969	G. Shonin V. Kubasov	118:42	Soyuz 6, 7, and 8 operated as group flight without actually docking; each conducted certain experiments, including welding and Earth and celestial observations
Soyuz 7	Oct. 12, 1969	A. Filipchenko V. Volkov V. Gorbatko	118:41	
Soyuz 8	Oct. 13, 1969	V. Shatalov A. Yeliseyev	118:50	
Apollo 12	Nov. 14, 1969	C. Conrad, Jr. R.F. Gordon, Jr. A.L. Bean	244:36	second manned lunar landing; retrieved parts of Surveyor 3 spacecraft

previously sterilized to prevent contamination by Earth organisms. Retrorocket and parachute braking were used. The capsules were equipped with television transmission, but the signals ceased shortly after landing, possibly because of spacecraft damage from high winds or from sinking into dust. The Mars 2 and 3 spacecraft continued to orbit Mars in highly elliptical orbits, transmitting a variety of scientific data.

Mariner probes

The United States Mariner program encompasses those interplanetary probes that are designed to pass close to Mars, Venus, and Mercury. Mariners 2 in 1962 and 5 in 1967 passed Venus within 22,000 and 2,500 miles (about 35,000 and 7,600 kilometres) and made temperature and atmospheric density measurements. Mariners 4 in 1964 and 6 and 7 in 1969 obtained photographs of the Martian surface and made significant analyses of the atmosphere. Mariners 6 and 7 made thermal maps of Mars by means of infrared radiometers. Mariners 1 and 3 were failures.

In May 1971 the U.S. launched Mariner 9 toward Mars. It arrived and was placed in eccentric orbit in November, while the planet was shrouded in a global dust storm with winds perhaps of 100 miles per hour. After several weeks the planet's thin atmosphere cleared and the orbiter's two television cameras transmitted clear photographs of the surface, revealing many new details and formations. Other sensors measured atmospheric pressure (about 3–8.3 millibars compared with 1,013 for Earth), temperature, the ionosphere, and the gravitational field. Large areas of the planet were mapped, and the two moons of Mars, Phobos and Deimos, were photographed.

Mariner 10 was launched in 1973 to explore Mercury. Swinging by Venus, utilizing Venusian gravity to increase velocity, the spacecraft flew by Mercury, obtaining the first close-up photographs of this planet.

One of the most exciting planetary missions in the his-

Table 3: Manned Space Flights (cont'd)

spacecraft	launch date	crew	duration (hr:min)	remarks
Apollo 13	April 11, 1970	J.A. Lovell, Jr. F.W. Haise, Jr. J.L. Swigert, Jr.	142:55	mission aborted because of explosion in Service Module; ship circled Moon, with crew using Lunar Module as "lifeboat" until just prior to re-entry
Soyuz 9	June 1, 1970	A.G. Nikolayev V.I. Sevastianov	424:59	duration record
Apollo 14	Jan. 31, 1971	A.B. Shepard, Jr. S.A. Roosa E.D. Mitchell	216: 2	third manned lunar landing
Soyuz 10	April 22, 1971	V. Shatalov A. Yeliseyev N. Rukavishnikov	47:46	docked with Salyut 1
Soyuz 11	June 6, 1971	G.T. Dobrovolskiy V.N. Volkov V.I. Patsayev	570:22	docked with Salyut 1; crew perished during return phase of mission
Apollo 15	July 26, 1971	D.R. Scott A.M. Worden J.B. Irwin	295:12	fourth manned lunar landing and first use of Lunar Roving Vehicle
Apollo 16	April 16, 1972	J.W. Young C.M. Duke, Jr. T.K. Mattingly II	265:51	fifth manned lunar landing
Apollo 17	Dec. 7, 1972	E.A. Cernan H.H. Schmitt R.E. Evans	301:52	sixth and final Apollo manned lunar landing
Skylab 2	May 25, 1973	C. Conrad, Jr. J.P. Kerwin P.J. Weitz	627:50	docked with Skylab; repaired damaged station; duration record
Skylab 3	July 28, 1973	A.L. Bean J.R. Lousma O.K. Garriott	1,427: 9	docked with Skylab; duration record
Soyuz 12	Sept. 27, 1973	V. Lazarev O. Makarov	47:16	checkout of improved Soyuz
Skylab 4	Nov. 16, 1973	G.P. Carr E.G. Gibson W.R. Pogue	2,017:16	docked with Skylab; duration record
Soyuz 13	Dec. 18, 1973	P. Klimuk V. Lebedev	188:55	astrophysical, biological, and Earth resources experiments
Soyuz 14	July 3, 1974	P. Popovich Y. Artyukhin	377:30	docked with Salyut 3
Soyuz 15	Aug. 26, 1974	G. Sarafanov L. Demin	48:12	failed to dock with Salyut 3
Soyuz 16	Dec. 2, 1974	A. Filipchenko N. Rukavishnikov	142:24	test of ASTP configuration
Soyuz 17	Jan. 10, 1975	A. Gubarev G. Grechko	709:20	docked with Salyut 4

Viking missions

tory of the U.S. space program began with the launching of Vikings 1 and 2 (1975). Each spacecraft consisted of two sections, one that would remain in orbit around Mars, while the other completed a soft landing on the surface. Both Viking 1 and 2 landers made successful descents to the surface in July and September 1976, where they conducted the first long-term *in situ* analysis of the surface material, atmosphere, and possible life-forms of another planet.

The first spacecraft to fly by Jupiter were Pioneers 10 and 11, launched by the U.S. in 1972 and 1973. Both returned physical data and hundreds of revealing photographs of the planet. Pioneer 10 remains on a trajectory and travelling at sufficient velocity to cause it to become the first spacecraft to leave the solar system. On board is a plaque for communication with extraterrestrial intelligence should any be encountered. Pioneer 11 is on a trajectory to pass close to the rings of Saturn.

Voyagers 1 and 2 were launched by the U.S. in August and September 1977 on a fly-by mission to Jupiter and Saturn.

MANNED PROGRAMS

By the late 1970s, only the United States and the Soviet Union had launched manned satellites (Table 3).

Vostok and Mercury. Both the United States and the Soviet Union early made manned flight a major goal in their space programs. The Soviet intercontinental ballistic missile was much larger than the United States counterpart, having been designed to carry a heavier warhead. The first Soviet manned spacecraft, Vostok 1, weighed over 10,000 pounds (4,500 kilograms), while the U.S. Mercury weighed only about a third as much.

The Soviet Union launched Yury Alekseyevich Gagarin into a single Earth orbit on April 12, 1961. In August 1962 the Soviet Union launched two manned space-

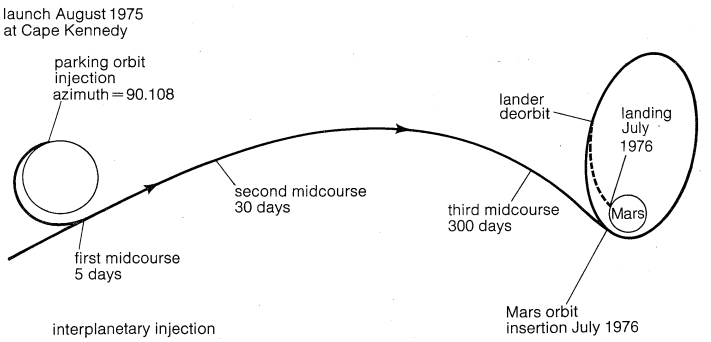

Figure 4: A typical Viking mission profile.
By courtesy of the National Aeronautics and Space Administration

craft in nearly identical orbits one day apart. In June 1963 a similar set of launches was made, one containing the first woman cosmonaut, Valentina Tereshkova.

At that time the U.S. had made only four orbital manned flights, and Soviet cosmonauts had logged nearly eight times as many man-hours in space as had U.S. astronauts. By May 1978, however, the U.S. had accumulated 22,503 hours of flight time compared with 19,823 hours by the Soviet Union.

Gemini and Voskhod. While the Vostok and Mercury flights had demonstrated that man could function while weightless and in space, neither spacecraft had operational manoeuvrability. The U.S. Gemini program was designed to develop objectives of rendezvous with a target vehicle and of docking, a capacity vital to the Apollo Moon-landing program. The dynamics of rendezvous with a target vehicle launched a day earlier called for extreme precision in tracking, timing of launch, and placement of spacecraft in almost identical orbit. A delay of one second in launch would allow the target vehicle to fly five miles beyond the rendezvous point. The Soviet Union meanwhile advanced to a three-man flight with Voskhod 1, October 12–13, 1964. On March 18, 1965, a two-man flight was made in which the cosmonaut Aleksey Leonov passed through an airlock to become the first man to float free in space. On Gemini 4, in June 1965, the United States astronaut Edward H. White II duplicated the feat. Called extravehicular activity (EVA), this manoeuvrability demonstrated the increasing ability of man to function in space. It also proved that man could adapt to weightlessness for as long as two weeks and readapt to the gravity of Earth.

First EVA's

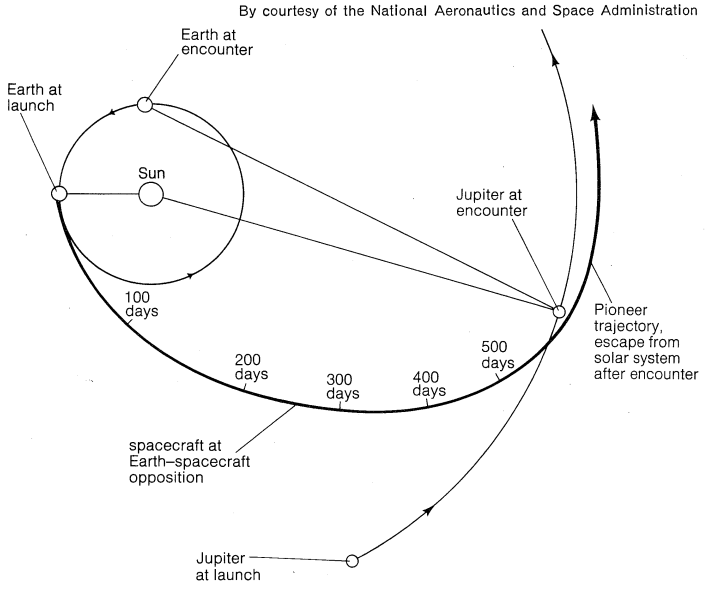

Figure 5: The Jupiter trajectory flown by Pioneer 10, launched March 2, 1972.

Soyuz. In April 1967 the Soviet Union launched Soyuz 1, called the largest, most complex spacecraft yet flown. V.M. Komarov, its cosmonaut, was killed in an apparent failure of the parachute recovery system. In October 1968 Soyuz 3 made rendezvous several times with the unmanned Soyuz 2, sent aloft a day earlier. Early in 1969 Soyuz 4 and Soyuz 5, launched on successive days, made rendezvous and docked; two cosmonauts left Soyuz 5 and transferred to Soyuz 4, undocked, re-entered, and landed. In October 1969, Soyuz 6, 7, and 8 were launched on successive days; welding experiments were performed, and the spacecraft landed with their combined crew of seven after five days in orbit.

In June 1970 Soyuz 9 established an endurance record for manned space flight, nearly 18 days. The cosmonauts reportedly required nearly two days to regain coordination and normal sleeping habits upon return to Earth. Soyuz 10, in April 1971, rendezvoused with a previously orbited "space station," Salyut. The flight lasted only two days, however, and it has been presumed that operational difficulties occurred. In June 1971, Soyuz 11 carried three cosmonauts to rendezvous with Salyut. Twenty-seven hours after launch, the cosmonauts transferred to the 47-foot- (14-metre-) long Salyut space laboratory. This successful flight ended in tragedy when a minor malfunction of a door seal during re-entry caused loss of the air in the spacecraft and the death of all three cosmonauts.

The flight of Soyuz 9

The remaining Soyuz missions flown by 1978 carried two-man crews. Soyuz 12 provided an operational test of new systems developed since the Soyuz 11 tragedy. Soyuz 13 performed a variety of scientific experiments. Soyuz 14, 15, 17, 18, and 20–27 were all related to one of the Salyut orbiting laboratories launched after April 1971.

The Salyut vehicle is equipped to conduct extended missions of scientific or manned military reconnaissance in Earth orbit. Interior space is approximately 100 cubic metres. Each of the first five Salyut stations eventually was abandoned and destroyed on re-entry. Soyuz 26 docked with Salyut 6 (a vehicle equipped with a docking port at each end) on December 11, 1977. On January 11, 1978, Soyuz 27 docked with the space station, bringing up supplies to the crew, and returned to Earth five days later. Soyuz 28 docked with the space station on March 3, 1978, and on March 16 the crew of Soyuz 26 returned to Earth in Soyuz 27, having set a duration record of 96 days in space. Soyuz 28 carried a Czechoslovakian cosmonaut, the first non-Soviet, non-U.S. person in space.

Apollo program. In May 1961 Pres. John F. Kennedy committed the United States to landing a manned spacecraft on the Moon "before this decade is out." The name given to the program was Apollo.

Several techniques for the lunar mission appeared to be feasible and were studied in detail. These included a direct method, whereby a single giant launch vehicle would launch a spacecraft toward the Moon. Near the Moon the spacecraft would be slowed down by its own propulsion system, called the lunar landing stage. Another propulsion system, the lunar takeoff stage, would launch the spacecraft from the Moon and send it toward Earth.

A second proposal, called the Earth-orbit rendezvous method, differed from the direct method in that two somewhat smaller launch vehicles would separately transport two parts of the spacecraft (*i.e.*, the lunar landing stage, and the lunar takeoff stage and spacecraft proper) into Earth Orbit. There they would be joined and then propelled as a single craft toward the Moon.

A third method, called the lunar-orbit rendezvous technique, was selected. This method would employ a single Saturn V launch vehicle to send the three-man Apollo spacecraft, weighing 100,000 pounds (45,000 kilograms), on a trajectory toward the Moon. Approximately 2½ days later, as the craft approached the Moon, its own propulsion system would place it in an orbit around the Moon. In lunar orbit one element of the spacecraft, called a Lunar Module (LM), with two men aboard, would separate from the mother ship and be flown toward the Moon, while the third man circled the Moon in the other

The lunar-orbit rendezvous technique

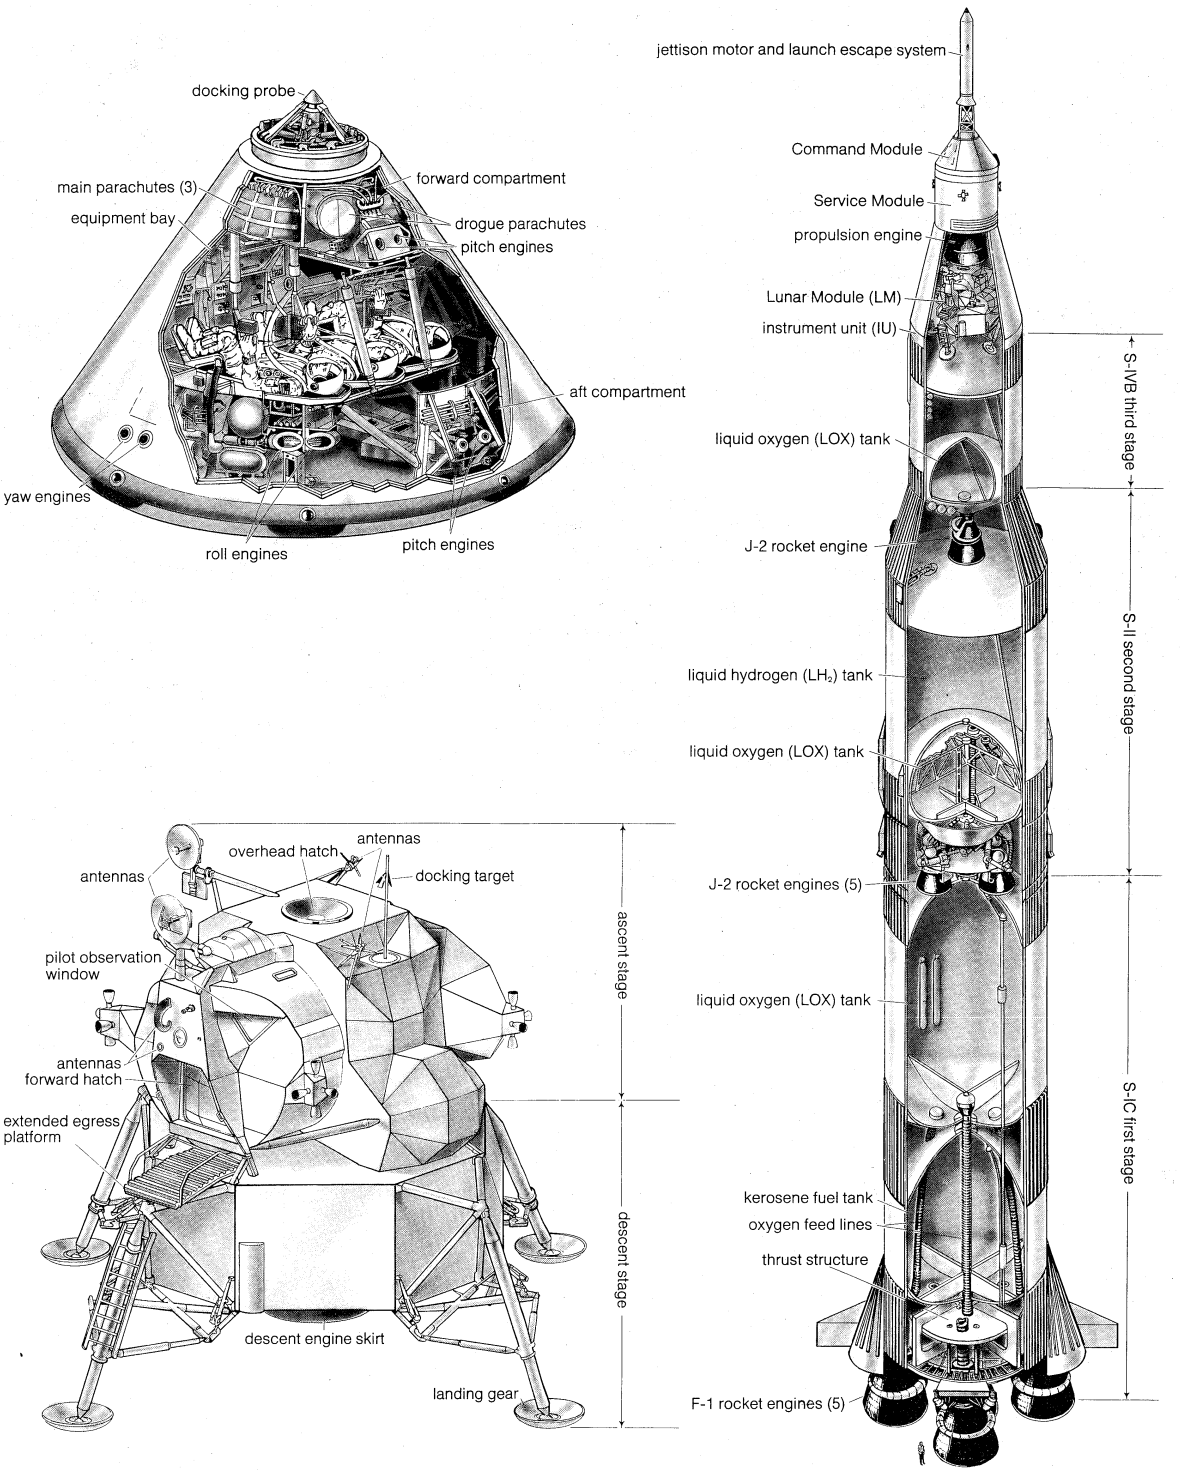

Figure 6: *The Apollo program.*
(Right) Saturn V launch vehicle and Apollo spacecraft, with details of (top left) the Command Module and (bottom left) the Lunar Module.

section of the spacecraft, the Command Module (CM). After executing a soft landing on the lunar surface, the two lunar explorers would make scientific observations and collect geological samples. After about one day, they would take off from the surface and fly toward a rendezvous with the Command Module in lunar orbit. Spacecraft propulsion would then eject the spacecraft from lunar orbit and send it back toward the Earth. Precise guidance and control on the return trip would allow the spacecraft to enter within the limits of the narrow re-entry corridor described above under *Re-entry and recovery*. Within the atmosphere the Apollo Command Module would have a limited degree of manoeuvrability.

Apollo modules

The Apollo spacecraft (Figure 6) consisted of three modules: command, service, and lunar. The Command Module was the spacecraft's control centre and housed the crew of three astronauts. It was conical in shape, 12 feet high and 13 feet in diameter, and weighed 10,000 pounds. The launch escape system, a tower-like structure above the Command Module, provided power to lift the Command Module up and away from the Saturn launch vehicle should an emergency occur after fuelling and before injection into orbit. Solid-propellant rockets provided this standby emergency power.

Below the Command Module was the Service Module, 12.8 feet in diameter, 22 feet long, and containing the

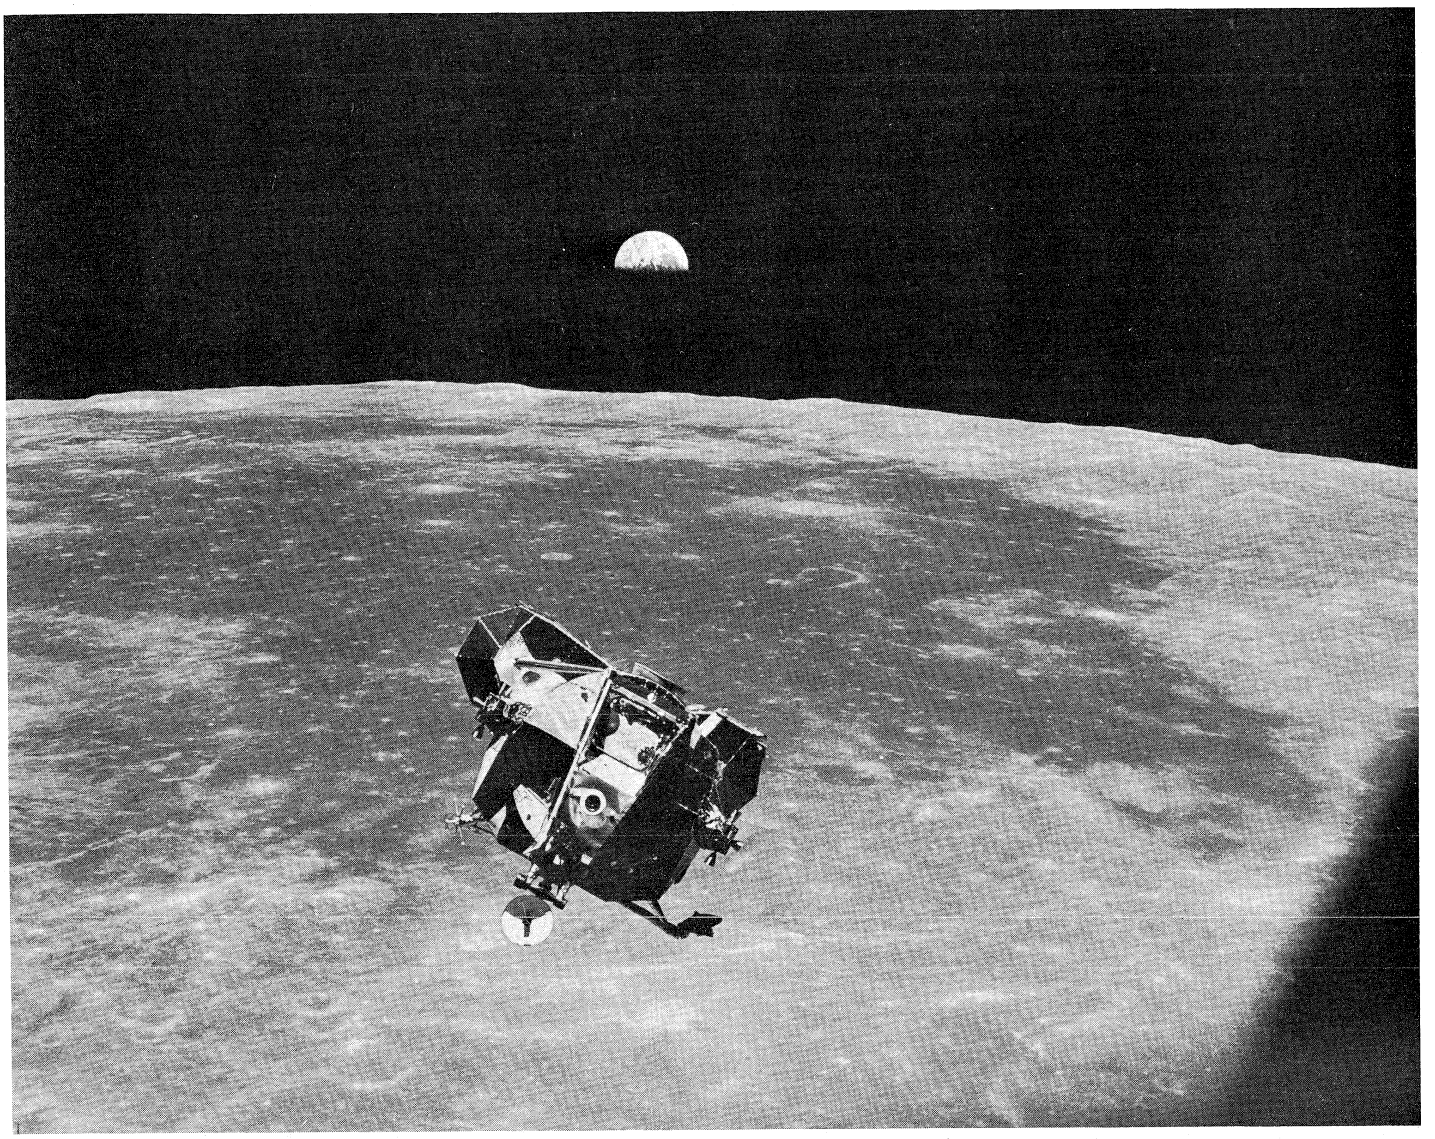

Figure 7: *Return of the first Lunar Module to the Apollo spacecraft.*
The Apollo 11 Lunar Module with astronauts Neil A. Armstrong and Edwin E. Aldrin, Jr., aboard, photographed from the Command Module by Michael Collins as it ascended from the lunar surface to rendezvous in orbit on July 21, 1969. The large, dark-coloured area in the background is Smyth's Sea (Mare Smythii), centred at longitude 85° E and latitude 2° S on the lunar nearside. The Earth is seen rising in the west above the lunar horizon.

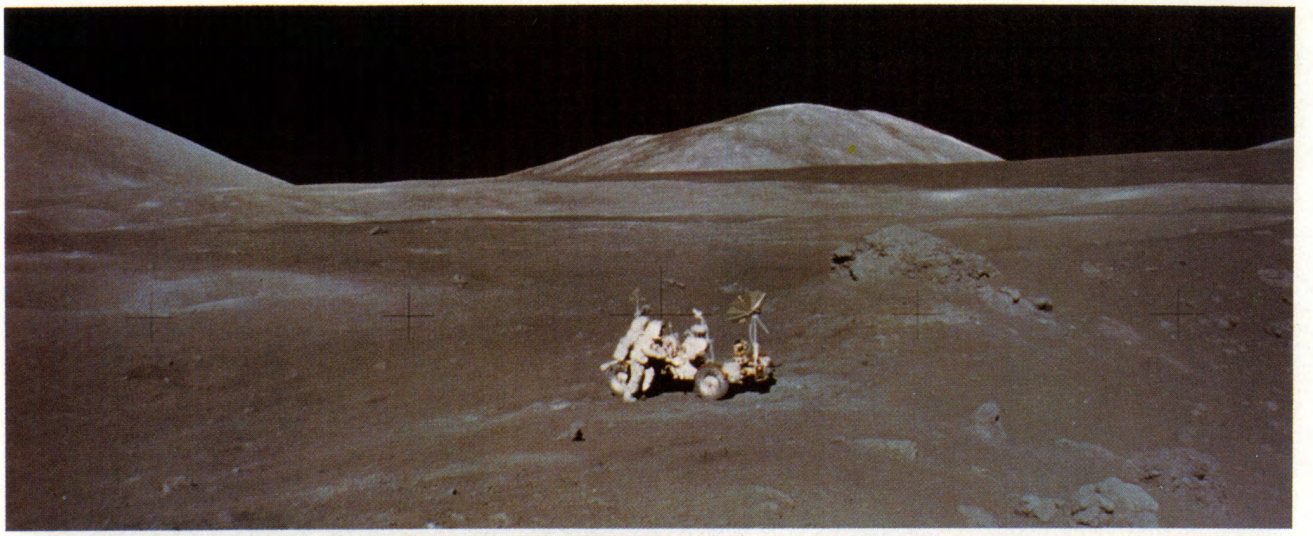
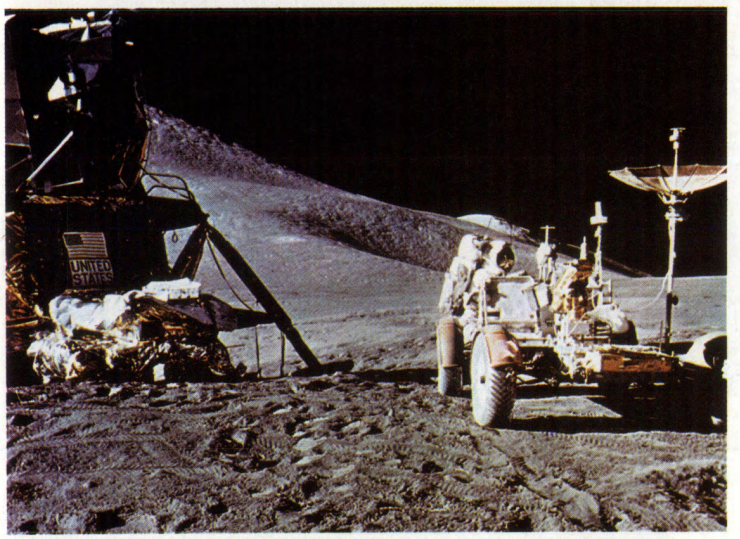
propulsion system for midcourse corrections, retrofire to achieve lunar orbit, and thrust to return from lunar orbit into Earth trajectory. The pressure-fed rocket engine was capable of developing 22,000 pounds of thrust, was ablating cooled, and used nitrogen tetroxide and hydrazine-type fuel.

Between the Service Module and the Saturn V launch vehicle was the Lunar Module (LM) adapter. This unit was 29 feet long and 21.7 feet in diameter where it joined the S-IVB stage, tapering to 13 feet where it joined the Service Module. The LM housed in this section was designed to carry two astronauts from lunar orbit to the surface of the Moon and return them to the Command Module. The LM was approximately 21 feet high and 11 feet in diameter, weighing 30,000 pounds (Earth weight). There were two engines, one with controllable thrust for descent to the surface of the Moon and the other with a fixed 35,000-pound thrust for ascent to rendezvous with the Command Module in lunar orbit. Both engines were pressure fed, ablating cooled, and used the same propellants as the Service Module engine.



The first manned Apollo flight, in Earth orbit, scheduled for February 1967, was delayed when on January 27, 1967, during a countdown rehearsal, a fire broke out inside the spacecraft cabin and spread rapidly in the concentrated oxygen environment at higher than sea level pressure. Three astronauts lost their lives.

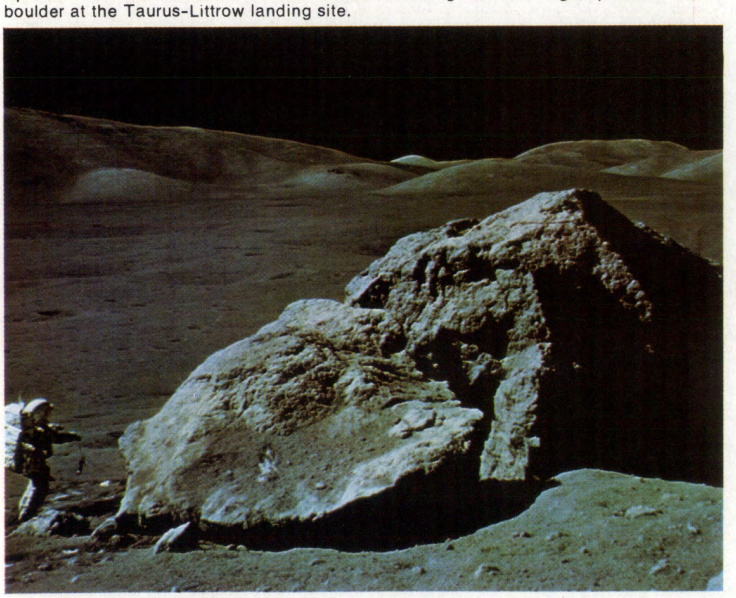
In November 1967 a Saturn V placed an unmanned Apollo in orbit. Two more unmanned Apollo flights were made and on October 11, 1968, Apollo 7, with three astronauts, tested the Command Module in a 163-orbit flight. Apollo 8, launched on December 21, 1968, after Earth orbit was injected into a translunar trajectory, inserted into lunar orbit for 10 orbits, and then returned safely to Earth. Live television broadcasts were made during the flight and while orbiting the Moon.



Apollo 9, launched on March 3, 1969, on a 10-day trip, checked out the Lunar Module operation in Earth orbit. Apollo 10 lifted off on May 18. Paralleling Apollo 8's flight into lunar orbit, two astronauts transferred to the LM and lowered their orbit to 46,900 feet (14,300 metres) above the Moon.

Apollo 11, launched July 16, 1969, manned by Neil A. Armstrong, Edwin E. Aldrin, Jr., and Michael Collins, repeated Apollo 10's flight to lunar orbit. Armstrong and Aldrin transferred to the Lunar Module, and descent and landing on the Moon were made July 20 at 8:17 PM Greenwich Mean Time, at 23.26° E and 0.41° N. Armstrong stepped onto the Moon's surface at 2:56 AM GMT. His first words were, "That's one small step for a man,

". . . one giant leap for mankind"



Apollo 17 scientist-astronaut Harrison Schmitt working at the Lunar Roving Vehicle at the Taurus-Littrow landing site. This is the area where Schmitt first spotted orange soil. Apollo 17 was launched December 7, 1972.

Apollo 15 astronaut James Irwin standing in back of the Lunar Roving Vehicle; the Lunar Module (LM) is at left with the modular equipment storage assembly (MESA) in front of it. Apollo 15 was launched July 26, 1971.

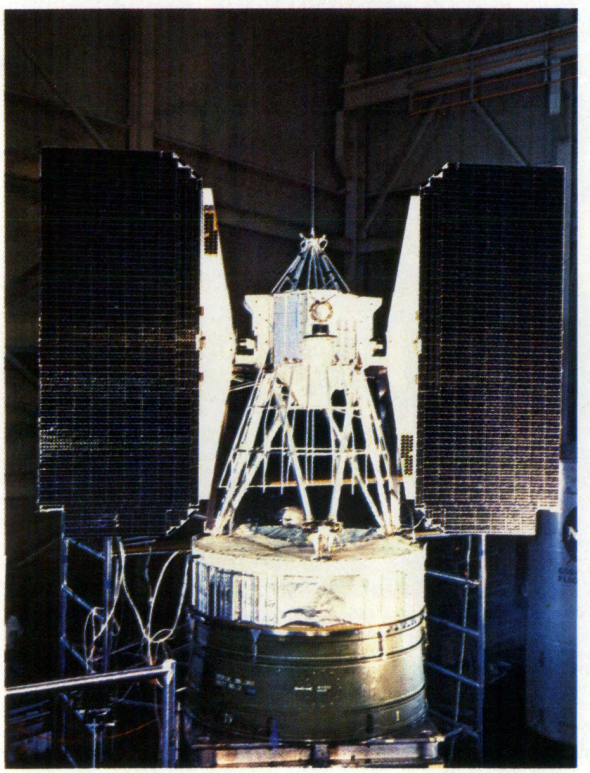
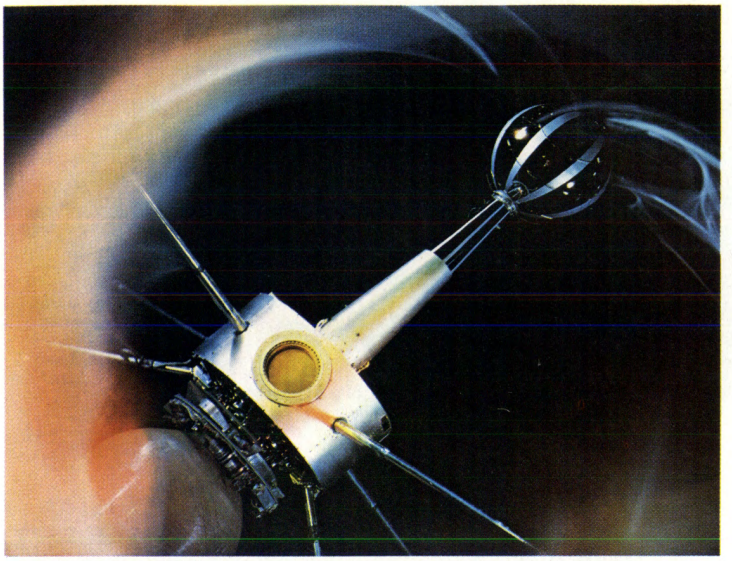
Telstar 1, launched July 10, 1962, relayed the first transatlantic television signals.

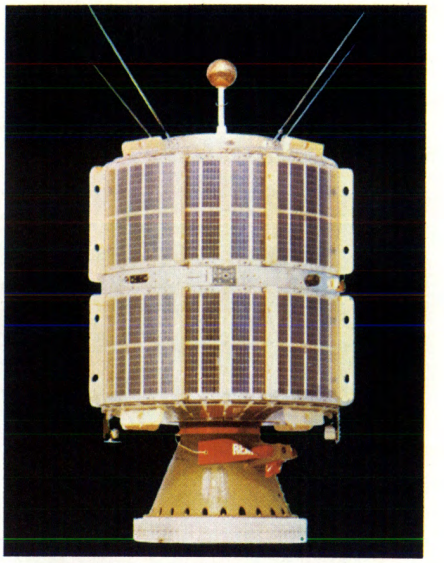


TIROS 7 (Television and Infra-Red Observation Satellite 7), launched June 19, 1963, transmitted cloud-cover photographs enabling meteorologists to track, forecast, and analyze storms.

U.S. applications satellites

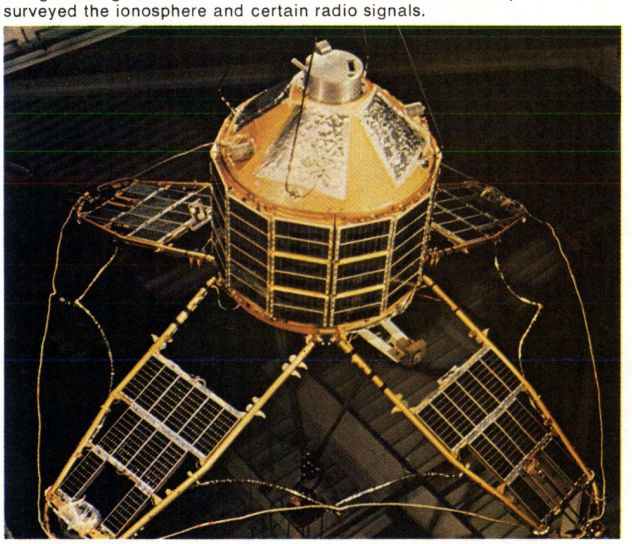


(Right) Photograph of Hurricane Camille that is the result of computer processing of data supplied by Nimbus 3 meteorological satellite. By observing hurricanes in colour, meteorologists can determine cloud heights using cloud temperatures. For example, ground or sea surface temperatures, or low clouds, appear purple; middle clouds appear yellow; high clouds appear blue; while the highest clouds, in the eye of the hurricane, appear gray. Nimbus 3 was launched April 14, 1969.

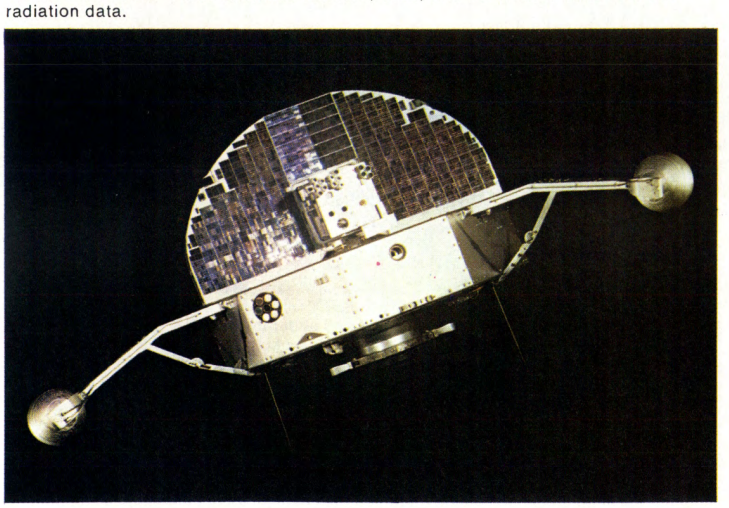


Composite photograph of the Olympia-Seattle-Tacoma, Washington, area transmitted from the Earth Resources Technology Satellite 1 (ERTS 1). Green, red, and infrared are recorded separately by the satellite and then combined to make the photograph. Healthy crops, trees, and other green plants appear bright red; barren land, cities, and industrial areas appear green or gray. Clear water is completely black and snow or ice shows as bright white. ERTS 1 was launched July 23, 1972.

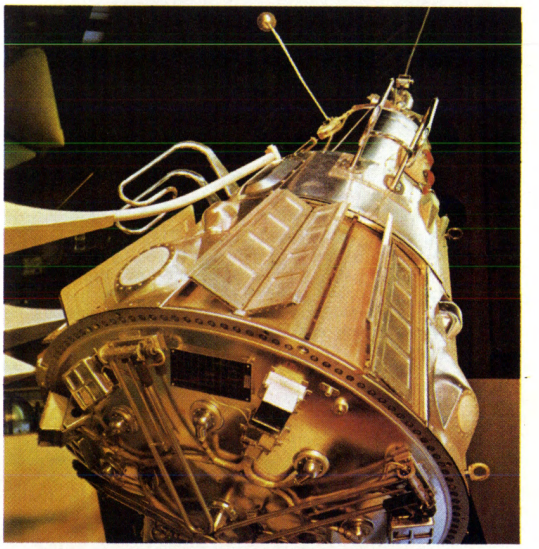
(Left) Nimbus 1, launched August 28, 1964, transmitted cloud-cover photographs.



The U.S. Explorer 10 shown undergoing testing in a NASA (National Aeronautics and Space Administration) laboratory. Explorer 10 was launched March 25, 1961, and relayed magnetic field data.

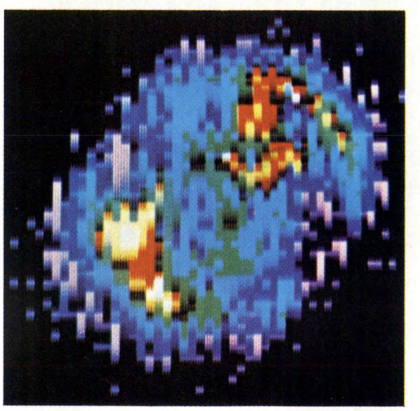


The European-designed and -built satellite Aurorae (ESRO 1A) that investigated the Aurora Borealis and other related phenomena of the polar ionosphere. Aurorae was launched October 3, 1968 by NASA.



Scientific satellites and space probes

The British Ariel 4 (U.K. 4) shown suspended with its solar panels deployed in flight configuration. It was launched December 11, 1971, by NASA and surveyed the ionosphere and certain radio signals.



The U.S. Orbiting Solar Observatory 1 (OSO-1) shown in a simulated space environment. OSO-1 was launched March 7, 1962, and transmitted solar flare and radiation data.

The Soviet Sputnik 3, the first instrumented multipurpose space laboratory. It was launched May 15, 1958, and transmitted information on atmospheric composition and pressure, positive ion concentration, primary cosmic ray data, etc.

Photograph of a solar storm transmitted by the U.S. Orbiting Solar Observatory 7 (OSO-7). The white regions show the most intense storm activity, with yellow and red clusters denoting lesser activity. OSO-7 was launched September 29, 1971.

Plate 8: By courtesy of (all but centre right) National Aeronautics and Space Administration; photograph, (centre right) Tass—Sovfoto

one giant leap for mankind." He reported sinking approximately one-eighth of an inch into the fine, powdery surface material, which adhered in a thin layer to his boots. Aldrin joined Armstrong, and together they spent about two hours taking photographs, collecting about 47.7 pounds (21.7 kilograms) of lunar soil (including two core samples), planting a United States flag, and deploying a solar-wind experiment, a seismic experiment package, and a laser beam reflecting device. They were seen on Earth television by means of a camera erected some distance from the Lunar Module.

The astronauts made their lunar ascent stage takeoff (Figure 7) on July 21, concluding a total lunar stay time of 21 hours 36 minutes. Transferring to the Command Module, they relanded on Earth in the Pacific on July 24. Because of possible contamination by organisms with unknown effect upon terrestrial life, decontamination and quarantine were employed.

Apollo 11 decontamination

Apollo 12, launched November 14, followed a flight plan similar to that of Apollo 11. The Lunar Module landed on the Moon on November 19 in the Ocean of Storms. Two Moon walks were made; a nuclear isotope-powered surface experiments package was emplaced, 75.6 pounds (34 kilograms) of lunar samples were collected, and an inspection was made of the Surveyor 3 spacecraft that had landed 2½ years before. Parts of the Surveyor were brought back to Earth for study.

Apollo 14, launched January 31, 1971, continued exploration of the Moon. Landing within 60 feet of the target area, the astronauts made two surface explorations totalling more than nine hours. A surface experiments package was emplaced, and 94.4 pounds (43 kilograms) of lunar rocks were brought back.

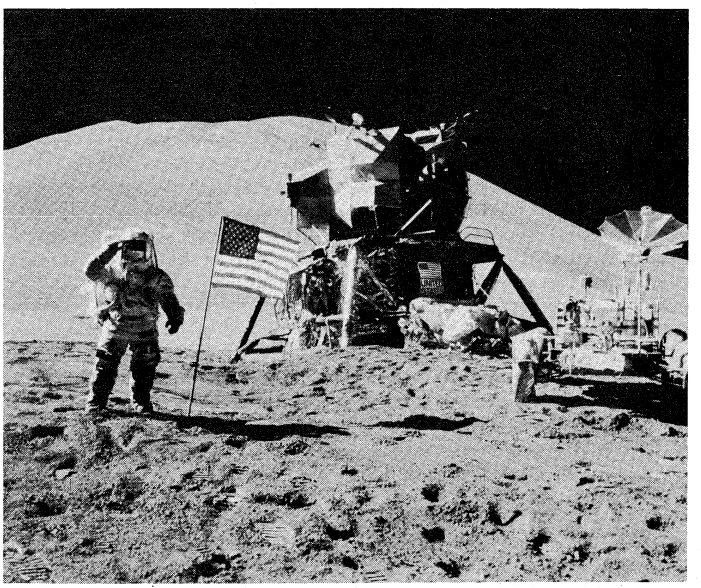


Figure 8: The Apollo 15 space mission's Lunar Module "Falcon," and the Lunar Roving Vehicle (right). Astronaut James B. Irwin is saluting the flag.
By courtesy of the National Aeronautics and Space Administration

Apollo 15 was launched July 26, 1971, and returned August 7, 1971. Landing on the Moon near Hadley Rille and the Apennine Mountains, it carried a four-wheeled, battery-powered Lunar Roving Vehicle that permitted extensive exploration (Figure 8). Weight of lunar material returned was 170 pounds (77 kilograms).

On April 16, 1972, Apollo 16 was launched. Landing in the Descartes region, it brought back to Earth some 215 pounds (98 kilograms) of lunar rocks and soil.

Apollo 17, the last U.S. mission to the Moon, launched December 7, 1972, broke previous records of lunar exploration time, distance travelled, and quantity of lunar samples returned (225 pounds [116 kilograms] from the Taurus–Littrow region).

Skylab and ASTP. Several additional manned missions to the Moon had been planned initially. With their cancellation, Saturn IB (Earth orbital) and Saturn V (lunar) launch vehicles, as well as Apollo Command and Service modules, became excess. This equipment was used for Skylab and the Apollo–Soyuz Test Project (ASTP).

Skylab, the first U.S. space station, was launched on May 14, 1973. Damage sustained during launching required an extensive and successful repair program carried out by the first two crews to visit Skylab. The station consists of four basic sections. The Orbital Workshop, a converted third stage (Saturn IVB) of Saturn V, includes a hydrogen tank divided into two floors to provide the basic living and work area for the crew. Space-suited astronauts may exit and re-enter the Skylab for work in space through the Airlock Module (AM). A Multiple Docking Adapter (MDA) is provided for docking the Apollo spacecraft to the Skylab, while an Apollo Telescope Mount (ATM) is a noninhabitable area containing experiments.

Between May and November 1973, three crews of three astronauts each lived and worked aboard Skylab for 171 days 13 hours. These missions contributed to understanding of the space environment and of the medical and biological implications of long-term space habitation.

The Apollo–Soyuz Test Project is the only cooperative U.S.–Soviet manned space mission. Launched on July 15, 1975, from their respective national launch complexes, the three-man Apollo and the two-man Soyuz 19 spacecraft rendezvoused and docked in orbit two days later by means of a U.S.-built docking module. The two spacecraft remained linked for two days while the astronauts and cosmonauts conducted joint Earth survey, astronomical, medical, and technical experiments. At the conclusion of the two-day joint mission, the Soyuz spacecraft returned to Earth while the Apollo crew remained in orbit for an additional five days. The ASTP demonstrated the possibilities of international cooperation in space as well as the feasibility of using the docking module as a rescue device.

Apollo–Soyuz Test Project

APPLICATIONS SATELLITES

The search for scientific knowledge, exploration of the unknown, and establishment of man's capability in space have been, and remain, primary goals of national space programs. Increasingly, however, Earth-oriented satellites (called applications satellites) of direct economic benefit to man are being placed in operation.

There are three general classifications of such satellites: communications, Earth survey, and navigation.

Communications satellites. In the decade following the passive reflector balloon-satellite Echo 1, communications satellites (comsats) became a significant part of global communications. The Intelsat 4 comsat, for example, launched in January 1971, was capable of handling 3,000–9,000 telephone circuits or 12 colour television channels, or a combination of both.

After 1975 improved Intelsat IVA satellites began to replace the Intelsat IV spacecraft in the international network. In addition, domestic comsats, such as Comstar, Satcom, and Westar in the U.S. and Anik in Canada, now meet the specific needs of particular nations. Voice, television, facsimile or high-speed data (or both) are relayed. Palapa 1 is a comsat bought by the government of Indonesia and launched in 1976 to provide 5,000 two-way telephone circuits aimed at linking the almost 1,000 inhabited islands of the Indonesian archipelago.

Other specialized communications satellites in service since 1976 include three Maritime Satellite systems (Marisats), designed to provide greatly improved ship-to-shore communications. Previously, 90 percent of ship-to-shore communications was by hand-operated radiotelegraphy, and ionospheric disturbances in poor weather often limited communications. Marisat provides high-fidelity voice, data, Telex, and facsimile services. In addition, emergency rescue operations would be speeded by immediate connection to rescue authorities.

Marisats

Two developmental Symphonie communications satellites, launched cooperatively by France and West Germany in 1974–75, have been placed in geosynchronous orbit to provide telephone, television, and data service. (See also SATELLITE COMMUNICATION.)

The United States Department of Defense has a "secure" satellite communications system, using both synchronous and lower altitude orbits. The United Kingdom has a military Skynet comsat system launched by the U.S.

Soviet Molniya comsats

The Soviet Molniya comsats operate in a 65° eccentric orbit with a 300-mile perigee over the Southern Hemisphere and 24,500-mile apogee over the Northern Hemisphere. This technique provides a longer time of eight to nine hours over the portion of the Earth visible to Soviet ground terminals. Thus, three of these satellites, properly spaced, make possible 24-hour coverage.

Applications Technology satellites (ATS) are a series of geosynchronous orbit satellites launched by the United States, their purpose being to test new instrumentation and advanced communications techniques such as higher transmission frequencies and improved transmission antennas. ATS 6, placed in orbit in 1974, explored the possibilities of direct broadcast communications from space through the use of inexpensive ground receivers. This geostationary satellite was used to conduct experiments involving the provision of improved communications services for isolated communities. Direct broadcast classroom and community educational programming was provided initially for students in Appalachian and Rocky Mountain regions. The potential value of the satellite for improving health services was demonstrated by providing an ATS 6 communication link between rural Alaskan clinics and medical advisers in major hospitals in the Northwest. The following year the satellite was moved around the Equator to a point above East Africa, from where a year-long experiment was performed in cooperation with the Indian government. Indian programs on such subjects as agriculture, health, hygiene, and family planning were broadcast to more than 2,400 remote villages and relayed to another 2,500 villages throughout India. In 1976 the ATS 6 was again positioned above the Equator to broadcast educational programs to the U.S. NASA's Communications Technology Satellite (CTS), a single experimental vehicle placed in orbit in 1976, has been used in a joint U.S.–Canadian project to explore new communications technologies utilizing higher transmission power at higher frequencies.

Earth survey satellites. This broad category of satellites has progressed from initial relatively simple photography to include many forms of observation of the Earth.

Weather. Meteorological, or weather, satellites operate globally. From a polar orbit, photographs of the Earth's surface are taken by television scanning and transmitted to Earth receiver stations. Since the Earth rotates constantly, total global coverage is possible. In addition, meteorological satellites in geostationary orbit have the advantage of continuous watch over large regions of the Earth. Seventy percent of the Earth is covered by water, and there are few observation stations in desolate and jungle areas. Global observation of weather and its movement by satellites has become important to all nations. Tracking of hurricane formation and movement has permitted advance warning, saved numberless lives, and minimized property damage.

The first meteorological satellite was TIROS—Television and Infra-Red Observation Satellite. TIROS satellites transmitted cloud-cover pictures enabling meteorologists to track, forecast, and analyze storms.

Meanwhile, NASA was developing meteorological satellites of greater sophistication in the Nimbus series. Nimbus 3 and 4, launched in 1969 and 1970, were designed to measure atmospheric water-vapour content and vertical temperature sounding of the atmosphere. These measurements enabled meteorologists to draw an accurate picture of vertical temperature and humidity profiles, making possible more accurate forecasts.

Transmission of cloud pictures

By 1972 more than 500 Automatic Picture Transmission stations were active in some 50 nations, each capable of receiving facsimile-printed transmissions of an area of about 1,700 square miles. Cloud pictures may be processed for retransmission by geostationary satellites to local ground stations. Transmission of infrared nighttime images, which indicate ground, water, and cloud-top temperatures, was begun in November 1970.

In late 1970 the first operational "second generation" weather satellite was launched. Twice the size and weight of TIROS, it had an important new instrument, scanning radiometers to obtain direct-readout and stored images of the Earth's night side. It provides global coverage at 12-hour rather than 24-hour intervals.

The world's first Synchronous Meteorological Satellite, SMS 1, was launched by the U.S. in May 1974. Following the launching of SMS 2 in February 1975, a Geostationary Operational Environmental Satellite (GOES) was placed in orbit in October to provide 24-hour coverage of U.S. weather. In addition, the SMS and GOES craft collect and relay information transmitted by unmanned, ground- or ocean-based sensor stations in isolated locations. They also contain instruments to study solar activity, X-radiation, and the Earth's magnetic field. The SMS test satellites and the operational GOES take part in the Global Atmospheric Research Program (GARP), an international project aimed at achieving improved understanding of the mechanisms that govern the world's weather.

Other elements in this worldwide system include the Japanese Geostationary Meteorological Satellite (GMS) and the European Space Agency's Meteosat, launched in 1977. Soviet weather satellites, called Meteor, have distributed weather photographs internationally since 1969. The completed system is expected to provide continuous global coverage of the weather.

Geodesy. Earth satellites offer a method of improving the world's maps. If the altitude of a satellite is known, the angles of simultaneous widely separated observations may be used to calculate a base line between the two points of observation. Satellite observations have made possible the "tying together" of landmasses of the world not hitherto possible.

Geodetic satellites

NASA launched its first Geodetic Earth Orbiting Satellite (GEOS 1) in 1965; it was followed by GEOS 2, carrying a variety of equipment. In 1970, 43 stations in 23 countries made observations. The aim was to provide a unified three-dimensional framework connecting all landmasses of the world within an accuracy of 33 feet (10 metres). In 1971 an International Satellite Geodesy Experiment program using GEOS 2 included most major nations.

By the use of laser beam techniques, extremely precise measurements may make it possible to record Earth movements associated with earthquakes. This may make possible future forecasting of these natural phenomena. Lageos (Laser Geodynamic Satellite), launched in 1976, was a new approach to the study of geodetics. A completely passive satellite, Lageos is essentially a brass core encased in an aluminum sphere covered with 426 retroflectors that allow ground-based laser ranging stations to take measurements for the study of continental drift, tides, and fault motions.

Lageos was placed in a very stable orbit 3,600 miles (5,793 kilometres) high, where it is predicted it will remain for some 8,000,000 years.

Earth resources satellites. Many other benefits may be derived from Earth survey satellites. By viewing the Earth's surface in different portions of the radiant spectrum, revealing images are obtained.

The U.S. launched the first Earth Resources Technology Satellite (ERTS) in 1972. In polar orbit at an altitude of about 560 miles (910 kilometres), it transmitted to the Earth multispectral images that provided data to hundreds of scientific investigators in many disciplines: agriculture, forestry, mineral and land resources, land use, and water and marine resources.

ERTS 1 was renamed Landsat 1, and in January 1975 Landsat 2 was orbited successfully. The two spacecraft are 180° apart in orbit, thereby providing a view of the same local area with the same sun angle every nine days. With only one satellite, 18 days would be needed for the same view.

More than 100,000 black and white pictures and photographs in strange, artificial colours produced from the multispectral scanning system were taken by Landsat I. Based on those pictures, more than 300 separate investigations were conducted, providing better understanding

of the Earth's surface features. Some of the most valuable uses of Landsat 1 have been estimating crop acreage; monitoring urban development and planning future land use; locating air and water pollution; mapping strip-mine and forest-fire scars; locating geologic formations that may indicate the presence of minerals and petroleum; updating maps and navigation charts; monitoring the advance of glaciers; and studying flood hazards and managing water resources.

Military reconnaissance satellites. As of 1977 the U.S. and the Soviet Union were the only nations with both the technological ability and the wealth to utilize satellites for photographic and electronic monitoring. Such programs have been conducted by both nations since about 1959; in fact, reconnaissance is the oldest use of the applications satellites. Although there has never been official disclosure of such programs by either country, the use of reconnaissance satellites continues by tacit agreement. Such satellites are credited with being the main technological base in nuclear-arms control under the terms of the Strategic Arms Limitations Talks (SALT).

The U.S. in the 1960s began use of two other types of military detection satellites, launched in pairs in the Vela program. One satellite detects the launching of large missiles by the infrared radiation emitted, the other detects above-ground nuclear fission and fusion explosions from the gamma rays emitted.

Navigation. This specialized class of Earth-oriented satellites, first launched by the United States Navy in 1960, originally was classified secret. The prime purpose of the Transit series of satellites was to enable nuclear submarines accurately to fix their position under all surface weather conditions. It made star sighting unnecessary. In essence a beacon in the sky, the system was revealed in 1967. Operationally the system is based upon observation of the Doppler shift of the satellite's transmitted signal. A major military advantage is the fact that a ship does not have to emit an electromagnetic signal. Three Transit satellites were launched in 1967 and another in 1968. Use of this navigation system by merchant ships is limited because of the requirement for expensive equipment.

Transit satellites

The Soviet Union has also announced an operational navigation satellite system. Certain of the Cosmos satellites have flown in ways that suggest that they are navigation satellites similar to the Transit system. In accordance with Soviet policy, no specific information has been released.

IV. Contributions to the physical sciences

Dealt with in this section are selected examples of new understanding resulting from the exploration of space—by rockets, satellites, and space probes.

Discoveries about the Earth. Before the advent of artificial satellites it was accepted that the shape of the Earth was, except for some high mountains and deep valleys, an ellipsoid; *i.e.*, a sphere, slightly flattened. Accurate observation of variations of the orbital path of Vanguard 1 proved that, on the contrary, the Earth is slightly pear-shaped, the distance from the Earth's centre to the North Pole being greater than the distance to the South Pole. Further observations of anomalies in the orbits of satellites have shown that the Equator is elliptical and that the surface gravity of the Earth has several "hills" and "valleys" varying as much as 100–300 feet from the average.

Originally it was thought that cloud patterns and weather systems were relatively small, perhaps a few hundred miles across. Photographs from space have shown that the Earth's cloud cover is completely organized globally. Coherent cloud cover systems have been found to extend for thousands of miles and to be related to other systems of similar dimensions. It was discovered that weather systems could be directly identified by their cloud structure, and thus it was possible immediately to locate important atmospheric phenomena such as fronts, storms, and hurricanes, and to chart their courses daily with accuracy.

Atmospheric density and variation with altitude above the Earth had been studied for many years by balloons and to some extent by sounding rockets. Observations of atmospheric drag on satellites and resultant lowering of orbits, however, revealed that variations in atmospheric density are related directly to solar flares and the impact of electrically charged particles about 26 hours after marked solar activity. Further, solar flares have been found to increase the temperature of the atmosphere by interaction of short-wavelength radiation atoms and molecules in the atmosphere. Recombination of the ionized particles is accompanied by the liberation of heat.

Although it had been postulated that some charged particles might be trapped in the Earth's magnetic field, Explorers 1 and 4 revealed a major phenomenon in geophysics: the existence of two permanent doughnut-shaped belts of high-energy radiation caused by trapped charged particles, 2,000–10,000 miles (3,000–16,000 kilometres) above the Earth.

Discovery of high-energy radiation belts

The earlier view of the ionosphere was that from 40–400 miles (60–600 kilometres) distinct layers of ionized atoms and molecules, known as the D, E, and F layers, existed and were necessary for radio communications. Evidence from space exploration is that ionization in the atmosphere is actually continuous but that peaks of concentration of electrons occur at altitudes where the existence of layers had formerly been postulated. Still higher, ionization is practically complete and extends to great altitudes.

Previously it was believed that the magnetic field of the Earth was similar in shape and symmetry to a short bar magnet, with the magnetic field extending outward into space. It has been learned from satellites that the Earth's magnetic field on the side toward the Sun is sharply bounded because of the solar wind. On the dark side of the Earth, in the direction away from the Sun, the field streams out in a long, thin tail beyond the orbit of the Moon.

Solar phenomena. Since ultraviolet rays and X-rays are absorbed in the atmosphere, measurements of these radiations from the Sun were made by sounding rockets in some of their first flights. Solar spectra have been continuously refined by spectrographic cameras carried aboard many satellites. Variation in measurements correlated with observed solar activity is providing new knowledge of the processes taking place within the Sun. Although the radiation of the Sun in the visible portion of the spectrum is constant, the ultraviolet and X-radiation are variable. From the information gathered by space exploration it also has been learned that the Sun radiates in the manner of an incandescent gas, that ultraviolet and X-radiation are generated not in the region of the solar disk but higher in the solar atmosphere, in the chromosphere and the corona.

Previously the solar wind, a constant outpouring of high-speed particles from the Sun, had been only postulated. Measurements from spacecraft and from experiments made on the Moon by Apollo astronauts have measured the number and rate of flow of these particles. The velocity of the solar wind is highly variable and ranges from 250 to 310 miles (400 to 500 kilometres) per second.

Interplanetary phenomena. The earlier view was that interplanetary space was empty of matter except for that thrown out from the Sun and for the clouds of particles that became visible as meteoroids on striking the Earth's atmosphere at night. From space exploration it has been learned that the solar wind flows continuously and at such velocities that the particles escape the solar system.

Earlier it was believed that the existence of electric fields in space was unlikely. The evidence based upon measurements in space is that such electric fields do exist.

The earlier view of the number of meteoroids in space was based mainly on conjecture. Actual measurements by Explorer 16, Pegasus, and other satellites have given actual data and determined the number of meteoroids (and their hazard) to be considerably less than expected.

Meteoroid measurements

Exploration of the Moon and planets. Detailed photographs of the Moon have made possible a nearly complete map, including the hidden far side. Soft-landing vehicles have televised views of the surface by remotely

controlled cameras, determined the physical and load-bearing characteristics of the soil, and performed chemical analysis by isotope back-scatter technique. Seismometers, laser reflectors, solar wind and ion detectors, charged particle measuring devices, magnetometers, and other data-gathering instruments have been set up. Six Apollo missions brought back 841 pounds (382 kilograms) of selected lunar rocks and soil for study.

The physical nature of the Moon has been revealed by space exploration in a way impossible before. The list of discoveries is long and detailed. Perhaps the most significant is that the age of the surface material studied has been determined to be 4,600,000,000 years. For much of that time the Moon has not drastically changed, but lunar history appears to have been complex. Because it has changed so little, a record of the Sun can be traced on the lunar surface. This type of data has many implications for Earth history. Most rocks found on Earth are less than 50,000,000 years old because of destruction, erosion, covering, and other processes.

Some of the other findings about the Moon are: no evidence of life or water; lunar rocks are similar to Earth rocks but have different chemical compositions; seismometers record numerous "moonquakes" about the time the Moon is closest to the Earth each month; there is a lunar magnetic field, but it is much weaker than the Earth's; the solar wind is not disturbed as it approaches the Moon, signifying that there is no layer of charged particles similar to the Earth's ionosphere; laser reflection makes it possible to measure Earth–Moon distance to within about nine inches.

Through Soviet and United States spacecraft travelling to the vicinity of Venus, much greater understanding has been obtained of this planet. The Soviet technique of parachuting specially protected capsules through the dense Venusian atmosphere, apparently to the surface, has confirmed cloud-covered surface temperatures approaching 1,000° F (540° C). The thick atmosphere is primarily carbon dioxide, probably more than 95 percent; water vapour, about 0.4 percent.

Data on Venusian atmosphere

Prior to 1964 it generally had been accepted that the atmospheric pressure on Mars is about 85 millibars. (Terrestrial atmospheric pressure is about 1,000 millibars.) Mariner 4 data indicated that Martian atmosphere was about one-tenth this pressure, an important factor in the design of Martian landers.

U.S. Mariner spacecraft have flown within 860 miles (1,380 kilometres) of Mars, photographing the polar caps and revealing some widespread cratering, not unlike that of the Moon. There were, however, flat featureless plains, possibly covered by dust or sand. The polar caps are crusted with frozen carbon dioxide possibly to a thickness of two feet (0.6 metre). The Martian atmosphere is composed almost entirely of carbon dioxide with only traces of water. Unlike that of the Earth, Mars's atmosphere does not shield it from ultraviolet radiation, and most of it reaches the surface. Since intense ultraviolet radiation destroys most molecules associated with life—as mankind knows it—Mars may not support living things.

Scientists will be studying the data returned from Vikings 1 and 2, which sent landing vehicles to the Martian surface, for many years to come. Already, however, these spacecraft have enormously expanded our understanding of conditions on Mars. The atmosphere of the planet is primarily composed of carbon dioxide, but traces of nitrogen, argon, krypton, xenon, and oxygen have also been identified. Humidity varies significantly, the summer hemisphere being more humid than the winter. Viking Orbiter data indicate that the polar regions are composed of layered sheets of water ice. The biological experiments have so far failed to uncover any evidence of life on the surface, nor has the presence of organic chemicals been detected. Some test results have indicated the possibility of unusual soil chemistry.

Astronomical phenomena. The earlier view was that the temperatures of stars could be calculated from the visible radiations that penetrate to the surface of the Earth. From space research it appears that inclusion of the ultraviolet radiation causes significant changes in the calculated temperatures of individual stars. Some stars are found to be cooler than previously believed, and a class of supergiant stars are hypothesized to be losing mass into the interstellar medium at a greater rate than was previously thought.

The earlier view was that much of the mass of the Milky Way galaxy, containing the solar system, was molecular hydrogen. The evidence obtained from spacecraft is that the quantity of molecular hydrogen is much less than was thought and undetectable with available instruments.

It was thought originally that stars radiated most of their energy in the visible regions of their spectra. The evidence from spacecraft is that in the case of some stars the energy output in the visible spectrum is exceeded by that in the ultraviolet, radio frequencies, or infrared, or all three. Such tremendous outpourings of energy have caused theories of stellar evolution to be reconsidered. At the least, they suggest that there may be sources of energy that far exceed man's current knowledge of nuclear energy technology.

Radiation outside the visible spectrum

Since many of the stellar distances are dependent upon determining the intensity of stellar sources, these discoveries of much greater total energy outputs may cause astronomers to double the estimated physical size of the known universe. New and different types of stellar sources, such as gamma and X-rays, are being discovered at a rapid rate. Astrophysics poses one of the most challenging fields of professional endeavour as a result of the new and puzzling data being obtained.

V. Proposed future missions

A logical extension of space exploration and space exploitation (by applications satellites) may be expected. Many programs are possible, but funds and decisions to conduct new missions are controlled by national and international political, sociological, and economic factors. Major disasters such as climatological changes or major wars could severely limit progress in space activities.

Planetary missions. In 1978, Pioneer 11 was heading for an encounter with the rings of Saturn, scheduled to arrive in September 1979; it was expected to obtain the first detailed information and photographs of this planet. Voyagers 1 and 2 will commence studies of Jupiter in early 1979 and of Saturn in 1980.

Pioneer Venus 1, launched on May 20, 1978, will spend one year circling Venus, conducting surface mapping studies with radar, and obtaining data on the atmosphere of the planet. Pioneer Venus 2, scheduled to be launched in August 1978, will dispatch a series of three small probes and one large one that will descend through the atmosphere, relaying data before striking the surface.

The Voyager mission to Jupiter and Saturn may be followed by a Jupiter Orbiter Probe spacecraft that will circle the planet and dispatch small probes through the layers of cloud that shroud it.

The success of the Viking mission may lead to more ambitious programs of exploration for Mars, perhaps in 1984. These will almost certainly include a Mars rover capable of moving over the surface and transmitting data to Earth for a long time. Under consideration is the possibility of return of Martian surface samples by 1990, in a manner similar to that used by the Soviet Luna 16.

The exploration of the outer planets of the solar system may begin with a Voyager flyby of Uranus and will undoubtedly be continued by later spacecraft. Other possible missions may include visits to comets and asteroids and to the large moons of Jupiter and Saturn.

For a mission nearer to Earth, a Lunar Polar Orbiter (LPO) is being considered for launching in the 1980s. The five lunar science surface packages left by Apollo astronauts were shut down in 1977. The LPO is of interest for global observations of the Moon and as a prototype for spacecraft to survey other planets.

Lunar Polar Orbiter

An ambitious study has been made of a possible spacecraft rendezvous with Halley's Comet during its next passage close to the Earth in 1985–86, a technically

difficult mission. Launching might take place in 1982, and ion propulsion might be used for the unique trajectory. Since the comet moves in a highly inclined retrograde orbit, the spacecraft would have to move to a point along the comet's orbit, slow to a stop, and then proceed along the orbit, regaining speed to match that of the comet.

Manned space programs. The American space program will enter a new era with the first operational flights of the reusable Space Shuttle in 1980. The shuttle will be launched vertically by two large solid-propellant strap-on boosters and three liquid-propellant main engines. The liquid oxygen/liquid hydrogen propellants are fed to the main engines from a large external tank that is jettisoned when empty.

Reusable Space Shuttle

The Orbiter is the central unit of the Space Shuttle system. A winged vehicle, it is launched vertically but re-enters the atmosphere and glides to a landing like an airplane. Five successful glide landings were made in 1977 by the protoype Orbiter, "Enterprise."

The Orbiter can be reflown for up to 100 missions. The boosters are also recovered and refurbished to be flown again. The significant savings in cost, compared to standard launch vehicles that are expended during the course of a single flight, will enable NASA planners to schedule more frequent missions. By the mid-1980s, shuttle launchings may become weekly occurrences.

The central portion of the Orbiter contains the cargo bay in which satellites or other materials can be carried into space. A Spacelab being constructed by a nine-nation European consortium for the European Space Agency will be among the early payloads launched aboard the shuttle. The Spacelab makes use of an arrangement of a module, where a life-sustaining environment is maintained, and two instrument pallets. A variety of experiments is planned, ranging from Earth observation to materials processing, communications, navigation, and space sciences. Like the shuttle, the Spacelab will be reusable. Duration of missions will average seven days, although extensions of up to 30 days will be possible.

An Interim Upper Stage (IUS) is also being developed for use with the Space Shuttle. This large solid-propellant rocket motor will be used to boost payloads, such as synchronous communications satellites, into higher orbits than those that can be reached by the shuttle. Thought is also being given to the use of the IUS for the Jupiter Orbiter Probe being proposed for 1982.

The shuttle will make it possible to undertake large-scale construction projects in space. The large external propellant tank can be carried into orbit to serve as the nucleus for a space station. The Space Shuttle will provide a reasonably economical means of voyaging into space regularly.

Applications satellites. Because this class of satellites is of direct economic benefit to mankind, all varieties may be expected to increase in number, size, and sophistication of design. Of particular interest is the concept of direct broadcast satellites which could permit direct reception of television broadcasts from space. Initially the broadcast power of communications satellites was limited, requiring large dish antennas for reception. Large comsats, however, pioneered by the U.S. ATS 6, have demonstrated that direct satellite transmission to home television receivers is possible. Many political and sociological factors are obviously involved in such a development.

Direct broadcast satellites

Beyond 1985. During the 1970s there was active speculation on possible construction of large space structures for a variety of purposes, such as generating electric power from solar radiation and beaming the power to receiving stations on Earth. Large solar reflectors have been proposed that could illuminate populous areas of the Earth at night, reducing requirements for street and road lighting. Powerful communication relay stations in orbit may make possible personal "wristwatch" telephones. Because of weightlessness in orbit, and the presence of high vacuum and wide temperature variation, pure and applied research could be carried out as well as unusual varieties of manufacturing processes.

Human beings may be expected, by their nature, to continue outward exploration of the solar system. Returning to the Moon, a permanent lunar base and even a permanent colony could be established. Manned expeditions to the moons of Mars as well as to the Martian surface, a two-year journey, are possible. There has even been speculation on the establishment of permanent colonies, or habitats, in space—perhaps at the libration points (L-4 and L-5) of the Moon. These possibilities are based upon extrapolation of known technologies. New inventions and discoveries in applied science, such as controlled fusion power, may be anticipated.

Predictions cannot be made with confidence. Some of the space missions suggested above, however, or even flight to the stars, although not considered possible or feasible with today's technology, may occur in the future. History suggests that it is unwise to state categorically that they cannot happen.

Space Law

Space law refers to those rules accepted by the nations of the world as legally binding on them and their nationals in conducting activities in outer space and on celestial bodies. While "outer space" has not as yet been formally defined by the nations, it is generally taken to mean the area beyond most of the earth's atmosphere at which an unpowered ar-

tificial satellite can remain in orbit, roughly 70–100 miles above the earth's surface and beyond.

Since the emergence of the modern nation-state in the 15th and 16th centuries, a substantial body of rules has developed by which the states regulate their dealings with each other. International law, reflecting the present largely unintegrated system of world order, is itself decentralized. The same states that make the law (by following custom until it is considered a legal rule, or increasingly, by making treaties) are "bound" by it, judge deviations from it, and on occasion enforce it. Yet in an increasingly technologically unified world, man's modest ability to penetrate beyond the limits of his atmosphere simply projects the possibility of conflict and misunderstanding into a new milieu. In the face of these new potentials it has been generally assumed that the most likely means to regulate relations would continue to be the appropriate, established rules of international law. As on the surface of the earth, international law sets the guides and limits that permit nations to operate, hopefully with a maximum possibility of accommodation and a minimum of conflict.

NEW DIMENSIONS AND OLD PRINCIPLES

Especially after the beginning of space flight with the Soviet satellite Sputnik 1 in 1957, diplomats and many writers began to consider which rules of international law might be applicable to man's activities in outer space and whether new rules were necessary. There was a general consensus that the bulk of already existing international law concerning the acceptable interactions of states, including the Charter of the United Nations with its limitations on the use of force, was indeed applicable to this new dimension. One doctrine of that law, governing the acquisition of title to new territory, required special attention.

As international law developed with respect to the earth's surface, it became established that certain areas, the high seas being the most notable example, were free for the peaceful use of all nations and were not subject to national appropriation (*res extra commercium*). Land areas that were empty or occupied by "barbaric" people were, however, considered as belonging to no one (*res nullius*) and hence available to whichever "civilized" nation claimed possession and could enforce this claim. Acquisition of sovereignty, the near absolute right of a state to control persons, things, and acts in a given area and to exclude nationals of all other states, required more than discovery and symbolic acts; reasonable control and effective occupation and use, at least to the degree possible, have been held necessary for a state to perfect such a claim.

From the outset, spokesmen for the space powers, the Soviet Union and the United States, for all other nations, and almost all scholars, uniformly agreed that outer space and the celestial bodies should not be considered *res nullius* in the traditional sense and that they were not to be subject to national claims of sovereignty. The concept that space and the celestial bodies are open to the peaceful use of all nations has now been formally made part of international law.

The first orbital space flights were achieved during the period of international scientific cooperation known as the International Geophysical Year (IGY 1957–58). This may help to explain why no state protested the flight over its territory of these satellites, even though in theory every nation has absolute sovereignty in the "airspace" over its land mass and territorial waters and permits no aerial flights there without its consent. This acquiescence has been taken by some as the basis at least of a rule of customary international law to the effect that such flights are outside national airspace, even when "above" a country, and that outer space is open for the peaceful use of all nations, although others argue that this acquiescence is not sufficient proof that states recognize an upper limit to their sovereignty.

THE ROLE OF THE UNITED NATIONS

The question of outer space use was first brought to the United Nations by President Eisenhower as part of the disarmament discussions of early 1957. Those discussions were not fruitful. Despite the fact that the intercontinental ballistic missile (ICBM) spends at least part of its flight time at altitudes that all would concede to be "outer space," control of the ICBM has not again been discussed as part of the outer space regime but has been left to general disarmament talks.

After the success of the Soviet Union's Sputnik 1 on Oct. 4, 1957, and of the United States' Explorer 1 on Jan. 31, 1958, both nations brought proposals for action concerning outer space to the UN in the fall of 1958. Discussions at the UN showed agreement on several legal issues: outer space was to be used for "peaceful" purposes only, general principles of law recognized by civilized nations were applicable to space; space was not subject to the extension of national sovereignty (as demonstrated by the lack of national objections to the satellites already flown). An ad hoc committee was established on Dec. 13, 1958, to consider legal and technical problems and possible international arrangements. This committee functioned through the spring of 1959 and, despite the Soviet Union's refusal to participate, due to its then widespread insistence on the inclusion of "neutral" and East European governments, its report in June 1959 set much of the tone of all that followed in the UN. It suggested, among other things, that it was premature to attempt to promulgate a comprehensive legal code or to create an internationally controlled regime for space activities, that the UN should play a modest role, and that it was unnecessary to define precisely the limits of airspace or outer space.

The Outer Space Committee

On Dec. 12, 1959, the ad hoc committee was transformed into a 24-member, permanent Committee on the Peaceful Uses of Outer Space ("Outer Space Committee") with five "neutral" states and seven Eastern European states, thus giving the Soviet Union the representation it demanded. Soviet-U.S. disputes over whether voting should be unanimous or by majority prevented Committee meetings in 1960 and 1961, however. Then, in the fall of 1961, the United States and the Western nations led the UN General Assembly in adopting, unanimously, a resolution (Res. 1,721, XVI, Dec. 20, 1961) that, for the first time, formally suggested principles to govern the exploration and use of outer space. While the UN's role continued to be deemphasized, the Secretariat was to provide a place for the registry of launchings "into orbit or beyond." Moreover, the resolution recognized: ". . . the common interest of mankind in furthering the peaceful uses of outer space and the urgent need to strengthen international cooperation in this important field," and commended to states the principles that: "(a) International law, including the Charter of the United Nations, applies to outer space and celestial bodies; (b) Outer space and celestial bodies are free for exploration and use by all States in conformity with international law and are not subject to national appropriation."

The Outer Space Committee, meeting as a whole and through legal and technical subcommittees, achieved some agreement in 1962 and early 1963, although Cold War differences between the U.S. and the U.S.S.R., especially over rights of observation from space, continued. By mid-1963, a great-power thaw set in, the principal demonstration of which was the Nuclear Test-Ban Treaty of August 1963, which, among other things, prohibited tests in the atmosphere and in outer space as well. On Oct. 17, 1963, with U.S.-U.S.S.R. agreement, the General Assembly adopted a resolution that recorded the understanding, achieved during the earlier Geneva disarmament negotiations, that no nuclear or other weapons of mass destruction would be stationed in outer space. Then, on Dec. 13, 1963, the General Assembly adopted the nine-point Declaration of Legal Principles Governing the Activities on States in the Exploration and Use of Outer Space. This declaration recognized the "common interest of all mankind" in space activities and that the exploration and use of outer space and the celestial bodies should be for the benefit of all men. Outer space and celestial bodies were "not subject to national appropriation by claim of sovereignty, by means of use or occupation, or by any other means," and were free for use by all states on a

basis of equality. All activities were to be carried on in accordance with international law, including the UN Charter; and states bore international responsibility for their acts in space, were liable for damages caused, and were to consult with other states before undertaking potentially hazardous activities. States retained ownership of their vehicles and control over their personnel; the astronauts were to be treated as "envoys of mankind" and were to receive all possible aid in the event of an emergency.

The declaration was hailed by some as the "Magna Carta" for outer space activities, and while General Assembly resolutions as such are not legally binding on members, several nations, including the United States, urged that this declaration, unanimously adopted, evidenced the present will and practice of the international community and was "international law as it is accepted by the members of the United Nations." Others stated that it was at least the basis for international rules. The Soviet Union and France were more cautious, urging that a treaty was essential to create binding rules.

THE OUTER SPACE TREATY

Whatever the view of the 1963 declaration as present law, the issue was resolved for most nations by the creation, under UN auspices, in December 1966 of an Outer Space Treaty (Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space, Including the Moon and Other Celestial Bodies). The treaty was signed on Jan. 27, 1967, by representatives of 63 nations and is now in force for most of the world's states. In 17 articles it reaffirms all the UN resolutions noted above. Thus, Article I declares that space shall be free for exploration and use by all states and that states shall facilitate and encourage international cooperation in such investigations; Article II states that outer space, the moon, and other celestial bodies are "not subject to national appropriation by claim of sovereignty, by means of use or occupation, or by any other means"; and Article III provides that a nation's activities in exploration and use of outer space shall be in accordance with international law, in the interests of maintaining international peace and security, and in the interests of promoting international cooperation and understanding. Article IV prohibits stationing in outer space any object carrying a nuclear weapon or any other weapon of mass destruction and installing such weapons on celestial bodies, or in outer space in any other manner, and prohibits establishing military bases and fortifications, testing weapons, or conducting military manoeuvres on celestial bodies, though military personnel may be used for scientific research or for any other peaceful purposes. Article V again calls astronauts "envoys of mankind" and provides that, in event of accident, distress, or emergency landing on the territory of another state or on the high seas, they will be given all possible assistance, including safe return. On celestial bodies, astronauts of different states are to render all possible assistance to one another.

No sovereignty

Article VI places international responsibility on a state for its activities in space, whether by governmental or nongovernmental entities. Nongovernmental entities must have authorization and "continuing supervision" by the state concerned. Article VII provides that the launching state and the state from whose territory or facility an object is launched are internationally liable for any resulting damages to the persons of another state. Article VIII states that jurisdiction and control is retained by the state on whose registry an object is carried and over the personnel thereof in outerspace or on a celestial body. Such objects or component parts are to be returned to the state of registry if found in another state. Article IX provides for cooperation and mutual assistance among states, who are to have due regard for the corresponding interests of other states and are to avoid harmful contamination of celestial bodies and of the environment of the earth through space activities. If potentially harmful interference with activities of another treaty state is foreseen, appropriate international consultations are to be undertaken upon the request of any of the states concerned before the planned activity is undertaken.

Article X calls for opportunities for states to observe the flight activities of other states as determined by agreements between them. Article XI provides for informing the UN secretary general as well as the public and the scientific community, to the greatest extent feasible and practicable, of the nature, conduct, locations, and results of a state's activities in outer space. Article XII advances this concept by providing that all space vehicles and installations on the moon or other celestial bodies will be open for inspection by other parties to the treaty, who are limited, however, by the need for advance consultation to assure that adequate safety precautions are taken and to avoid interference with normal operation of the space facility.

THE CONTINUING DEVELOPMENT OF SPACE LAW

As a result of the continuing work of the Outer Space Committee, an Agreement on the Rescue and Return of Astronauts and the Return of Objects Launched into Outer Space was signed on April 22, 1968, by 44 nations and is now in force for the space powers and most other states. It makes more precise the requirements of safe and unqualified return of astronauts, provides that the launching authority may be obliged to share in the cost of recovering a vehicle but not an astronaut, and asserts again the permanent ownership and control of the launching state. It was not until 1970 that a draft treaty on liability was substantially completed under UN auspices as a supplement to earlier UN resolutions and the 1967 Outer Space Treaty.

Communications. The area of most intense concern over the peaceful uses of outer space is that of communications. Satellites already have demonstrated their utility in adding to existing techniques for communicating between widely separated earth points and promise revolutionary changes in decreased costs and widespread international use. The United States, in the Communications Satellite Act of 1962, established a hybrid entity, the Communications Satellite Corporation (Comsat), with stock held in part by the public and in part by U.S. communications companies and with several directors appointed by the president to provide service through the space medium. Comsat has, in turn, become the U.S. "representative" and the manager of the International Telecommunications Satellite Consortium (Intelsat), functioning under special and interim agreements and linking countries generating some 90 percent of all present international telecommunications traffic through communications satellites. The Soviet bloc has a similar arrangement, based on the Soviet Union's Molniya ("lightning") system.

Problems as well as encouraging prospects exist. In addition to the possible creation of competitive systems, there are demands that, internationally, the United States yield greater control in Intelsat to other nations and, within the United States, that Comsat give up its monopoly on domestic use of communications satellites. Since some locations in space are better than others for placing satellites, disagreements over "usurpation" may occur. For decades the International Telecommunications Union (ITU) has allocated radio frequencies, which are a limited resource, among the nations; here too the demand for frequencies for space use and problems of conflicting uses are growing increasingly acute. In addition to these forms of competition, there is a potent source of future conflict in direct broadcast satellites, capable of communicating directly into a home receiver, which may be used as vehicles for the transmission of information and ideas in propaganda wars.

Other arrangements. In addition to the general agreements discussed above, a large number of other international agreements exist. The United States, for example, has entered into some hundred bilateral treaties, executive agreements, or memoranda of understanding with other nations and separate jurisdictions concerning such disparate matters as tracking and data acquisition, launchings for other states, communications testing, meteorology, training for scientists, and the provision of a satellite-television educational system for India. Joint U.S.-U.S.S.R.

arrangements exist in the fields of meteorology and communications, and the Soviet Union also has made a number of bilateral agreements. In addition, the Western European countries have cooperated in the European Space Research Organization (ESRO) and in the effort to develop a launch capability in the European Space Vehicle Launcher Development Organization (ELDO).

International organizations

In addition, a number of international organizations with very widespread membership among the nations have participated in one phase or another of space developments and hence in the creation of the background for law. The ITU has already been mentioned. The International Civil Aviation Organization (ICAO) now sets standards for international flight in airspace and may exercise a role where air and space flight interact. Others that have considered space matters include the World Meteorological Organization (WMO), the United Nations Educational, Scientific, and Cultural Organization (UNESCO), the World Health Organization (WHO), and the International Atomic Energy Agency (IAEA). Moreover, the space nations have utilized a special group of national science experts, meeting as the Committee on Space Research (Cospar), for some coordination of national space programs, for the exchange of information, and for discussion of potentially harmful space experiments and the problems of contamination.

Problems and future developments. Though space law has seen a remarkable growth in a relatively short time, through customary law, treaty, and resolution, problems remain unresolved. These include the need for a more precisely defined limit to airspace (and hence to national sovereignty) and for resolution of the problem of control and ownership of whatever resources there may be on celestial bodies, quite apart from claims of sovereignty. Disagreement continues as to whether observation from space is always permissible, which has been the U.S. view, or whether it is "spying" and should therefore be barred, as the Soviets maintained (though this is no longer vigorously pressed since both space powers are observing from space); and no solution has yet been found to the dispute as to whether the restriction of space to "peaceful" uses bars *all* military activity (soviet view) or only aggressive military activity (U.S. view). There is also a need for the creation of a treaty dealing more precisely with liability questions; for an agreement on the future role of the UN itself; on the appropriate entities for the operation of international communications nets; and on appropriate devices for multinational cooperation in space ventures. Of these, the successful negotiation of a liability convention seems the most imminent. Despite this list, consensus to date on the scope of space law is extensive and, in view of the great costs of space exploration and the likely absence of serious international conflict over space activities in the short run, the legal structure, with some additions, is probably adequate for the present. Whether it would be able to assure the peaceful exploitation of a major breakthrough in space resource technology remains unclear.

Space Perception

Human beings have been interested in the perception of objects in space at least since the question of how a picture or image arises in the human eye was first asked. It was popularly thought in ancient Greece that objects are seen because they emit what was imagined to be a continuous series of extremely thin "membranes" in their own image, which fall upon the eye and there merge into the picture that is perceived. Only after long experimental research was a more tenable conception reached, in which space was described in terms of three dimensions or planes: height (vertical plane), width (horizontal plane), and depth (sagittal plane). These planes all intersect at right angles, and their single axis of intersection is defined as being located within perceived three-dimensional space—that is, in the "eye" of the perceiving individual. Man does not ordinarily perceive a binocular space (a separate visual world from each eye), but sees a so-called Cyclopean space, as if the images from each eye fuse to produce a visual field akin to that of Cyclops, a one-eyed giant in Greek mythology. The horizontal, vertical, and sagittal planes divide space into various sectors: something is perceived as "above" or "below" (the horizontal plane), as "in front of" or "behind" (the vertical plane), or as "to the right" or "to the left" (of the sagittal plane).

The study of space perception developed rapidly in the second half of the 19th century and still more rapidly during the 20th.

Many modern psychologists who deal with perceptual function hold that the study of space perception is rapidly becoming a distinct branch of psychology in its own right. This special field of investigation within psychology concentrates on the factors contributing to the perceptual articulation (organization) of objects in space (*e.g.*, on cues to depth perception, movement, form, colour, and their interactions), or dwells on particularly interesting special problems such as that of amodal perception (*e.g.*, the question of how one perceives that there are six sides on a cube, even though only three of them can be directly visible at once). Another special problem is the effect of the so-called mirror-ego on perception. It is questioned, for example, whether, when one's skin is touched while he is looking at himself in front of a mirror, he experiences the touch as if it were in the mirror image or perceives it to be in contact with his own body as it actually appears in front of the mirror.

Perception and orientation

Space perception research also has tended to become a distinct specialty because of indisputable evidence that behaviour in this area is involved in orienting the individual to his environment. Specifically, man's orientation in space typically seems to reflect his strivings (*e.g.*, to seek food or to avoid injury). He would not be capable of effective orientation behaviour, however, unless the environmental information reaching him through the various sense organs were articulated (perceptually organized) in one way or another, permitting objects in space to be perceived at least approximately in a way that corresponds to their physical "reality" (*i.e.*, to their "actual" condition as stimuli). Such perception is called veridical perception, despite philosophical disputes about perceptual truth or verity (see EPISTEMOLOGY). Without some degree of veridicality of what is perceived to be physical space, one should be unable to efficiently seek food, flee from his enemies, or take part in social interaction. This means that, in service to one's veridical perception (direct perception of stimuli as they exist), one must also experience changing stimuli as if they were stable (invariant); that is, one experiences so-called perceptual invariances. Even though the sensory image of an approaching tiger grows larger, for example, one tends to perceive that the animal's size remains unchanged. One must be capable of perceiving objects in his environment as having relatively constant characteristics (as to size, colour, and so on) despite considerable variations in stimulus conditions.

Primary gravitational effects. Not all perception of space, however, is veridical; *i.e.*, it may fail to correspond to reality. A large number of perceptual effects have been demonstrated in which space as perceived deviates from reality in some systematic way. These are cases of nonveridical perception; for example, it has been demonstrated experimentally that the three basic spatial planes (hor-

izontal, vertical, and sagittal) dominate the ability of the individual to localize visual objects in nearby space. Carefully controlled experiments show that objects tend to be perceived as lying closer to these basic dimensions or planes than they really are. Part of the explanation of these perceptual discrepancies in visual experience may lie in the force of gravity, which undeniably affects the individual from the moment of conception onward, pulling a man's viscera and muscles "down" toward the centre of the earth. The various perceptual phenomena indicative of nonveridical perception nevertheless do not generate chaos in one's perception of space, as might theoretically be expected; indeed, most often they serve to simplify and to articulate the perceived characteristics of surrounding space. If all of the mass of sensory information available at a given moment were perceived veridically, the flood of data might so confuse the perceiver that he would be unable to orient himself appropriately. In other words, some degree of selectivity in perception in general appears to be demanded for the survival of the individual. Ideally, information about the environment is perceived only as it is relevant to the goals, needs, or physiological state of the individual at a given moment.

Selective perception

Visual factors in space perception. On casual consideration, it might be concluded that the perception of space is based exclusively on vision. After closer study, however, this so-called visual space is found to be supplemented perceptually by what are clearly identifiable as cues from auditory (sense of hearing), kinesthetic (sense of bodily movement), olfactory (sense of smell), and gustatory (sense of taste) experience. In addition to these, a number of other spatial cues, such as vestibular stimuli (sense of balance) and other modes for sensing body orientation, must be taken into account. These various (*e.g.*, visual, olfactory) "spaces" are not found to be perceptually independent of one another; powerful experimental evidence shows them to interact in producing unified perceptual experiences.

It is nevertheless undeniable that the individual ordinarily receives the largest part of his information about the environment through the sense of sight; balance or equilibrium (vestibular sense) seems to rank next in importance. It has been shown that in a state of total darkness the orientation of an individual in space is mainly dependent on sensory data deriving from vestibular stimuli. The dominance of visual stimuli in the perception of space becomes particularly understandable when it is noted that vision is a so-called distance sense; it is capable of gathering information from extremely distant points in the environment, reaching out to the stars themselves. Hearing is also considered a distance sense, as is smell, though the space they encompass is considerably more restricted than that of vision. All the other senses, such as touch and taste, are usually considered to be proximal (proximate or direct) senses—*i.e.*, conveying information about the space in direct contact with the perceiving individual's body. Strictly speaking, the latter senses may, on occasion, function over distances. The smell of rotten eggs (produced by hydrogen sulfide gas) several yards away may be associated with a taste experience if the gas dissolves in the perceiver's saliva.

The eye has often been compared to a camera; this is, of course, a very rough comparison, but it is possible to think of the retina (the back surface of the inside of the eye) as if it were the film in a camera and of the lens within the eye as analogous to the single lens of the camera (see EYE AND VISION, HUMAN). Just as in a portrait photographer's camera, the picture (image) that is projected from the environment onto the retina is upside down. While it might be expected that the perceiver therefore would experience space as turned upside down, normally this does not happen. Some sort of perceptual mechanisms within the individual enable him to see his environment right side up; the exact nature of these mechanisms is under study, yet remains poorly understood. But the process of perception seems to involve at least two inversions: one (optical) inversion of the image on the retina; another (perceptual) associated with nerve impulses in the visual tissues of the brain.

Experiments have been carried out with people who were wearing special optical devices (*e.g.*, as spectacles) that reverse the right–left or up–down dimensions of images as normally received at the surface of the retina. At first the person becomes disoriented, but when he wears such a device all the time, he gradually learns to cope with space correctly while the special glasses are on. Indeed, he reorients himself to his environment to the point that he visually begins to perceive objects as if they were right side up again. This is evidence that the individual can become visually adapted in his perception of space to a new set of stimulus cues that deviate considerably from those previously learned. The process changes direction when the optical distorting device is removed; at first the basic visual dimensions appear reversed to the subject who has adapted to the spectacles. Within a short time, however, a new adaptation occurs; the subject quickly reorients himself to the earlier, well-learned, normal visual cues and perceives his environment as normal once more.

PERCEPTION OF DEPTH AND DISTANCE

The perception of depth and distance depends on information transmitted through various sense organs. Sensory cues indicate the distance at which objects in the environment are located from the perceiving individual and from each other. Such sense modalities as seeing and hearing are known to transmit depth and distance cues and are in substantial degree independent of one another. Each modality by itself can produce consistent perception of the distances of objects. Ordinarily, however, the individual relies on the collaboration of all his senses, (so-called intermodal perception).

Gross tactual–kinesthetic cues. In his perception of the distances of objects located in nearby space, one depends on his tactile (tactual or touch) sense. In tactile experience, however, kinesthesic experience (sensations of muscle movements and of movements of the sense-organ surfaces) normally is so closely associated that investigators lump the two as tactual–kinesthetic cues.

Tactual–kinesthetic sensations enable one to differentiate his own body from the surrounding environment. The body of the individual seems to function as a perceptual frame of reference—that is, as a standard against which the distances of objects are gauged. One's perception of his own body may vary from time to time, and so its role as a perceptual standard is not always consistent. It has been found that the way in which the environment is perceived also affects one's perception of his own body. Thus, for example, it has been shown experimentally that one experiences his own arm as growing longer when he is using it to point at some object off in the environment.

Man's own body as a perceptual standard

Cues from the eye muscles. When one looks at an object at a distance, the effort arouses activity in two eye-muscle systems called the ciliary muscles and the rectus muscles. The ciliary effect is called accommodation (focussing the lens for near or far vision), and the rectus effect is called convergence (moving the entire eyeball). Each of these muscle systems contracts as a perceived object approaches. The effect of accommodation in this case is to make the jellylike lens more convex (fatter), while the rectus muscles rotate the eyes to converge on the object as it comes nearer. One's experience of these muscle contractions provides him with cues to the distance of objects.

Beyond the cues of accommodation and convergence, the size of the retinal image also serves to indicate how far one is from an object. The larger the image on the retina, the closer one judges the object to be. Some workers theorize that these sensory cues activate inherited (nativistic) tendencies immediately to perceive such sensory attributes as size without the need for learning. Modern efforts to study these cues have been especially directed toward physiological changes in the body that may be related to depth perception; whether one's perception of depth is totally inborn (nativistic), and thus independent of learning, however, remains most controversial.

Accommodations and convergence provide reliable cues when the perceived object is at a distance of less than about 30 feet (9 metres) and when it is perceived binocularly (with both eyes at once).

Visual cues. Perhaps the most important perceptual cues of distance and depth depend on so-called binocular disparity; that is, since the eyes are imbedded at different points in the skull, they receive slightly different (disparate) images of any given object. The two retinal images of the same object seem to be combined perceptually in the brain into one three-dimensional experience. The degree of disparity between the two retinal images, so-called binocular parallax, depends on the difference between the angles at which an object is fixed by the right eye and by the left eye. Thus, in looking at the indicator needle on a pressure gauge, for example, one will make slightly different readings because of parallax if he uses first the left eye alone and then the right eye. The greater the parallax difference between the two retinal images, the closer the object is perceived to be.

Binocular disparity

The phenomenon of binocular disparity functions primarily in near space because with objects at considerable distances from the viewer the angular difference between the two retinal images diminishes. Visual disparity nevertheless can be used in estimating greater distances by simply using optical devices that magnify the parallax distance separately for each eye. Such devices include artillery range-finding devices and old-fashioned, three-dimensional picture viewers called stereoscopes.

In what is called visual movement parallax, distance cues are obtained from retinal changes that depend on the interposition of objects in space. Thus, when the individual moves his head either from side to side, or forward and backward, the retinal image of a nearby tree moves more, while that of a distant tree moves less. Unlike binocular disparity, which functions only in binocular vision, movement parallax is especially important for judging distance when only one eye is used (monocular vision).

Another group of visual images called perspective projections provide perceptual cues that are independent of whether there is monocularity or binocularity of vision. Although estimates of distance based on such perspective effects as the apparent distant fusing of railroad tracks in a single point are incompletely understood, they are often considered to depend heavily on learning. Such phenomena illustrate the tendency of the individual to integrate perceptions into consistent and invariant wholes. Experiences of perspective may be generated by putting appropriate lines in an oil painting (linear perspective), by gradations in the tint of the paint (colour perspective), and by viewing the surface of the earth from an airplane (aerial perspective).

Still another group of visual cues of depth and distance consists of apparent differences in object brightness. In experimental studies it is found that the brighter an object appears, the closer it seems to be. Thus, a white card against a dark background seems to recede or to move forward as the level of illumination on the card is experimentally varied. Similar effects can be induced by changing the colour (hue) of an object—*e.g.*, from bright red to dark red.

Auditory cues. Auditory cues for depth perception include sound intensity (loudness), auditory pitch, and the time lapse between visual perception and auditory perception (for example, one hears a distant cannon after seeing the flash and smoke of the explosion).

Hearing in depth

Changes in pitch function as depth cues because when a moving object (*e.g.*, an automobile) is emitting sound waves (*e.g.*, from its horn), the pitch of the sound seems to rise when the object is approaching the perceiver; to fall when it is moving away. (For additional discussion of these points, see PERCEPTION OF MOVEMENT; ILLUSIONS AND HALLUCINATIONS.)

INTERRELATIONS AMONG THE SENSES

The development of human ability to perceive space normally depends on the interaction of the senses (modalities) of sight and touch. Toward the end of its first year, a child eagerly begins to touch and to explore objects with his hands. Compared with his visual apparatus, which begins to function more efficiently at a later time, the child's sense of touch at this stage of development is delicately and effectively sensitive. By touching objects that are placed at various heights and distances from him, the child learns excellent tactual ways of perceptually evaluating what must be a highly ambiguous world as transmitted by his relatively immature visual apparatus.

The part played by other modalities (*e.g.*, hearing) does not appear to be as fundamental in perceptual learning among young children. By contrast, people are most seriously hampered in learning a detailed, well-articulated perceptual appreciation of space without vision or touch; most people (including those who are blind) may find it difficult to imagine how impoverished an understanding of space one would have if there were only auditory cues. It is well known that people with full sensory endowment learn to locate the sources of sounds by consulting both their visual and tactual experiences. There are subtler forms of sensory interaction as well; for example, one is more accurate in turning a pointer toward a distant source of sound (*e.g.*, a buzzer) if the pointer is simultaneously illuminated whenever there is buzzing. Such anchoring of one sense to another as a basis for spatial perception is vividly illustrated by experiments with laboratory animals.

Experiments with animals

Young monkeys have been taught to discriminate, on the basis of tactual perception alone, differently shaped objects (balls, cubes, cones, and cylinders, all about the size of a matchbox). That is, each animal was given two of these objects at a time and was allowed to feel them with its hands without seeing them. The animal's choice of one specific shape (say, a cube) and its rejection of another (say, a cone) were rewarded with bits of food. When this selective tactual response had been learned, the animal was given the same tasks of selection, this time to be performed visually (by looking at pictures of the same objects). Under these conditions the animal often was able to discriminate the visually presented figures correctly. This phenomenon (called cross-modal learning) may be explained as a transfer effect based on earlier visual–tactual learning (see TRANSFER OF TRAINING).

Success in orientation, in moving about effectively and without accident in everyday pursuits, is most probable when environmental information at any given time is available through as many senses as possible. When the range of sensory stimuli that forms the usual basis for the experience of perceptual space is experimentally reduced, one's success in orientation is impaired. When visual cues are sharply reduced for sighted people, they complain of disorientation, akin to groping around in a diffuse, undifferentiated fog. Indeed, injuries are all too common even when one seeks in the dark to negotiate such familiar territory as his own bedroom.

Apparently, by learning about systematic relationships that exist among a number of simultaneously available stimuli, people can perceive distances more or less correctly. The retinal image of an object 100 yards (91 metres) away is so much smaller than the image of the same object at a distance of 10 yards (9 metres) that (if they relied solely on the sizes of retinal images) people might perceive moving objects to shrink or grow rather than to recede or approach.

Experiments have shown that the distance (in depth) between selected objects in photographs is most accurately estimated when the objects have been filmed in a richly organized environment—*e.g.*, many people standing at different distances from the camera. On the other hand, it is most difficult indeed to reliably perceive even the relative depth of two vertical rods when they are presented against a background in which other cues have been reduced or eliminated.

Perceptual constancies. In general, the considerable range of sensory information offered by isolated local stimuli is typically controlled, sifted, and corrected by the perceiver. The specific nature of these "corrections to conform to reality" generally depends on the unique combination of simultaneously presented stimuli at any

given moment. In this way, one's spatial perception tends to ensure that he experiences the continually changing circumstances of the environment in which he moves and lives with some degree of stability or constancy.

This "realistic" perception, based on one's awareness of the apparently real, physical world, serves as the basis for one's practical adjustment and survival and appears clearly in a group of perceptual experiences of so-called object constancy. In the experience of size constancy, for example, within a radius of a few hundred yards from the observer, the size of objects is perceived to remain roughly constant no matter where they are. Constancy of form means that an object is perceived to retain its fixed characteristic shape regardless of variation in the angle at which it is observed; for example, a pencil seen end-on only shows a small circular profile but is still perceived as a pencil. Colour constancy clearly illustrates the way in which the brightness and hue experienced over the surface of an object is determined by direct comparison with other objects; a lump of coal still is perceived as black whether the sun is shining brightly or whether there is a dull, leaden sky.

Path recognition: navigation in space. Different animal species are equipped in various ways for the recognition of their path of movement. Earthbound species of animals often use olfactory (smell) signals in recognizing paths of varying distance; this is encountered both among social insects (*e.g.*, ants) and among many mammals (the dog sniffing from tree to tree). Certain insect larvae can retrace their path of movement by using as guides extremely fine webs or filaments spun during their advance. Many species seem to navigate by the sun, the angle between the rays of the sun and the organism's own path being held constant. The ability of migratory birds to orient themselves by stars in twilight or at night is most impressive (see MIGRATION, ANIMAL). In addition to cues offered by the stars and other heavenly bodies, such stimuli as the effects of gravity, temperature changes, and direct visual observation of landmarks such as rivers all seem to contribute to path recognition among animals.

Use of smell to judge distance

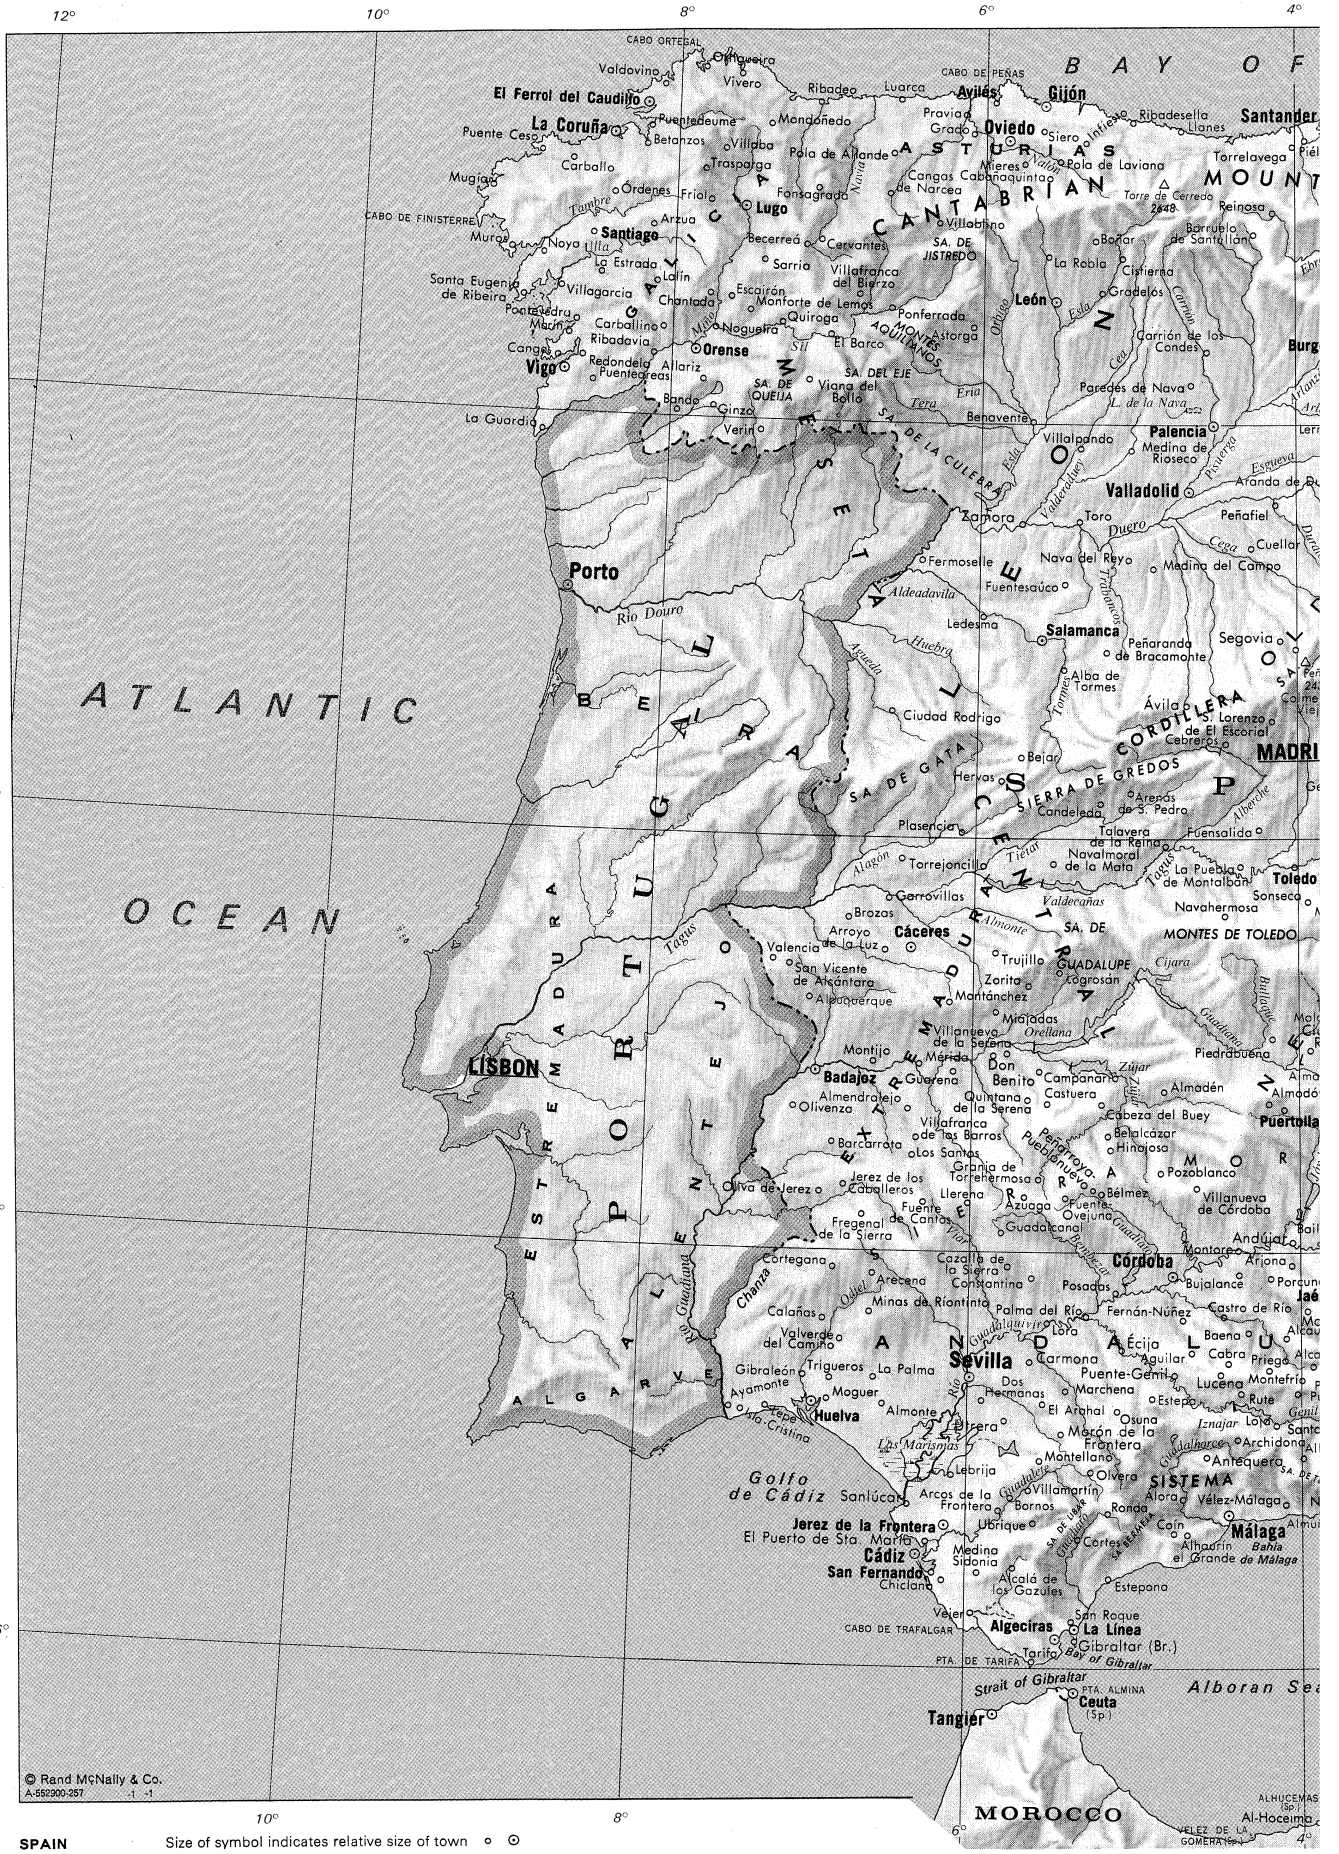
With the burgeoning of aviation and rocket-flight technology, there has been a growing research effort to increase understanding of the sensory basis for human navigation in space. Reliable perception of the vertical and horizontal dimensions and preservation of perceptual constancy for these dimensions during flight are based on the parallel activity of vision and the vestibular sense (balance, or equilibrium). Even in flying small, privately owned aircraft it has been shown that the pilot becomes disoriented unless he preserves visual control of the horizontal dimension; he cannot safely rely on the information conveyed by his sense of balance to inform him that a wing tip, for example, is dipping dangerously low. While the sense of balance ordinarily depends on the effect of gravity, the movement of an airplane produces additional (so-called centrifugal and centripetal) forces, particularly as the plane tilts or changes direction, which easily mislead one's vestibular (balance) receptors. For this reason, in high-altitude flying the horizontal line of the surface of the earth is simulated for the pilot by an optical display in front of him that works on the same principles as does a television screen.

Even greater demands on the human senses of vision and balance are made in space flights, since one is effectively weightless in outer space. At one laboratory maintained by the U.S. Navy, an enormous, very slowly rotating cylindrical chamber has been constructed. Variations in the perceptual sensitivity of people remaining for variable periods (even days at a time) in this simulated "outer space" environment are studied in an effort to anticipate the short-term and long-term effects of interplanetary flight.

Social and interpersonal aspects of space perception. Many animal species that use nests, lairs, or dens and care for their young act to defend a specifically delimited territory against interlopers. This process is clearly observable in birds and among seals during breeding season. Apparently territorial behaviour depends on a rather precise perception of space, since the animal ceases its defensive manoeuvres when an interloper passes out of the territory by moving across the "border." The social distances maintained by primates (*e.g.*, people and apes) are theorized to be the result of territorial groupings. Modern architecture is held to be dominated by an inborn human tendency to divide groups into small, separate family territories (just as birds do), the result being such structures as apartment houses. Geographical distance may also be maintained to separate individuals who belong to different social classes or races, as is observed in the ethnic neighbourhoods or ghettos of large cities.

Territorial distance

Theories of space perception. An early theory put forth by the Anglican bishop George Berkeley at the beginning of the 18th century was that the third dimension (depth) cannot be directly perceived in a visual way since the retinal image of any object is two-dimensional, as in a painting. He held that the ability to have visual experiences of depth is not inborn (nativistic) but can only result from logical deduction based on observational (empirical) learning through the use of other senses (*e.g.*, touch).



Although modern research fails to verify the importance Berkeley placed on reason in perception, contemporary theories still include both nativistic and empiricistic considerations. According to empiricistic theorists, spatial perception develops primarily as the result of learning; indeed, during the early stages of his development, the individual gradually does seem to learn something about the significance of observable (empirical) spatial cues. It is just as difficult, however, to deny the nativistic concept that space perception is based on the innate (hereditary) structure of sense receptors and the nervous system; for example, the ability to detect differences in the size of two-dimensional figures seems to be inborn (that is, the differences seem to be immediately recognizable without training or learning). For a considerably more detailed discussion of early and modern theories of space perception and of perceptual phenomena in general, see PERCEPTION.

Spain

Lying at the southwestern end of the European continent, Spain occupies about 85 percent of the Iberian Peninsula. With Portugal, which forms its western boundary, it is shaped like the hide of a bull, the neck pointing toward Africa in the south and a large base formed by the Pyrenees mountains and the Bay of Biscay in the north. It is separated from France by the small principality of Andorra and by the Pyrenees; and in the far south lies the small peninsula of Gibraltar in the Bahía de Algeciras, which has been under British sovereignty since 1713. Off Spain's eastern coast lie the Balearic Islands, and the Canary Islands, in the Atlantic Ocean, off the coast of Africa, also belong to Spain. Other Spanish territories include the Spanish Sahara in northwest Africa and the cities of Ceuta and Melilla in northern Morocco. The total area of Spain is 297,670 square miles (770,963 square kilometres), of which the Spanish Sahara comprises 102,703 square miles, while the remaining 194,967 square miles constitute what is officially defined as the national

territory: Peninsular Spain; the Balearic and Canary Islands; the cities of Ceuta and Melilla; and certain small islands off northern Morocco. By the 1970 census, Spain was the home of just over 34,000,000 people, almost 76,500 of whom lived in the Spanish Sahara, with the remainder inhabiting the national territory as defined above.

One of the most ancient countries of Europe, Spain was also long one of the most powerful and, from the 16th to the 19th century, ruled a large empire in the Americas. Except for Brazil, Latin America today owes its language and essential culture to Spain. The people of Spain have been notable for their regional separatism; and history has borne witness to their peculiar pride and code of honour and to their austere and fervent devotion to the Roman Catholic faith, most remarkably in Old and New Castile on the bare central plateau, the Meseta. Spanish culture, with a heritage as African and Mediterranean in character as it is European, has given much to the Continent and to the world since Roman times.

The present constitution

Under the present constitution, Spain is a kingdom ruled by General Francisco Franco under emergency powers given to him during the Spanish Civil War (1936–39). His proclaimed heir is Prince Juan Carlos de Borbón y Borbón, who will assume the powers of head of state or be designated king in the event of Franco's death or disability. From an economic point of view, Spain has followed a liberal course since the mid-1950s; and this has favoured foreign investments and tourism, leading to impressive economic development. In the sphere of international relations, Spain is a member of the western bloc, linked to the North Atlantic Treaty Organization (NATO) through bilateral agreements with the United States. Spain is a member of the United Nations and its specialized agencies, as well as of most European technical organizations. It cooperates with the Council of Europe on cultural matters and has signed a preferential agreement with the European Economic Community, or Common Market. Spain maintains special relations with Latin American countries and Interamerican organizations and has established diplomatic relations with some countries of the socialist bloc including the Soviet Union but not the People's Republic of China.

This article concentrates principally on peninsular Spain. For related information, see MADRID; BARCELONA; PYRENEES RANGE; GUADALQUIVIR RIVER; TAGUS RIVER; SPAIN, HISTORY OF.

I. The land

THE NATURAL ENVIRONMENT

Physical geography. With the exception of the southern triangle of Jerez–Cadiz–Gibraltar, the Iberian Peninsula forms an irregular quadrangle, bordered on the east and southeast by the Mediterranean and on the west, southwest, and most of the north by the Atlantic Ocean. Most of the peninsula is occupied by the Meseta, a vast plateau with approximately the same boundaries as the historical Kingdom of Castile. The average height of the plateau is 2,000 feet, although its northern part is slightly higher than the southern section. The Meseta is almost completely surrounded by mountain ranges: the Cordillera Cantábrica (Cantabrian Mountains) in the north; the Sistema Ibérico (Iberian System) from the Cantábrica to the southeast; the Sierra Morena in the south; and the lower mountains on the border with northern Portugal in the northwest. The southern plateau descends gently towards Portugal, whereas the transition from the northern plateau to Portugal is marked by rugged terrain and mountain ranges. The Meseta is divided by the Central Range, which extends across the plateau to the north of Madrid and runs all the way from the Sistema Ibérico to Portugal.

The Meseta

Around the central plateau, five natural regions can be identified. First, in the northeastern Spain, there is the valley of the Río Ebro, enclosed by the Sistema Ibérico in the southeast, the Pyrenees and the Cordillera Cantábrica in the north, and the mountains of Catalonia and other coastal ranges in the west. Second, there is the valley of the Guadalquivir River in the south, which is separated from the plateau by the Sierra Morena and from the Mediterranean by the Sistema Penibético (Baetic Cordillera) in the southeast but which has unimpeded passage to the Atlantic in the southwest. Third, there is the region of the coastal area of Valencia, in the east, descending from the southern Iberian ranges toward the Mediterranean, down the valleys of several small rivers. Catalonia, a mountainous region between the valley of the Ebro, the eastern Pyrenees, and the Mediterranean, forms the fourth natural region. Finally, there is northern Spain from the Pyrenees to the west, a mountainous country forming several small regions separated from each other by high mountains.

Geological features. Geologically, the peninsula forms a great massif (not to be confused with the Meseta, which it partly overlaps), bordered on the north, east, and south by mountain folds. This massif is a fragment of the former Hercynian continent, which formed across Europe at the close of the Carboniferous period (about 345,000,000 to 280,000,000 years ago). During the Mesozoic (225,000,000 to 65,000,000 years ago), the Hercynian system was shattered, and large portions sank below the sea. During the Tertiary Period (between 65,000,000 and 2,500,000 years ago), deposits of the Jurassic and Cretaceous seas, together with the earlier Tertiary beds, were crushed against the old massif to form the ranges bordering the Meseta. Later movements contorted and fractured the peninsula to give it its present general shape.

The Hercynian massif

The Balearic Islands are composed of mountain ranges of moderate altitude, not exceeding 5,000 feet. The Ca-

nary Islands, however, are of volcanic origin and have the highest peak among the Spanish territories, the Teide (12,190 feet [3,716 metres]), in the island of Tenerife.

Drainage and soils. The most important drainage systems are found in the plateau and the two large valleys of the Ebro and the Guadalquivir. The plateau has three main drainage systems, all flowing into the Atlantic: the Río Duero (Douro) in the northern plateau and the Tagus (Tajo) and Guadiana in the southern plateau. While the Duero and the Tagus follow an almost parallel course from the Iberian range to the west coast of Portugal, the Guadiana turns south and empties into the Gulf of Cadiz (Golfo de Cádiz) on the southern coast, at the frontier between Portugal and Spain. The Ebro follows an almost straight course from the northern mountains to the Mediterranean, collecting waters from the Pyrenees and the Iberic Range. The Guadalquivir flows from the east to the southwest, gathering waters from the Sierra Morena and the Sistema Penibético. In the southeastern peripheral regions, the two most important rivers are the Júcar and the Segura.

From a mineralogical point of view, three main regions can be distinguished in Spain. Crystalline rocks predominate in the central and peripheral basins, whereas the east and north have an abundance of limestones. The soils may be described as generally acid-humid in the northwest, calcareous in eastern and southern Spain, and siliceous in the Cantábrica, northern Iberian, Carpetovetónica, and Sierra Morena ranges, as well as in the Duero Valley and the mountains of Zamora and Salamanca. As in most of the western Mediterranean, erosion has played a very important role in the degradation of the soils, especially in the high areas of the plateau and the eastern and southern zones. In addition to natural erosion, man has contributed considerably through the destruction of forests. Since the 1920s, however, the government has carried out an impressive job of reforestation. Soils are generally better preserved in the north and in the Balearic and Canary islands.

Soil erosion

Climate. Spain is located in the temperate zone of the Northern Hemisphere, between the latitudes of 27° and 44° N. With the Balearic Islands and the cities of Ceuta and Melilla, Spain belongs climatically to the western Mediterranean, with some internal differences.

It is exposed both to the westerly North Atlantic winds, which dominate during most of the year, and to the warm, dry airstream that blows less frequently from the Sahara. The Pyrenees, however, play a very important role in the Spanish climate, for they constitute the northern boundary of the subtropical airstream during the summer months, thereby maintaining dry weather conditions over most of the country.

Three basic types of climate predominate within the peninsula: the coastal climate of the Atlantic and Mediterranean seaboards; the continental climate of the plateau and the valleys of the Ebro and the Guadalquivir; and the mountain climate of areas above 3,000 feet. Northern Spain, from Galicia to northern Catalonia, is characterized by moderate, even temperatures and high rainfall. Thus, La Coruña, in the northwest, ranges from 48° F (9° C) in winter to 64° F (18° C) in summer, while the annual rainfall is about 38 inches. The plateau has a continental climate, with lower rainfall and greater temperature variations. Thus, Albacete, in the southeast of the plateau, varies between 40° F (4° C) in the winter and 75.0° F (24° C) in the summer, while the annual rainfall is below 15 inches. The valleys of the Ebro and the Guadalquivir also have a continental climate, drier and colder in the Ebro and warmer and more humid in the Guadalquivir. Catalonia, Valencia, and the Balearic Islands enjoy more temperate weather, with higher rainfall in Catalonia.

Vegetation and animal life. *Vegetation.* There are four main vegetation areas: north, centre, south, and southeast. Northern Spain, enjoying humid weather, is covered with deciduous forests and meadows. It is basically a green country, good for forestry and pastures, as well as the cultivation of maize (corn), apples, and other products that thrive in humid areas. The northern plateau and the Ebro Valley, with low levels of humidity and extreme temperatures, are mostly used for grains. The upper Ebro Valley, the southern plateau, Andalusia, and the eastern regions produce olives and grapes. Valencia and the irrigated areas of Murcia are noted for their citrus fruits, particularly oranges. There are some semidesert areas in the valley of the Ebro, around the city of Zaragoza, and in southeastern Spain in the province of Almería. The most common trees are the olive and the evergreen oak, as well as the cork tree in the southwest. Pines and other coniferous trees are found in mountainous areas all over the country.

Fruit growing regions

Livestock. Cattle are raised in the north and in the mountainous areas of central and southern Spain. Sheep are the most common stock animals in the plateau region. Pigs are raised in most of Spain, particularly in the west and northwest. Goats are mostly raised in the south of the peninsula and in the islands. Mules and donkeys are still generally used all over Spain, particularly in the south, for work and transportation.

Wildlife. The larger species of wildlife are almost extinct in Spain, although bears and wolves can still be found in the Pyrenees and some of the northern mountain areas. The Spanish ibex (*Capra pyrenaica*) is threatened with extinction, and most are found within preserves. Other types of wildlife, such as deer or wild pigs, can be found in preserves all over Spain. Minor game, such as partridge, grouse, duck, and rabbit or hare, abound throughout Spain.

Fish. The Spanish coasts are rich in fish and shellfish, particularly in the Atlantic and the Bay of Biscay. Spanish fishermen, however, obtain most of their catches beyond territorial waters, in the North Atlantic and south of the Canary Islands.

THE HUMAN IMPRINT

Traditional regions. Because of the geographical diversity and the great variety of climates and vegetation, as well as for historical reasons, regional differences are very important in Spain. The country is divided into 15 traditional regions (two of which are the Canary Islands and the Balearic Islands). In the northern plateau are the regions of Old Castile and León. These two regions, together with New Castile, south of the Cordillera Carpetovetónica, constitute the larger region of Castile; and inhabitants of these three regions are generally called Castilians. The region of Old Castile also includes the province of Santander, between the Cordillera Cantábrica and the Bay of Biscay. The inland region of Extremadura and the coastal regions of Murcia and Andalusia in the south were also part of the historical Kingdom of Castile; but their inhabitants are not considered Castilians, and they have their own particular features. The northern seaboard is divided into three historical regions: Galicia, in the northwest; Asturias, between Galicia and Santander; and the Basque Provinces, bordering France. South of the Pyrenees are three historical regions: Navarre, in the western Pyrenees, also considered a part of the larger Basque country; Aragón, which covers most of the valley of the Ebro; and Catalonia, in the northeast. Finally, the region of Valencia covers a large section of the Mediterranean coast between Catalonia and Murcia.

A strong Moorish influence distinguishes Andalusia from Castile, while Asturias obtains its individuality from its position of near isolation in the Cordillera Cantábrica. Differences among the central regions are more subtle: for example, landscape, dialectal differences, and historical border. Even so, with the possible exception of the three Castilian regions, the inhabitants consider themselves essentially different from each other.

Regional consciousness

Human settlement. Spain is a predominantly industrial country, with less than 30 percent of the population involved in agriculture and other forms of primary production. There has been a sharp movement from the country to the cities since the 1930s, and this economic and structural change is of paramount importance in understanding modern Spain.

Traditional Spanish rural settlements vary widely from

one region to the next. Northern and Mediterranean Spain and the islands follow a pattern of small settlements, surrounded by agricultural land. On the other hand, the plateau and the valleys of the Ebro and the Guadalquivir are characterized by highly concentrated rural populations inhabiting large towns. These differences are connected with the history and the landscape of the different regions.

Most of the population lives in towns of 10,000 or more inhabitants. The size of towns does not, however, always reflect their economic activity. In southern Castile, Extremadura, Murcia, and Andalusia, large towns of 20,000 or 30,000 people may concentrate mainly on agricultural tasks, while smaller towns in the Basque country or Catalonia may be predominantly industrial. The two main urban centres are Madrid, the capital, in New Castile, and Barcelona, on the Catalonian coast. Madrid has an approximate population of 3,500,000 and Barcelona over 2,500,000; but, whereas Madrid has a high concentration within a small area, metropolitan Barcelona covers a large area, divided into several cities interspersed with agricultural and undeveloped land. Other large urban concentrations include: Greater Bilbao, in the Basque country; Greater Valencia, in the east; Zaragoza, in the Ebro Valley; and Seville, in the lower Guadalquivir Valley. There are 26 other cities with more than 100,000 inhabitants.

Urban centres

II. The people

HISTORICAL ORIGINS

Because of its position between two continents and its relative accessibility from the Mediterranean, Spain has been invaded and inhabited by many different peoples. In prehistoric times, peoples from North Africa and western Europe settled in the peninsula, including the Celts, in the north. The Mediterranean coast appears to have been settled by North Africans, whereas the Basques probably occupied a larger area than the present Basque country. Ancient Greek and Phoenician settlements were established on the eastern and southern coasts, and Carthaginians founded large colonies in the southeast (around what is now Cartagena); but only the Romans were able to conquer the entire area, subjecting it to intensive romanization. After the fall of the Roman Empire, Suebi, Vandals, and Alani razed the country; and the Goths established a kingdom in Spain between the 5th and 8th centuries. The Arabs invaded the peninsula in 711 and were only driven out of Spain in 1492. These eight centuries of Arab influence, together with the prolonged Roman colonization, have left a permanent imprint on the Spanish population.

The Roman conquest

After almost five centuries of consolidation of the Spanish state, the population has become unified racially; and, with the possible exception of the wandering Gypsies, there are no recognizable racial minorities. Somehow, the Spanish population has incorporated into its genetic pool something from each of the succeeding invaders.

Linguistic groups. *Castilian.* Pure Spanish (or Castilian) is the official language of the country; in addition to being the school, administrative, judicial, and commercial language of Spain, it plays a similar role in most Latin American countries. It is basically a Latin language, with some traces of the languages spoken in Spain before the Roman conquest and some Arab influence in the everyday vocabulary. There are, however, important linguistic minorities within Spain—in the Mediterranean regions, in Galicia, and in the Basque country.

Catalán. The most widely spoken and strongly rooted of the non-Castilian languages in Spain is Catalán, a Romance language closely related to the French Provençal or Languedoc. Catalán is the basic language of Catalonia, the Balearic Islands, and Valencia. The Valencia dialect of Catalán, however, has a strong Castilian influence. Catalán is a highly developed language, with a wealth of literary tradition in the areas of poetry, novel, and drama. There has been a revival of the language as an attempt to regain cultural and political autonomy against the increased process of centralization of the national government.

Gallego. Modern Portuguese originated in Gallego, a Romance language still spoken in the region of Galicia. Gallego was once the first literary language of the peninsula, but it has lost importance both in geographical extension and identity. It has been widely influenced by Castilian and is barely spoken in the Galician cities, although it still survives in the countryside and among the Galician fishermen. There is some revival of the language among intellectual circles of the region, but it has not reached the proportions of the Catalán cultural renaissance.

Basque. The most distinctive of the non-Castilian languages is found in the Basque country. Basque is neither a Romance language nor of Indo-European extraction. Its origins are uncertain, but it was spoken in large areas of the peninsula before the Romans conquered Spain. Over the centuries the language has diminished in importance, and, in recent times, it is found mostly in the countryside and in fishing villages and rarely heard in the two larger Basque cities of Bilbao and San Sebastián. Basque regionalism, however, has found the language a vehicle for separatist, or autonomist, ideals; and there is also a revival of interest in Basque in intellectual circles.

Basque separatism

Other dialects. Within the Castilian areas there are some dialects spoken in remote places, such as the Bable in the northwestern mountainous fringes of the plateau. There are also minor dialectal differences in vocabulary and pronunciation between the different regions. The best Castilian is reputed to be spoken in Old Castile, especially in the provinces of Burgos and Valladolid. Marked differences of pronunciation are observed in Andalusia and the Canary Islands, where the spoken language bears similarities to that of Latin America. Regional intonation and dialectal expressions can also be identified in the Castilian of Basques, Cataláns, and Gallegos. The Castilian-speaking immigrants and their descendants living in Catalonia constitute a large and relatively underprivileged minority (within a national minority), particularly in the metropolitan area of Barcelona, and they are called *els altres Cataláns* ("the other Cataláns").

Ethnic groups. *The Gypsies.* The Spanish population is basically homogeneous in race and culture, and the only racial minority within Spain is the Gypsies. While a large number of Gypsies have been integrated, there still remain a substantial number who lead a nomadic life and who can be seen on Spain's main roads, driving mule or donkey carts or begging or peddling in the cities. Their number is estimated at about 200,000. They do not identify with the values and customs of the majority of Spaniards, although they have Spanish citizenship and profess the Catholic faith. The greatest number are found in Andalusia, especially in Granada; but important groups are also found in some northern cities, such as Valladolid, in Old Castile, and Tarragona, in Catalonia.

Arab and Basque influences. Different racial features are still recognizable in some of the regions. Thus, Andalusia and the southeast still have an Arab imprint because of the long duration of Arab settlement in those areas; and in northern Spain natives of pure or semipure Basque stock have facial characteristics that distinguish them from the average Spaniard. In the other regions, the intermingling has been so complete that it is difficult to identify racial features.

Religious groups. *Roman Catholicism.* The Spanish population is basically Roman Catholic, and this is the official religion of the state. Although most Spaniards belong to the Catholic Church and are baptized, married, and buried within the church, active participation in church work is very small, with a large percentage of the population alienated from the church, especially since the tragic Civil War of the 1930s.

Religious minorities. Non-Catholic minorities are estimated at a total of 50,000 persons or about one and a half per 1,000 of the total population of the country, not including foreigners residing in Spain. Most of the non-Catholic population is Protestant; and while no reliable statistics are available, it appears that the larger sects are the Church of the Brethren (estimated membership, 5,500) and the Evangelical Baptist Church (estimated at

4,600). Recently, however, Jehovah's Witnesses have developed a strong proselytizing campaign, which has had its greatest success among the poorer sections of the population. Eastern Orthodox and non-Christian groups constitute a very small number. Among non-Christians, the Jewish community is the most important. The government has changed recently from a position of intolerance in religious matters to toleration of non-Catholic churches, provided that their membership and properties are registered with the state.

DEMOGRAPHY

Birth and mortality rates. The population of Spain, including the Canary and Balearic islands, totalled 34,000,000 in the early 1970s. The birth rate, at just under 20 per 1,000, is slightly above the average birth rate of Europe and North America but well below the figure for most developing countries. The long-range trend of the birth rate is one of decline, and this has been accentuated since the mid-1960s, with a marked preference for small families—notwithstanding the official position of the church and the government against most methods of birth control. The mortality rate is about 8.9 per 1,000, and the natural increase of the population is about 10.7 per 1,000, but this increase is partly offset by emigration. The natural rate of growth is unevenly divided throughout the country. The highest rates are registered in the Canary Islands (18 per 1,000) and in the southern regions of Murcia (14 per 1,000), and Andalusia (13 per 1,000). The Basque country, in the north, also has a high rate of natural growth of the population (13 per 1,000), whereas the lowest birth rates are found in the plateau, especially Old and New Castile.

Immigration and emigration. Traditionally, Spanish emigration has been to the Spanish-speaking countries of Latin America. After World War II, however, and especially during the 1950s and 1960s, there has been a radical change in emigration patterns. While there is still a trickle of emigrants to Latin America, this is offset by an almost equal number of immigrants and repatriates from that area, particularly from Cuba, Uruguay, and Argentina. On the other hand, since the mid-1950s most Spanish emigrants have chosen western Europe, the majority temporarily but some on a permanent basis. According to official figures, there are about 270,000 Spanish workers in western Europe, mostly in the Federal Republic of Germany, France, and Switzerland. This figure, however, should probably be doubled or tripled to reflect more accurately the true situation (including unregistered emigrants), and the total of Spanish workers in western Europe has been variously estimated at between 500,000 and 1,000,000. Spain has received some immigrants of its own, although nothing approaching the number of emigrants. After World War II, a number of eastern Europeans settled in Spain; and during the 1960s thousands of Cubans and Spaniards residing in Cuba emigrated to Spain as a result of the Cuban Revolution. Portuguese migrant workers have also found jobs in Spain. Finally, a

The emigrant work force

substantial number of retired senior citizens from western Europe and the United States have become permanent or semipermanent residents in Spain. In 1970 there were nearly 150,000 registered foreigners living in Spain, of whom some 45,000 held a labour permit, while many others probably worked without such a permit.

Rural depopulation

Internal migration has become particularly important since the end of the Civil War, showing the familiar industrial pattern of movement from the country to the cities. This has caused most Spanish cities to double or even triple their population since the mid-1930s, whereas the population as a whole has grown by only one-third. Many small villages, especially in Castile, have become almost uninhabited and in a few cases are completely deserted. The main centres of attraction for internal migration are the cities of Madrid and Barcelona. Madrid has attracted immigrants mostly from the centre and the northwest, while Barcelona has drawn its migrants from the east and the south. Other large cities, such as Bilbao, Valencia, Zaragoza, and Seville, have also attracted large numbers of immigrants, and this is true of most provincial capitals. The development of tourism has also brought workers to the resort areas of the Costa Brava (Catalonia), Costa del Sol (Andalusia), and the southeast (Alicante).

The distribution of the population. About 65 percent of the Spanish population is found in the coastal regions, whereas the plateau and the valley of the Ebro, with over one-half of the national area, possess only one-third of the total population. Thus, excluding the Spanish Sahara, much of which has a desert character, the average density of 175 inhabitants per square mile (or 68 per square kilometre) is not equally spread throughout the country; and while the coastal regions of the Basque country, Galicia, Catalonia, Valencia, and the Balearic Islands have population densities approaching those of industrial western Europe, the northern plateau, Navarre, and Aragón are almost deserted by European standards. One-third of the entire population of the inland regions is concentrated in Madrid, and this accentuates the semideserted character of the central areas. Although the metropolitan area of Barcelona also has a high percentage of the peripheral population (18 percent), this is more evenly divided among the coastal regions. Only some areas of eastern Andalusia and Murcia approach the low densities of the plateau. Most of the Spanish population now inhabits cities with populations of 10,000 or more, and the trend toward urbanization is increasing. Spanish cities have not yet developed extensive suburbs, and the urban population is heavily concentrated in high-rise apartments. The growth of suburbs is already noticeable, however, in Barcelona and Madrid, as well as in Bilbao.

Current problems and future trends. With open spaces still available and a moderately decreasing birth rate, Spain is not facing a population explosion as such, although some of the urban areas have achieved high densities. Increasing industrialization and urbanization, however, are causing problems of overpopulation and economic imbalance in the dense metropolitan areas of Madrid, Barcelona, and Bilbao and in the industrial area of the province of Guipúzcoa in the Basque country. Pollution has become an urgent problem in these and other industrial regions. There is increasing contamination of rivers and some of the coastal areas, and these developments are threatening both the freshwater supplies and the fish resources of the country. A peculiarly Spanish problem is posed by the massive influx of tourists (more than 20,000,000 per year), especially during the summer months. This sudden increase of population during the summer (a 60 percent increase over the normal Spanish population) is beginning to create problems of its own, by reducing the space available for recreation and oversaturating public services, such as health, roads, transportation, and public accommodations.

The tourist problem

Spanish public opinion, especially in the larger cities, did not become aware of the problems of pollution and overpopulation until the late 1960s. In November 1971 the Spanish government announced a program to fight pollution, with substantial financial appropriations for this purpose. As for the problems of overpopulation, the official position of both the Catholic Church and the government inhibits the development of an effective family planning program. On the other hand, the government has initiated a policy of industrial decentralization to limit the dangers of excessive urbanization, and there are studies in progress to develop self-supporting new towns around the larger metropolitan areas. (M.Me.)

III. The national economy

Spain has one of the fastest growing economies in Europe and in the early 1970s was in the process of transformation from an underdeveloped to a developed country. Its transitional status is reflected in its still comparatively low standard of living; even after a decade of explosive growth, the country's gross national product per head is well below that of Italy though above that of Portugal. But from about the mid-1950s, when Spain emerged from a period of economic as well as political isolation, its development, especially in trade with other countries, has been notable. In 1958 it joined the International Monetary Fund, in 1959 the Organization for European Economic Cooperation (now the Organization for Economic Co-operation and Development, or OECD), and in 1963 the General Agreement on Tariffs and Trade. It became an associate member of the European Economic Community in 1970. To complete its transition to developed status, Spain needs ever-increasing industrial investment and modernization of equipment. In the early 1970s, Spain, in common with many other countries, was suffering from a certain degree of business stagnation; and inflation, while less severe than in more developed countries, was also a problem.

SOURCES OF NATIONAL INCOME

Mineral resources. Spain has one of western Europe's largest coal-mining industries; in the early 1970s its output was over 13,000,000 metric tons a year but appeared to be declining. Pits are situated chiefly in the Asturias, but there are also some in the lower hills of Sierra Morena. Unfortunately, there is a surplus of steam-raising coals and a shortage of the coking coal needed by the booming steel industry. Supplies of the latter, therefore, have to be imported. By the mid-1960s, a radical reorganization of the industry was begun, and this has continued into the 1970s; uneconomic pits were closed, while investment was diverted to those having the greatest potential.

Discoveries of petroleum and natural gas have so far proved disappointing, though in 1970 there were reports of a promising offshore Mediterranean field. The originally rich veins of hematite (rubious iron ore) of Bilbao are now nearly worked out, but Spain is relatively rich in other minerals, most of which are exported. Mercury is obtained from the ancient mines of Almadén in Ciudad Real, and there is also a good supply of tungsten, lead, zinc, potash, pyrites, and some uranium oxides.

Spain struck one of the world's most spectacular finds of phosphate rock in the 1960s, in the desert of Bu Craa in the Spanish Sahara. The government is believed to have committed huge sums for the development of these reserves, which involves the construction of a railway line and port.

Agriculture, forestry, and fishing. Although Spain is one of western Europe's largest agricultural producers, the barrenness of much of the countryside has always made agriculture and cattle rearing difficult. With the recent rapid increase of manufacturing industry, it is not surprising that the proportion of national income provided by agriculture has steadily declined: from something over 27 percent in the late 1950s, it dropped to a little more than 13 percent by 1970. Yet, despite the relative decline, agriculture has maintained a small real growth rate, the more notable in that the proportion of agricultural labourers is constantly diminishing, from about 40 percent of the total working population in the mid-1960s to under 30 percent in the early 1970s.

The two main problems confronting Spanish agriculture are social and environmental; these involve, respectively, the *latifundia*, large estates owned by absentee landlords,

and the still more intractable difficulty springing from the uncertain climatic conditions and the general infertility of the land. The *latifundia* are mainly in the south, in Extremadura, Andalusia, and La Mancha, and although some attempt at division of them was begun in 1939, progress has not been great. More success has been achieved, however, in the amalgamation of small holdings into viable farm units.

Uncertain rainfall has a serious effect on crops, and land is mostly poor, with widespread soil erosion as a result of years of overtilling and overgrazing. Frost is frequently a formidable threat to the Valencian orange crop. With periodic widespread drought, irrigation has been an obvious necessity, and the earliest large canals and dams for this purpose, such as the Canal Imperial de Aragón on the Río Ebro, were built in the 18th century. Major irrigating projects have been carried out in the 20th century, and it was estimated in the mid-1960s that about one-third of the total river flow was controlled by about 140 major reservoirs. In the 1960s more dams were under construction, and water-storage capacity was being almost doubled.

Wheat, the most important cereal crop, accounts for about one-quarter of the value of all agricultural produce, but the government is trying to encourage growers to concentrate instead on fodder crops, such as barley. Barley is already grown in the southeast, while the wheat-producing areas are mainly in Old Castile, Aragon, New Castile, and Extremadura. The cereal lands, those which are less well irrigated, are farmed according to traditional practice, with a two-year rotation of crops. Pulses are a staple crop of the Meseta Central, while rice is grown in Valencia and the Ebro Delta. Potatoes, beans, and onions are also produced. Spain, in common with other western European countries, has a surplus of high-quality sugar beet production.

Citrus fruit and wine production

Spain's most successful adaptation to its difficult Mediterranean climate has been in citrus fruit production, which rose from 2,000,000 tons in 1961 to over 2,500,000 tons in 1971. Citrus fruit is grown mainly in Valencia and Castellón. Other areas specialize in other fruits; apples and pears are grown in the north and northwest, figs and almonds in Castellón and Alicante, and peaches and apricots in Murcia. The main crop of the *latifundia* is olives, almost the whole yield of which is made into oil. Vines are grown especially in La Mancha, La Rioja, and the hills of Catalonia, Valencia, and Málaga. As the third largest wine-producing country in Europe, Spain suffers from overproduction of inferior wines, although brandy and sherry from Cádiz and Jerez de la Frontera and dessert wines from Valencia and Málaga are in demand. Hemp, cotton, and tobacco are also grown, in comparatively small quantities.

Sheep and cattle rearing is very important, and Spain has one of Europe's largest sheep and goat populations (more than 17,800,000 sheep in 1972). More than half the cattle are concentrated in the humid north, especially dairy cows in the Cordillera Cantábrica. Sheep, concentrated on the Meseta Central, are of three main breeds: the long-wooled churro, the short-wooled merino, and the manchegan. Goats are best suited to the arid conditions of the southeast, and pigs are reared in the holm-oak woodlands of Extremadura.

Some afforestation is practiced to counter soil erosion. Fishing is concentrated mainly on the northern and western Atlantic coasts and is particularly important in Galicia, where Vigo is the main fishing port. The catch, averaging more than 1,000,000 metric tons a year, comprises mainly sardines, anchovies, hake, cod, tunny, bream, mollusks, and crustaceans.

Power and energy resources. Power shortages have often seriously restricted Spanish industrial production, especially in times of drought. Although Spain is a mountainous country in which, it might be thought, considerable hydroelectric power could be produced, the relatively low rainfall restricts capacity, and all profitable hydroelectric potential had been developed by the early 1970s. Much thermal electricity is produced by the abundant steam-raising coal, and imported petroleum is also used. Because of the impossibility of further hydroelectric expansion and the cost of imported petroleum, Spain has a relatively ambitious building program for nuclear power stations; in 1971 it already had a production capacity of 600 megawatts, with a further capacity of 1,000 megawatts under construction. Another reason for its development of nuclear power is that Spain is one of the world's major producers of uranium, which it may eventually hope to process itself instead of, as at present, importing enriched uranium.

Manufacturing. Although historical inertia and traditionalism long hampered the development of Spanish industry, the country's industrial growth rate since the mid-1950s has been one of the fastest in the world, and, in the early 1970s, industry was contributing about 35 percent of the total national output. Some manufacturing industries are long established and are now supported by heavily protectionist policies. The historical regional location of light industries is still operative: Manises, in Valencia province, is a centre for ceramic works; paper has been manufactured since Moorish times at Játiva, in the same province; Béjar, Segovia, Soria, and Burgos have long been woollen centres; and cotton manufactures are concentrated around Barcelona. Other light industries include a variety of textiles, clothing and footwear, food processing, liqueurs and wine, and light engineering. Chemical industries include the production of nitrogen fertilizers, which reached 596,000 tons in 1971. During the 1960s, massive investment was made in newer, high-technology industries.

Industrial growth

Heavy industries are largely centred in the north, where metallurgical works are found in Santander and the Basque provinces. Bilbao has been a steel centre since the Middle Ages. Madrid has engineering works as well as the Pegaso motor factory and the Hispano aircraft works. Passenger cars and commercial vehicle production had reached 528,000 vehicles by 1971, and crude oil refining more than 30,000,000 tons. Perhaps the most successful and competitive of Spain's heavy industries is shipbuilding; with an output of 875,000 gross tons in 1971 and around treble that figure on order from Spanish yards, Spain ranked as the sixth largest shipbuilding nation in the world.

Financial services. The central bank is the Banco de España, in the profits of which the government has participated since 1922. The dealings of the commercial banks are government regulated and are controlled by the Institute for Medium and Long-Term Credit. The majority of corporate borrowers, both public and private, have recourse either to these banks or to the state-owned holding corporation and public development bank created in 1941, the Instituto Nacional de Industria (INI). Largely because the public prefers to keep its savings on deposit rather than invest in securities, the banks control more than half of the issued capital of Spanish limited-liability companies. A considerable amount of private investment is also financed from abroad, and the Spanish stock market has thus remained relatively undeveloped. In the early 1970s the most important sources were West Germany, the United States, Switzerland, the United Kingdom, and France, in that order. The most important sectors of the economy thus affected were chemicals (32 percent) and real estate (13 percent).

Foreign trade. Importing considerably more than it exports, Spain has a visible trade deficit, which averaged about 125–155,000,000,000 pesetas a year in the late 1960s and early 1970s. Trade is most frequent with member countries of the European Economic Community (to which Spain is affiliated with associate status) and, after them, with member countries of the European Free Trade Association and with the United States. There is also some trade with Latin America. Food and agricultural exports, mainly citrus fruit, wines, fish products, and olive oil, still account for about 35 percent of the total bulk of exports, but the proportion is gradually declining. Raw materials exported are mainly iron ores and pyrites, while cotton goods, textiles, and clothing also have a steady market. Engineering and heavy industrial exports, such as ships, automobiles, and electrical goods,

are increasingly important. Some agricultural products have to be imported, notably cereals, animal products, and vegetable oils. Spain also imports raw cotton as well as textile products; petroleum and its products are a heavy import item, and engineering goods are also brought in.

Spain's rapid growth in the 1960s was made possible because imports were allowed to outstrip exports so greatly. The resultant gap was mainly financed in two striking ways. First, Spain became, in the mid-1960s, one of the world's most popular centres of tourism; visitors in 1971 alone numbered more than 26,700,000. Secondly, Spain exports labour to other European countries, and workers' remittances sent home contribute substantially to the country's balance of payments.

MANAGEMENT OF THE ECONOMY

Private enterprise and the role of government. Government influence over the economy is very strong in Spain. A large number of concerns are state-owned, including the railways and shipping, telephone services, radio and television, and hotels. The state also has large holdings of ordinary shares in a wide range of industrial companies, mostly through the medium of the Instituto Nacional de Industria (INI). This corporation, run by the Ministry of Industries, is the sole owner of several important companies and has significant share holdings in about 70 others, representing all facets of the industrial economy. In some industries, such as coal, basic steel, petroleum and petrochemicals, and automobile manufacture, INI's participation in individual firms has had an influence on the development of the whole sector. As in other developing countries, the national development bank plays a vital role quite out of proportion to its actual financial holdings.

Taxation and public spending. The collection of revenue by means of taxation was one of the least efficient features of the Spanish economy in the 1960s. Although incomes rose rapidly during the period, central government tax revenue did not rise proportionately and in 1969 was still well below that in other countries of similar development status. While direct taxation has maintained a growth reasonably proportionate to incomes, the system of indirect taxation seems to have been inadequately framed and has apparently failed to derive adequate profit from the boom sales of consumer goods, such as cars, which were a feature of the late 1960s.

During the 1960s, the government had only limited success in reducing the financial subsidies that had traditionally been given to certain favoured producers and which at one time had, indeed, played an important part in generating dynamic growth. But by the end of the decade much of this support, such as the subsidization of what had become surplus agricultural produce, was being directed into activities that were becoming increasingly uneconomic, while other projects that genuinely needed government help tended to be neglected. Works of national importance suffered least, and official programs for transportation and communications and for energy and major irrigation projects have been well maintained. The main area of neglect was in social and educational services; enrollment rates for primary education and literacy rates in general are among the lowest in western Europe. But money was beginning to be appropriated for educational purposes under the four-year development plan of 1968 to 1971 and in the plan for the period from 1972 to 1975 even larger sums were to be allocated.

The changing role of government investment

Trade unions and employer's associations. Spain's trade-union structure, the syndicalist system, has been an integral feature of the country's political development ever since the end of the Civil War in 1939. Broadly speaking, most organized economic concerns, comprising mainly the manufacturing and service industries and a substantial section of agriculture, are covered by "syndicates." In theory, these syndicates represent simultaneously the interests of employers, workers, and the state, and their formal structure still reflects the Fascist preoccupations of the 1930s and 1940s. As framed, the corporate structure of the syndicates would seem to allow neither workers nor employers sufficient independence to engage in viable collective bargaining.

Early in 1971 the Spanish Parliament finally approved a new, government-sponsored basic law for trade-union activities. Although the vertical and comprehensive structure of the syndicates was retained—under the control of a cabinet minister, the minister for syndical relations—the new law allowed management, technicians, and workers to set up independent associations. Workers could hold meetings and would be able to appeal in the courts against certain types of government decisions. But even in its new form, Spanish industrial and trade-union organization is still far from even approximating that of the countries of the European Economic Community. Spain's admission as a full member of the EEC would, of course, require a full organizational correspondence in this respect. The official syndicalist system, moreover, seems to have lost ground decisively to unofficial labour organizations, which have been operating illegally and successfully despite police harassment. In face of this development, the government appeared visibly divided between those who saw no alternative to maintaining and, if necessary, increasing repression, and those who were above all concerned about the serious economic effects of the increasing chaos in industrial relations.

Problems in the labour movement

Contemporary economic policies. Although it is normal for national economic policies to exhibit contradictory elements, in Spain the latent conflicts are more basic than in many other countries. From the late 1950s a group that came to be known as the technocrats was trying to modernize and internationalize the Spanish economy. The convictions underlying their policies were that adjustment would be easier and more successful in the context of rapid, overall growth and that this would be stimulated by encouraging competition. In the late 1960s, in order to exercise greater control over the management of the economy, the technocrats decided that fiscal and monetary policies must be strengthened and tightened.

The technocrats, whose power base was originally in the planning departments, were so successful that it became fashionable to believe that they had effective control of the economy. In a cabinet reshuffle in 1969 they did take over major cabinet posts, including the direction of foreign policy, but their appearance of success stemmed partly from the fact that the overall performance of the economy was at that time reasonably satisfactory. Their influence on individual sections of the economy was, however, apparent rather than real, and their successful manipulation of overall policy did not mean that they had managed to reform particular monetary institutions and practices. They failed adequately to effect the reduction or elimination of subsidies, and particular business decisions remained subjected to far greater government regulation in Spain than in other Western industrialized economies. In particular, the technocrats failed to dominate or perhaps even to influence two vital aspects of the economy: industrial relations and the relation between the central government and the various regions. Thus, although they had successfully brought Spain within reach of becoming one of the developed industrial states of Europe, they had not altered the basis of the economy sufficiently to make Spain's industry competitive with that of its neighbours.

ECONOMIC PROBLEMS AND PROSPECTS

For a variety of reasons, the 1970s presented to Spain more problems than had the 1960s. It seemed impossible, for purely statistical reasons, that the high growth rate of the 1960s could be maintained, and the average was expected to fall from 7.3 percent a year to a maximum of 6 percent. But expensive restructuring and modernization of equipment would remain imperative, especially in the coal-mining and textile industries, as well as in the agricultural sector, if the economy was to become internationally competitive. Industrial relations seemed likely to cause trouble, and the most profitable use of the taxation system had not yet been devised. Furthermore, uncertainties about political developments in Spain after the

end of Franco's rule affected both internal planning and confidence and the flow of foreign investment into Spain. (E.I.U.)

TRANSPORTATION

The Roman heritage

The first system of communications established on the Iberian Peninsula dates back to Roman time, and traces of the extensive Roman road network still remain. A new system of highways was not built until the 18th century, during the reign of the first Bourbon kings. Since their capital, Madrid, was situated in the heart of the country, the new system took the form of radial highways extending to the periphery of the peninsula. During the 19th century and into the 20th, efforts were made to consolidate the system of public works. The maintenance and improvement of highways has, since 1964, been one of the chief features of successive plans for economic and social development that have been undertaken.

The highway system. In Spain there is a total of about 50,700 miles (81,600 kilometres) of highway maintained nationally and a further 35,900 miles (57,800 kilometres) maintained by various provincial and local authorities.

The principal improvements being effected in the contemporary highway system were set forth in the Red de Itinerarios Asfálticos (Network of Asphalt-Paved Roads, or Redia) program, approved in 1966. Under this plan, some 3,100 miles of frequently travelled state highways were to be given a coating of asphalt over coal brick and made wide enough for at least two lanes of traffic. Provision was also made for heavy vehicles to travel in slow lanes built on strong ramps. By the early 1970s two-thirds of the highways concerned had been treated under the plan, which was scheduled for completion before mid-decade. In addition to the work being carried out under the Redia program, some 3,700 miles of macadamized road were being paved with asphalt in each year of the early 1970s, and a smaller number of arterial highways were also under construction in the major cities.

Motorway construction

Construction of a motorway (expressway) network was initiated in 1962, and, five years later, tolls were introduced. The motorway program provided for the construction of one kilometre of motorway for each 30,000 inhabitants. At the end of the first decade of the plan's operation, more than six major motorway links were in total or partial use, and a Third Development Plan envisaged the construction of twelve more. At the start of the present decade, there were almost 4,400,000 vehicles (including tractors) in circulation on Spanish roads. More than half of these were passenger cars (*turismos*), and the number of vehicles in operation was found to be increasing at a rate more than 10 percent per year, a situation that gave transportation planners much food for thought.

Railroads. Spain was only the ninth European nation to undertake the construction of railroads, beginning with the lines between Barcelona and Mataró (1848) and between Madrid and Aranjuez (1851). During the second half of the 19th century, the national railroad system was gradually expanded, with Madrid as its centre. The legal arrangement under which the Spanish railroads operated was one of indirect government ownership, whereby the state granted concessions to private companies or individuals for the construction and management of the railroads during a 99-year period, after which the railroads with all their installations and rolling stock would become the perpetual property of the state. This arrangement was radically changed in 1941 by the passage of the Ley de Bases de Ordenación Ferroviaria y de Transportes por Carretera (Law Establishing Basic Rules of Operation for Railway and Highway Transportation), creating the National Network of Spanish Railroads, Red Nacional de los Ferrocarriles Españoles (Renfe). The Civil War of 1936–39 had done considerable damage to the railroads, and it was said that only the take-over of operations by the state could save them from economic disaster. The greater part of the rolling stock belonging to the railroads consisted of outmoded equipment. In 1964 a major long-term modernization plan was initiated. Outstanding among the new equipment introduced was the Talgo, a light train of Spanish design, drawn by an electrically powered locomotive with two diesel motors. By the early 1970s the entire Spanish railroad network totalled some 12,000 miles of track, approximately one-quarter of which was electrified. The major cities of Madrid and Barcelona possessed metropolitan subway networks, and there were plans for the construction of a subway in Seville.

Ports and waterways. Spain has about 200 ports situated along its 2,425 miles of littoral—one-third of which is insular and two-thirds peninsular. Of these, 26 ports service more than 80,000 tons of shipping annually. The total of merchant shipping handled exceeds 140,000,000 tons annually, but the greater part of it—including almost all foreign trade—is handled by a very small number of ports, notably Cartagena, Santa Cruz de Tenerife, La Luz and Las Palmas de Gran Canaria, Barcelona, and Bilbao.

In addition to their important role in foreign trade, a good number of ports are indispensable to basic sectors of the internal Spanish economy, notably steel mills, petroleum refineries, and naval construction. In addition, the fishing industry, in which Spain held second place in Europe and about tenth worldwide in the early 1970s, is strongly influenced by the quality and the type of port facilities available.

In Spain, as in many other countries, maritime trade is assisted by various forms of state intervention, including premiums for shipbuilding and subsidies to specific maritime companies that are regarded as helpful, if not income producing, to the nation. Transport services operating between the peninsula and the Balearic Islands, the Canary Islands, Ceuta, Melilla, and various ports of the Spanish Sahara are known as "Sovereignty Lines." They are assigned to national shipping concerns on a competitive basis under government regulation, although the present major concessionaire, the Transmediterranean Corporation, has a concession granted for a 70-year period. Other companies receiving subsidies include the important Spanish Transatlantic Company, which offers services to the United States, the Caribbean, and Mexico, and also the Ibarra Company, which services the Mediterranean–Brazil–La Plata route.

State subsidies and concessionaires

Air transport. Under a 1940 law the Iberia Spanish Airlines Company was granted exclusive rights to provide regular domestic air services, but a 1960 law did away with this monopoly, replacing it with a 15-year renewable concession. Administratively, air transport is handled by two corporations: Iberia and Aviaco. Aviaco —in which Iberia is the largest stockholder—is a member of the European Air Charter Carriers Association. There are also a number of private companies that operate nonscheduled flights both within and without the country. By the early 1970s the Spanish airlines had a total of about 170 planes, half of them jets, running services in over 30 countries and employing some 18,000 persons. More than 6,500,000 passengers and about 80,000 tons of freight were being transported annually. In Spain itself there were over 40 airports, half of them exclusively for civilian use and a third open to international traffic. By the early 1970s the total annual movement through the national airports exceeded 27,000,000 passengers and was rising rapidly year by year. The busiest airport was that of Palma, which alone handled almost a fifth of the total, while Madrid, Barcelona, Las Palmas, Málaga, and Tenerife airports all handled more than 1,000,000 passengers.

IV. Administration and social conditions

CONSTITUTIONAL AND POLITICAL FRAMEWORK

The Fundamental Laws and the role of the Cortes. Considered as a political entity, Spain is officially designated as a Catholic, social, and representative state, which, in line with its historic traditions, is constituted as a kingdom, under the first article of the Law of Succession.

Spain has what is characterized as an open constitutional system that was set up in 1938 and which comprises a complicated series of laws designated as fundamental.

The system began with the Labour Charter of March 9, 1938, and was later amplified by a series of laws and amendments passed in 1942, 1945, 1946, 1947, and 1958, all culminating in 1967 in the Organic Law of the State. These Fundamental Laws regulate all the matters traditionally included in national constitutions, as well as a number of specific questions and problems peculiar to the Spanish nation. The Law of the Principles of the National Movement (1958) comprises a declaration of fundamental political principles. The rights and the duties of individuals are established in two statutes: that of Labour and that of the Spanish People. The Organic Law of the State (1967) treats of the organization of power, personified in the head of state, as well as of the government and the tribunals of justice. The Law of Succession (1947) states the prerogatives of the Council of the Realm. The system of indirect representation is treated in two of the Fundamental Laws: The Constitutive Law of the Cortes (1942, amended 1946), insofar as it affects the latter; and the Organic Law of the State, in its relation to the National Council. Direct representation is regulated by the Law of the National Referendum (1945). Any abrogation or modification of the Fundamental Laws is subject not only to the approval of the Cortes but also to a national referendum.

According to the first article of its constitutive law, the Cortes is the highest organ of participation by the Spanish people in the affairs of state. Its principal duty is that of elaborating and approving laws, subject to the overall approval of the head of state. It is made up of 561 members, called procurators, designated partly through limited election (as in the case of trade union representatives) and partly through direct election (as in the case of "representatives of the family" comprising both the heads of families and married women). There are also procurators representing the provinces (two for each province), while each municipality with more than 300,000 inhabitants also has its representative. The members of the National Council (see below *Political organization*) are also procurators, as are some two dozen ministers and presidents of distinguished organizations and an equivalent number of representatives of professional schools and other associations. Finally, there are representatives from cultural organizations and members designated directly by the head of state.

Composition of the Cortes

The term of office for the procurators is four years, but those who belong to the Cortes by virtue of their position in another office cease to be members when their tenure in such office expires. The president of the Cortes is appointed by the head of state from among three procurators proposed to him by the Council of the Realm. The Cortes has two vice presidents and four secretaries elected by the procurators themselves from among their number.

The structure of the government. *Central administration.* Under Article 6 of the Organic Law of the State, the head of state is the supreme representative of the nation, personifies national sovereignty, exercises supreme political and administrative power, and has a wide range of other important functions. He gives his sanction to the laws that have been approved by the Cortes and may, at the instance of the Council of the Realm (see below *Regional and Consultative Bodies*) and with its approval, return a law to the Cortes for further consideration. He may also initiate national referenda. He also directs the government of the kingdom through the Council of Ministers.

The role of the head of state

The head of state may propose to the Cortes the person he wishes to have succeed him, under conditions laid down by the Law of Succession. Such a proposal was made in the early 1970s, when the Cortes took the first step toward provision for a successor to Gen. Francisco Franco by approving the designation of Prince Juan Carlos de Borbón y Borbón, following whom the regular order of succession would be according to dynastic line, without the necessary approval of the Cortes.

The Council of Ministers is the highest central organ after the head of state. The government, as constituted by the Council of Ministers, may be convoked by the head of state and is presided over by the latter when he attends its meetings. The Organic Law of the State establishes the office of the president of the government, although up to the early 1970s no provision had been made for filling it, since the positions of head of state and president of the government were in fact both held by Franco. It is officially incumbent upon the president of the government to represent the government of the nation, to direct general policy, to insure the coordination of all the organs of government and administration, and to propose the names of those he wishes to have as ministers. There may be one or more vice presidents, while the regular ministers themselves number 18, excluding three ministers without portfolio, who are not heads of an administrative department but who form part of the government by virtue of their appointment. The ministers, in the early 1970s, were still both named and retired entirely according to the will of the head of state, but provision has been made for this role to be filled by the president of the government, when that office was filled.

The appointment of ministers

Regional administration and consultative bodies. Civil governors represent the central government in each one of the 50 provinces of Spain. They are appointed by the Council of Ministers after being proposed by the Ministry of the Interior and also serve as provincial heads of the National Movement (see below *Political organization*). Each ministry also normally has delegates in the provinces.

Mayors are the heads of local government in the various municipalities. In cities other than provincial capitals, they also represent the central government and are entrusted with maintaining public order as commissioned by the civil governor.

The Council of the Realm, which has precedence over other consultative bodies of the nation, assists the head of state on those matters that fall within his exclusive competency. In addition to its functions as a consultative body, it also has other duties related to certain high-level appointments, including that of proposing the names of the candidates from whom the president of the Cortes will be selected and making nominations for the Supreme Court of justice, the Council of State, the Court of Exchequer, and the National Economic Council. The Council of the Realm is composed of *ex officio* councillors and representatives of the Cortes.

The Council of State is the highest administrative consultative body and acts through plenary session, permanent committees, and its various divisions. The National Economic Council is the consultative, advisory, and technical organ in matters of importance that affect the national economy.

Local administration. The provinces, together with the municipalities, form what is called the local administration. The Spanish provincial system was definitively established, after several unsuccessful attempts, in 1833. By the 1970s the national territory was divided into 51 provinces, including the African province of the Spanish Sahara. Each province has its provincial House of Deputies with a president. The former is constituted as a corporation by the president and the provincial deputies, of whom there is one for each judicial district elected from among the mayors and city councilmen by electors of the municipal governments; these are in addition to other deputies who represent corporations and various provincial economic, cultural, and professional bodies, such as the Trade Union Organization.

The provincial and municipal hierarchy

Spain has about 9,000 municipalities, the government and administration of which are handled by mayors and municipal councils. The mayor is president of the municipal corporation and at the same time represents the state administration. In the provincial capitals and municipalities of more than 10,000 inhabitants, the mayor is appointed by the Ministry of the Interior. In the case of other municipalities, the appointment is made by the civil governor of the province with the approval of the Ministry of the Interior.

Municipal government comprises the mayor-president and the councilmen, whose number varies from three to 34, depending on the number of local inhabitants. One-

third of their number is made up of representatives of the heads of families; another third of members of labour organizations from within the limits of the municipality; and the final third of the economic and professional organizations located therein.

Political organization. *The National Movement.* The law of the principles of the National Movement officially characterizes the latter as the Spanish people united by law and order. It is open to all Spaniards and avowedly seeks to serve the nation by promoting political life and fostering harmonious living on a well-ordered basis. The chief organs of the movement are its national leadership and, as a collective body, the National Council. The president of the government is also the head of the National Movement and president of its National Council. The secretary general, appointed by the head of state at the instance of the president of the government, holds the rank of minister.

The Trade Union Organization. Spaniards participating in labour and production constitute what is officially known as the Trade Union Organization, which is made up of industrial, agrarian, and public utility unions. These unions have the status of public corporations with a representative basis and enjoy juridical standing in their respective spheres of competence. Within these spheres associations of management, technicians, and workers have been established. These groups, it is officially held, organize for the defense of their particular interests and also in order to take part in the wider life of the community.

The system of representation. The Spanish system of representation is officially defined as an organic democracy, operating through representatives of families, municipalities, trade union organizations, corporations, and professional schools. On the highest level, it functions through the Spanish Cortes.

Organic democracy defined

Besides the elections of family representatives to the legislature (two for each province), there are also direct municipal elections to elect councilmen who represent the family; elections of representatives of family organizations to the National Council; and elections of members of provincial councils and local units of the National Movement.

All men and women who are over 21 years of age are also entitled to vote in national referenda held to consider important matters. Finally, the governing bodies of the trade union organizations, with the exception of the secretariat, are elected by free and secret suffrage.

Justice. Spanish judicial structures alone possess the faculty of passing judgment and applying the laws, the executive being forbidden to interfere in judicial affairs. Each judicial structure, of whatever rank, is officially the sovereign judge in its own field of competence and is subject only to the law. The judges are experts who must show their competence in a competitive examination before being granted admission to their respective corps. The fiscal magistrates, or public prosecutors, number over 270, while those of the judicial branch number almost, 1,000. Promotions and the filling of vacancies takes place according to a seniority system.

The role of the Supreme Court

In the administration of justice, the Supreme Court is the highest judicial body. It has its seat in Madrid but possesses national jurisdiction. The Supreme Court may function in plenary session, as a disciplinary court, as a judicial council, and as a court of justice through its six divisions. On a lower level, there are 15 territorial courts handling civil cases of various kinds and 50 provincial courts that try criminal cases.

The jurisdiction of the petty courts (*juzgados*) extends to the "judicial districts", of which there are almost 500. These courts try civil cases and draw up criminal indictments. The municipalities, depending on their size, are seats of the municipal courts (almost 240), district courts (almost 500), and petty courts (nearly 8,200). The labour magistracy has special jurisdiction over disputes arising between employers and employees and matters involving social security and industrial accidents. There is also a juvenile court system and a Court of Exchequer (Accounts Court) responsible for the auditing and verification of state accounts.

The Spanish penitentiary system consists of two general types of prison—preventive prisons and central, or corrective, prisons. The former comprise the provincial prisons and district prisons and also houses of detention, workhouses, farm colonies, and so on. The central prisons are of two types, each numbering less than a dozen: the common central prisons and the special prisons. The total prison population of Spain in the early 1970s was just under 14,000 and was claimed to be one of the lowest for any nation in Europe.

The armed forces. The Spanish army is organized into 11 captaincies general, while the navy has three departments, and the air force is organized into three regions. Military service is obligatory for all male Spaniards who are not exempt by reason of physical defects. Active duty is ordinarily for 18 months but may be shortened when circumstances warrant.

The Junta of National Defense

The three forces are unified in the Junta of National Defense, which comprises the ministers of the military departments, the chief of the supreme staff, and the chiefs of staff of the army, navy, and air force. The supreme commander is the head of state.

SOCIAL SERVICES AND SOCIAL CONDITIONS

Educational services. The Spanish educational system, based on the General Law for Education (1970), is divided into the following units: preschool education; general basic education; *bachillerato* (see below); university education; professional formation; and continuing education for adults. All these types of education are given in both public and private institutions.

The General Law for Education, which was directed toward a complete reform of the educational system, is being put into effect gradually and is expected to be fully in force by the late 1970s or early 1980s. Associated reforms include free and obligatory basic general education until age 14; removal of rural–urban differentials in educational opportunity; equal access to the university; and university autonomy and the creation of new universities. Aid to students is also given in a broad variety of scholarships, loans, and other subsidies.

Preschool education. Preschool education comprises games, language activities, observation of nature, and related activities. It is not obligatory and is offered without charge in public schools. There are nursery schools for children between two and three years of age and kindergartens for those between four and five years old.

General basic education. Designed for children between six and 13 years of age, general basic education is divided into two stages: in the first (for children between six and 10), the studies are of a general nature; in the second (for children from 11 to 13), basic preparation for the *bachillerato* is given, and the pupils also receive training in practical activities. In both public and nonpublic institutions, general basic education is obligatory and without charge. Upon the successful completion of this program of studies, the pupils receive a diploma—the basic baccalaureate—signifying that they are school graduates. By the early 1970s, there were over 135,000 schools offering this kind of education to well over 4,700,000 pupils.

The bachillerato. The *bachillerato* program of studies, which follows the general basic education program, covers a three-year period for pupils between 14 and 16. The curriculum includes required subjects, electives, and a measure of technical or professional training. The title of *bachiller* enables the student to enter second-level professional schools or the pre-university course required before admission to the university proper. More than 2,800 schools grant the *bachillerato:* they have a total enrollment of well over 1,500,000 students.

The *bachiller* and entry to higher education

University education. University education is preceded by an orientation course that lasts for one year and that is open to those who hold the *bachillerato* or who have completed their second-level professional studies. The course is planned and directed by the university but is taught in schools that offer the *bachillerato.*

University education proper may be undertaken in university schools, which generally have a single three-year

program of studies, or in faculties or advanced technical education schools. In the latter case, there are three cycles or programs of study: a first devoted to basic disciplines over a three-year period; a second, of specialization, which lasts for two years; and a third, of specialization and preparation for research and teaching.

Students who have completed their studies in a university school or the first cycle of a faculty or technical school obtain the diploma that enables them to work in their field of competency. Those who complete studies through the second cycle receive the degree of licentiate (*licenciado*), engineer, or architect, allowing them to practice professionally or to continue their studies in the third cycle. The completion of studies in the third cycle, together with the writing and approval of a thesis, leads to the degree of doctor in the field of specialization.

In the early 1970s Spain possessed a dozen state universities, three autonomous ones, and four under private auspices. There are eight faculties (university "colleges" or "schools"). Many of the universities are of ancient foundation. The total number of students in attendance was more than 157,000 by the early 1970s.

Professional training. Professional education is given on three levels of varying length, according to the field of specialization, but always covering a period of more than two years for each level. To begin studies upon the first level, it is necessary for the student to have completed his general basic education. This level of studies must be undertaken by those who do not hold the *bachillerato.* Admission to second-level professional courses is granted to those who hold the *bachillerato* or who have completed first-level professional courses. Courses in professional formation on the third level are open to those who have completed the first cycle of studies in a university faculty or advanced technical school; university graduates; and those who have completed their second-level professional courses together with the necessary complementary courses.

Other institutions. A variety of other educational institutions also exist in Spain. These include schools of fine arts, applied arts, and artistic crafts; the schools of social work, and of teachers of physical education. Other centres, which used to exist independently but are now gradually becoming affiliated with the universities, include the schools of diplomacy, public administration, jurisprudence, and of archives and libraries. Twelve labour high schools have their own distinctive character. They confer the *bachillerato laboral* and prepare their students for a wide range of industrial occupations.

Social Security. The law concerning Social Security (1963) is based on what is technically known as unification of the risk factor—that is, every case of inadequate salary or absence of income is considered in the same way, whatever may be its cause. Likewise, all payments are made on 75 percent of the basic salary. The Ministry of Labour administers the Social Security program through the National Institute of Welfare and the Mutual Labour Insurance organizations, together with others that operate in certain specified areas, notably farm labour and maritime workers. The result of the 1963 law was the unification of an already existing group of programs for the insurance of industrial workers into one single program called Social Security. The creation of an obligatory health insurance program has meant that a type of insurance that formerly benefitted only a specific sector of the population has been expanded to insure the extension of its benefits to a much larger number.

Administration of the Social Security program

In order to provide assistance to its beneficiaries, the obligatory health insurance scheme operates over 60 centres scattered throughout the country, and five times that number were planned for the 1970s. There were also almost 500 outpatient clinics.

Housing. The Ministry of Housing, created in 1957, brought together under one head such organizations as the Office of Architectural Planning and the National Housing Institute that had formerly been in charge of housing inspection and the construction of new units. Not included was the Service for the Reconstruction of Devastated Areas, which had been established for the rebuilding of the country following the destruction caused by the Civil War of 1936–39.

The first step taken toward the creation of a housing policy by the present authorities, however, was the passage, in 1939, of the Law of Protected Dwellings, the purpose of which was to promote large-scale construction of housing for the poorer classes. The instrument for implementing this policy was the National Housing Institute. Contemporary housing policy also includes such measures as housing provided on credit for families of limited income, who also enjoy tax exemption and similar benefits.

To control land speculation and the resulting scarcity of building sites and, hence, the high cost of acquiring them, the Ministry of Housing has adopted the policy of creating new cities or new urban areas rather than choosing to undertake urban renewal or land expropriation projects. During the 1945–70 period, almost 1,500,000 homes were built under state direction, and building has continued—at an accelerating rate—into the 1970s. The National Institute of Colonization has also undertaken the building of more than 200 new towns.

Control of land speculation

Public order. Because of its long tradition and special characteristics, the Spanish Civil Guard is singled out from among the various kinds of security police as a typically Spanish institution with its origin in the earlier *hermandades* (literally "brotherhoods"), a reference to a kind of rural police force established by the Catholic kings. It is organized along military lines for the accomplishment of its duties as a rural police force. In addition to watching over and preserving public order particularly in rural areas, it has several other specific tasks, including the patrolling of frontiers and the prevention of smuggling. The Civil Guard has also proved to be efficient in carrying out the duty most recently entrusted to it, namely, that of serving as highway traffic policemen and providing assistance for motorists in distress.

Organizationally, the Civil Guard forms part of the general administration of the Ministry of the Interior and has as its commanding officer a lieutenant general of the army.

The maintenance of public order in general is the duty of the General Security Administration, to which are attached the General Police Corps and the Armed Police Corps.

Social conditions. *Income and cost of living.* The policy of the present authorities with respect to salaries was originally established with the promulgation of the National Labour Regulations, which were intended to prevent the growth of any economic activity unless it was able to provide those who worked at it with a salary sufficient to maintain a decent standard of living. The excessively general character of these regulations, however, made the application of them in specific instances extremely difficult. This situation was remedied by the passage of the Law of Collective Agreements (1958), which served to establish a basis for collective bargaining between workers and employers. By the early 1970s more than 80 percent of the workers who were not self-employed were partners to such agreements.

The Third Plan of Development (1972–75), although it did not set a definite figure for the minimum wage to be paid, reviewed the matter annually in its relation to the cost of living and the rate of economic growth, both of which influence the salary adjustments reached through the agreements described.

The increase in consumer spending on the part of the Spanish family—which has now attained a level comparable to that of developed countries—is, Spanish authorities feel, one of the most favourable indicators of the real advances being made by the national economy. In recent years family consumption has shown a decided tendency toward a change from spending on food and clothing to greater expenditures for housing and services. The consumption of durable goods depends on the growth rate of the gross national product: in years when this exceeded 7 percent, there was a marked expansion in consumption, with a corresponding reduction during the years in which a slower growth rate holds.

Family consumption patterns

Generally speaking—and there are notable exceptions—the rate of increase in consumer spending during recent years is considered by the government to be satisfactory. There has been a levelling off of differences in the standard of living between the rural and urban population, particularly with respect to services and basic goods.

Health factors. Official public health services are under the administrative control of the National Department of Health, a division of the Ministry of the Interior. Its work is complemented by that of numerous other institutions, including the National School of Health, the National Anti-Tuberculosis Association, the National Cancer Institute, and so on. State, local, and private groups collaborate actively in the field of preventive medicine. In 1960, infant mortality during the first year of life—always a significant gauge of national health standards—was 43.7 per 1,000. By 1970 it had declined to 27.8 per 1,000. The ratio of 14 doctors to each 10,000 inhabitants is also relatively high when considered in relation to the low per capita income of the nation. Industrialization has caused an increase in the absolute number of industrial accidents but, relative to the present population, the number has decreased.

Recent years have witnessed important advances toward the eradication of malaria and tuberculosis. Finally, it may be noted that the life expectancy of the Spaniard increased from 69.7 years in 1960 to about 70.5 years in 1970.

To maintain its progress, Spain has about 1,650 establishments offering medical and surgical care. Public and private institutions, taken together, have more than 160,000 beds.

Social and economic divisions. Social conditions in general and social classes in particular have changed greatly in Spain over the last 30 years, a fact admitted by all observers. Growing economic prosperity has, in the Spanish view, brought an increase in the number of working class entering the middle class. At the same time, it is held that economic differences are disappearing within the various sectors of the middle class itself. Opportunities for university and technical education are increasing and are expected to play an important role in bringing about a fuller equalization of economic status among the different social groups. The figure of outstanding prestige today is undoubtedly the technical expert, whose work in both industry and administration is becoming increasingly important.

V. Cultural life and institutions

THE CULTURAL MILIEU

The Romanization of the greater part of the inhabitants of the Iberian Peninsula brought with it a diffusion of classical culture that was to influence permanently the cultural development of Spain as a nation. Specifically, the deep assimilation of the cultural ideals of Rome enabled them to survive the barbarian invasions that followed Rome's collapse.

During the ensuing centuries of Muslim domination and the entire period of the Reconquest (the expulsion of the Africans from Iberia), Spain continued to develop her unique culture by incorporating elements of both Islāmic–Oriental and Jewish civilizations. This amalgamation of cultures is, perhaps, the explanation for the development of the characteristic Spanish culture, which, while not removed from what is peculiarly European, does not correspond to it fully.

Serving as a meeting place for two distinct cultural worlds, the Islāmic–Oriental and the western European, Spain has performed an important task in the dissemination and extension of culture. The classic works of Greek antiquity were translated into Latin and later into Castilian; and a knowledge of both Arab and Jewish culture was passed on to other European nations. The Castilian tongue, which was to become the national and official language, acquired vigour and maturity and soon became outstanding among all the languages of Europe. So strong did Spanish culture become that the term Golden Age—which, in Spain, comprises both the 16th and 17th centuries—can be applied not only to the political, literary, and artistic creations of the period but also to its outstanding achievements in theology, philosophy, law, and science.

Traditional Spanish culture, however, being deeply religious in character and specifically Catholic in outlook, found itself farther and farther removed from the cultural life of the rest of Europe, as the latter (from the 18th century onward) assumed an increasingly secular quality. The critical nature of this stage in Spain's development is apparent in the conflict that arose during the 19th century between the nationalistic and the more European-oriented sectors of her society. Spanish culture has also had enormous impact in the New World.

In the prevailing Spanish viewpoint, Christian inspiration, a humanistic outlook that fosters appreciation of the worth of the individual, a certain eclecticism, and a striving toward universality of spirit are seen as characteristics of Spanish culture in every age. Contemporary Spain, it is felt, finds itself open to the most recent intellectual currents of the rest of Europe, and indeed further afield, but does not as a result intend to relinquish her own characteristic modes of thought and behaviour. It would seem that the mission of Spain continues to be that of creating her peculiarly national forms of Western culture.

THE MAJOR ARTS

Architecture. Architecture that finds its inspiration in classic sources is represented in Spain today by the work of several outstanding figures. They include Luis Gutiérrez Soto (who designed the Air Ministry in Madrid); Luis Moya (responsible for the Labour University of Gijón); and Pedro Muguruza (designer of the magnificent war memorial, the Valley of the Fallen, near Madrid). The major contemporary architects

An intermediate position between tradition and modernity is held by Miguel Fisac, who has worked chiefly in Madrid, and Juan Antonio Coderch, who has been well known in Barcelona.

Younger architects accorded acclaim by Spanish critics include Vázquez Molezun, who, together with José Antonio Corrales, designed the Reader's Digest Building in Madrid; Javier Carvajal, the designer of the Spanish Pavilion at the 1964 New York World's Fair; and Javier Sáenz de Oiza, architect of the Torres Blancas Building in Madrid. Felix Candela has also become internationally known for his work outside of Spain, especially in Mexico.

Sculpture. José Planes, Cristino Mallo, and especially Juan de Avalos have worked along the traditional lines of representational sculpture. A forerunner in the use of the nonrepresentational style was Angel Ferrant, who also worked with representational sculpture, as did Carlos Ferreira and Jorge de Oteiza. The work of Pablo Serrano is significant for its abstract style, and Eduardo Chillida gained world renown in a very short time for his sculptures in metal.

Painting. Three of the outstanding painters of the 20th century have been Spaniards: Pablo Picasso, Salvador Dalí, and Joan Miró; however, they all spent much of their working lives outside Spain. In addition, the list of contemporary Spanish painters is long. The best known artists who do representational painting more or less traditional in style include Francisco Arias, known best as a landscape painter, and also Agustín Redondela, Alvaro Delgado, Juan Antonio Morales, all portrait painters. Various types of stylized painting have been done by Antonio Saura, Juan Ponc, and Juan Brotat, while the better known pure abstractionists include Pablo Palazuelo, Rafael Canogar, Luis Feito, Antonio Tapies, Modesto Cuixart, Juan José Tharrats, and Manuel Millares. Famous 20th-century painters

Music. The internationally significant generation of musicians to which Manuel de Falla, Joaquín Turina, Conrado del Campo, and Oscar Esplá belonged was succeeded by a generation of composers born at the turn of the 20th century. They include Federico Mompou, whose work follows the French impressionistic style; and Ernesto Halffter, often considered to be the truest of the disciples of Falla and who, like his master, has sought to combine both aristocratic and popular elements in his

Innovative composers

music. Composers whose work reveals a tendency to greater innovation include Xavier Montsalvage and Joaquín Homs. The same tendency is even more clearly expressed in the works of Cristóbal Halffter, Luis de Pablo, and Carmelo Bernaola, three figures of international renown in the world of avant-garde music. Among guitarrists, Andrés Segovia, Narciso Yepes, and Regino Sáinz de la Maza all enjoy a worldwide reputation, as do such vocal artists as Victoria de los Angeles.

Literature, drama, and film. The illustrious traditions of Spanish literature continue to influence contemporary writers, and the *Don Quixote* of Cervantes has been characterized as the 17th-century prototype of the modern Spanish novel.

The Civil War (1936–39) represented a watershed in Spanish arts as well as politics, driving many artists in disparate fields into exile while substantially altering the focus for those who remained or emerged subsequently. Among its effects was the shift in predominance from poetry to the novel, though the Generation of 1927 movement in poetry, especially through such pre-eminent figures as Vicente Aleixandre and Dámaso Alonso, continued to influence a host of postwar poets, including Salvador Espriu, Gabriel Celaya, Blas de Otero, and José Hierro. The best known of 20th-century Spanish poets outside their own country, however, remained the lyric poet Juan Ramón Jiménez, winner of the Nobel Prize for Literature in 1956, and Federico García Lorca, who is perhaps even more renowned as a dramatist. In both poetry and drama Lorca echoed an earlier Spain. His poetry is alive with the labyrinthine and sensuous imagery of a Moorish Spain of several centuries past. The few plays he wrote before he was murdered during the Civil War are both richly poetic and emotionally elemental in their actions, harkening back to the works of Lope de Vega and Pedro Calderón de la Barca, which helped the Spanish stage of the 17th-century Golden Age rival that of Elizabethan England in vigour and popular appeal.

Major 20th-century novelists include Ramón Pérez de Ayala, who touched his philosophical themes with an Asturian humour; Gabriel Miró, who was occupied with more poetic themes; and Ramón José Sender, who returned to greater realism and social commentary; as well as Max Aub and Francisco Ayala. During the early 1940s the postwar novel began to emerge in the work of such writers as Camilo José Cela and Carmen Laforet, who influenced a younger group including José María de Ginorella, Jesús Fernández Santos, Juan Goytisolo, Luis Goytisolo-Gay, and Juan Marsé. Criticism, previously led by José Ortega y Gasset, champion of a pure, depersonalized art, passed to such younger observers as José Luis Cano and José María Castellest.

In the film, Spain is most widely known for the work of the expatriate director Luis Buñuel, many of whose often heavily symbolic films are regarded as among the major examples of cinematic art. Within Spain, Juan Antonio Bardem and Luis Garcia Berlanga were among those who renewed the nation's film industry in the postwar period, while Carlos Saura assumed major rank in subsequent years.

TRADITIONAL SURVIVALS

The fiesta. The form of popular tradition that remains most intensely alive in the Spain of today is that of the fiesta, or popular festival, which never fails to have a certain amount of religious significance even though it may be essentially nonreligious in character. After having been preserved for centuries, the fiestas have now been incorporated into the activities carried on by the Ministry of Information and Tourism and consequently can anticipate not only a larger audience but also a continuance of their existence. Each locality, no matter how small, has its own festival, celebrated in honour of a saint for whom the town feels a particular devotion. The list of local festivals is, as a result, almost interminable, but three outstanding ones are the Fallas of Valencia, the April fair of Seville, and the festivities honouring San Fermín in Pamplona. Although the festivals are found all over Spain, it is interesting to note that the coastal regions, despite the fact that they are more exposed to foreign influences, are precisely those which have best preserved their typical festivals.

The bullfight. The bullfight, too, may be considered something of a hybrid celebration, since it possesses certain characteristics of a sport as well as those of a popular festival. It is customarily regarded, however, as the most typical of Spanish festivals and as the Spanish national fiesta par excellence, even though bullfighting is found in other countries, particularly those of Hispanic America. The tradition of bullfighting can be traced back to very ancient times, but the present style of fighting the bull on foot dates back only to the 18th century.

Other traditional features. There are seemingly innumerable other forms of traditional activity, and many objects still used in daily living also have their roots deep in the past. Some change is taking place, but other activities continue to exist as they have in the past, notably in the remote rural areas. Spanish houses, for example, reflecting as they do both the varying regional climates and the exigencies of a pre-industrial society, still continue to be constructed more or less as they were many years ago. On the other hand, the traditional or typical regional garb has undergone a slow evolution as to style, although certain costumes are still considered characteristic of the regions in which they originated.

Traditional arts and crafts, grouped together under their official name of *artesanía* (handicrafts), have become the object of government protection, designed to insure their continued existence in the face of the increasing mechanization of industry. Organizations devoted to this end include the Artisans' Trade Union, whose efforts have been complemented by the work of the National Handicraft Enterprise, a branch of the National Industrial Union. The promotion of handicrafts is also carried on by the Sección Femenina de Falange (Women's Division of the Falange Party), an organization which has also helped keep alive popular traditions in folkloric music, song, and dance through its performing groups, Coros y Danzas (Chorus and Dances).

POPULAR CULTURE

In Spain, cultural affairs, as distinct from educational matters, are handled by the Ministry of Information and Tourism through its Division of Popular Culture and Public Spectacles. The latter subsidizes various organized groups, such as Casas de Cultura—the Houses of Culture, which contain libraries, lecture rooms, and exhibition halls, and also give theatrical and musical performances—as well as sponsoring cultural events of many types. One of the moving forces behind these activities is a desire on the part of the government to make it possible for outlying sections of the nation to enjoy at least in part the cultural opportunities to be found in the large cities.

In the realm of theatre, the diffusion of culture is carried out through the national theatres, the festivals of Spain, and the theatre campaigns held in the provinces. The national theatres are: the Teatro Español, which stages premieres and also has a large repertory of both national and foreign plays; the María Guerrero Theatre, which presents modern and contemporary plays; the Teatro de la Zarzuela, which produces lyric theatre; and the Teatro Nacional de Cámara y Ensayo (the National Experimental Theatre), which specializes in the production of avant-garde plays. All of these theatres are located in Madrid.

The festivals of Spain, specially established to further the cultural decentralization of the country, have enabled a great number of people who would not otherwise have had such an opportunity to attend theatrical performances, dance exhibitions, and concerts. More than 100 such festivals are held annually throughout Spain.

Annual festivals that enjoy international prestige are the Musical Festival of Granada and the Musical Fortnight of San Sebastián. The International Theatre Festival, located in Madrid, also attracts highly qualified foreign theatrical companies. There are also other special festivals (such as that of the opera, also celebrated in Ma-

drid) held to meet needs that the cultural activities of private individuals have failed to fulfill.

This type of cultural promotion can only be carried out effectively if it is pursued on a continuing national basis. In 1965, therefore, the Ministry of Information and Tourism set up a national network of what were called Teleclubs. The ministry supplies to these centres (which numbered over 4,000 by the early 1970s), free of charge, a television set, daily and weekly newspapers, books, records, and various audiovisual aids. The Teleclubs are directed by a specially trained supervisor. Spanish publishing houses have also made a substantial contribution to the diffusion of popular culture by making high-quality, but moderately priced, books available on a mass basis. Annual book fairs are also becoming increasingly popular. The efforts of the Division of Popular Culture to raise the cultural level of the population are also furthered, it is held, by a variety of nation-wide campaigns.

The role of Teleclubs

CULTURAL INSTITUTIONS

The Academies and related bodies. Spanish cultural institutions have deep and rich roots in the nation's past. The oldest of the Spanish academies is the Royal Academy of Language, usually called the Royal Spanish Academy, which was established by King Philip V in 1713. Its primary purpose is "to cultivate and to set standards for the purity and elegance of the Castilian tongue." An essential aspect of this task involves the publication by the Academy of a Dictionary of the Language and other works, as well as the granting of prizes. Spain also possesses the internationally known Royal Academy of History; the Royal Academy of Fine Arts of San Fernando; the Royal Academy of Exact, Physical and National Sciences; the Royal Academy of Moral and Political Sciences; and the Royal National Academy of Medicine. All the academies form part of the Institute of Spain, founded in 1938 as a coordinating organization.

The Royal Spanish Academy

The Higher Council of Scientific Investigation, created in 1939, directs research activities of some 225 scientific centres located throughout the entire nation. The Institute of Hispanic Culture is a corporation dedicated to the preservation of the cultural community of *hispanidad* (*i.e.*, those of Spanish origin). It has as its chief purposes the study, defense, and diffusion of Hispanic culture and the promotion of mutual understanding among Hispanic peoples. The institute maintains cultural exchange departments, possesses a commissariat in charge of expositions and also the important Hispanic Library, the collection of which numbers more than 300,000 volumes. There are over 40 institutes of Hispanic culture located in 18 countries of North and South America. These collaborate with the parent institute in Spain, which has almost 20 affiliated Hispanic-American cultural associations within the country itself.

The famous athenaeums (which carry on varied cultural activities) are located in 20 different Spanish cities. Founded in the 19th century as private political clubs, they have since been gradually transformed into groups influencing the artistic and literary life of their home city. The Casas de Cultura, through lectures, expositions, concerts, and libraries, perform analogous functions in smaller towns.

Art galleries and museums. The great national art gallery is the world-famous Prado in Madrid. Installed in a magnificent building, it holds a unique place among the great museums of the world. Its collections and galleries have been enlarged in recent years by the acquisition of many of the Spanish paintings that were done in the 19th century.

Other important museums include the Museo de la Real Academía de Bellas Artes de San Fernando, Madrid, the Museum of Ancient Art in Barcelona, and those of fine arts in Bilbao and Seville. Collections devoted to specific aspects of the art of Spain are found in other museums: thus, religious sculpture is housed in the National Museum of Sculpture in Valladolid; and the art of El Greco is recognized in his museum and house in Toledo.

The Army and Naval Museums in Madrid are interesting from the historical viewpoint, as is the Maritime Museum in the royal arsenals of Barcelona. In addition to numerous provincial and municipal museums, there are others belonging to the cathedrals, dioceses, and parishes. The various museums of the National Patrimony, housing collections that form part of the former royal patrimony, are also very significant. Finally, the country is rich in private museums, including the Cerralbo in Madrid and the Marés in Barcelona. New museums include the Sephardic Museum in Toledo; the Museum of Costume and the Picasso Museum in Barcelona; and the Museum of Abstract Art in Cuenca.

It is notable, however, that in a country that possesses great artistic and historic treasures and in which art, particularly religious art, is alive and active *in situ*, the activity of museums of necessity plays only a secondary role.

Libraries and archives. The most important of Spain's famous historical libraries is that of El Escorial, which served as a model for other European libraries up until the 19th century. The Royal Library, established in the 18th century, was in the following century transformed into the National Library of Madrid. It has very valuable collections that originally belonged to private libraries or to monasteries that were confiscated by the government. The Private Royal Library, or Palace Library, the libraries belonging to the royal academies, that of the Higher Council of Scientific Investigation, and the public libraries of the provinces form a broad library network throughout the entire country.

The Royal Library

In addition to a great number of smaller archives—regional, local, special, ecclesiastical, and private—Spain has four great general archives in which are assembled the historic documents of the nation. They are: the National Historical Archives, in Madrid; the General Archives of Simancas; the General Archives of the Indies, in Seville (which contains documents relating to the government of the Spanish overseas empire); and that of the Crown of Aragon (of supreme importance for the study of medieval history), in Barcelona.

Other cultural bodies. The National Orchestra, which was founded in the period immediately following the Civil War of 1936–39, has devoted itself chiefly to the promotion of interest in symphonic music. The Symphony Orchestra of Spanish Radio and Television, which gave its first concert in 1965, has, in its shorter existence, been able to reach a wide audience through the use of the communications media. Both these orchestras are located in Madrid, as are two others with a long and brilliant history: the Symphony and the Philharmonic. Outside the capital, the principal Spanish orchestra is the municipally supported City Orchestra of Barcelona.

Spain has only one theatre for opera that has a regular season for its performances, the Lyceum Theatre in Barcelona, a private enterprise. The Festival of the Opera, however, which, in some respects, corresponds to a short opera season, is held every year in Madrid. Similar festivals, also of brief duration, are held in several of the provincial capitals.

The March Foundation (founded 1955) is outstanding among foundations under private auspices. Its cultural activities include the giving of prizes, grants for research, scholarships for study in Spain or abroad, and annual contributions to the study of literature and the fine arts, as well as subsidies to institutions and enterprises interested in culture. It also publishes books.

The influence of private foundations

The number of literary prizes established has increased notably in recent years; the 17 national prizes for literature remain, however, as the oldest and most distinguished. Other important prizes include the "Nadal" and the "Planeta" for the novel; and the "Adonais" for poetry.

COMMUNICATIONS MEDIA

The press. The promulgation of the Press Law in 1966 led to a profound change in the journalistic world of Spain. The stationary situation that prevailed under the press regulations established in 1938 had, indeed, shown a certain tendency toward change in recent years, but it was not until the passage of the new law that press moved

into a phase of extraordinary activity. The three basic principles enunciated in the new law—liberty of expression, liberty of enterprise, and free choice of a director—are said to have changed the relationship that formerly existed between the state and the press. Now that government controls have been reduced and the exercise of them is subject to juridical norms, the Spanish press, it is generally acknowledged, has acquired a quite remarkable dynamism, and the number of publications has increased. By the early 1970s, almost 100 morning papers were published in Spain, along with several dozen evening ones.

Radio broadcasting. The first radio broadcasts made in Spain were carried out by an experimental station in Madrid in 1923, and in the following year, the first transmitters—privately owned and operated—were installed in Barcelona and Madrid.

After the Civil War had ended in 1939, a national radio broadcasting service was established, centred on the group of transmitters located in Arganda, in the province of Madrid. In 1951, when the Ministry of Information and Tourism was created, the government-operated radio and television stations were placed under its direction. Technical improvements were made, and a national plan for radio broadcasting was worked out.

In 1960 the first station of Radio Peninsular devoted entirely to the broadcasting of music was set up, and, since then, stations of a similar type have been established in several of the provincial capitals. The first FM transmitter was installed in Madrid in 1957 by Radio Nacional de España, to be followed by several others of the same type. All private transmitting stations broadcast simultaneously in FM and AM.

State and private broadcasting

Before 1936 the only radio broadcasting done in Spain was under private auspices; privately owned stations now coexist with the official network. Almost all the privately owned transmitters, of which there are almost 200, are organized into the SER Chain (Spanish Radio-broadcasting Society). They are either regional or local stations. The transmitters that belong to the National Movement and to the Catholic Church, as well as those operated by private persons, are not under state control.

Television. The state has a monopoly over television programming, and the first daily program was set up in Madrid in 1956. By the 1970s the Spanish television network covered the entire national territory through its "First Program," utilizing microwave links. The "Second Program," initiated in 1965, operates on the uhf band. It should be noted that the complicated topography of the country makes television broadcasting on a national scale difficult.

In 1964 a production centre for television programming was installed and inaugurated in Prado del Rey. Its purpose is to give general direction to the many hours of television programmed on the Spanish network. By the early 1970s there were five such centres in existence, with a total of 17 studios, but colour television in Spain is still in the developmental stage, although well over 40 percent of Spanish families possessed television sets.

FUTURE PROSPECTS

In the Spanish viewpoint, the expectations for normal political development for Spain in the years ahead are based on a continuation of current trends. The geographical location of Spain—with links to the European, Mediterranean, African, and American worlds—will doubtless continue to exert a powerful influence. Irreversible trends toward modernization and industrialization, already in evidence, will, it seems, lead to further links with the European community. The future of the country will depend heavily on the successful blending of a venerable tradition with the technological and industrial traditions that have already come to dominate northern Europe but from whose influence Spain has hitherto been isolated by virtue of its marginal position. (E.L.O.M.)

BIBLIOGRAPHY

General works: The *Anuario Estadístico de España*, published annually by the Spanish Government, contains general statistical information about the country. The *Enciclopedia Universal Ilustrada Europeo-Americana*, 70 vol. (1908–30, and supplements), provides detailed information about Spain, its regions, and its towns, especially in vol. 21, *España*, and under "España" in the supplements. PASCUAL MADOZ, *Diccionario geográfico-estadístico-histórico de España y sus posesiones de ultramar*, 16 vol. (1846–50), is still a valuable reference book. STEPHEN CLISSOLD, *Spain* (1969), is an informative book about the country and its regions, the history of Spain, and its present political and economic situation. JAMES MICHENER, *Iberia: Spanish Travels and Reflections* (1968), provides an impressionistic and largely subjective vision of the country.

The Land: General information about Iberian geography may be found in books about the Mediterranean area, especially JAMES MCINTOSH HOUSTON, *The Western Mediterranean World: An Introduction to Its Regional Landscapes* (1964); and MAX SORRE, *Peninsules mediterranéennes*, vol. 1, *Généralités. Espagne et Portugal* (1934). MANUEL DE TERAN (ed.), *Geografía de España y Portugal* (1952–58), dedicates its first four parts to Spain and is the most complete work on the subject. HERMANN LAUTENSACH, *Iberische Halbinsel* (1964), constitutes a comprehensive geography of the Iberian Peninsula. WILLIAM BAYNE FISHER and HOWARD BOWEN-JONES, *Spain: An Introductory Geography* (1966), is a general manual. EDUARDO HERNANDEZ-PACHECO, *Fisiografía del solar hispano*, 2 vol. (1955–56), gives an extensive account of Spanish physical geography. ADOLPH SCHULTEN, *Iberische Landeskunde. Geographie des antiken Spanien*, 2 vol. (1955–57), is an exhaustive scholarly work on the geography of the Iberian Peninsula in early historic times.

The people: The FUNDACION FOESSA, *Informe sociológico sobre la situación social de España* (1970), is a detailed survey of Spanish society, with extensive statistical information. JULIO CARO BAROJA, *Los pueblos de España. Ensayo de etnología* (1946), is a well-documented account of the development of the Spanish people, from prehistoric times to present-day ethnological regions.

The Economy: A general survey in English of the Spanish economy is GEORGE HILLS, "Spain Under Franco: The Economic 'Miracle' 1959–67," in his *Spain* (1970). The Organization for Economic Cooperation and Development publishes occasional economic surveys of Spain in several languages, which contain much basic information. RODNEY H. MILLS, *The Spanish "Miracle": Growth and Change in the Spanish Economy, 1959 to mid–1965* (1966), is a staff economic study for the Board of Governors of the Federal Reserve System. BUSINESS INTERNATIONAL, S.A., *Spain in Transition: Patterns of Growth, 1968–1971* (1968), is a survey for business readers. RICHARD HUMBERT, *Spain* (1970), is a similar study published by the United States Bureau of International Commerce.

Transportation: Las Obras Públicas (annual), an account of the activities of the Ministry of Public Works for the year; INSTITUTO NACIONAL DE ESTADISTICA, *Primera Encuesta Nacional sobre transporte de mercancías por carretera* (1970), contains the results of a survey made during 1969 on highway goods transportation; JOSE IGNACIO RAMOS TORRES and MARCOS MARTIN BLANCO, *El Transporte en España: Organización y magnitudes económicas* (1966), a study of the Spanish transportation system, with emphasis on economic and legal aspects; COMISARIA DEL (II) PLAN DE DESARROLLO ECONOMICO Y SOCIAL, *Transportes* (1967), and official analysis of the evolution, problems, objectives, investments, and operations of the Transport Division.

Administration and social conditions: Anuario Político Español (annual), a nonofficial publication, political in nature, that examines social and economic questions; MINISTERIO DE EDUCACION Y CIENCIA, *La Educación en España: Bases para una política educativa* (1969), the so-called "White Book," which outlines in detail the measures to be carried out in compliance with the General Education Law of 1970; INSTITUTO NACIONAL DE ESTADISTICA, *Encuestas de presupuestos familiares* (1970), contains the results of surveys on Spanish family budgets made in 1967 and 1968; RODRIGO FERNANDEZ-CARVAJAL, *La Constitución Española*, 2nd ed. (1969), a well-ordered explanation of the basic principles of the Spanish constitution; SERVICIO INFORMATIVO ESPANOL, *Leyes fundamentales del Estado* (1967; Eng. trans., *Fundamental Laws of the State: The Spanish Constitution*, 1967); *Informe económico* (*Economic Report*), a general review of the economy issued annually by the Bank of Bilbao, containing interesting information on prices and salaries; FUNDACION FOESSA, *Informe sociológico sobre la situación social de España* (1970), detailed, if dense, itemized statistical information; MINISTERIO DE LA GOBERNACION, *Legislación electoral española* (1971), a legislative handbook on the Spanish electoral system; RAMON MARTIN MATEO, *Manual de derecho*

administrativo (1970), a complete summary of the Spanish system of administration; *Plan Nacional de la Vivienda: 1961–1976* (1962), an explanation of the 15-year National Housing Plan; "La Vivienda," in *El Gobierno informa*, vol. 2 (1964), an official document of housing program history.

Cultural life and institutions: *Anuario de la radio-televisión española* (annual); CARLOS AREAN, *1971: Balance del arte joven en España* (1971), a brief treatment of the most recent tendencies in Spanish art, architecture, painting, and sculpture; ANIBAL ARIAS RUIZ, *La televisión española* (1970); JUAN ANTONIO GAYA NUNO, *Historia y guía de los museos de España*, 2nd ed. (1968), an excellent overall view of Spanish museums; and the same author's *La pintura española del siglo XX*. (1970); JUAN JOSE TOMAS MARCO, *Música española de vaguardia* (1970); DIRECCION GENERAL DE BELLAS ARTES, *Museos y colecciones de España* (1969).

(M.Me./E.L.O.M.)

Spain, History of

This article traces the history of the Iberian Peninsula from prehistoric times to the present. Portuguese history from the establishment of the independent monarchy in the 12th century AD is treated in PORTUGAL, HISTORY OF.

This article is divided into the following sections:

I. Spain to *c.* AD 500
- Pre-Roman Spain
- Roman Spain
- Visigothic Spain to *c.* 500

II. Christian Spain, *c.* 500–1479
- The Visigothic kingdom
- Christian Spain from the Muslim invasion to *c.* 1260
- Christian Spain, *c.* 1260–1479

III. Muslim Spain
- Political history
- Social and economic life
- The culture of Muslim Spain

IV. Spain from 1479 to 1700
- United Spain under the Catholic kings
- Spain under the Habsburgs

V. Spain since 1700
- The early Bourbons, 1700–53
- The reign of Charles III, 1759–88
- Charles IV and the French Revolution
- The French invasion and the War of Independence, 1804–14
- Ferdinand VII, 1814–33
- Isabella II, 1833–68
- The Revolution of 1868 and the Republic of 1873
- The restored monarchy, 1875–1923
- Primo de Rivera (1923–30) and the Second Republic (1931–36)
- The Civil War
- Franco's Spain, 1939 to present

I. Spain to c. AD 500

PRE-ROMAN SPAIN

Prehistory. The earliest human fossils found in the Iberian Peninsula are those of Neanderthaloid men, dating from about 200,000 BC, whose remains have been discovered at Gibraltar, Játiva (Valencia), and Bañolas (Gerona). But utensils found in Algeciras, Madrid, the Provincia de Soria, Lisbon, and elsewhere point to the existence of even earlier habitation. This indirect evidence suggests that the peninsula was inhabited as early as 500,000 BC. The most important sites are the camps of elephant hunters found at Madrid, Torralba, and Ambrona (Soria), where many animal bones have been discovered. The Neanderthaloids and other pre-*sapiens* disappeared with the last glaciation, when Old Stone Age (Paleolithic) cultures advanced in the peninsula.

The Paleolithic period

One of the most remarkable achievements of the Upper Paleolithic was in the realm of art. The famous Paleolithic cave paintings found at such sites as Pindal, Peña de Candamo, Castillo, El Pendo, Pasiega, Ribadesella, Altamira, and elsewhere in the peninsula represent a broad historical period extending roughly from 25,000 to 10,000 BC. The animals depicted in the paintings are cold-weather varieties—bison, bulls, horses, goats, wild boars, bears, lions, mammoths, reindeer, rabbits, and seals.

The transition to the Neolithic Period coincides with a climatic change the full effects of which came about gradually (beginning around 10,000 BC) and drove the food animals northward. The archaeological deposit at Muge, near Lisbon, undoubtedly belongs to the beginnings of this age, which, in its early stages, is sometimes called Mesolithic. Deposits of great quantities of ocean and river shells, Crustacea, and the remains of birds, fish, oxen, and swine attest to the diet of these early Neolithic men. In Santimamiñe (Vizcaya), a similar economic pattern is found. There are also two important cave sites near Valencia: at Las Cuevas del Oro and at Dos Aguas. At the height of the Neolithic Period, approximately between 4000 and 3000 BC, rock painting flourished in the region of the Levantina, appearing in the open air, sheltered by rock overhangs. Many isolated animal figures are depicted, but human beings are also seen, comprising narrative scenes of hunting, herding, dancing, fighting, and even honey gathering from a hive located on top of a rock. The figures are small and exhibit considerable movement and vitality. The men are shown using bows, and the women usually appear wearing only a long, bell-shaped skirt. The Neolithic Period in western Europe, however, lagged far behind that of the eastern Mediterranean. In the West, cave dwelling persisted, and although agriculture and husbandry were known, their practice was only minimal. Settlements were quite rudimentary, being no more than simple groupings of shelters. This was an exclusively coastal culture and did not extend inland.

The age of metals

The Neolithic came to an abrupt end around 2500 BC with the beginning of the use of metals in the south. It was at this time that the first large population centres were formed, along with monumental burial sites; it was at this time also that agriculture, cattle raising, mining, and metallurgy (beginning with copper, then bronze) underwent a period of extraordinary development. It appears that these arts may have been brought from the Aegean, not, however, as the result of an invasion but apparently as the result of a sporadic penetration of "technicians." Concurrently, maritime trade flourished, thereby explaining the presence of artifacts from all over the Mediterranean, among them ivory, turquoise, kallaite, obsidian, and amber (perhaps from the Baltic). The new economy brought forth a new social organization, founded in a type of monarchy, the support of which came from an aristocracy based on wealth, who lorded it over a more or less enslaved population. This culture, the Almería, ranged over the south of the peninsula, from Algarve to Cabo de la Nao and from the Strait of Gibraltar to the Tagus River, extending inland in the Levantina and the Meseta Central. The high point in the development of this culture was reached between 3000 and 2000 BC. The best known centres were those in the southeast (Almizaraque and Los Millares) and in the southwest (Vilanova de San Pedro and Zambujal). Settlements with round or oval houses were built on fortified hilltops, indicating a life of constant danger. In Los Millares, the people of the Almería culture raised wheat, barley, millet, rye, lentils, chick-peas, grapes, and olives; as domestic animals they had sheep, swine, oxen, horses, and dogs. Among their usable plants were linen and cotton for fabrics and esparto for baskets, shoe soles, ropes, and nets. At the same time, copper was being used. Contemporary with Los Millares was the mining centre at Almizaraque, where copper and silver were processed, as evidenced by crucibles and slag heaps found next to the mines. This was the culture that built large megalithic burial vaults with corbel-arched ceilings. These tombs are entered from the outside by a tunnel and are covered by a cone-shaped mound. Tombs of this type are found at El Romeral (Antequera), Matarrubilla (Seville), and Soto (Huelva), and there are partial remains at Alcalar (Algarve). In contrast, the dolmen at Viera (Antequera) consists of a rectangular chamber, and the famous "cave" at Menga (Antequera) is slightly oval. The latter is the most remarkable monument of its kind. In its construction, 31 enormous stone slabs were used, weighing a total of 1,600 tons. The flat roof was supported by three thick pillars. The dolmen culture spread through the rest of the peninsula and through Europe, giving rise to distinct dolmenic "provinces" in the central and Atlantic zones. These cultures also reached Italy, Corsica, Sardinia, and

North Africa. Accompanying this expansion was an excellent ceramics industry characterized by campaniform, or bell-shaped, utensils, incised with geometric designs.

El Argar culture

Toward the beginning of the 2nd millennium, in the same region (Almería), El Argar culture appeared, in which the metallurgy of bronze, silver, and gold notably flourished. This industry was no longer in the hands of foreigners but constituted instead a native enterprise that produced for domestic consumption (weapons, jewelry, utensils) as well as for trade abroad. The result was a lively trade with other centres in the eastern Mediterranean. But there were substantial differences from previous cultures: dwellings had a rectangular floor plan, and the dead were buried individually in baskets or large urns beneath the floors of the houses, not in collective vaults, as in the previous epoch. Villages continued to be built on hilltops and were well fortified. Governed by kinglets or princes who were supported by an aristocracy, this culture, which at first was limited to the southeast, spread throughout the southern, the central, and the Levantina regions and reached the Balearic Islands. Its apogee came roughly between 1700 and 1000 BC. It was around this time that the kingdom of Tartessus appeared, along with the first Phoenician and Greek colonies.

Tartessus. Near the beginning of the 1st millennium, Spain entered written history. Passages in the Bible and in Greek and Latin texts refer to Tartessus (biblical Tarshish), an important centre of trade, especially in tin. The Tartessians were by this time sailing the Atlantic, southward along the African coast as well as northward in search of tin in the northeastern part of the peninsula and in the Cassiterides Islands (Scilly Islands). With this supply of tin and with the copper found around Huelva, a strong bronze industry developed that was mentioned by the Greeks. The Tartessians had a writing system, and while inscriptions have survived, they have not yet been translated. They also had a literature, but nothing of it remains. Their government was a hereditary monarchy, and while the names of several of the Tartessian kings are known, only one, Arganthonios, has historical status. Arganthonios, who reputedly lived 120 years, died in the middle of the 6th century BC, shortly before the Battle of Aleria (Alalia *c.* 540), whereby the Carthaginians gained control of the Mediterranean. His friendship with the Greeks and with the Phocians, to whom he loaned money to fortify their city against the Persians, brought reprisals against Tartessus by the Carthaginians. The exact location of Tartessus has yet to be established, and even the ancient writers themselves were in doubt about it. All that can be said at present is that it was undoubtedly situated along the coast between Huelva and the Strait of Gibraltar, perhaps in the direction of the mouth of the Guadalquivir or the Guadalete rivers.

Arganthonios

Phoenician colonization. Textual sources reveal that Phoenicians from Tyre (Sūr, Lebanon) arrived on the peninsula shortly before 1100 BC, the traditional date of the founding of Gadir (Cádiz). This date, established by the Greek philosopher Poseidonius in Cádiz itself, is historically acceptable, though some historians place the Phoenician landing in the 8th century. The Phoenicians were attracted by the thriving trade in metals at Tartessus, the flourishing agriculture of Andalusia, and the rich fishing business of the coast that stimulated such allied industries as preserving, salt evaporation, and the extraction of purple dye from shellfish.

The Phoenician colonies founded after Gadir were Baria (Villaricos), Abdera (Adra), Sexi (Almuñécar), and Malaca (Málaga), all of which minted their own coins, although not until relatively late. Many processing and preserving plants for fish were established along the entire southern coast, and scattered agricultural centres were established inland. Ibiza was founded as a fishing colony by the Carthaginians in 654, though the dates of the founding of the rest of the colonies are not known. There is no definite information about Cádiz from before the 6th or 5th centuries. Hoards of jewelry and a human-shaped sarcophagus in the Phoenician style have been found in graves there, but nothing remains of the great Temple of Melqart (Hercules), and many other monuments have been lost to the destructive action of the sea along the Cádiz coast. At Baria many artifacts have been found, along with great numbers of painted ostrich eggs. Ibiza's many underground chambers at Puig des Molins have yielded terra-cotta objects, necklaces of glass paste beads, and Greek vases. Important statues of Tanit have been found in the temple at Cuyram, and terra-cottas of a very primitive type have been uncovered at Isla Plana. But the most spectacular finds have been made at the necropolis at Sexi, where Egyptian alabaster amphorae, dating from the 10th century, have been found in tombs from around 700 BC. Inland, engraved combs have been found in tombs at Carmona and Osuna; also important are the treasury found at La Aliseda (Cáceres) and at Sines and the many series of bronze pitchers found all over the western part of the peninsula, from the Strait of Gibraltar to the interior of Castilla (Castile). All the artifacts date from the 7th century BC.

After the fall of Tyre to the Assyrians, the Phoenician colonies were taken over or protected by the powerful Phoenician daughter city of Carthage in North Africa. The Carthaginians quickly turned the resources of the peninsula to the task of creating a staging area for attacks against Rome. Hamilcar landed in Spain in 237, taking possession of the entire south and southeast of the peninsula, where he founded Akra Leuke (Alicante). Shortly thereafter, Hasdrubal founded Carthago Nova (Cartagena), and Hannibal readied his attack against Rome after assuring the subjugation of the native peoples of both mesetas. In 219 Hannibal's successful siege of Saguntum (Sagunto), an ally of the Romans, precipitated the Second Punic War (see PUNIC WARS). The Carthaginian conquest of Spain provided the Carthaginians not only with the silver necessary to finance the wars but also with a nearly inexhaustible supply of mercenary soldiers. Hannibal crossed the Alps in 218, attacking the Romans on their home ground. But even as Hannibal ravaged the Italian peninsula, the Romans attacked the Carthaginians in Spain. In 218 the Roman general Publius Scipio landed at Emporia and achieved a temporary success. In 210, Scipio Africanus, the son and namesake of Publius Scipio, took command and won a series of brilliant victories. Scipio first took Tarraco, then Carthago Nova (209), and after a victory at Ilipa (Alcalá del Río, near Seville), he overran Cádiz (206), marking the end of Carthaginian domination in Spain.

The Punic Wars

Greek colonization. Thanks to the greater number of written accounts, much more is known about the Greek colonization. In the 9th and 8th centuries, Greeks were sailing the coasts of the peninsula, and their explorations paved the way for the subsequent arrival of the Phocians. According to the Greek historian Herodotus, the first Greek to reach Tartessus was Colaeus of Samos in the mid-7th century. As early as the 7th century, the Phocians founded Hemeroscopium (near Denia) and Mainake (near Málaga). These colonies maintained close contact with the Tartessians, whose king, Arganthonios, protected and aided them. It was probably also at this time, or shortly thereafter, that Meidakritos, Euthymenes, and Euphemus of Caria sailed along the Spanish coast. Toward 600 BC, the Phocians founded the city of Massilia (Marseille), opening the way for new settlements in the northeast. Emporiae (Ampurias) appeared at this time, and the Rhodian colony of Rhodae (Rosas) was populated by Phocians. Both cities minted their own coins, beginning in the 5th century. The Battle of Alalia (*c.* 540) brought not only the fall of the kingdom of Tartessus but also the collapse of the Greeks' two southernmost colonies, Mainake and Hemeroscopium. Later, with the arrival of Greeks from Sicily and Magna Graecia (southern Italy), contacts with the northeastern coast of Spain were re-established, and there followed the founding of Alonae (Benidorm?) and other trading centres. Of these colonies, only one, Emporiae, has been identified and excavated. Artifacts found there date from the end of the 7th century, and among them are abundant ceramics, representing all Greek styles, along with terra-cottas, figured bronzes, and coins. The most outstanding piece of sculp-

ture is a large marble statue of Asclepius, dating from the 4th century. Few Greek inscriptions, however, have been found. Only the above-mentioned places are referred to as colonies, but textual evidence reveals a considerable number of Greek place names, all of them along the coast, which must refer to trading posts or even smaller population centres. Active trading flooded the Spanish coasts with Greek products. From the Pyrenees to the mouth of the Tagus, great numbers of Greek ceramics have been and continue to be discovered, ranging in date from the 7th century to the Hellenistic era. Many bronze statues, some of them quite large and dating as far back as the 6th century, have also been found, as well as two ancient Greek helmets, also made of bronze. Finally, coins from throughout the Greek world, from Massilia to the Crimea, have also been discovered. These coins span the entire period from the earliest mintings up until the Alexandrine era, with those from Greece, Sicily, and southern Italy in particular abundance.

The Iberians. The broad designation of Iberian culture is generally applied to the civilization that grew up in the south and east of the peninsula during the five or six centuries prior to the birth of Christ. The designation Iberian is derived from the usage of contemporary classical writers. From Neolithic times forward, there were no cultural changes that necessarily imply any change in the ethnic composition of the peninsula. The only important outside influences that brought about any change are those from the East, beginning with the Punic and, later, the Greek settlers. It may be assumed, therefore, that the Tartessians and other peoples who inhabited the Mediterranean coast of Spain were descended from the Neolithic and Chalcolithic peoples of the peninsula, whose direct ancestors may have been closely linked to prehistoric peoples who inhabited "white Africa" from the Red Sea to the Atlantic and the Canary Islands. During the 1st millennium, the ancient Iberians, the creators of the great cultural centre of Tartessus, were subject to the pressure of the Greek and Phoenician–Carthaginian colonization. These maritime influences gave rise in later years to a singular and progressive culture that may quite correctly be called Iberian.

Origins of the Iberians

Iron was in widespread use among the Iberians, who developed a complex economy based on agriculture, stock breeding, fishing, industry (mining, metallurgy, weapons, jewelry, preservatives, textiles, ceramics, thrown pottery), and including general commerce, both domestic and foreign. Cities grew apace, and almost all of the Iberian cities mentioned by ancient writers were highly developed before the Roman conquest. Houses were rectangular in shape. Cremation was universally practiced, and cemeteries often contain rich furnishings, such as Greek vessels, Punic artifacts, damascene weapons, and native pottery. Political organization was monarchical, with a king, princes, and dukes assisted by a council of elders. But there were also popular assemblies in times of stress. In general, these kings were politically independent, although sometimes a single king controlled many cities in military alliance. The Iberians possessed written laws, apparently in verse form, and were highly accomplished in several of the arts, including music and the dance.

Cities were built on well-defended hillocks; individual houses, with straw roofs, were made from rubblework and molded adobe bricks. To judge from the large stone cellars that have been found in Andalusia—in Tutugi (Galera, Granada), Tugia (Toya, Granada), Basti (Baza, Jaén), Almedinilla, Iponuba (Baena, Córdoba)—there must have been public buildings of monumental dimensions, although nothing remains of them. Stone sculpture shows a strong early Greek influence, attested to by the sphinxes found at Agost and El Salobral, the androcephalic bull from Balazote (Albacete), and griffins like the one found at Redován. Temples, particularly those at Albacete, have yielded hundreds of large human figurines, both male and female, in both standing and sitting positions. In general, these are votive statues, used to ward off evil. Among them, the most important are several heads, parts of full-length figures, and the "Gran Dama Oferente" from the Cerro de los Santos. Above all, there is the famous bust of the "Lady of Elche," apparently of late date, perhaps from the 1st century BC, adorned in gold.

The "Lady of Elche"

It is known that large-scale mural painting was practiced, depicting scenes of hunting, fishing, warfare, and civil ceremonies, but only scant indications of its existence have survived. Some idea of what it was like may be seen in the painted ceramics from Azaila, Numantia, and Liria. This thrown pottery, of excellent workmanship and exhibiting a surprising variety of forms, first appeared with decorations consisting of simple straight-line and circle designs and geometric motifs. But in its final period, corresponding with the wars of resistance against the Roman conquest in the 2nd and 1st centuries BC, this ceramic art was characterized by the depiction of narrative scenes embracing a great variety of decorative motifs, ranging from war and large game hunting to domestic or popular scenes, such as processions, dances, and the earliest known bullfights. These scenes were rendered in a somewhat childlike linear style but with considerable narrative strength. Iberian ceramics were exported to southern France, Liguria, central Italy, Sicily, and North Africa in the 1st century.

Iberian silverwork and goldwork was exceptionally rich; silverwork predominated in the fashioning of vases, paterae (earthenware drinking saucers), and jewelry. Decorative patterns were inlaid on weapons, dishes, and the like, and at times Iberian inscriptions were added. The most important known Iberian treasures are those of Tivissa (Tarragona), which include a beautiful set of dishes, its various pieces nielloed, or engraved, with religious themes. Other Iberian treasures have been found at Abengibre, Salvacañete, Mogón, and Santisteban. Outstanding pieces of goldwork were found in the treasure of Santiago de la Espada (Jaén) and are similar to the jewelry worn by the "Lady of Elche."

The Iberians developed early a system of writing. The Iberian alphabet has an older (6th–5th century) Western phase called Tartessian and a derived Eastern phase called Iberian. There are both Greek- and Phoenician-derived letter forms in the 28-character alphabet, most of which is of unknown origin. Many inscriptions exist, but few words—except place-names on the coinage, struck by many cities in the 3rd century—can be read. No bilingual inscriptions have been found. The Iberians retained their writing system until the Roman conquest, when the Latin alphabet came into use.

The Iberian language

The Celts. While the Iberian culture of the south and the east flourished under the influence of colonizers from the eastern Mediterranean, in the central and western parts of the peninsula, the cultural level was still quite primitive and rooted in the Copper and Bronze ages. But the 9th through the 8th centuries witnessed the gradual and peaceful penetration of the peninsula by peoples from across the Pyrenees from central Europe. These peoples, named Celts by Greek and Roman writers, were primarily herdsmen and agriculturalists—and they were able to smelt iron. In spite of constant reinforcement from new migrations, these people were often absorbed into the native population. This gave rise in a mixed people known as the Celtiberians. In other cases, the native cultural identity was erased almost in its entirety and was supplanted not only by Celtic customs and beliefs but also by the Celtic language, as is attested by the vast number of place-names and family names in certain areas. This new culture never reached the level of the coastal Iberian culture. The Celts did not have their own system of writing; they did not strike coins; nor did they practice sculpture or painting. The Celts did, however, excel in pottery techniques and in ornamental design, characterized by elaborate geometrical patterns. Their weapons and jewelry were exceptionally well made, always from gold (bracelets, torques), and they had mastered such difficult techniques as damascene. The round-shaped dwelling was replaced by the rectangular floor plan. But in the northwest (Galicia, Asturias, and the north of Portugal), the Celtic culture remained virtually unaffected by the native culture it encountered. The houses con-

tinued to be built with a circular floor plan, and the dead were buried beneath the floor of the dwellings themselves, reminiscent of the prehistoric cultures found at Los Millares and El Argar, and they continued in this area, at least with respect to the round floor plan, until well into the Middle Ages and are even found surviving today, although only in remote areas. This "Round House Culture" is also referred to as the "Castro" culture, after the arrangement of towns on fortified hilltops.

ROMAN SPAIN

The conquest. Scipio's landing in Emporia (218) during the Second Punic War began the Roman conquest of Spain. The Carthaginians were expelled by 206, and over the next two centuries the Romans, against a grudging and stubborn resistance, extended their hegemony over the peninsula. It is significant that in the same year that Cádiz fell, Italica, the first Roman settlement, was established there.

Native uprisings

The harshness of the Roman conquest provoked a large-scale uprising among the Lusitanians (Lusitani) and the Celtiberians that threatened Rome's hegemony in the peninsula. But Rome's vast resources and its superior command ended, first, with the assassination of the rebel leader Viriathus (Viriato) in 139, and, later, with the siege of Numantia, which fell only after a lengthy resistance that required Rome to use 60,000 men against a city of only 4,000 (133). The presence of Scipio Africanus, the adopted son of the Scipio who defeated Hannibal, was even called for before the city fell at last. In 138 the Romans arrived in Galicia (Gallaecia), in 121 they landed in the Baleares (Balearic Islands), and in 105 they drove out the Cimbrians and the Teutons who had made their way into the peninsula.

Early in the 1st century BC, political wars between Marius and Sulla in Rome brought about the revolt of Sertorius, who was on the verge of creating in Spain an independent state, having organized the native populations along Roman lines and having fought successfully against Metellus and Pompey. But the war became lengthy, and rivalries began to erode the original enthusiasm for the cause. The assassination of Sertorius allowed Pompey the final victory in this civil war in 72. The wars between Caesar and Pompey also had their repercussions in Spain. The Battle of Ilerda (Lérida), in 49, gave Caesar his decisive victory and put all of Spain into his hands. But Pompey's cause had many followers in Baetica (Pompey had died in 48), and Pompey's sons Sextus and Gnaeus took refuge there after the defeat at Thapsus (46). With the remaining members of the defeated armies in Spain and many partisans, they were able to build a powerful army. But the sudden arrival of Caesar put a quick end to this dangerous faction in the Battle of Munda (45), where Caesar won a decisive victory. Gnaeus died while fleeing, and Sextus succeeded in escaping from Spain. The armies in these civil wars were made up for the most part of Spaniards, either as legionnaires or as auxiliaries. This fact, along with the great zeal among the adherents to either side of the issues, is evidence of the intense Romanization that had taken place in much of the country.

The Cantabrian War

The final stage of the Roman conquest was the Cantabrian War (29–19 BC) launched by the emperor Augustus. The assault on the Cantabrian mountains was carried out from three bases of operations: Segisama, for the eastern sector (Santander); Asturica, for the central (Asturias); and Bracara Augusta, for the western (Galicia). Seven legions participated, which, along with auxiliaries, amounted to some 70,000 men. The Emperor himself accompanied these forces, aided by the generals Agrippa, Carisius, and Antistius. A naval squadron kept watch on the coast. After the Cantabrian War, the whole of Spain was under Roman domination, and peace was interrupted only by events occurring outside the country.

One such occurrence was the revolt of Galba against Nero in AD 68. The uprising was begun by Vindex in Gaul, but the central figure was Galba, at that time governor of Tarraconensis. From that time on, the Roman legions took more responsibility than the Senate for naming the emperor, and they no longer took into account the place of the emperor's birth or his social class. The 2nd-century Roman emperors Trajan and Hadrian, both born in Spain, were the first two emperors of provincial origin to be elected by the Senate. An event of great importance during this time was the Moorish invasion of 172–175. Armies of Moors crossed the Strait of Gibraltar, invaded Baetica and Lusitania, and laid siege to Singlia Barba and Italica. At the end of the 2nd century, struggles took place for succession to the throne after the death of Commodus. Supporters of Albinus rallied part of the auxiliary forces of the Seventh Gemina Legion (Legio VII Gemina), then quartered in what is now León, against Septimus Severus. Around the middle of the 3rd century the Franks entered Spain, took Tarraco, and, after crossing the Strait of Gibraltar, drove into Mauretania, where they were dispersed.

Administration. The Romans first divided provincial Hispania into two sections, Ulterior and Citerior, but this arrangement underwent certain alterations by Augustus,

From F. Lot, *The End of the Ancient World;* Routledge & Kegan Paul Ltd., London (published in the U.S. by Barnes & Noble, Inc.)

Spain at the end of the 4th century AD.

The provinces

who created three provinces: Hispania Tarraconensis, Hispania Baetica, and Hispania Lusitania. Their respective capitals were in Tarraco (Tarragona), Corduba (Córdoba), and Emertia Augusta (Mérida). In the late 3rd century, Diocletian made Spain into a single diocese and subdivided Tarraconensis into three new provinces: Tarraconensis, Carthaginiensis (along with the Baleares), and Gallaecia. In addition, he joined to the Diocesis Hispania the new Provincia Mauretania Tingitana (Tingis: Tanger), which took in all of northern Morocco. Of the three Augustan provinces, Baetica, which was considered pacific, had senatorial status and was administered by the Roman Senate through a proconsul. There were no occupational troops in such a province. The others were "imperial" provinces and were thus governed through delegates appointed by the emperor and were controlled by occupational troops.

Justice was administered through *conventus juridici.* Baetica had four such administrative districts: Astigitanus, Cordubensis, Gaditanus, and Hispalensis. Tarraconensis had seven districts: Tarraconensis, Caesaraugustanus, Carthaginiensis, Cluniensis, Asturicensis, Lucensis, and Bracaraugustanus. Lusitania had three: Emeritensis, Scalabitanus, and Pacensis. There were thus a total of 14.

Roman forces in Spain

Complete information is not available concerning the exact numbers and the composition of the forces that Rome sent into Spain during the conquest. Some 30,000 men, not including the native auxiliaries, took part in the battles of Viriathus and Numantia. With Augustus' reign, the record is more precise. In the Cantabrian War about

40,000 legionnaires were used; when joined by auxiliaries their number reached a total of about 70,000. With the wars over, the legions were slowly withdrawn, so that around the middle of the 1st century AD only one legion remained. It was later replaced by another one whose permanent base (garrison) was León.

The peninsula supplied the Roman Army with great numbers of auxiliaries in the first century of the empire. Somewhat more than 100 units, alae and cohorts, were composed of men recruited from the least Romanized regions of Spain—Lusitania, the far north, and the northern *meseta*. The majority of them saw action on the Rhine and Danube fronts, although they also fought in Britain, North Africa, and the East.

The decisive factor in the Romanization of Spain was the extension of Roman citizenship. At first colonists of Roman or Italian origin living in Roman colonies in Spain were considered citizens. These colonies were established chronologically as follows: seven were created before Caesar, six during his reign, and three between Caesar and Augustus. Fourteen colonies were then founded by Augustus himself, and four between Augustus and the Flavians. Geographically, the colonies were distributed in the following manner: 12 in Baetica, 16 in Tarraconensis, and five in Lusitania; that is, a total of some 33 colonial seats of government, including some that did not receive the official designation of "colony." It must be noted that the colonization did not follow a studied plan but was determined instead to a great extent by the availability of suitable expropriated territory. In the area where the most conflicts developed (the civil war between Pompey and Caesar, in particular), more punitive action was taken against certain cities, and, consequently, there was in these places more *ager publicus* ("public land") to be distributed among the Roman legionnaires. The total number of Roman colonists may have reached 60,000. But since transient natives of the peninsula could in various ways also obtain Roman citizenship, the total increased by a considerable number. At the beginning of the empire, there were already 24 municipalities of Roman citizens and 48 cities under the *jus Latii* (Latin right). When these figures are added to those for the 33 colonies, there is a total of 142 cities under Roman law, with a population that may have reached 250,000 to 300,000.

Cities

Beyond this there still remain, however, nearly 300 cities and great numbers of non-Romanized people who are not accounted for. The complete Romanization of the Hispanic territory was not achieved until the Edict of Vespasian (74), which extended rights of the empire to all those Spaniards who did not previously have them. The rest of the empire had to wait until the Edict of Caracalla (212), which made Roman citizens of all persons in the empire.

These political advances were accompanied by great steps forward in the process of urbanization. In Tarraconensis, the western borders of which were very little urbanized at the time of Augustus, there were 293 settlements, 179 of which had a capital and 114 of which were rural. A century and a half later, the number of cities had risen to 248, an increase of 69; and the number of rural localities had fallen to 27, a decrease of 87.

Society and culture. Native languages (Iberian and Celtic), and the Greek and Phoenician that were still spoken in what had been their colonies, had virtually disappeared by the end of the 1st century BC, at least in Baetica and in the important cities and Romanized provinces. Languages spoken in the more remote centres of population were much longer in disappearing, and Basque survives even into the 1970s as an example of one of the pre-Roman tongues of the peninsula. It can be said, however, that by the time of Caesar, Latin was the universal language for the cultivated citizens of the peninsula, and there soon developed a native Hispano-Roman literature.

Religion in the Roman period

With regard to religion, in addition to the gods and minor deities of the Roman pantheon, who were quickly identified with the gods of the native Hispanic peoples, there were also adherents of many exotic religions originating in Persia, Asia Minor, Egypt, and North Africa. The most widely practiced religion appears to have been the worship of Isis, followed by the worship of the Magna Mater. Several of these beliefs were brought into Spain before the Roman conquest (Melqart, Tanit-Caelestis, Magna Mater). The majority of the remaining ones were introduced during the empire.

There is no evidence as to how Christianity was first introduced into Spain. It is quite possible that St. Paul visited Spain at some time between 63 and 67, but it is difficult to distinguish historical fact from legend concerning the "seven apostles." It is certain, however, that in the 2nd and 3rd centuries there were Christian communities throughout the peninsula. The most reliable documents on martyrs speak of persecutions of Christians in various locations under Prudentius. Shortly before (evidently), the Edict of Milan (313) called together the Council of Iliberri (Granada), which was attended by 19 bishops and 24 presbyters. The Nicene Council (325) was directed by Osio, the bishop of Corduba. The emperor Theodosius I (379–395), a Spaniard, made Christianity the only tolerated religion in the empire. The ascetic Priscillian spread the Manichean heresy throughout the western part of the peninsula during the second half of the 4th century, and the heresy persisted into the 6th century. Besides Priscillian, other Christian writers of note were Osio, Juvencus, Prudentius, and Orosius.

Roman remains

Archaeology has brought to light numerous monuments from this era—basilicas, amphitheatres, aqueducts, baths.

Monuments to Roman construction remain in many parts of the peninsula. Roman walls are to be found in Barcelona, Tarragona, Zaragoza, Idanha, Evora, and elsewhere. Bridges stand at Alcántara, Mérida, Piedras Albas, Alconétar, Chaves, Villa Formosa, Bibey, Salamanca, and Villa del Río, and aqueducts in Segovia, Mérida, and Tarragon. The entire peninsula is crossed by Roman roads, the principal ones going from Cádiz (the Via Augusta) along the Río Guadalquiver and continuing along the Levantina coast, from Cartagena north through Valencia and Tarragona to Narbonensis. Another road follows the Ebro from Tarragona to Galicia. Roman lighthouses are found at La Coruña and Caepionis Turris (Chipiona). Sites of military encampments are at León, Numantia, and elsewhere. Castles were built at Lousa and Benavente. Carmona has a necropolis, and there are mausoleums remaining at Tarragon, Fabara, Sádaba (two), Zalamea la Real, and Jumilla. Roman palaces and villas, many with mosaics, are found at Clunia, Milreu, Italica, and many other sites.

Roman art is also abundant throughout the peninsula. Principal centres for sculpture were Barcelona, Tarragona, Mérida, Italica, and Córdoba, while the centres for portrait work were at Italica, Córdoba, Cádiz, Tarragona, and Barcelona. There remain about 40 pagan sculptured sarcophagi, originating primarily in the south, the coast of the Levantina, and the central region. Mosaic work is common in all of the peninsula, with the exception of the northwest and the north.

Spaniards of great importance in the culture of Rome were writers such as the Senecas, Lucan, Mela, Martial, Quintilian, Columella, Canius Ruffus, Decianus, and Moderatus. Trajan, Hadrian, and Theodosius were Spanish emperors, and the Balbos and Lucius Licinius Sura were statesmen of note.

VISIGOTHIC SPAIN TO C. 500

There were many precedents to the great invasions by Germanic tribes of the beginning of the 5th century. Incursions by the Cimbrians and Teutons, the Franks, the Alemanni (Alamanni), and the Ostrogoths were signs of the growing threat to the empire. On the other hand, the peaceful infiltration and coexistence of the barbarians with the Romans along the interior border zones brought about the "barbarization" of the empire on every level, even in its high command. In 401 the Visigoths, under Alaric, crossed the Alps, descended on Italy, and in 410 sacked Rome. Other tribes, made up of Suebi, Alans, and Vandals, had crossed the Pyrenees the previous year (409). After two years of turmoil and anarchy, they at

last ceased their movement, signing a treaty of alliance (*foedus*) with Rome that conceded them military settlements within the empire. The Suebi and the Asdingi Vandals settled in Galicia (Gallaecia), the Silingi Vandals in Baetica (Vandalusia = Andalusia), and the Alans in Lusitania and Carthaginiensis. Tarraconensis was occupied only after Ataulphus had been made king of the Visigoths and had invaded the Provincia, where he died the same year. The occupation of the peninsula by Germanic tribes was then complete. Wallia (415–419), through an agreement with Honorius, founded the kingdom of Tolosa in federation with Rome. With this agreement made, Wallia immediately attacked the Vandals and Alans of Andalusia and crushed them. The Vandals who survived joined with their Galician brothers and conquered Cartagena and Seville and, after sailing from Tarifa, crossed the Strait of Gibraltar under the command of Gaiseric (Genseric) and landed in North Africa (429). The Suebi, now in exclusive control of Galicia, established themselves there as an independent kingdom. They later divided the entire western region of the peninsula among their elite troops and extended their effective rule as far as the Tagus River. The kingdom of Galicia, as such, disappeared in 585.

Wallia

With Euric (466–484) the kingdom of Tolosa (Toulouse) became unified and independent from Rome. This kingdom's powers extended through the Galliae (except for the northern zone) and through the Hispaniae (except for Galicia, which continued, along with its Lusitanian possessions, to be a kingdom dependent on the Suebi). Euric was at that time the most powerful ruler in the West. He issued the first laws, which, because of the continuing predominance of Latin culture, were written in Latin, drawn up by Roman jurists, and were influenced heavily by Roman law (475). With the Alans and the Silingi Vandals having been defeated by Wallia and with the Asdingi Vandals in Africa, the only powers in the peninsula were the Suebi in the northwest and the Visigoths. Demographically and ethnically, they stood for very little, numbering only about 250,000, as compared with the 7,000,000 Hispano-Romans of the peninsula. But power was almost exclusively in their hands. They lived in relative harmony with the Hispanic people, a situation made possible largely by two great leaders, Orosius and Idatius, who strongly favoured the idea of a unified Spain under Visigothic protection.

When the Suebi and the Visigoths had arrived in Spain, they were to a great extent already Romanized; thus, there was no drastic cultural difference between the invaders and the invaded. Furthermore, for many years the Visigoths were considered allies and collaborators with the empire and, to a certain extent, its protectors. With the pact of 418, the Visigoths agreed to recognize the supreme authority of the Emperor and to submit to Roman political and administrative organization. The Visigoths arrived in Spain already bearing a certain political and social organization, although it is true that many aspects of it underwent important changes. They brought with them an elective monarchy that was assisted by a popular assembly made up of all free men who were eligible to go to war. The population of Visigothic Spain, however, was composed of two completely distinct societies. On one hand, there was the Hispano-Roman populace with its own laws, its Latin culture, and Catholic Christianity; and on the other hand, there were the Arian Visigothic invaders, who, even though they were a minority, held military power. They were ruled by a sovereign who, in theory, had authority only over his own people and not over the Hispano-Romans, since there was a code of Roman laws for these native people and a tradition of Visigothic common law for the invading people. Two-thirds of the land was redistributed into Visigothic hands, although vast territory remained unoccupied because of the scant numbers of the new colonists. A ban against marriage between Visigoths and Hispano-Romans lasted until its abolition by Leovigild (568–586). The Visigothic capital, which was originally in Tolosa, was transferred later to Toledo (Toletum) with the reign of Leovigild.

(A.G.y B.)

II. Christian Spain, c. 500–1479

THE VISIGOTHIC KINGDOM

Given their distinctive laws and customs and their profession of Arian Christianity, the Visigothic absorption by the Hispano-Roman population of perhaps 6,000,000 was not easy. Visigothic control of the peninsula remained incomplete so long as the Suebi (Suevi) maintained an independent kingdom in Galicia (Gallaecia) and the Basques refused submission to any external authority. Moreover, the Hispano-Romans in the southeast welcomed there the restoration of Byzantine rule early in the 6th century. Leovigild (568–586), the most capable of the Visigothic kings, who borrowed the Roman symbols and trappings of monarchy and ruled from a central position at Toledo (Toletum), made significant strides toward peninsular unification by conquering the Suebi and subjugating the Basques. Leovigild's attempt to convert the Hispano-Romans to Arianism, however, provoked a revolt in the southern province of Baetica under the leadership of his son, Hermenegild, who had accepted the Catholic religion. Rebel expectations of Byzantine help were unfulfilled, and so the uprising was finally crushed.

The evident futility of Leovigild's religious policy prompted his son, Recared (586–601), to convert to the Catholic faith professed by the majority of the people. His conversion, together with that of the Gothic nobles and bishops, removed one of the chief barriers to the assimilation of the two peoples. Thereafter, the Hispano-Romans, with less reason to be beguiled by Byzantium, developed a new and strong loyalty to the Visigothic monarchy. This facilitated the conquest of the last Byzantine strongholds in the peninsula during the reign of Swinthila (621–631). From then on, the Visigoths ruled over all of Spain.

Conversion of Recared to orthodoxy

The conversion also symbolized the triumph of Hispano-Roman civilization over the barbarians, and it helped to forge an alliance between the crown and the church. Realizing that the bishops were the leaders and spokesmen for the majority, the kings assumed the right to appoint them and to summon them to the Councils of Toledo. Those assemblies, though primarily ecclesiastical, had an extraordinary influence on the political life of the kingdom. After listening to the royal message describing problems of greatest concern, the prelates enacted appropriate canonical legislation as well as decrees relating to secular business, such as the election of the king or cases of treason. The bishops, in their councils, became a principal support of the monarchy, but in their quest for an ordered political regime, they lost some of their independence.

The monarchy was elective, partly because of aristocratic opposition to hereditary succession and partly because of a lack of natural heirs. Knowing the chronic Gothic tendency to assassinate the king, the bishops introduced the ceremony of anointing to give him a sacred character and to make known to all that he was under God's protection. In order to curtail the disorders attendant upon a royal election, they also elaborated an electoral procedure. The king ruled with the aid of a household (*officium palatinum*) based upon Roman models, and when important business required it, he took counsel with assemblies of magnates and other prominent persons (*aula regia*). Territorial administration was entrusted to dukes, counts, or judges. They were also responsible for the towns where self-government had long since decayed. Provinces and other administrative districts were essentially survivals from the Roman era. The economy was mainly agricultural, and there is scarcely any evidence of commercial or industrial activity.

The influence of Roman civilization can also be noted in the steady subordination of Germanic law to the law of the Hispano-Roman majority. The *Liber Judiciorum*, a code of law promulgated around 654 by Recceswinth (649–672), in both its structure and its substance gives testimony to Roman influence. Intended to have territorial rather than personal application (as was the case with barbarian customary law), it reflected a persistent accep-

The *Liber Judiciorum*

tance of Roman legal principles. Yet there are Germanic elements in the code, such as the ordeal of cold water. The *Liber Judiciorum* was one of the chief legacies of the Visigothic era and a tribute to the Hispano-Romans who were responsible for creating it.

The persistence of Roman tradition is also evident in the remarkable outburst of cultural activity in the 7th century. St. Isidore, bishop of Seville (Hispalis) from *c.* 600 to 636, friend and counsellor of kings, was a voluminous author who left his mark upon the entire medieval era. His works include a history of the Visigoths, a monastic rule, theological treatises, and, above all, the *Etymologies*, an encyclopaedic work that attempted to summarize the wisdom of the ancient world.

At the close of the 7th century, the Visigothic monarchy entered upon a critical time. The deposition, through trickery, of King Wamba (672–680), a competent ruler who tried to reform the military organization, indicated the trend of events. Numerous plots threatened his successors, who sought to blame the unrest upon the Jews, whom they tried to convert to Christianity or to reduce to slavery. Factionalism reached a climax when Witiza (700–710) died, hoping to leave the throne to his son; but Roderick, duke of Baetica (710–711), was acclaimed instead. Witiza's family apparently appealed to the Muslims in North Africa to help them overthrow Roderick. In response, Tāriq ibn Ziyād, the Muslim governor of Tangier, landed at Gibraltar (Calpe) in 711 and defeated King Roderick and the Visigoths near Río Guadalete on July 19. The conquest of the rest of Spain, left leaderless by the death of the king, followed quickly. The Visigothic kingdom perished, but its memory survived to inspire the kings of Asturias-Leon to attempt the reconquest of Spain.

CHRISTIAN SPAIN FROM THE MUSLIM INVASION TO C. 1260

The question of peninsular unity is central to the history of Christian Spain from the Muslim invasion in the 8th century to the advent of Ferdinand and Isabella in the late 15th. The Muslims destroyed what unity the Visigoths had been able to impose and introduced religious, cultural, legal, linguistic, and racial differences that impeded their assimilation by the natives. In the ensuing centuries, several Christian states emerged in the northern mountains; partly as a matter of self-preservation, partly for religious hostility, and partly to vindicate the Visigoths, they embarked upon the Reconquista (Reconquest). Their progress depended upon the strength of Muslim Spain at any given moment. In times of Muslim weakness or disintegration, the Christians usually made important gains. The kings of Asturias-Leon-Castile, eventually the largest state, aspired to dominance over the whole peninsula, but their ambitions were challenged and often thwarted by the rulers of Portugal, Navarre, and Aragon-Catalonia, which began to assume definitive form in the 11th and 12th centuries. The Reconquista was largely completed by the middle of the 13th century, with only the small Muslim kingdom of Granada (Gharnāṭah) surviving as tributary to Castile until 1492.

In the later Middle Ages, the problems of peninsular unity took on a new aspect as the kings of Castile tried to gain control of the other Christian states by marriage, diplomacy, and war. The Trastámara dynasty, which came to power in Castile in the late 14th century, consistently pursued this aim. It was achieved in part by Ferdinand and Isabella, whose marriage united Aragon and Castile. They also conquered Granada, thereby terminating the Reconquista, but their attempts to bring Portugal into a family union by marriage failed. In any case, the diversity of languages, laws, and traditions that had developed in the medieval centuries was not erased simply by the political union of kingdoms.

The Christian states, 711–1035. Christian resistance to the Muslim conquest began in the mountains of Asturias, where Visigothic nobles took refuge and joined the native mountaineers in opposing the invaders. Their leader was Pelayo (718–737), a Visigothic lord whose victory over the Muslims at Covadonga, around 722, later was hailed as the beginning of the Reconquista and the "'salvation of Spain." Under King Alfonso I (739–757), the Asturians occupied Galicia, abandoned by rebelling Berber troops who had been garrisoned there. Farther south, he laid waste the Duero River Valley, which remained for many years a no-man's-land separating Christian and Muslim Spain. In the western Pyrenees, the Basques seem to have regained their independence; and the Franks, after expelling the Muslims from Septimania, began to penetrate into northeastern Spain. Charlemagne's attempt to take Saragossa (Saraqusṭah) in 778 failed, but his forces eventually moved into Catalonia, seizing Barcelona in 801. The Franks organized this region into several counties, later known collectively as the Spanish March. For several centuries, the March was linked by political and cultural ties to the Carolingian Empire and then to the Kingdom of France.

"Salvation of Spain"

While the Catalans tended to be oriented to the north, the Asturians looked southward and under Alfonso II (791–842) cautiously moved their capital to Oviedo, where they attempted to restore the institutions of the Visigothic monarchy.

A breakdown of effective government in Muslim Spain in the late 9th century enabled Alfonso III (866–911) to cross enemy frontiers at will in search of plunder and to capture important places, notably Porto. Alfonso also began the process of colonizing the lands stretching southward to the Duero that had been depopulated for so long. On his eastern border, he erected many castles as protection against Muslim attacks, thus giving the area its name, Castile, and its distinctive character. The first extant Christian chronicles of the Reconquista were compiled during this period and sought to establish an essential continuity between the Visigothic and Asturian kingdoms. The Asturians saw themselves as the legitimate heirs of Visigothic power and tradition and consciously assumed responsibility for the reconquest of Muslim Spain. Future challenges to Asturian leadership were beginning to take shape, however, in the northeast, where a strong Basque kingdom, centred at Pamplona in Navarre, appeared under King Sancho I (905–926). In Catalonia, Count Wifred of Barcelona (873–898) took advantage of the disintegration of the Carolingian Empire to assert his independence and to secure control of several other counties. The dynasty he founded ruled in Catalonia until the 15th century.

Alfonso III

Encouraged by the expansion of the Asturian kingdom and evident Muslim weakness, García I (911–914) moved his capital southward from Oviedo to the city of León. The optimism revealed by this action was shattered during the course of the 10th century as order and unity were restored in Muslim Spain under the rule of the caliphs of Córdoba (Qurṭabah). Muslim incursions into the Christian north were resumed and caused great destruction, though from time to time the Christians achieved some successes. Ramiro II (931–951) defeated the caliph ʿAbd ar-Raḥmān III at Simancas in 939, a truly remarkable feat. Yet within his own kingdom, Ramiro was faced with the growing defiance of the Castilians, who, as frontiersmen exposed to the hazards of daily conflict with the enemy, seem to have had little use for Leonese tradition and law. Their count, Fernán González (*c.* 930–970), successfully resisted the kings of Leon and laid the basis for Castilian independence.

As the century progressed, the Christian position steadily deteriorated. Muslim ascendancy was demonstrated clearly by the procession of envoys representing Ramiro III of Leon (966–984), Sancho II of Navarre (970–994), Count Borrell of Barcelona (*c.* 940–992), and Count García Fernandez of Castile (970–995), who came to Córdoba to offer homage and tribute to the caliph. Even in these depressed circumstances, the Leonese seem to have maintained the traditional Asturian claim to the Visigothic inheritance. As a more explicit assertion of peninsular hegemony, they elaborated a concept of a Hispanic empire centred at León. The theory no doubt served to bolster morale at the close of the century when all the Christian states suffered from the scourge of al-Manṣūr, who assumed dictatorial power in the caliphate. In order to distract the Muslims from his usurpation, he

The scourge of al-Manṣūr

led armies on annual invasions of the north. In 985 he defeated Count Borrell and burned Barcelona; three years later he plundered León and many other towns.

The breakup of the caliphate following al-Manṣūr's death freed the Christian states from the threat of destruction. Count Ramón Borrell of Barcelona (992–1018) even gained a measure of retribution by intervening in the Muslim civil wars and sacking Córdoba in 1010. Alfonso V of Leon (999–1028) used the respite from war to repair his kingdom and in 1017, at a council held at León, promulgated the first general laws for the government of the realm. The cessation of Muslim attacks also encouraged a renewal of rivalry among the Christian states. For a few years, Sancho III the Great, king of Navarre (1000–35), succeeded in lording it over the rest of Christian Spain. During his reign, contacts with northern Christendom became more frequent. The pilgrimage route to Compostela, a principal avenue of French influence, was developed; the Cluniac reform of the monastic life was introduced, and feudal ideas began to affect the structure of aristocratic society. In pursuit of his own aggrandizement, Sancho III, who already held the counties of Aragon, Sobrarbe, and Ribagorza and numbered Count Berenguer Ramón I of Barcelona (1018–35) among his vassals, seized the county of Castile and threatened Vermudo III of Leon (1028–37). In 1034, Sancho occupied the city of León and assumed the title of emperor, but his triumph was cut short by his death in the following year.

The medieval empire, 1035–1157. Although Sancho III brought under his sway all the Christian states with the exception of Catalonia, he rejected the Leonese tradition of a unified, indivisible kingdom and preferred to regard his dominions as a family patrimony to be shared among his sons. Thus, he gave the kingdom of Navarre to García III (1035–54); Ferdinand I (1035–65) received Castile; and Ramiro I (1035–63) obtained Aragon, to which he added Sobrarbe and Ribagorza in 1045 after the murder of a fourth brother, Gonzalo. As each of the sons bore the royal title, Castile and Aragon were elevated to the status of kingdoms. Although Vermudo III had regained possession of Leon, he was defeated and killed in 1037 by Ferdinand I, who annexed his kingdom and took the imperial title. For the next 30 years, he aspired to domination throughout Spain, overcoming his brothers on the battlefield, conquering Coimbra, and compelling the petty Muslim rulers (*reyes de taifas*) of Toledo (Ṭulayṭulah), Seville (Ishbīliyah), and Badajoz (Baṭalyaws) to pay him tribute.

Ferdinand's contemporary Count Ramón Berenguer I of Barcelona (1035–76) was actively developing Catalan interests and relationships among the lords of Languedoc, in southern France. He also promulgated the earliest legal texts included in the compilation of Catalan law known as the *Usatges de Barcelona* ("Usages of Barcelona").

At his death, Ferdinand I followed his father's custom and divided his kingdoms between his sons, giving Castile to Sancho II (1065–72) and Leon to Alfonso VI (1065–1109). Discord promptly arose and ended only with Sancho's murder in 1072. Alfonso VI thereupon reunited the two kingdoms, but he had to swear to the Castilian nobility that he had had no hand in his brother's death. Chief among the Castilians, who now became his vassals, was Rodrigo Díaz de Vivar, known to history as El Cid Campeador. Court jealousies eventually forced him into exile, and for a time he served the Muslim king of Saragossa before becoming the protector of the king of Valencia.

Alfonso VI

The division of Muslim Spain into several small kingdoms enabled Alfonso VI to levy tribute upon them, but he decided to conquer them and in 1085 received the surrender of Toledo, the fall of which had great symbolic importance because it had been the ancient seat of the Visigothic monarchy, and its possession strengthened the king's claims to hegemony in Spain. For this reason, he called himself "Emperor of Toledo," but he also used the title Emperor of the Two Religions to emphasize his ascendancy over both Christians and Muslims. The conquest brought his frontiers to the Tagus and resulted in the incorporation into his kingdom of large numbers of Muslims and Jews, who in times past usually had withdrawn to the south in the face of advancing Christian armies. Large numbers of Mozarabs, or Arabic-speaking Christians, also lived in Toledo and its environs. The interaction among these differing religious and cultural traditions became especially intense in the ensuing years.

The fall of Toledo alarmed the other petty kings in Muslim Spain, who invited the Almoravids, a fanatical Muslim sect in North Africa, to come to their aid. The Almoravids crushed the Christian army at Zalacca (az-Zallāqah) in 1086, but they also swallowed up the petty kingdoms. The reunification of Muslim Spain kept Alfonso VI on the defensive for the rest of his reign and made further progress in the Reconquista temporarily impossible. The Cid successfully defended Valencia against the Almoravids, but after his death in 1099 his followers had to abandon the city. The Almoravids were then able to occupy the whole of eastern Spain as far north as Saragossa.

The deeper Christian involvement in the world of Islām brought about by these events was counterbalanced by the steady growth of northern European influences, especially that of the papacy. Pope Gregory VII (1073–85), who spearheaded the general reform of the church, imposed uniformity of liturgical practice by insisting upon the abandonment of the ancient Mozarabic liturgy native to Spain and its replacement by the Roman. His assertion of papal sovereignty over Spain was not admitted by the Spanish rulers, and he did not press it. In addition, French monks and clerics discovered ecclesiastical fortunes in Spain, and French knights came to participate in greater numbers in the wars of the Reconquista. Two of them, the cousins Raymond and Henry of Burgundy, married the daughters of Alfonso VI, Urraca and Teresa, and so became the progenitors of dynasties that ruled in Leon and Portugal until the late 14th century.

After Alfonso VI's death, Urraca (1109–26), now widowed, succeeded him. She married Alfonso I of Aragon, "the Battler" (1104–34), but disharmony between them kept the kingdom in constant turmoil. Alfonso I eventually retired in disgust to his own kingdom. Urraca's son by Raymond of Burgundy, Alfonso VII (1126–57), restored the prestige of the Leonese monarchy and affirmed Leonese aspirations to predominance in Spain by being solemnly crowned as emperor in the cathedral of León in 1135. This was apparently the first and last imperial coronation in Spain. Within a few years, however, two formidable challenges to Leonese ascendancy appeared in the newly formed federation of Aragon and Catalonia and in the newly independent kingdom of Portugal.

Alfonso I of Aragon, after ending his marriage to Urraca, conquered Saragossa in 1118, thus advancing his frontiers to the Ebro. Shortly after, he made an extraordinary incursion into the heart of Muslim Spain to liberate the Mozarabs of Granada (Gharnāṭah), whom he settled in Aragon. Thereafter, the Mozarabic population in Muslim Spain seems to have been negligible. When he died, he bequeathed his realms to the military Orders of the Hospital, the Temple, and the Holy Sepulchre, but his people refused to accept this. The Navarrese, who had been subject to Aragonese rule since 1076, elected their own king, García IV (1134–50), and the Aragonese summoned the dead king's brother, Ramiro II (1134–37), from a monastery to become their king. He assumed the responsibility only long enough to marry and to father a child, Petronila, who could inherit the kingdom. She was betrothed in 1137 to Count Ramón Berenguer IV of Barcelona (1131–62), who was entrusted with the administration of the kingdom. The child by this marriage, Alfonso II (1162–96), united in his person the kingdom of Aragon and the county of Barcelona, a union of peoples with different traditions, interests, and languages, which survived innumerable vicissitudes throughout the medieval era. Catalonia developed as a maritime power, interested in expansion in the Mediterranean, while Aragon, a landlocked region, remained largely agricultural, dominated by a landed aristocracy. Each region retained

its distinctive laws and institutions, and there was strong opposition on both sides to any attempt at assimilation. The term crown of Aragon appropriately describes the federation of the two territories.

The crown of Aragon

In the west, the county of Portugal, a part of the Kingdom of Leon, which Alfonso VI had given to Teresa and Henry of Burgundy, began to emerge as an independent state. Their son, Afonso I Henriques (1128–85), rejected Leonese overlordship and assumed the title of king, around 1139. In order to protect himself, he became a vassal of the papacy, pledging to pay an annual tribute; but the Pope did not explicitly recognize him as a king until 1179.

The Almoravid Empire, meanwhile, began to break up as a result of internal discord and the rise of the Almohads, another North African Muslim sect. Taking advantage of the Muslim civil wars, the Christian rulers penetrated deeply into Muslim Spain and made some significant conquests. In 1147, Afonso I, with the help of a crusading fleet from northern Europe, conquered Lisbon, while Alfonso VII and Ramón Berenguer IV, aided by Pisan ships, captured the great seaport of Almería on the southeastern coast. In the following year, the count of Barcelona seized Tortosa (Ṭurṭūshah) and Lérida (Lāridah), thereby completing the expansion of Catalonia and extending its frontiers to the mouth of the Ebro. The Almohads, however, after destroying Almoravid power, invaded Spain and reduced all the Muslim areas to their rule. In 1157 they reconquered Almería (al-Marīyah) and thereafter effectively checked any further Christian progress.

The rise of Castile and Aragon. Alfonso VII died in the same year. By dividing his realms between his sons, Sancho III (1157–58), to whom he gave Castile, and Ferdinand II (1157–88), who received Leon, he shattered the unity he had tried to impose upon the peninsula and ruined the concept of a Leonese empire. Although the Almohads kept the Christians on the defensive, Alfonso VIII of Castile (1158–1214) and Alfonso II of Aragon were confident enough of ultimate success to conclude a treaty in 1179 partitioning Muslim Spain. The territory of Valencia (Balansiyah) was reserved for Aragonese reconquest, while the rest of Andalusia fell to Castile. Rivalries among the Christian princes quickly arose, however, when Alfonso VIII tried to dominate his colleagues. Common action against the Almohads was impeded, and in 1195 they inflicted a humiliating defeat upon the king of Castile at Alarcos (al-Arak), south of Toledo. Realizing the seriousness of the Muslim threat, the other Christian kings made peace with Castile. In 1212, Alfonso VIII, supported by Sancho VII of Navarre (1194–1234) and Peter II of Aragon (1196–1213) and by contingents from Portugal and Leon, achieved a remarkable victory over the Almohads at Las Navas de Tolosa (al-'Iqāb). His triumph opened the road to Christian penetration into Andalusia, and it sounded the death knell for the Almohad Empire.

Active participation in the Reconquista was only one aspect of Aragonese policy. The king of Aragon, as ruler of Catalonia, also had significant interests in southern France, where several lords were his vassals. The Albigensian heresy was spreading through the region, however, and Peter II, while no friend of heretics, concluded that his rights there were jeopardized by the crusade launched by Pope Innocent III against them. When Peter tried to rescue his brother-in-law, the count of Toulouse, he was defeated and killed by the crusaders at Muret in 1213. His death marked the beginning of the end of Catalan ambition and power in southern France.

Advance against the Almohads

The steady collapse of the Almohad Empire in the second quarter of the century enabled the Christian rulers to carry the Reconquista almost to completion. James I of Aragon (1213–76), after a turbulent minority, conquered Majorca (Mayūrqah) in 1229. This was the first important step in the overseas expansion of Catalonia and the first great manifestation of Catalan naval power. He then began the more arduous task of conquering the kingdom of Valencia, but he was distracted briefly by the possibility of annexing Navarre. When Sancho VII died without children, the Navarrese proclaimed his nephew, Count Theobald of Champagne (1234–53), as their king, and thereafter Navarre was drawn closer to French politics. Putting aside his ambitions in Navarre, James I received the surrender of the city of Valencia in 1238 and promulgated a code of law for his new realm, which formed the third constituent element in the crown of Aragon. For the first time, thousands of Muslims were incorporated into his dominions.

In the meantime, Alfonso IX of Leon (1188–1230) was advancing southward to the Guadiana (Wādī Ānā), taking Mérida (Māridah) and Badajoz in 1230 and opening the road to Seville. Upon his death, his son Ferdinand III, already king of Castile (1217–52), by virtue of inheritance from his mother, Berenguela, daughter of Alfonso VIII, was received as king of Leon, thus reuniting the two realms for good. With their combined resources, he conquered Córdoba in 1236, Murcia (Mursiyah) in 1243, Jaén (Jayyān) in 1246, and Seville in 1248. Only the Kingdom of Granada remained in Muslim hands, but it was subject to the payment of annual tribute to Castile. For this reason and because it did not constitute any evident threat, serious attempts to conquer it were seldom undertaken in the next two centuries.

Society, economy, and culture. In the first 300 years following the Muslim invasion, Christian society and institutions developed slowly, but substantial change came rapidly in the 12th and 13th centuries. Among the reasons for this were a general rise in population, increasing contacts with northern Europe, participation in the common European growth of trade and town life, and progress in the reconquest.

By the middle of the 13th century, the kingdoms of Leon-Castile, Aragon-Catalonia, Navarre, and Portugal had attained the frontiers they were to have, with only slight modification, until the close of the medieval era. The crown of Aragon was unique among them because it was a confederation of several distinct entities: the kingdoms of Aragon, Valencia, and Majorca, and the principality of Catalonia.

The principle of hereditary succession was established early, but the idea of election survived in the acclamation of the king when he was anointed and crowned in accordance with Visigothic tradition. Peter II of Aragon was crowned in Rome by the Pope, whose vassal he became, thereby subordinating his kingdom to papal suzerainty. The king ruled with the collaboration of his household, whose chief officers were the chancellor, ordinarily a prelate or cleric responsible for the dispatch of royal letters and the keeping of records, and the *mayordomo* and *alférez* (*majordom* and *senyaler* in Catalonia), magnates whose tasks were, respectively, the management of the household and royal estates and the command and organization of the army. Magnates also served as administrators of provinces and in Castile were known as *merinos* or, later, as *adelantados*. In Catalonia, the several counts originally governed their counties in the name of the Carolingian emperors, but they became in fact independent, and by the 11th century, the counts of Barcelona established an effective sovereignty over the principality. Vicars (*vegueros*), responsible for justice, and bailiffs (*batlles*), for taxes, administered Catalan territorial subdivisions. Bishops, magnates, monasteries, and military orders often enjoyed the privilege of immunity, whereby royal officials were forbidden to enter their estates to administer justice or to collect taxes, except in case of negligence. Among the most important immunities were those of the archbishop of Compostela in Galicia and those of the military orders in the region south of Toledo.

As the old Roman concept of the state had been obscured, private and personal relationships of a feudal character had considerable influence upon the governmental and military structure. The development of feudalism was greatest in Catalonia due to its contacts with France, but in the western states it was retarded and incomplete. The Catalan nobles were vassals of the count of Barcelona, to whom they owed military and court service in return for fiefs, and they often had vassals of their own. In the west, royal vassals had the same obliga-

tions, but ordinarily they did not receive fiefs nor did they give fiefs to their vassals. The magnates, known as *ricos-hombres* (*i.e.*, rich or powerful men) in the west and as *barones* in Catalonia, usually were vassals of the king or count and served as his principal counsellors and as the backbone of the military organization. Nobles of secondary rank, called variously *infanzones, fijosdalgo, caballeros* or *cavallers*, usually were vassals of the magnates.

Inasmuch as the economy of the Christian states was mainly agricultural, the king and nobles of both ranks were landlords who derived the greater part of their income from the exploitation of landed estates. Peasants living on the estates cultivated the soil and paid a variety of rents and services to their lords. The burden fell heaviest upon the serfs (*solariegos* in Castile, *payeses de remensa* in Catalonia), who were effectively bound to the soil and denied freedom of movement. Catalan serfs, especially, were subject to abuse by their lords by means of the so-called evil usages. Leonese peasants occupying lands known as *behetrías* enjoyed the right of freely choosing their lord and of changing their allegiance as they wished, but this right was being limited in the 13th century. Peasants who were willing to accept the risks and the adventure of living on the frontier were the freest of all, and like pioneers in all ages, they developed a strong sense of personal worth and independence.

The serfs

As the Reconquista progressed, the crown encouraged the colonization of the Duero Valley by erecting fortified urban centres (*concejos*) with extensive rural areas dependent upon them. The people who settled there received charters (*fueros*) defining their liberties and giving them rights of self-government under their own elected magistrates (alcaldes). The economy of these towns was based not so much on industry and commerce as upon the raising of sheep and cattle and the booty taken by the urban militia in the wars of the Reconquista. Aragonese and Catalan towns enjoyed a lesser degree of autonomy, but the latter began to achieve a real importance as mercantile centres. The incorporation of such cities as Toledo, Saragossa, Lisbon, Córdoba, Valencia, and Seville greatly increased the urban population and contributed substantially to the development of trade and industry. Artisans appeared in greater numbers and began to organize guilds; a merchant class engaged in buying and selling on a large scale and commonly using money as a medium of exchange also emerged. The development of shipbuilding at such places as Santander and Barcelona made possible a native overseas-carrying trade.

The advance of the Reconquista also added large numbers of Muslims and Jews to the Christian kingdoms. The former, known as Mudéjares, were settled chiefly in rural areas, though there were always important Muslim quarters in the towns. The Jews lived mainly in the cities, where they were involved in trade and moneylending and were often employed as royal tax collectors. Both Muslims and Jews were permitted to practice their religions and to govern themselves according to Islāmic or Judaic law, but they were subject to the payment of regular tribute, and from time to time the Jews were assaulted by their Christian neighbours.

In view of the growing administrative, military, and economic importance of the towns, the crown summoned their representatives to meet in the royal council with prelates and nobles. In 1188 at León, Alfonso IX held the first such assembly (*curia plena*), but similar gatherings began to be held regularly in the other states in the early 13th century. Meetings of the Cortes, as these assemblies were called, served a number of purposes, one of which was to enable the king to obtain consent for the levy of extraordinary taxation to meet ever increasing financial needs caused by the expansion of royal activities and responsibilities. Parliamentary growth in the peninsular kingdoms was a manifestation of a common European phenomenon, but it is noteworthy that it occurred earlier in Spain than elsewhere.

Government of the towns

The Reconquista was also accompanied by the restoration of bishoprics or the expansion of older ones. Spain was divided ecclesiastically into five metropolitan sees: Toledo, which claimed the primacy, Tarragona, Braga, Compostela, and Seville. Papal intervention in their affairs became much more frequent in the 12th century. Monastic reforms emanating from Cluny and Citeaux in France profoundly affected religious life in the 11th and 12th centuries. Early in the 13th century, the mendicant orders, the Franciscans and Dominicans (whose founder was the Spaniard Domingo de Guzmán), spread through the peninsula. The military orders of the Temple and the Hospital, originating in the Holy Land, appeared in Spain in the 12th century, but in the second half of the century, several indigenous orders were founded—Calatrava, Alcántara, Santiago, and Avis. These knights tried to observe the monastic life, but they also provided much of the armed might responsible for the successes of the Reconquista.

The clergy were the guardians of the cultural tradition and the authors of the scant literary remains of the first centuries of the Reconquista. In the 8th century, the adoptionist controversy over the nature of the Trinity engendered many polemical works; the writings of the Mozarabs of Córdoba, Eulogius (died 859) and Alvarus (died 861), illustrate the difficulties faced by Christians living under Muslim rule. Under the influence of northern Europe, theology, philosophy, and Roman and canon law became formal subjects of study in the universities of Palencia and Salamanca, founded early in the 13th century by Alfonso VIII of Castile and Alfonso IX of Leon, respectively. The existence of the universities was problematical for some time, but eventually Salamanca attained international renown. In the meantime, a vernacular literature was developing, and around 1140 there appeared the first great epic in the Castilian tongue, *The Poem of the Cid*. The output of Spanish writers was still slim, however, though the historical works of Rodrigo Jiménez de Rada, archbishop of Toledo (died 1247), set the pattern for future generations of Spanish historians.

CHRISTIAN SPAIN, C. 1260–1479

Castile and Leon, 1252–1479. In the late medieval centuries, a power struggle developed between the kings of Castile, who sought to concentrate all authority in their hands, and the nobility, who tried to use the monarchy for their own aggrandizement. The struggle began during the reign of Alfonso X the Wise (1252–84), who is perhaps best known for the literary and scientific labours accomplished by the scholars who enjoyed his patronage. From a political standpoint, his reign ended in failure. Although he showed some interest in continuing the Reconquista and had to suppress a revolt by the Mudéjares of Andalusia and Murcia, he preferred to play a larger role upon the European scene. In 1257 he was elected Holy Roman emperor and spent most of his energy and resources in the next 17 years trying to overcome a rival candidate and to win papal recognition. His extraordinary need of money for this purpose eventually brought to a head a domestic crisis that had been developing since his first years in power.

Like his father, Ferdinand III, Alfonso perceived the need for a uniform royal law that would supersede all local and regional laws, such as the *fueros* of the towns and the Liber Judiciorum used in Leon (and translated into Castilian as the Fuero Juzgo on the orders of Ferdinand III). A code of law, known as the Fuero de las Leyes, intended to be common to the whole realm, was prepared; it was the earliest redaction of the Siete Partidas, the great code that received definitive form early in the 14th century. The new code drew heavily upon Roman law, but the King's attempt to impose it provoked outcries from the nobles and from the towns. In 1272 they forced him to confirm their traditional laws and customs and to abandon the attempt to create a single body of law for the kingdom. This disappointment was followed in 1274 by the Pope's final rejection of Alfonso X's claims to the empire. In 1275 Alfonso's eldest son and heir, Fernando de la Cerda, died, and the King recognized Fernando's son, Alfonso de la Cerda, as his successor. The King's second son, Sancho, refused to accept this decision, and, posing as the defender of the nobles against

Legal reform

the crown, took up arms against his father. An assembly of nobles, prelates, and townsmen deprived Alfonso X of his right to rule and entrusted the government to Sancho, but civil war raged until the King's death.

Sancho IV (1284–95) had to contend with domestic and foreign opposition in support of his nephew, and he was also threatened by invasion from Morocco. The latter danger initiated a long struggle to control the Strait of Gibraltar and thus to close that invasion route. The minority of Ferdinand IV (1295–1312) saw a renewal of efforts on behalf of Alfonso de la Cerda, but he was finally persuaded to renounce his claims to any share in the royal inheritance. In 1309 the King captured Gibraltar (Jabal Ṭāriq), but the Muslims recovered it a quarter century later. Disorders recurred in the minority of Alfonso XI (1312–50), but when he came of age he crushed his opponents among the nobility with great brutality. For 25 years he waged war against Granada. In 1340, with help from the other Christian states, he won a great victory over the combined forces of Granada and Morocco at Río Salado, thereby putting an end to any further Moroccan attempts to gain a foothold in Spain. Four years later he seized Algeciras (al-Jazīraha al-Khaḍrā'), but his effort to take the adjacent fortress of Gibraltar ended with his death as a victim, like so many other thousands, of the Black Death.

Conflict between the crown and the nobility flared again in the reign of Peter I the Cruel (1350–69), whose half brother, Henry of Trastámara, an illegitimate son of Alfonso XI, challenged his right to rule. To further his aims, Henry secured French support, and in 1366, with a mercenary army commanded by Bertrand du Guesclin, he was able to expel Peter from the kingdom. The King, however, persuaded Edward, the Black Prince, to assist him in regaining his throne. The combined Anglo-Castilian forces routed Henry of Trastámara at Nájera in 1367. But once the Black Prince withdrew, Henry and du Guesclin returned; they defeated and killed Peter at Montiel in 1369.

Henry II (1369–79), the first of the Trastámara dynasty, had to defend his title against his neighbours in the peninsula and to overcome domestic opposition. But he succeeded in consolidating his position and was even able to supply ships to support his French allies against the English. One consequence of the French alliance was Castilian recognition of the Avignonese pope during the Great Western Schism. The ambitions of the Trastámara family to unify the peninsula were revealed when Henry's son John I (1379–90) claimed Portugal by right of marriage. His intervention evoked the spirit of nationalism among the Portuguese, who defeated him at Aljubarrota in 1385. In the next year, John of Gaunt, duke of Lancaster, who had married Peter I's daughter, claimed the Castilian throne and with Portuguese help invaded Galicia. The campaign failed, however, and he made peace in 1388, agreeing to the marriage of his daughter Catharine to Henry III, oldest son of John I. Thus the enmity between the two branches of the Castilian royal house was laid to rest.

Avignon papacy

During the minority of Henry III (1390–1406), the nobility again tried to further their own fortunes at the expense of the crown, but when the king came of age he effectively repressed them. The long reign of his son, John II (1406–54), proved to be disastrous to the prestige and authority of the crown. Stability was maintained during his minority by his uncle, Fernando de Antequera, who acted as regent until his election as king of Aragon in 1412. Fernando's sons, Henry and John of Navarre, continued to participate actively in Castilian affairs and tried to dominate the King, but the royal favourite Alvaro de Luna had already gained ascendancy over the King and successfully resisted these intrigues. For most of the reign, he was the effective instrument of royal power, and only in 1453 was the King persuaded to be rid of him and to order his execution.

Rivalry among the nobles for influence and power was intensified during the reign of Henry IV (1454–74). Juan Pacheco, marquess of Villena, long dominated the King, but others succeeded in winning royal favour. Henry's alleged impotence caused the magnates to cast doubt upon the legitimacy of the infanta Joan, who, it was charged, was the child of the queen and of Beltrán de la Cueva, one of the King's most recent favourites. In derision, the little girl was called La Beltraneja. Henry IV disowned her at Los Toros de Guisando in 1468 and recognized his sister Isabella as heir to the throne. Villena and his followers evidently hoped to be able to control her, but they were mistaken. Although she had promised not to marry without her brother's consent, she did precisely that in 1469. Her husband was Ferdinand, son and heir of the king of Aragon. Angered by this, Henry IV tried to deprive Isabella of her rights, but when he died, she was proclaimed as Queen Isabella I (1474–1504). Afonso V of Portugal, who was betrothed to Joan (La Beltraneja), invaded Castile on her behalf, but in 1479 she renounced her claims. In the same year, Ferdinand ascended the Aragonese throne, thus effecting the personal union of Aragon and Castile.

The infanta Joan

Castilian institutions, society, and culture. The reemergence in the 13th century of the idea of the state as a public institution, partly as a result of the revival of Roman law and the rediscovery of Aristotle's *Politics*, had important consequences for the development of the Castilian monarchy. As the embodiment of the state, the king (whom the Siete Partidas described as God's vicar on earth) tended to concentrate power in his own hands. The jurists who staffed and dominated the royal bureaucracy tried to push royal claims to authority as far as they would go. The influence of Roman law, though originally opposed, grew steadily, and when Alfonso XI promulgated the Ordenamiento de Alcalá in 1348, the place of Roman law and legal procedure in the courts was assured. The royal tribunal (*audiencia*) was reorganized in the reign of Henry II, but it did not receive definitive form until the end of the Middle Ages. The tendency toward centralization also prompted the crown to intervene more frequently in the government of the towns, where rivalry among factions was becoming endemic. The urban aristocracy, originating as a class of non-noble mounted warriors, had gained control of the government and tended to exclude the lower orders from participation, while seeking the status of nobility—with its attendant exemption from taxation—for themselves. In order to repress urban conflicts, the crown began to send corregidores (governors) to supersede local governmental officials; at first this was a temporary measure, but by the 15th century it had become a permanent arrangement.

The trend toward absolutism encountered opposition both from the nobility and from the Cortes. Under pressure from the Cortes, John I in 1386 organized a royal council (*consejo real*) composed of representatives from the three estates, who would have a permanent influence on royal policy. The experiment failed, chiefly because the nobility succeeded in gaining control of the council and in the 15th century used it for their own advantage. The magnates wielded great power in the territorial administration of the realm, for they held the posts of *adelantado mayor* (governor) in Castile, Murcia, and Andalusia. Moreover, the Trastámara kings gave the magnates extensive territorial lordships as well as lordships over some of the principal towns and cities. In so doing, the crown divested itself of control of some of the major bulwarks of royal power in the past. In general, a proaristocratic mentality pervaded Castilian society in the 15th century, encouraging the usurpation of royal authority by the magnates.

The Cortes played a prominent role in the political life of the kingdom, especially from about 1250 to 1350, and again during the reigns of the first two Trastámara kings, who needed its support to consolidate the dynasty. The Cortes met frequently to give consent to taxation (*servicio*) for fixed periods and for specific purposes. Ferdinand IV was compelled to declare formally that he could not levy an extraordinary tax without consent, and John I had to allow the Cortes to audit his accounts. Petitions presented by the Cortes and accepted by the king became the law of the land. The role of the Cortes was circumscribed in the reigns of John II and Henry IV, who

The Cortes

abused the rights that the assembly had gained in the 14th century. The crown often appointed the procurators to represent the towns, and the number of towns summoned declined steadily. Many towns were not summoned because they were held in lordship by magnates who claimed to speak for them.

The Castilian economy, for the most part, remained agricultural and pastoral. Sheep and cattle grazing became extremely important as immense pasturelands were opened up in Extremadura and Andalusia. The Mesta, a national sheep-raising organization chartered by Alfonso X, wielded great influence. The manufacture of woolen cloth became an important industry in the towns, but on the whole the urban middle class was weak, and a powerful guild organization never really developed. The urban aristocracy, which had come to power in the wars of the Reconquista, was not inclined to engage in trade and crafts. A substantial maritime trade with England, Flanders, France, and Portugal was carried on by the ports of the Bay of Biscay. The Genoese maintained a large colony at Sevillé, the chief southern port, and had a great share in the carrying trade originating there.

The Black Death

The outbreak of the Black Death in the middle of the 14th century contributed to a radical decline in population and a steady succession of social and economic upheavals. In order to compel workers to accept the same wages as before the plague, Peter I enacted the Ordenamiento de Menestrales in 1351. Forty years later, social unrest vented itself in a great pogrom against the Jews, which quickly spread to many parts of the peninsula. Accepting Christianity rather than death, many Jewish converts (*conversos*) attained prominence in various aspects of public life, but they were always held in suspicion and accused of practicing Judaism in private. Deliberate attempts were made to exclude them from important positions by requiring them to prove *limpieza de sangre*; *i.e.*, that their ancestry was untainted by Jewish or Muslim blood.

Culturally, Castile was now fully integrated into western European life. Alfonso X gave great impetus to learning and to the development of Castilian as a literary language. Under his aegis, translations from the Arabic were undertaken, a "General Chronicle" of Spain was written, the Siete Partidas was compiled, and he personally gained renown as the author of the *Cantigas de Santa María*, a collection of more than 400 poems. His nephew Juan Manuel (died 1349) won lasting fame as the author of *El Conde Lucanor* (a collection of Oriental fables), the *Libro de los estados* (a treatise on social classes), and numerous other works. His contemporary Juan Ruíz, the archpriest of Hita (died *c.* 1350), who wrote the *Libro de buen amor*, ranks as one of the greatest medieval poets. Interspersed with beautiful hymns in praise of the Virgin Mary are ribald and comic poems of love. A series of royal chronicles relates the history of this period. Perhaps the best among them are the chronicles of the reigns of Peter I, Henry II, John I, and Henry III by Pedro López de Ayala (died 1407), a brilliant writer who searched for motives and who realized the importance of social and institutional developments. In the 15th century, the influence of the Italian Renaissance was being felt at the court of John II, a patron of many poets and scholars. Among them were the marquess of Santillana (died 1458), whose lyric poems have great beauty; Jorge Manrique (died 1479), whose *Coplas*, written on the death of his father, are a reflection on the vanities of the world; and Fernán Pérez de Guzmán (died *c.* 1460), whose *Generaciones y semblanzas* is a series of sketches of the characters and personalities in the court of Henry III.

Aragon, Catalonia, and Valencia, 1276–1479. The aristocratic challenge to royal power that characterized Castilian history of the later Middle Ages was also evident in the kingdom of Aragon. The growing influence of Roman law and lawyers evoked protest in both Aragon and Catalonia. In 1265, at the Cortes of Egea, James I had to confirm traditional Aragonese laws and agree that the nobles should be tried by the *justicia*, a judge appointed by the king from the knightly class rather than from the ranks of professional jurists. The controversy reached an acute stage during the reign of Peter III the Great (1276–85), who received Aragon, Catalonia, and Valencia as his share in the inheritance while his younger brother James received the kingdom of Majorca.

Annexation of Sicily

Peter III conquered Sicily in 1282 in the wake of the rebellion against French rule known as the Sicilian Vespers. Peter's wife represented Hohenstaufen claims to both Naples and Sicily, in opposition to Charles of Anjou, to whom the papacy had awarded the kingdom. The annexation of Sicily was the second major step in the expansion of Catalonia into the Mediterranean, but it was also the cause of a long international conflict with serious domestic complications. The Pope excommunicated and deposed Peter III, offering his realm to a French prince. In the midst of these troubles, the Aragonese nobles formed a union to defend their liberties and in 1283 forced the King to grant the General Privilege. Confirming the right of the nobles to be judged by the *justicia*, the King also promised to convene the Cortes annually and to take its counsel in matters affecting the realm. He made similar promises in Catalonia and Valencia, but there he could count more fully on the support of his subjects. The crusade launched against him by the Pope and led by King Philip III of France ended in failure, but the problem of Sicily remained the primary concern of Peter's three sons.

Alfonso III (1285–91) inherited the peninsular dominions and also annexed Majorca because of his uncle's treachery during the crusade. His younger brother, James, inherited Sicily. Together, they struggled valiantly to overcome the formidable opposition of the papacy, the French, and the Angevins. The Aragonese nobles again threatened the King and compelled him to issue two privileges in 1287, confirming the rights already ceded by his father and allowing them to appoint and to remove certain members of the royal council. James II (1291–1327) succeeded his brother as king of Aragon, but in order to obtain an undisputed title, he yielded his rights to Sicily in 1295 and also restored Majorca to his uncle James. In compensation, Pope Boniface VIII gave him title to Sardinia. The third brother, Frederick, was proclaimed king of Sicily, and in 1302 the Pope finally agreed to accept him. The Catalan Company, a mercenary force that had fought in the Sicilian wars, found employment thereafter in the Byzantine Empire and eventually established lordship over the duchy of Athens in 1311. Sicily and Athens, though not directly under the rule of the king of Aragon, remained outposts of Catalan influence and power.

James II, who achieved a favourable modification of his frontier with Murcia, occupied Sardinia only in 1325. Genoa contested Aragonese rights, and a series of wars on this account took place during the reigns of Alfonso IV (1327–36) and Peter IV the Ceremonious (1336–87). In 1343, Peter IV dispossessed his cousin, the king of Majorca, for disloyalty and reunited that kingdom to the crown of Aragon. A constitutional crisis arose in 1347 when the King proclaimed his daughter as heir to the throne, contrary to the ambitions of his brother, the Count of Urgel, who argued that only males could wear the crown. The Aragonese union, which had been relatively quiet in the preceding reign, renewed its challenge to royal authority and forced Peter to confirm the privileges granted by his predecessors. The Valencian nobility also formed a union and extorted similar concessions, but the ravages of the Black Death and the triumph of the royalists over the Aragonese at Epila in 1348 enabled the King to dissolve the union and to tear up its privileges. The union never appeared again.

The constitutional crisis of 1347

After midcentury, Peter IV had to defend his realm against a vigorous invasion by Peter I of Castile. He supported Henry of Trastámara's bid to gain the Castilian throne, but his subsequent efforts to secure territorial concessions from Henry II were unsuccessful. In 1377, however, he was able to reincorporate Sicily into the dominions of the crown of Aragon. Although Peter IV was inclined to neutrality in the Great Western Schism, his son John I (1387–96) recognized the Avignonese pope. Continued unrest in Sardinia and Sicily occupied much of his attention and that of his younger brother and

successor, Martin I (1396–1410). The death of the latter without immediate heirs created the most critical situation ever to confront the crown of Aragon. Numerous claimants came forward, but none had wide support. In order to resolve the issue, the estates of Aragon, Valencia, and Catalonia appointed nine commissioners who met at Caspe. Their decision, the compromise of Caspe, published in 1412, declared that the throne belonged by right of inheritance to Fernando de Antequera, brother of King Henry III of Castile. Despite opposition from the Count of Urgel, Ferdinand I (1412–16) became the first of the Trastámara family to rule in Aragon and thereby prepared the way for the eventual union of Aragon and Castile. His principal accomplishment was the withdrawal of obedience from the Avignonese pope Benedict XIII, thus helping to bring the schism to an end.

His son, Alfonso V the Magnanimous (1416–58), generally neglected his peninsular realms to pursue ambitions in Italy. There he seized the Kingdom of Naples in 1443, aspiring to dominate the rest of Italy and even to extend his power into the eastern Mediterranean. His long absence from Aragon fostered a spirit of discontent that reached a crisis during the reign of his brother, John II (1458–79), who inherited the mainland kingdoms as well as Sicily. (Naples was given to Alfonso V's illegitimate son, Ferrante.) By his marriage in 1420, John had become king of Navarre, thus adding a third kingdom to the Trastámara holdings. Conflicts with his son, Prince Charles of Viana, alienated his subjects and aroused overt Catalan hostility. When Charles died suddenly in 1461, many supposed he had been poisoned. The Catalans, who had grown restive because of economic and social hardships, revolted and tried to find another king to rule over them. Meanwhile, Louis XI of France took advantage of the situation to occupy Roussillon and Cerdagne, thus laying the groundwork for future hostilities between France and Spain. By 1472, however, John II had succeeded in overcoming the Catalan revolt and was able to assist his daughter-in-law Isabella in securing the Castilian throne. When he died in 1479, his son Ferdinand succeeded as king of Aragon and Sardinia, and his daughter Eleanor inherited Navarre.

Aragonese institutions, society, and culture. During the late Middle Ages, the Aragonese confederation, amplified and at times dismembered or nearly so, consisted of the essential nucleus of Aragon, Catalonia, and Valencia. In 1319 James II declared the indissoluble union of these three states. From time to time, Majorca, Sicily, Sardinia, and Naples were added to, occasionally separated from, and finally reunited to the crown of Aragon. An attempt to sever parts of Valencia for the benefit of Peter IV's younger brother was opposed not only by the King but also by the people of Valencia. Only at the close of the Middle Ages was the Aragonese federation menaced by dissolution, when the Catalans rebelled against John II and tried to secede, without success. The crown of Aragon had been held as a fief of the papacy ever since Peter II in 1204; this allowed the papacy to intervene directly in Aragonese affairs and even to try to dispose of the throne.

As in Castile, the bureaucracy was much more complicated; it came to be dominated by jurists who encouraged royal absolutism. Peter IV, known as the Ceremonious, took special care to organize the administration around the four principal officials—the chancellor, the chamberlain, the majordomo, and the *mestre racional*, or chief financial officer. There was intense opposition in each of the several states to the employment of non-natives in administrative positions. Even after the suppression of the union of Aragonese nobles by Peter IV, the *justicia* continued to be the ordinary judge in litigation involving them, but he always served at the king's pleasure.

The king's oldest son usually was named as procurator general for all the realms and served as his father's lieutenant. In Valencia and Majorca, which the king visited only occasionally, a procurator or governor general became a permanent representative of the crown. The towns gained a much greater degree of self-government, though the crown was represented in them by a vicar or *justicia*. In Barcelona, a council of five acted as the executive authority, responsible to a larger *consell de cent*, or council of 100.

Revisions of the law

The Usages of Barcelona remained the basic law for Catalonia and Majorca, and in 1251 James I had to pledge that Roman law would not replace them. After the conquest of Valencia, he promulgated the Fori regni Valentiae (1240), a code of law—largely Roman—for use in that kingdom. The customary law of Aragon was compiled in the Code of Huesca, promulgated in 1247. As additions were made to it, a new compilation called the Fueros de Aragón was issued in the 15th century.

The states of the crown of Aragon developed a vigorous parliamentary structure. Each of the mainland states had a parliament, and from time to time the king convened a general assembly for all three. In 1283, at Barcelona, Peter III made two significant pledges of fundamental importance for Catalan constitutional development. He promised to convene an annual Corts "to treat of the good estate and reformation of the land," and he also promised not to make any general statute for Catalonia without the consent of the Corts. Although the assembly did not meet annually, it did gain great power in legislation, as the body of constitutions and *capitols de Corts* enacted in these gatherings makes clear. The parliaments in the three states also voted taxes. The Catalans, distrustful of the crown in this respect, created a commission of the Corts to control collection and expenditure of taxes authorized by the assembly. This commission became permanent in the latter part of the 14th century and was known as the Diputació del General de Catalunya, or simply the Generalitat. It represented the Catalan community when the Corts was not in session, and it assumed the responsibility for defending Catalan liberties against royal encroachments. Similar bodies were created in Aragon and Valencia early in the 15th century.

In Aragon proper, agriculture and pasturage were the chief economic activities. In lower Aragon and Valencia, farming was largely in the hands of the numerous class of Mudéjares, Muslims living under Christian rule and retaining many of their own institutions. The manufacture of woolen goods was the main industry in the towns of Catalonia, where a strong guild organization was developed. Barcelona and Valencia ranked among the major ports of the Mediterranean, trading with Tunis, Alexandria, Sicily, Sardinia, the Holy Land, and the Black Sea area. Settlements of Catalan merchants and consuls to represent their interests were found in many of the principal African ports. A compilation of Catalan maritime law, known as the *Llibre del consolat de mar* (*Book of the Consulate of the Sea*), was prepared about 1370 and quickly gained general acceptance in Europe.

Massacre of the Jews

After the Black Death worked its destruction, frequent social and economic crises disturbed the peace and resulted in such horrors as the massacre of the Jews in Valencia and other cities in 1391. The decline of trade, financial difficulties, and the failure of many private banks in the late 14th century added to the general misery. In Barcelona a popular party (the Busca) began to agitate against the ascendancy of the wealthy urban aristocracy (the Biga) and helped to bring on the Catalan revolt against John II. The *payeses de remensa* joined in the struggle in hopes of gaining their liberty.

The crown of Aragon enjoyed a flourishing cultural life in the late Middle Ages. James II, in 1300, founded the University of Lérida, the first in Aragonese territory, and others were later established at Huesca, Barcelona, and Saragossa. Outstanding representatives of the university tradition were the Dominicans St. Raymond of Peñafort (died 1275)—a great canonist—and St. Vincent Ferrer (died 1419), a preacher of exceptional eloquence. A series of historical works, generally regarded as gems of Catalan literature, helped to mold the vernacular as a literary language: *The Chronicle of James I*, purportedly written by the King himself; Bernat Desclot's *Chronicle of the Reign of King Pedro III*; Ramón Muntaner's *Chronicle*, recounting the adventures of the Catalan Company; and the *Chronicle of Peter IV*, of which the King claimed to be the author. The most prolific writer of the era, equally facile in Latin, Catalan, and Arabic, was

Ramón Llull (died 1315). A philosopher, theologian, and mystic, he was also an active propagandist concerned about the recovery of the Holy Land and the conversion of the Muslims. His writings include *The Book of the Lover and the Beloved*; *Blanquerna*, a romance; and *The Book of the Order of Chivalry*. Francesc Eiximenis (died 1409) was best known for his *Lo Crestià*, an encyclopaedic work dealing with moral and political theory; and the poet Ausiàs March (died 1459) explored the psychological dimensions of love. (J.F.O'C.)

III. Muslim Spain

POLITICAL HISTORY

The conquest. During the 7th century, Byzantine strongholds in North Africa gave way before the Arab advance. Carthage fell near the end of the century, and in the early 8th century the caliph al-Walīd I appointed a new governor in the west, Mūsā ibn Nuṣayr, who annexed all North Africa as far as Tangier (Ṭanjah), leavin his general Ṭāriq ibn Ziyād to administer and Islāmize the native Berbers. Only Ceuta (Sabtah), which was supplied from Spain by the Goth Witiza, remained in Christian hands (see also NORTH AFRICA, HISTORY OF; CALIPHATE, EMPIRE OF THE).

But the Muslim invasion of Spain was the result of Visigoth invitation rather than Muslim initiative. The death of Witiza in 709 precipitated civil war in the Visigothic kingdom, in which the dispossessed family of Witiza and their partisans appealed to Mūsā for support against the usurper Roderick (see above *The Visigothic kingdom*). Ṭāriq crossed the Strait of Gibraltar with a Berber army and in 711 decisively defeated Roderick at a battle the precise location of which is disputed.

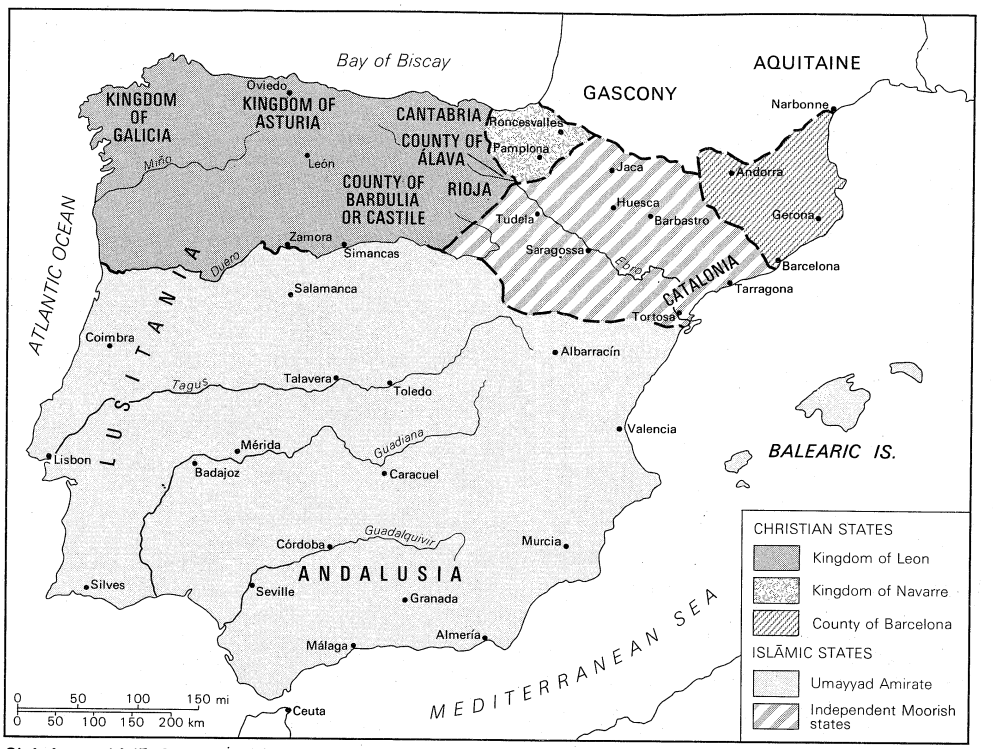
Ṭāriq

Ṭāriq, having accomplished his purpose, should have returned to Africa; but, believing that the legendary treasure of Solomon was located at Toledo (Ṭulayṭulah), he marched north and took the city. Much to his surprise, many Spaniards submitted to him voluntarily. In the following year, Mūsā himself brought an Arab army to the peninsula. Mūsā reduced Mérida (Māridah), the last stronghold of Roderick's followers, entered Toledo (Ṭulayṭulah) and Saragossa (Saraguṣṭah) (modern Zaragoza), and may have crossed the northern Meseta Central, forcing the Visigoths to submit or flee. Both Mūsā and Ṭāriq were recalled to the East by the Caliph; by the time of their departure most of the Iberian Peninsula was under their control.

The swift surrender of the peninsula to an army numbering at most 20,000 men appears to be accounted for by the fact that the Hispano-Visigoth society had not yet succeeded in achieving a compact and homogeneous integration. The Goths and Hispano-Romans preserved a clear consciousness of their differences, while lords and vassals found themselves in opposite camps because of profound economic and social factors. The Jews, harassed by the legal ordinances of Toledo, were particularly hostile toward the Christian government. Moreover, the Muslim conquest brought advantages to many elements of society: the burden of taxes was on the whole less onerous than it had been in the last years of the Visigoth epoch; serfs who converted to Islām advanced into the category of freedmen (*mawlās*) and enrolled among the dependents of some conquering noble; Jews were no longer persecuted and were placed on an equal footing with the Hispano-Romans and Goths who still remained within the Christian fold (the Mozarabs). Thus, in the first half of the 8th century, there was born a new and quite different society in Muslim Spain. The nobility of blood was now comprised of the Arab invaders ranked on the basis of the date of their arrival in the peninsula. The *baladiyyūn* were those Arabs who entered Spain in 712 under Mūsā ibn Nuṣayr; the Syrians were those who arrived in 740 under Balj. After the Arab aristocracy were the Berbers, who constituted the majority of the invading troops and whose numbers and influence constantly increased over the course of the centuries because of their continual influx from Africa. The Muslims, or *mawlās*, and their descendants, the *muwallads*, comprised by far the majority of the population, since, as indicated above, economic motives induced a considerable number of landowners to abandon Christianity. Then came the Mozarabs, whose numbers diminished in the course of the centuries; the Jews; and, on a lesser scale, Turkish and eastern European slaves who entered the peninsula later.

Muslim society

This new society was still in a period of gestation when decisive clashes took place between the Muslim troops, led by ʿAbd-ar-Raḥmān al-Ghāfiqī, and the army of the Franks, under Charles Martel at Poitiers (732). Between 711 and 756 Spain was ruled as part of the amirate dependency of Damascus. The period is so called because the governors of the peninsula were appointed, in the final analysis, by the Umayyad caliph at Damascus. This was a turbulent era, marked by continuous civil wars and by armed clashes between Arabs and Berbers. A major Berber uprising against the Arabs in Africa produced powerful repercussions in the peninsula. The Arab army that the caliph dispatched from Syria to subdue the Berber dissidents was defeated. The Syrian army under Balj was forced to seek refuge in Ceuta, whence it moved on to Spain, where its leaders seized power in Córdoba (Qurṭubah). This situation was altered with the establishment of an independent amirate (756) by ʿAbd ar-Raḥmān I ad-Dākkil, an Umayyad prince who, having succeeded in escaping from the slaughter of his family by the ʿAbbāsids, arrived at Córdoba and became politically independent of them (not religiously; he did not adopt the title of caliph).



The independent amirate. The dynasty of the Andalusian Umayyads (756–1031) marked the zenith of the Arabic civilization in Spain. Its history may be divided into two major periods—that of the independent amirate (756–929) and that of the caliphate (929–1031)—and may be interpreted as revolving around three persons of like name—ʿAbd ar-Raḥmān I (756–788), II (822–852), III (912–961)—and one dictator, al-Manṣūr (976–1002).

ʿAbd ar-Raḥmān I was the organizer of the new Arab state. Cruel, energetic, and devoid of scruples, he vigorously checked all dissident elements in the peninsula. He endeavoured to base his power on the Eastern aristocracy affiliated with his house and heaped upon it property and riches, though he nonetheless treated it ruthlessly when it showed signs of rebellion; he protected the religious authorities who represented orthodoxy, and, through a series of punitive campaigns, he held in check the Christians of Asturias, who sought to reoccupy the desert to the north of the Duero. In the eastern part of the country he was troubled by intrigues of the ʿAbbāsids, and in the north he had to cope with the ambitions of Charlemagne, who menaced the valley of the Ebro (Ibruh). Charlemagne failed ignominiously in being forced to raise the siege of Saragossa and in the course of his retreat he suffered a defeat at Roncesvalles (778), which is celebrated in the great medieval epic *La Chanson de Roland*. The Franks had to be content with occupying the upper valleys of the Pyrenees. The Frankish advance ended with the Muslim seizure of Barcelona (Barshilūnah) in 801 and Old Catalonia.

ʿAbd ar-Raḥmān I's successors, Hishām I (788–796) and al-Ḥakam I (796–822), were confronted with severe internal dissidence among the Arab nobility. A rebellion in Toledo was put down savagely, and the internal warfare caused the amir to increase the numbers of Slav and Berber mercenaries and to impose new taxes to pay for them.

The reign of ʿAbd ar-Raḥmān II

ʿAbd ar-Raḥmān II inaugurated an era of great political and cultural splendour for Muslim Spain. The arrival in Spain of the Persian musician Ziryāb, for example, marked the beginning of a sharp "Orientalization," or, more precisely, of an "Iraquization" of customs that lent sophistication and refinement to the court. Certain technical advances were introduced, such as the technique of cutting rock crystal by ʿAbbās ibn Firnās and the importation of exotic seeds by the poet al-Ghazāl. ʿAbd ar-Raḥmān's greatest problems sprang from his restless vassals in the Ebro Valley, namely, the convert Banū Qasī family and, above all, before his death, from the Mozarabs,

Christian and Islāmic states of Spain in 910.
Adapted from W. Shepherd, *Historical Atlas;* Barnes & Noble Books, New York

who, incited by extremist chiefs Alvaro and Eulogio (the latter, after his death, being canonized), sought to strengthen their ideas through the aura of martyrdom and began to revile publicly the Prophet Muḥammad—an action punishable by death (850). ʿAbd ar-Raḥmān II sought to persuade the "criminals" to retract, by alleging some pretext or by affirming that the insult had been proffered involuntarily. Failing in this effort, he was obliged to impose the death penalty. The "vogue" of seeking martyrdom voluntarily continued even after the death of the Amir. Both the latter and his successors, however, comported themselves with extraordinary tact and sought to soften the rough edges of friction, and this persecution, provoked by the Christians themselves, took a toll of 53 victims, the last of whom found themselves disavowed by their own ecclesiastical authorities.

In foreign policy ʿAbd ar-Raḥmān II conducted intensive diplomatic activity: he exchanged ambassadors with the Byzantine Empire and with the Frankish king Charles the Bald and maintained friendly relations with sovereigns of Tāhart, which supplied Spain with needed grain. He was able to confront the constantly growing incursions of the Northmen, whom he defeated in the vicinity of Seville. Furthermore, he established permanent defenses against the Viking invaders by the creation of two naval bases, one facing the Atlantic at Seville and another on the Mediterranean shore at Pechina near Almería.

His successors, Muḥammad I (852–886), al-Mundhir (886–888), and ʿAbd Allāh (888–912), were confronted with a new problem, which threatened to do away with the power of the Umayyads—and perhaps with Islām itself—in the peninsula: namely, the *muwallads*, who, having become more and more conscious of their power, rose in revolt in the north of the peninsula, led by the powerful Banū Qasī clan, and in the south (879), by ʿUmar ibn Ḥafṣūn. The struggle against both these enemies was long and tragic—especially against the latter, who was well protected by the walls of the fortress of Bobastro near Córdoba. Ibn Ḥafṣūn was on the verge of delivering the final blow to the Umayyad dynasty, but he lacked the power to win the decisive Battle of Poley (891), which, if it did not put an end to his excursions, at least confined them to eastern Andalusia. ʿAbd Allāh was able to reduce the rebels one after the other, starting with the weakest, and, when he died, he left in the hands of his grandson, ʿAbd ar-Raḥmān III, more than sufficient means to challenge Ibn Ḥafṣūn successfully. The latter, moreover, committed the political stupidity of reverting to the Christianity of his Spanish ancestors, and, consequently, he was deserted by numerous *muwallads*, who regarded themselves as good Muslims. When Ibn Ḥafṣūn died in 917 his sons were forced to capitulate, and in 928 ʿAbd ar-Raḥmān III was able to capture the hitherto impregnable fortress of Bobastro.

The Caliphate of Córdoba. One of the first political problems of an international nature that was posed for ʿAbd ar-Raḥmān III was that of his juridical status vis-à-vis the ʿAbbāsid caliphate at Baghdad. As long as religious unity existed in the Islām dominions, the Umayyads in Spain were content to acknowledge the religious leadership of Baghdad. When after 910 there grew up in Tunis the heterodox caliphate of the Fāṭimids (*q.v.*), ʿAbd ar-Raḥmān III did not hesitate to proclaim himself caliph or to adopt the caliphal title of an-Nāṣir (929). The new Muslim state, known as the Caliphate of Qurṭubah, was to rule in Spain for little over a century. His internal situation was already almost assured; the last bulwarks of resistance were not long in capitulating (Toledo, 933), and from that time on he was able to devote all his efforts to foreign affairs. As to Christian Spain, his successes were meagre, and, what was more serious, he suffered a severe defeat in 939 at Simancas (Shānt Mānkus). From then on, however, the internal debilitation of the Kingdom of Leon enabled him to restore his predominance in its peninsula by political means. He consolidated his position by a series of embassies to the Roman emperor Otto I, to the Christian sovereigns of the peninsula, to the Pope, and to Constantinople. He furthermore extended his protection to the Muslim pirates who established a base in southern France. In Africa the Fāṭimids fought the establishment of an empire that would reach as far as the Atlantic and encompass Andalusia (al-Andalus). And, in order to forestall a Fāṭimid attack on Spain, an-Nāṣir occupied Melilla (Malīlah) and Ceuta (931). Intense naval warfare between the two western caliphates coincided with clashes on land in Morocco and attempts at subversive wars in the enemy states. In the latter area, an-Nāṣir came near to overthrowing the Fāṭimid caliphate by his support of the rebel Abū Yazīd; the conflict between the Umayyads and the Fāṭimids dragged on and ended when the latter conquered Egypt (969) and lost interest in Morocco,

thus leaving a power vacuum that was rapidly filled by the Umayyads.

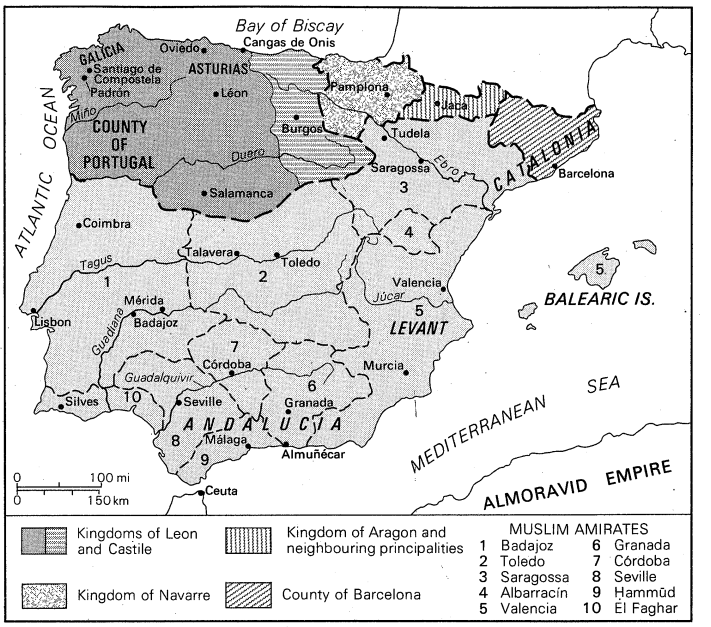
An-Nāṣir was succeeded by his son al-Ḥakam II (961–976), who adopted the caliphal title of al-Mustanṣir. His reign was peaceful, and he succeeded in resolving the problem of Morocco, thanks to the strategic ability of General Ghālib and the policy of the general of the African army, Abuʿ Āmir al-Maʿāfirī, later known as al-Manṣūr, the Victorious One (Almanzor).

Al-Manṣūr

On the death of al-Mustanṣir, his throne was occupied by his son, a minor, Hishām II al-Mu'ayyad, who grew up under the tutelage of his mother, Aurora, and of the prime minister al-Muṣḥafī, who before long was liquidated by al-Manṣūr (governed 976–1002). The latter succeeded in eliminating all temporal power of the caliphs, whom he dominated, and acquired dictatorial power for himself.

He won complete control over Morocco, which he transformed into the viceroyalty of Córdoba, and he arrested the expansion of the Christian kings from the north through a series of raids—usually every six months—in which he sacked nearly every Christian capital. With the support of a professional army consisting predominantly of Berbers, many of them recent arrivals from Africa who obeyed him blindly, he managed to dispense with the Arab aristocracy, which for the most part was pro-Umayyad, and to hold in check the influence of the slaves, whose numbers had been increasing since an-Nāṣir had placed them in posts of high responsibility. But this balancing of forces—Arabic aristocracy, Berbers, and slaves—could only be sustained by the strong hand of a ruler such as himself.

Al-Manṣūr played the role of a grand lord. A protector of poets and scholars, he concealed his rationalism under a cloak of piety and was the darling of the *faqīh*s (scholars versed in the traditions of Islām); he contrived to attract to himself the outstanding poets of that era. At the time of his death, after a victorious campaign in Aragon, he succeeded in leaving a robust and well-organized state for his son al-Muẓaffar.



Al-Muẓaffar (1002–08) continued the policies of his father. He hemmed in Hishām II and fought against the Christians, but he died prematurely; his brother ʿAbd ar-Raḥmān Sanchuelo lacked the fortitude to maintain the structure built by his father. An uprising that sought to vindicate the political rights of Hishām II, whom Sanchuelo kept in seclusion, resulted in his death and brought about the beginning of the end of the Umayyad dynasty in Spain.

The ṭā'ifas. Upon the death of ʿAbd ar-Raḥmān Sanchuelo, 21 years of unrest followed (1009–31), during which al-Mu'ayyad was lost trace of and during which constant clashes occurred among Arabs, Berbers, and the slaves. The consequence of those years of anarchy was the formation of numerous independent kingdoms, or *ṭā'if*as, which may be classified into the following: (1) Arab factions in the valleys of the Guadalquivir (al-Wādī al-Kabīr) and Ebro rivers; (2) Berber factions in the Meseta Central, in the steppelike part of Aragon, in Granada (Gharnāṭah), and in nuclei dispersed throughout western Andalusia (Gharb al-Andalus); and (3) groups of slaves in the east.

The political history of the period constitutes an uninterrupted series of internecine wars. Pre-eminent is the confrontation between the Arab factions, under the leadership of Seville (Ishbīliyah), governed by the dynasty of the Banū ʿAbbād, and the Berbers, presided over by Granada. Little by little, Seville succeeded in uniting southern Spain under its aegis. This state was ruled over, first of all by al Muʿtaḍid, a sovereign devoid of scruples, who pretended at first to have found the vanished Hishām II al-Mu'ayyad (at the most, the pretender was a mat maker from Calatrava who bore some resemblance to the old caliph), and then by a poet-prince, his son al-Muʿtamid. In the east, except for a brief period when the petty state of Denia (Dāniyah) built a powerful fleet that enabled it to stage incursions throughout the western Mediterranean as far as Sardinia, the various *ṭā'if*as preserved a certain static equilibrium; farther to the north, the various *ṭā'if*as also wasted their time in interminable internal quarrels.

This fragmentation facilitated the expansion of the Christian states of the north, which, lacking the demographic potential to repopulate the lands they had succeeded in occupying, wisely annexed only those that they were capable of repopulating and garrisoning. The Christian states also imposed a heavy economic burden of tribute on the *ṭā'if*as. Christian armies forced the Andalusian petty kings to buy peace by paying annual tribute, the famous *parias*. This tribute, while it revitalized the economy of the Christian states, created sharp friction between the Muslim authorities and their subjects. The *ṭā'if*as had constantly to increase the yield from their imposts, and they constantly laid new and heavier tax burdens on their subjects; when cash was lacking, they devaluated the currency, minting low-standard coins that were not accepted by the Christians. This, in turn, gave rise to new tax increases and to popular discontent, which was considerably aggravated by the clerical party of the *faqīh*s. Furthermore, the petty local courts were characterized by extravagant luxury and lavish public outlays. This situation rendered Andalusia ripe for the foreign intervention that came when the Castilians occupied Toledo (1085), the key to the Meseta Central and to the peninsula. The factional chiefs, alarmed by the Christian advance, called in the help of the Almoravids.

Spain in 1037.

The Almoravids. The Almoravid ruler Yūsuf ibn Tāshufīn entered the peninsula and by a slow advance reached the fields of az-Zallāqah, north of Badajoz (Baṭalyaws), where in 1086 he defeated a Castilian army under Alfonso VI; then he became an independent prince either unwilling or unable to exploit their victory. For four years Almoravid policy in Spain remained indecisive, but it appears that the siege of Aledo (1088) convinced Yūsuf ibn Tāshufīn of the urgent necessity of putting an end to the *ṭā'if*as if he were going to rescue Spanish Islām. In 1090–91, he deposed their rulers—except for Banū Hūd of Saragossa—and inflicted a series of defeats on the Christians. Only one of the chiefs of state, Rodrigo Díaz de Vivar (the Cid), exiled from his native Castile by King Alfonso VI, was able to resist the Africans, and he furthermore set himself up in an independent kingdom—a new *ṭā'if*a, that of Valencia. The figure of the Cid—the Lord, a title that the Arabs conferred upon him—is quite curious: first he served as a mercenary under Alfonso VI; then he became an independent prince in the east, ruling over states that were entirely inhabited by Muslims. He led a retinue of men who were hardened

in combat and who understood nothing of the ways of peace. He had the good fortune, however, of finding efficient administrators from among the Mozarabs residing in his states; also, his superb grasp of Almoravid tactics enabled him to overcome his numerical inferiority. Upon his death, Valencia remained under the control of his men until 1102, when they had to evacuate it and seek refuge in Castile. After the fall of Valencia, the Almoravids were unopposed; and in 1110, under ʿAlī ibn Yūsuf (1106–43), they occupied Saragossa.

The conquest of Saragossa, however, marked the beginning of the Almoravid decline. The Aragonese king Alfonso el Batallador (the Battler) and his stepson, Alfonso VII of Castile, launched renewed Christian assaults against the entire frontier of Islām in Spain. The Almoravids, who after 1121 experienced serious difficulties in Africa as a result of the preachings of a Berber reformer, Ibn Tūmart, could not successfully parry the blow; indeed, they had to hire Christian mercenaries to help them. In 1118 Saragossa fell into the hands of the Battler, who furthermore reconquered a large part of the valleys of the Jalón and of the Jiloca. A resounding Almoravid victory over the Aragonese at Fraga (Ifrāgah) in 1134 bore no fruit, because the Almoravids lacked the resources to exploit their victory.

The Almohads. In Africa, the Almohads finally triumphed, and ʿAbd al-Muʾmin (1130–63), successor to Ibn Tūmart, was able to turn his attention to Spain and to undertake the integration of all the Muslim states—the second *ṭāʾifas*—formed under the shield of the latest internecine wars caused by the Almoravid decline. Of these states, there stood out especially that under Ibn Mardanīsh (1147–72), who, with a largely Christian army, succeeded in becoming the master of the entire Levant.

The Almohads assumed the title of caliph, introduced a series of severe religious measures, and sought to strengthen their states through religious unification, in practice, by compelling the Jews and Christians to emigrate. Two great sovereigns, Abū Yaʿqūb Yūsuf (1163–84) and Abū Yūsuf Yaʿqūb al-Manṣūr (1184–99), raised western Islām to the zenith of its power. Taking advantage of the quarrels that divided the Christian kingdoms of Castile and Leon, al-Manṣūr defeated the sovereign of the former, Alfonso VIII, in 1195 at the Battle of Alarcos (al-Arak); but, despite this victory, he proved unable to exploit his triumph—repeating the fate that befell the Almoravids after al-Zallāqah. Years later, during the reign of his successor an-Naṣīr (1199–1214), the Christians avenged this defeat in the Battle of Las Navas de Tolosa (al-ʿIqāb). This battle created a power vacuum into which stepped some of the *ṭāʾifas* or petty kingdom states, prominent among which were those of Banū Hūd of Murcia (Mursiyah) and of the Naṣrids of Arjona (Arjūnah) (later also of Granada). The policies of the two states were quite divergent: Muḥammad ibn Hūd (1228–38) emphasized resistance to the hilt on the part of the Muslims against the Christians who, led by Ferdinand III the Saint, were occupying the Guadalquivir Valley; Muḥammad I ibn al-Aḥmar (ruled in Granada 1238–73), on the other hand, acknowledged himself to be a vassal of the King of Castile and even helped him against his own co-religionists. This realistic policy enabled him to preserve in his possession the territory of what are now the provinces of Málaga, Granada, and Almería, together with portions of neighbouring provinces. Thus, after the middle of the 12th century, after the reconquest of Jaén (Jayyān), Córdoba, Seville, and Murcia by the Castilians and of Valencia and the Balearic Islands by the Aragonese under James I the Conqueror, there no longer remained any independent dominions of Islām in Spain, except Granada and the tiny area of Crevillente (Qarbalyān), which soon disappeared.

Granada. The Naṣrid dynasty founded by Muḥammad ibn al-Aḥmar in Granada, however, was destined to endure for two and a half centuries. The Muslims of Granada lacked sufficient forces to constitute a genuine danger to the Christians, who limited themselves to collecting tribute and launching, from time to time, an attack against them, snatching from them some city or other. The people of Granada, for their part, always bore in mind what had happened in the cases of the Almoravids and the Almohads, who, having arrived from Africa as auxiliary troops, ended up by becoming masters in Spain. Vis-à-vis the new Moroccan empires, particularly that of the Banū Marīns, they maintained a policy of balance of power. They permitted the influx of African volunteers to enroll in their army to fight against the Christians but never permitted the crossing of the Strait of Gibraltar by

massive organized contingents. The years between 1302 and 1340 are of an extraordinary complexity from a diplomatic as well as a military point of view. Both Morocco and Castile vied for the possession of the Granadine ports of Tarifa (Ṭarīf) and Algeciras (al-Jazīrah al-Khaḍra'), ports that dominated the Strait. Granada, therefore, allied alternately with the Africans and Christians, hoping thus to maintain the balance of power. A fourth state, Catalonia, torn by discord under James II, aspired to obtain a larger slice of the Reconquista and intervened with its fleet and laid siege to Almería (al-Marīyah), under the pretext of a crusade (1309).

When Ismā'īl I (1314–25) ascended the throne, another branch of the Naṣrid family gained the power. Ismā'īl was able to check the reconquest ambitions of Alfonso XI—who later, in 1340, with the aid of the Portuguese, won a decisive victory over the Berber army of Abu'l-Ḥasan at the Battle of the Salado.

The defeat of the Berbers and the lack of interest in reconquest on the part of the successors of Alfonso XI created a favourable climate for Granada, which found itself free from political pressures of both Moroccans and Castilians. During the reign of Muḥammad V (1354–59; 1362–91) Granada reached its greatest splendour; its ministers included some of the most learned men of the epoch, such as the historian Ibn al-Khaṭīb, the physician Ibn Khātima, and the poet Ibn Zamraq. It protected Ibn Khaldūn, the great philosopher of history.

The reign of Muḥammad V

During this era there grew up also the institution of the "judge of the frontier," *juez de la frontera y de los fieles del rastro*, a Moorish official who heard Christian complaints against the Granadinos; this did much to reduce frontier incidents between Moors and Christians.

Little is known about the decline of the Naṣrid dynasty, since with Ibn al-Khaṭīb died the last great Muslim historian of Andalusia. The extant records and reports from the 15th century are as a rule from Christian sources or from the tales of travellers. The narrative poems that are of the utmost interest as historic sources for other periods in Muslim history are completely lacking in this era. The conventional verses of the king-poet Yūsuf III (1408–17) or the anonymous Arab poet of the romance *Abenamar, Abenamar, moro de la morería* do little to illuminate the history of this period. More illustrative, however, are the neglected verses of ʿAbd al-Karīm al-Qaysī (*c.* 1485), an esteemed member of Granada's middle class, who eschewed classic themes and wrote of such mundane phenomena as the increase in the cost of living or the decline in the power of the sovereign.

Foreign relations enjoyed a long period of tranquillity as a result of the ghastly losses of life from the Black Plague (1348–51) and, afterward, from the internal wars that weakened Christian Castile. Furthermore, border incidents were quickly disposed of by the "judge of the frontier and the faithful of the trail." Only an occasional confrontation served to remind the Muslims and Christians that the Reconquista had not yet come to an end. In the 15th century, however, the Reconquista proceeded apace. Prince Ferdinand seized Antequera (Antaqīrah) in 1431; Jimena and Huéscar fell in 1435, Huelma in 1438, and Gibraltar in 1462. One result of these events was that the people of Granada became increasingly less tolerant of Christians, and the Granadine *faqīh*s professed the most extreme xenophobia. This policy, common to both point to the existence of a Granadine school of law, which before long exerted an influence on the other side of the Strait; for the Moroccans, subjected to the constant pressure of the Portuguese—who had gained possession of their coastal areas (Ceuta, first, in 1415)—realized like the Granadinos that the only way to escape Christian hegemony was through the profession of the most rigorous Islāmic ideals and in the practice of the most extreme xenophobia. This policy, common to both sides of the Strait of Gibraltar, did not achieve equal results. It saved Morocco from the hands of its enemies, but in Granada it became the *casus belli* for the campaign that was to inaugurate the end of the Reconquista.

The sultan Muley Hacén (Abū al-Ḥasan ʿAlī) refused to pay the annual tribute he owed to the Catholic kings and seized the fortified town of Zahara (1481), thus launching hostilities that were destined to liquidate the last bastion of Andalusian Islām. The campaign proved to be difficult for the Christian army despite the discord that split the royal Granada family, and that was exploited in Machiavellian fashion by Ferdinand the Catholic: Boabdil (Arabic: Muḥammad Abū ʿAbd Allāh), son of Muley Hacén, rebelled in Guadix against his father and was recognized in Granada with the aid of the Abencerrajes, a powerful Granada family. Muley Hacén, however, who had taken refuge in Málaga, succeeded in re-

The end of Andalusian Islām

capturing the capital with the assistance of the Zegries, or border people. But he was successfully deposed by his brother, el Zagal (Abū ʿAbd Allāh Muḥammad az-Zaghall—the Valiant One), who was supported by the Venegas family.

Boabdil was captured by the Catholic kings during his attack at Lucena and, in order to regain his freedom, signed the Pact of Córdoba, in which he pledged himself to deliver the portion of the kingdom that was in the hands of el Zagal, in exchange for help from the Castilians to recover Granada, part of which (Alhambra) was still in the hands of Muley Hacén. The latter and el Zagal allied themselves against Boabdil, who had to flee and seek asylum in the court of the Catholic king. The death of Muley Hacén in 1485 enabled Boabdil, with the help of the inhabitants of Albaicin, to occupy the Alhambra. El Zagal, who had been routed by the Christians before Vélez Málaga, in 1487 retreated to Guadix and, being incapable of further resistance, delivered his states to the Catholic kings and emigrated to Tlemcén (1491). Taking advantage of this civil war, the Christians had seized Ronda, Marbella, Loja, Málaga, and Razo and were in a position to lay siege to Granada. When the siege began, the population divided into factions: one consisted of pacifists and the other of belligerent persons who, despite their quarrels, fiercely defended the city.

By the end of 1491, the situation became desperate, and Boabdil capitulated, but, before making the news public, he brought a detachment of Castilian troops into the Alhambra on the night of January 1–2, for the purpose of avoiding a disturbance on the part of his vassals that might render it impossible for him to comply with the terms of the pact. The official surrender, and with it the end of Muslim occupation of the peninsula, took place the following day, January 2, 1492.

SOCIAL AND ECONOMIC LIFE

Society. In discussing the influx of the Muslims into Spain, the various categories of the population that settled there were earlier pointed out: Arabs (*baladiyyūn* and Syrians), Berbers, *muwallads*, Mozarabs, Jews, and slaves. The Muslim masses continued to increase during the early centuries of the occupation, because of the wave of conversions that markedly reduced the number of Christians. Precise figures cannot be given, but it is estimated that at the time of the conquest some 4,000,000 Spaniards inhabited the peninsula, while the total number of immigrant Arabs did not exceed 50,000. The population was primarily rural, and large cities were few in number. At the end of the 10th century one can estimate the following urban populations: Córdoba, 250,000; Toledo, 37,000; Almería, 27,000; Granada, 26,000; Saragossa, 17,000; Valencia, 15,000; and Málaga, 15,000.

At the peak of the administrative pyramid was the amir, caliph, sultan, or king, depending on the era, and all the functionaries exercised their power by delegation from the sovereign, who embodied within himself all executive, legislative, and judicial authority, even though at times he delegated power to a *ḥājib* (chamberlain) or, after the 11th century, to a prime minister (*dhū al-wizāratayn*). In the discharge of his functions he was assisted by various viziers. At times, there was, at the head of the various departments, a *kātib*, or official secretary. The provinces were governed by *wālī*s who enjoyed wide autonomy. There existed no uniform municipal organization, and the duties fulfilled by some officials cannot be considered as representative; such are, for example, the chief of police (*ṣāḥib al-shurta*) and the market inspector, known until the 10th century as *ṣāḥib al-sūq* (zabazoque) and later as *muḥtasib*. The Muslim cities of Spain, with their baths, parks, markets, mosques, and high cultural level, were quite different from and, some believe, superior to those of Christian Europe.

The military

The army was based on the voluntary recruitment of soldiers or on contracts with them from abroad. The units (*jund*), grouped according to the places of origin of their men, were strategically deployed along the borders and possessed extraordinary mobility at the time of the caliphate. Holding castles close to the enemy lands as their bases of operation, they were glad to welcome into their midst the Muslims, who were eager to die in combat, in order thus to open for themselves the gates of paradise. These volunteers, who became more and more numerous with the passage of time and about whom numerous details are known, were frequently second class soldiers, since they enrolled during years when they constituted a hindrance rather than a source of help. The *marina*, or navy, organized by ʿAbd ar-Raḥmān II, remained an effective force until the middle of the 14th century.

The entire state structure was supported, theoretically, on a foundation of the most rigid Islāmic orthodoxy and interpreted by the Mālikī school, which in Spain manifested special characteristics of hyperconservative nature. It is not known whether the school acquired these traits upon settling in the peninsula because intolerance was indigenous to the inhabitants there or whether it indoctrinated the Spanish Muslims in this manner, who transmitted it, in turn, to the Christian reconquerors.

The economy. The Moorish conquerors divided the lands seized from the Christians by force of arms and operated them, as a general rule, by means of "tenant farmer" leases. Possibly about the 10th century the woodlands achieved their widest expansion, and the cultivation of irrigated lands was encouraged by means of drastic regulations, which, however, were favourably received. Plants used in the manufacture of textile (flax, cotton, esparto grass, and silk) as well as those with medicinal properties were protected by the state.

In addition to agriculture, the raising of livestock (Christian sheep and Arabian horses) occupied a central position in the peninsular economy. As in the Roman period, lead, iron, gold, and mercury were mined. Domestic industry, which never went beyond the handicraft state, culminated in the production of luxury cloths such as silk (a state monopoly), in the tanning of hides (Cordoban leather), and in the export of ivory objects. Commerce was selective and carried on in products "of low weight and high value" that frequently reached the most remote regions of the known world. There are reports of Andalusian travellers as far as Sudan, central Europe, and even China.

The evolution of economic life was conditioned by political events; in proportion as the productive centres passed into Christian hands, the commercial vigour of the Muslims kept diminishing. No phenomenon is more illustrative of this than the confidence attached to the currency. In the 11th century, Barcelona was counterfeiting Muslim coins; in the 14th century, Granada was doing the same with Barcelona coins.

THE CULTURE OF MUSLIM SPAIN

Arab civilization in the peninsula reached its zenith when the political power of the Arabs began to decline. In the 8th century, in the years immediately following the conquest, there are no traces of a cultural level higher than that attained by the Mozarabs who lived among the Arab conquerors. All available evidence points to the fact that in this period popular works of medicine, agriculture, astrology, and geography were translated from Latin into Arabic. Many of these texts must have been derived from the *Etymologies* of Isidore of Seville and from other Christian writers. In the 9th century, the situation was changed abruptly: the Andalusians, who travelled east in order to comply with the injunction to conduct a pilgrimage to Mecca at least once in their lifetimes, took advantage of their stay in those regions to enhance their knowledge, which they then introduced into their native country.

Literature. In the 9th century there flourished such court poets as ʿAbbās ibn Nāṣih, ʿAbbās ibn Firnās, Yaḥyā al-Ghazāl, and the knight Saʿīd ibn Jūdī. Towering above all these, however, is Ibn Hāniʾ, nicknamed the "Mutanabbī of the West," who by virtue of his religious ideas was obliged to forsake his native land and enter in the service of the Fāṭimid caliph al-Muʿizz. In the 10th century, another bardic tradition grew up around al-Manṣūr. Bards performed the functions of modern jour-

Poetry

nalists; they accompanied their protector on war expeditions and celebrated his exploits in verse the singsong rhyme of which became engraved in the folk memory of the people of Andalusia. This occasional poetry did not always attain literary heights, but at times that was indeed the case. And al-Manṣūr himself chose as "poet-journalists" the foremost talents of his time—men such as Ibn Darrāj al-Qasṭallī, ar-Ramādī, Sa'īd of Baghdad, at-Ṭalīq, and numerous others. And it was in the 10th century that Ibn Faraj of Jaén deemed himself to possess sufficient background to compose the *Kitāb al-Hadā'iq* ("Book of Orchards")—the first anthology of Andalusian poets. This was soon followed by another, that of the physician Ibn al-Kittānī.

The highest peak in Islāmic literature in Spain was attained during the era of the *ṭā'ifa*s, when the poet-king al-Mu'tamid established an embryo of an academy of belles lettres, which included the foremost Spanish intellects, as well as Sicilians who emigrated from their native land before its conquest by the Normans. Other petty kings in the peninsula endeavoured to compete with al-Mu'tamid but did not succeed in assembling a constellation of writers of comparable stature.

In the 12th century, in the Andalusian Levant, outstanding poets included Ibn Khafajā of Alcira and his nephew Ibn az-Zaqqāq. In the era of greatest decadence in the 13th century were Abū al-Baqā' of Ronda (*c.* 1285), Ibn al-Khaṭīb, Ibn Sa'īd al-Maghribī, and Ibn Zamraq, whose verses are preserved in the stuccos of the Alhambra.

Prose

In Arab literature, including that of contemporary times, poetry possesses greater vitality than prose. But, even so, it is necessary to mention Ibn Shuhayd (*c.* 1035), author of a work that lent inspiration to al-Ma'arrī for his *Risālat al-ghufrān* ("Epistle of Pardon"). The prolific Ibn Ḥazm of Córdoba (died 1064) wrote the delightful *Tawq al-ḥamāmah* ("The Ring of the Dove"), dealing with love and lovers, which is still popular today. The enormous output of Ibn Ḥazm is not possible to enumerate here. Nevertheless, it suffices to cite his *Kitāb al-fiṣal,* a history of religions that was not surpassed by Western scholars until well into the 19th century. Another polymath was the vizier-historian Ibn al-Khaṭīb (died 1375). Two 12th-century histories of literature, by Ibn Bassām and Ibn Khāqān, are excellent sources of information concerning the apogee of Andalusian letters. Often the best grammars and dictionaries of a language are written by authors living in the peripheral zones who endeavour to prevent gross errors being committed by their countrymen in the region. This perhaps explains why Andalusia, located at the western fringe of the Muslim world, produced works that to this day are used as texts in certain traditional Islāmic universities. Among these grammarians should be mentioned al-Zubaydi, tutor of Hishām II and Ibn Maḍā of Córdoba, who proposed a drastic reform of grammatical methods. Ibn Mālik of Jaén's didactic poem *Alfiyya* ("The Thousand Verses") constitutes an excellent handbook of grammar; and Abū Ḥayyan of Granada (died 1344), who emigrated to the east, wrote an outstanding commentary on the Qu'ran as well as the first Turkish grammar. In the field of lexicology the blind Ibn Sīda of Denia (died 1066) is pre-eminent; he was also the author of a sort of "dictionary of ideas."

In the field of Qu'rānic science there stand out Abū 'Amr of Denia and Ibn Fierro of Játiva, whose handbooks made possible the correct cantilation, or intonation of the chanting, of the Qu'rān. Also produced there were various collections of *ḥadith*s (traditions referring to the Prophet), but none of these was of particular importance. In this domain, the Andalusians were imitators of the East, and personalities such as Ibn 'Abd al-Barr, a certain Ibn Rushd (the grandfather of Averroës), and an Ibn 'Āṣim are of merely marginal interest.

The first extant chronicles in Muslim Spain, such as the *Ta'rīkh iftitāḥ al-Andalus* ("History of the Conquest of Spain"), by Ibn al-Qūṭiya, date back to the 10th century. In the *ṭā'ifa* era the pre-eminent Spanish historian is Ibn Ḥayyān of Córdoba (died 1076), whose *Muqtabis,* preserved for the most part, is an anthology of historic texts based to a great extent on the work of his predecessors. From the point of view of human interest are the *Memoirs* of the king Ziri 'Abd Allāh, who was deposed by the Almoravids and who sought to justify in those memoirs his deeds as a statesman. In the Naṣrid era is found the frequently aforementioned Ibn al-Khaṭīb. The works of the North African historians Ibn Khaldūn and al-Maqqari (died 1631) supply much information concerning the Arab domination of Spain.

Science. In the mid-11th century, the *qāḍī* of Toledo, Ibn Ṣā'id, composed a noteworthy handbook of history of science that contained much information on technical subjects. Mathematical sciences received little attention, but mention should be made of Maslama of Madrid (died 1008), who probably took part in the translation of Ptolemy's *Planispherium* and made some contributions to pure mathematics. Also during the heyday of Granada, there was al-Qalaṣādī, commentator on Ibn al-Bannā', who did important work on fractions. Despite their lack of interest in the physical sciences, the Andalusians excelled in astronomy, both theoretical and practical. An array of these scholars sought to simplify the astrolabe, and finally al-Zarqālī (died 1087) achieved success by inventing the apparatus called the *azafea,* which was widely used until the 16th century. Al-Zarqālī also anticipated Kepler by suggesting that the orbits of the planets are not circular but ovoid. Jābir ibn Aflaḥ (12th century) criticized the Ptolemaic system.

Astrology was popular in Muslim Spain, and the Umayyad rulers, after 788, maintained an official astrologer in their courts. The most widely used astrological treatises were those of the Tunisian 'Alī ibn Abī Rijāl and another anonymous scientist, who made a translation from Vulgar Latin into Arabic in the 8th century. This book was translated from Arabic into Spanish during the era of Alfonso under the title of *Libro de las Cruces* ("Book of the Crosses").

Natural science

The treatises on esoteric or occult subjects attribute to Maslama two works on natural science that are not properly his but may be ascribed to one of his pupils. They are *Ghāyat al-ḥakīm* ("The Goals of the Scholar"; also known as *Picatrix*) and *Rutbat al-ḥakim* ("The Step of the Scholar"). Greater interest is merited by the *Materia Medica,* a revision of the Eastern Arabic text of the 1st-century Greek physician Pedanius Dioscorides, ordered by an-Naṣir, on which Jews, Arabs, and Christians collaborated. Gradually, the Andalusian Arabs kept adding new medicinal "simples" (which described the properties of various medicinal plants) to those described by Dioscorides, and the last eminent essayist on the subject, Ibn al-Bayṭār (died 1248), describes more than 1,400 of these. The Arabs of Andalusia were familiar with the texts of the great Latin classics relating to natural science, and Ibn Wāfid, Ibn Baṣṣāl, and Ibn al-'Awwām (11th and 12th centuries) quote Varro, Virgil, and others. The most notable geographers in Muslim Spain were al-Bakrī (died 1094), who wrote the *Kitāb al-masālik wa-l-mamālik* ("Book of Highways and of Kingdoms"), and al-Idrīsī (died 1166), who was in the service of Roger II of Sicily and is the author of the leading universal geography composed by the Arabs. Somewhat later (1323) there appeared the first Arabic nautical map, possibly of Granadine origin. In technology, Muslim Spain was noted for its windmills and for its manufacture of paper. (J.V.G.)

IV. Spain from 1479 to 1700

UNITED SPAIN UNDER THE CATHOLIC KINGS

The union of Aragon and Castile. When Ferdinand II (1479–1516, also Ferdinand V of Castile from 1474) succeeded to the crown of Aragon in 1479, the union of Aragon (roughly east Spain) and Castile (roughly west Spain) was finally achieved, and the Trastámara became, after the Valois of France, the second most powerful monarchs in Europe. The different royal houses of the Iberian Peninsula had long thought in terms of a union of their crowns and had practiced intermarriage for generations. Nevertheless, the union of the crowns of Castile and Aragon was far from inevitable in the last quarter of

the 15th century. A union between Castile and Portugal was equally feasible, and it has been argued that it would have made more sense, for it would have allowed the two western Hispanic kingdoms to concentrate on overseas exploration and expansion, and it would not have involved Castile in Aragon's traditional rivalry with France. The reasons that led John II of Aragon to arrange the marriage of his son and heir, Ferdinand, with Isabella of Castile, in 1469, were essentially tactical: he needed Castilian support against French aggression in the Pyrenees. In Castile an influential party of magnates, led by Archbishop Carillo of Toledo and opposed to King Henry IV, supported the succession claims of the princess Isabella, the King's sister, against those of his daughter, Joan. They were anxious for the help and leadership of the Aragonese prince and content with the alliance of a country in which the magnates had such far-reaching privileges as the Aragonese nobility. It needed a forged papal dispensation for the marriage, the blackmailing of Henry IV into (wrongly) denying the paternity of his daughter (Joan), and, finally, several years of bitter civil war before Ferdinand and Isabella defeated Joan's Castilian supporters and her husband, Alfonso V of Portugal.

Reasons for union

Ferdinand and Isabella ruled jointly in both kingdoms and were known as the Reyes Católicos (Catholic Kings). It was, however, a union of crowns and not of kingdoms. In size, institutions, traditions, and, partly, even in language, the two kingdoms differed greatly. Within the Kingdom of Aragon, Aragon and Valencia (easternmost Spain, halfway up the coast) each had about 270,000 inhabitants, of whom some 20 percent and more than 30 percent, respectively, were Moors and Moriscos (Moors officially converted to Christianity). Catalonia (northeast Spain) had about 300,000 inhabitants. In each of these kingdoms the powers of the crown were severely limited. The barons ruled their estates like kings, dispensing arbitrary justice over their peasants. In Catalonia they had the right to wage private war. In Aragon anyone arrested by order of the king could put himself under the jurisdiction of a *justicia* who held his office for life and was therefore independent of the king's pleasure. It was this highest judge who crowned the kneeling king and made him swear to observe the *fueros*, the laws and privileges, of the kingdom. It is now known that the formula "We who are as good as you swear to you who are no better than we, to accept you as our king and sovereign lord, provided you accept all our liberties and laws; but if not, not" is a forgery, most probably of the mid-16th century. It does, however, summarize very well the relations between the kings of Aragon and the Aragonese nobility.

Ferdinand made no attempt to change this position; nor did he do so in Catalonia, where the crown had just emerged successfully from a long and confused civil war. The nobility and the urban aristocracy of Barcelona (Spain's northeast coast) had been faced by violent social movements of the peasants and the lower classes of the cities and were themselves riven by family and factional strife. The crown intervened, mainly on the side of the lower classes but, inevitably, in alliance with some of the noble factions and against the French who had taken the opportunity to occupy Cerdagne and Roussillon. In 1486 Ferdinand settled the Catalan problem by a compromise, the Sentencia de Guadalupe, which effectively abolished serfdom and the more oppressive feudal obligations of the peasants, in return for monetary payments to the lords. Otherwise, the political and legal privileges of the rural nobility and the urban aristocracy were left intact. Effectively, therefore, Ferdinand made no attempt to strengthen the powers of the crown and to give the principality a more efficient system of government. One hundred and fifty years later his successors were to pay a high price for this failure. In the meantime, Ferdinand had given Catalonia peace, a considerable degree of social stability, and the opportunity to make good the ravages of the civil wars and the losses of commercial markets to Italian competitors. This opportunity was only partially taken by the Catalans. They failed completely to prevent the Genoese from establishing a dominant position in the economy of Castile and, more especially, in the vital and rapidly expanding Atlantic trade of Seville (south Spain, 90 miles [140 kilometres] north of Gibraltar). The union of the crowns of Aragon and Castile therefore led to neither a political and institutional union nor to an economic integration of the Iberian Peninsula.

Catalonia's situation

Castile. Castile, too, was a poor country. Much of its soil was arid, and its agriculture was backward. The armed shepherds of the powerful sheep-owner's guild, the Mesta, drove their flocks over hundreds of miles, from summer to winter pastures and back again, spoiling much cultivated land. Despite the violent hostility of the landowners, the government upheld the Mesta privileges, since the Mesta paid generously for them and was supported by the merchants who exported the raw wool to the cloth industry of Flanders (modern Belgium). The power of the Mesta and the harm it did increased in the 16th century, for the Catholic Kings supported its privileges, anxious, as always, to increase their revenues by following the line of least resistance. Thus, the impoverished Spanish peasant was unable to buy the manufactures of his urban industries, and hence the Castilian towns remained comparatively small and their industries underdeveloped, compared with those of Italy and the Netherlands. Only the cities of Andalusia (south Spain) were relatively large, but, except for Seville, they were not primarily trading or manufacturing centres but were dominated by an urban nobility living on revenues from the surrounding countryside.

Underdeveloped Castilian industries

In the northern provinces of Castile there lived a large class of minor nobles, the hidalgos. The inhabitants of Guipúzcoa (by the westernmost French border) even claimed that they were all of noble birth. But the south, New Castile (southeast of Madrid), Extremadura (southwest of Madrid), and especially Andalusia—that is to say, those provinces most recently reconquered from the Moors—were the domain of the great nobility. There the families of the Enríquez, the Mendoza, the Guzmán, and others owned vast estates, sometimes covering almost half a province. They had grown rich during the 15th-century boom in wool exports to Flanders, at a time when there were more than 2,500,000 sheep in Castile, and it was they, with their hordes of vassals and retainers, who had attempted to dominate a constitutionally almost absolute, but politically weak, monarchy.

It was in this kingdom that the Catholic Kings determined to restore the power of the crown. Once this was achieved, or so it seemed, the liberties of the smaller kingdoms would become relatively minor problems. Like their contemporary, Henry VII of England, they had the advantage of their subjects' yearning for strong and effective government after many years of civil war. Thus, they could count on the support of the cities in restoring law and order, without having to make any important concessions to the Castilian Cortes. The Cortes of Toledo of 1480 accepted the appointment of corregidores, or royal officials, to supervise the administration of the principal towns. At the same time, both municipal efficiency and civic pride were enhanced by the obligation imposed on all towns to build a town hall (*ayuntamiento*).

With the great nobles it was necessary to move more cautiously. The Catholic Kings revoked usurpations of land and revenues by the nobility if these had occurred since 1464, but most of the great noble estates had been built up before that date and were effectively left intact. From a contemporary chronicler, Hernán Pérez del Pulgar, historians know how they proceeded piecemeal but systematically against the magnates, here using a nobleman's defiance of the law, there a breach of the peace or of a pledge, to take over or destroy his castles and thus his independent military power. Even more effective in dealing with the nobility was the enormous increase in royal patronage. Isabella was stage manager to Ferdinand's election as grand master of one after another of the three great orders of knighthood: Santiago, Calatrava, and Alcántara. This position allowed the King to distribute several hundred commanderships with their attached income from the huge estates of the orders. Equally important

was royal control over all important ecclesiastical appointments, which the Catholic Kings insisted on with ruthless disregard of all papal claims to the contrary. In the Spanish dependencies in Italy, Ferdinand claimed the right of exequatur, according to which all papal bulls and breves (authorizing letters) could be published only with his permission. There exists a letter of Ferdinand to his viceroy in Naples, written in 1510, in which he upbraids the viceroy for permitting the Pope to publish a brief in Naples, threatens that he will renounce his own and his kingdoms' allegiance to the Holy See, and orders the viceroy to arrest the papal messenger, force him to declare he never published the brief, and then hang him. In Spain the Catholic Kings had no formal right of exequatur, but they and their Habsburg successors behaved very much as if they did. From now on the Spanish clergy had to look to the crown and not to Rome for advancement, and so did the great nobles who traditionally claimed the richest ecclesiastical benefices for their younger sons.

Perhaps most effective of all in reducing the political power of the high nobility was their virtual exclusion from the royal administration. The old royal council, a council of great nobles advising the king, was transformed into a bureaucratic body for the execution of royal policy, staffed by a prelate, three nobles, and eight or nine lawyers. These lawyers, mostly drawn from the poor hidalgo class, were entirely dependent on the royal will and became willing instruments of a more efficient and powerful central government. The Catholic Kings set up a Council of Finance (1480, but not fully developed until much later), the Council of the Hermandad (1476–98), the Council of the Inquisition (1483), and the Council of the Orders of Knighthood (for the administration of the property and patronage of the orders of Santiago, Calatrava, and Alcántara), and they reorganized the Council of Aragon. Charles I and Philip II were later to continue this work and to add further councils, notably those of the Indies (1524) and of Italy (1558).

When Isabella died, in 1504, the nobles appeared to be tamed and politically innocuous. In fact, their social position and its economic basis, their estates, had not been touched. Of the soil of Castile 97 percent was owned by 2 or 3 percent of the population, and some 50 percent of this was owned by a quite small number of families, mostly linked through intermarriage. In 1520 Charles I agreed to their demand for establishing a fixed hierarchy of rank, from the 25 grandees of Spain, through the rest of the titled nobility, down to some 60,000 hidalgos, or caballeros, and a similar number of urban nobility, all of them distinguished from the rest of the population, the *pecheros*, by far-reaching legal privileges and exemption from direct taxation. The Laws of Toro (1505), extending the right to entail family estates on the eldest child, further safeguarded the stability of noble property. The Catholic Kings had therefore shifted the balance of political power within the traditional ruling classes of Castile in favour of the crown, but they had not fundamentally altered the economic and social position of these classes.

Nobility's strong base

The Spanish Inquisition. With its large Moorish and Jewish populations, medieval Spain was the only multiracial and multireligious country in western Europe, and much of the development of Spanish civilization in religion, literature, art, and architecture during the later Middle Ages stemmed from this fact. The Jews had served Spain and its monarchs well, providing an active commercial class and an educated elite for many administrative posts. But, inevitably, their wealth created jealousy and their heterodoxy hatred in a population that traditionally saw itself as the defender of Christianity against the infidel. The Catholic Kings, ever good tacticians, profited from this feeling. In 1478 they first obtained a papal bull from Sixtus IV setting up the Inquisition to deal with the supposedly evil influence of the Jews and *conversos* (converted Jews). Since the Spanish Inquisition was constituted as a royal court, all appointments were made by the crown. Too late, Sixtus IV realized the enormous ecclesiastical powers that he had given away and the moral dangers inherent in an institution the proceedings of which were secret and that did not allow appeals to Rome.

With its army of lay familiars, who were exempt from normal jurisdiction and who acted both as bodyguards and as informers of the inquisitors, and with its combination of civil and ecclesiastical powers, the Spanish Inquisition became a formidable weapon in the armoury of royal absolutism. The Supreme Council of the Inquisition (or Suprema) was the only formal institution set up by the Catholic Kings for all their kingdoms together. Nevertheless, they thought of it primarily in religious and not in political terms. The Inquisition's secret procedures, its eagerness to accept denunciations, its use of torture, the absence of counsel for the accused, the lack of any right to confront hostile witnesses, and the practice of confiscating the property of those who were condemned and sharing it between the Inquisition, the crown, and the accusers—all this inspired great terror, as indeed it was meant to do. The number of those condemned for heresy was never very large and has often been exaggerated by Protestant writers. But during the reign of the Catholic Kings, several thousand *conversos* were condemned and burned for Judaizing practices. The whole family of the philosopher and Humanist Luis Vives was wiped out in this way. Many more thousands of *conversos* escaped similar fates only by fleeing the country. Many Catholics in Spain opposed the introduction of the Inquisition, and the Neapolitans and Milanese (who prided themselves on their Catholicism and who were supported by the popes) later successfully resisted the attempts by their Spanish rulers to impose the Spanish Inquisition on them. Even in Spain itself, it was the sumptuous autos-da-fé, or the ceremonial sentencings and executions of heretics, rather than the institution and its members that seem to have been popular. But most Spaniards never seem to have understood the horror and revulsion that this institution aroused in the rest of Europe.

The fate of the *conversos*

The first inquisitor general, Tomás de Torquemada, himself from a *converso* family, at once started a propaganda campaign against the Jews. In 1492 he persuaded the Catholic Kings to expel all Jews who refused to be baptized. Isabella and most of her contemporaries looked upon this expulsion of about 170,000 of her subjects as a pious duty. At the moment when Spain needed all its economic resources to sustain its new European position and its overseas empire (see below), it was deprived of its economically most active citizens and laid open to exploitation by German and Italian financiers.

The conversos. Nevertheless, the expulsion of 1492 did not signify the end of Jewish influence on Spanish history, as used to be thought until quite recently. It is not, however, easy to establish a clear-cut direction or pattern of this influence. At the end of the 15th century, there may have been up to 300,000 *conversos* in Spain, and the majority of these remained. They had constituted the educated urban bourgeoisie of Spain, and the richer families had frequently intermarried with the Spanish aristocracy and even transmitted their blood to the royal family itself. After 1492 their position remained precarious. Some reacted by stressing their Christian orthodoxy and denouncing other *conversos* to the Inquisition for Judaizing practices. Others embraced some form of less conventional, more spiritualized Christianity. Thus the followers of Sister Isabel de la Cruz, a Franciscan, organized the centres of the Illuminists (Alumbrados), mystics who believed that through inner purification their souls should submit to God's will and thus enter into direct communication with him. While they counted some of the high aristocracy among their numbers, most of the Illuminists seem to have been *conversos*. Again, it was among the *conversos* that Erasmianism (after Erasmus, a famous Humanist of the time), a more intellectual form of spiritualized Christianity, had its greatest successes in Spain. The Erasmians had powerful supporters at court in the early years of Charles I, when, as emperor, his policy was directed toward the healing of the religious schism by a general reform of the church. But in the 1530s and 1540s, the enemies of the Erasmians, especially the Dominican Order, launched a systematic

Converso reactions

campaign against them. The Inquisition annihilated them or forced them to flee the country, just as it had done in the case of the Illuminists as early as the 1520s. Nevertheless, the influence of Erasmus did not completely disappear from Spanish intellectual life, and it has been traced into the latter part of the 16th century.

But the majority of the *conversos* and their descendants probably became and remained orthodox Catholics, playing a prominent part in every aspect of Spanish religious and intellectual life. It has now become clear that without them the "Golden Century" of Spain would be inconceivable. They ranged from such saints as Teresa of Avila and St. John of God, one a mystical writer and founder of convents, the other an organizer of care for the sick, to Diego Laínez, a friend of St. Ignatius of Loyola and second general of the Jesuit Order. They included Fernando de Rojas, author of *La Celestina*, the first great literary work of the Spanish Renaissance, and, two generations later, Mateo Alemán, who wrote a picaresque novel, the *Guzmán de Alfarache;* and they could boast Luis de León, a Humanist and poet; a Dominican, Francisco de Vitoria, perhaps the greatest jurist of any country in the 16th century; and another famous Dominican, the defender of the American Indians and historian of the Indies, Bartolomé de Las Casas.

These, with Luis Vives, mentioned earlier, are only the most famous among the many distinguished *converso* names who played such a central and varied role in creating the cultural splendours of Spain's "Golden Century." It is an extraordinary phenomenon that had no parallel anywhere else in Europe before the 19th or even 20th century. Any attempt at an explanation is bound to be speculative, but the following may be suggested. The Spanish Jews and *conversos* formed a comparatively large section of the relatively small educated elite of Spain who were primarily responsible for the cultural achievements of the period. The *conversos*, moreover, having deliberately broken with the Jewish tradition of Talmudic (from the Talmud, the body of Jewish civil and canonical law) scholarship, found the glittering Renaissance world of Christian Spain ambivalently attractive and repellent but always stimulating. Their response to this stimulus was probably sharpened, their need to excel given a double urgency, by the hostility that they continued to meet from the "old" Christians. For these latter were very much aware of the ubiquity of the *conversos*, however much these were assimilated, and many resented it bitterly. Religious, racial, and even anti-aristocratic class prejudices combined to create the obsession with "purity of blood" (*limpieza de sangre*), which became characteristic of the Spaniards in the 16th and 17th centuries.

Converso contribution

It first crystallized with a statute of *limpieza*, imposed in 1547 on the cathedral chapter of Toledo, by which purity of ancestry from the taint both of *converso* blood and from any accusations of heresy by the Inquisition was made a condition of all future ecclesiastical appointments. The author of this statute was Archbishop Siliceo, a man of humble and hence, by definition, untainted origins, who had found himself despised by the aristocratic canons, many of whom, however, had *converso* blood in their veins. In 1556 Philip II gave his royal approval to the statute on the grounds that "all the heresies in Germany, France and Spain have been sown by descendants of Jews." As far as Germany and France were concerned, this remark was sheer fantasy, and it is especially ironic that, just at this time, Pope Paul IV, at war with Spain, described Philip II himself quite correctly as a Marrano, or descendant of Jews.

But statutes of *limpieza* now spread rapidly over Spain. They helped to perpetuate a set of values, the equation of pure ancestry, orthodoxy, and personal honour, which certainly helped to prevent the spread of heresies in Spain but which in the long run had a blighting effect on Spanish society, the more so as they were linked so closely with the basically corrupt institution of the Inquisition. For not only did they encourage the practice of denunciation, with inevitably corrupting and divisive effects, but they also educated generations of Spaniards to see their personal honour as a value depending on a set of circumstances substantially outside their own control or achievement.

Deadening effect of *limpieza* statutes

The conquest of Granada. The impact of the Moors on Spanish life and traditions had been rather different from that of the Jews. It was most evident, perhaps, in the position of women in southern Spain, who for long remained semi-veiled and in much greater seclusion than elsewhere in Christian Europe. It was evident also where Jewish influence was practically nonexistent, in the visual arts and especially in architecture. Not only did houses in southern Spain for a long time continue to be built facing inward, on to a patio, but a whole style of architecture, the Plateresque, derived from an imaginative fusion of the Moorish and the Christian: classical Renaissance structures were decorated with Gothic or Renaissance motifs but executed in the Moorish manner, as if a carpet had been hung over the outside wall of the building. This charming style, which was invented during the reign of the Catholic Kings, spread far and wide over Spain and eventually even to the New World.

To Ferdinand and Isabella, the Moorish problem presented itself in the first place in a political and military form, for the Moors still ruled their independent Kingdom of Granada (Spain's southeast corner). The Catholic Kings had to concentrate all their military resources and call on the enthusiastic support of their Castilian subjects to conquer the kingdom in a long and arduous campaign, which ended with the capture of Granada (some 130 miles east of Seville), the capital, in 1492. In this campaign Gonzalo Fernández de Córdoba, the "Great Captain," developed the tactics, training, and organization that made Spanish infantry almost unbeatable for 150 years. The Moors were granted generous terms and religious freedom. But, against the advice of the saintly Hernando de Talavera, the *converso* archbishop of Granada, who was trying to convert the Moors by precept and education, the Queen's confessor, Francisco (later Cardinal) Jiménez de Cisneros, introduced forced mass conversions. The Moors rebelled (1499–1500) and, after another defeat, were given the choice of conversion or expulsion, Jiménez and Isabella did not regard this new policy as a punishment of the Moors for rebellion, for Christian Baptism could never be that. It was rather that the rebellion released them from their previous undertaking, which they had entered into only with misgivings. Though many Moors chose conversion, the problem now became virtually insoluble. There were never enough Arab-speaking priests or money for education to make outward conversion a religious reality. The Moriscos remained an alien community, suspicious of and suspect to the "old" Christians. There was with the Moriscos very little of the intermarriage with Christians and of the deliberate acceptance of Spanish Christianity that, in spite of all the statutes of *limpieza*, allowed the *conversos* to become such an integral part of Spanish society.

Hopelessness of the Moorish position

Acquisition of Naples. Ferdinand's foreign policy was dominated by the traditional Aragonese rivalry with France along the Pyrenees and in Italy. Aragon still held Sicily and Sardinia from the much more extensive medieval Aragonese empire. French intervention in Italy, from 1494, gave Ferdinand his chance. Charles VIII of France, to secure his southern flank while he led his army into Italy, agreed to return to Ferdinand the counties of Cerdagne and Roussillon (Treaty of Barcelona, 1493), which Louis XI had seized during the Catalan civil wars, in 1463. But it was through Ferdinand's own diplomacy and through the generalship of Gonzalo de Córdoba that he acquired the Kingdom of Naples (1503). For the first time the union of Aragon and Castile had shown its strength, and Spain now rivalled France as the most powerful state in Europe. Ferdinand had carefully arranged the marriage of his children to strengthen his diplomatic position against France by alliances with Portugal, England, and Burgundy (which ruled the Netherlands). The unexpected deaths of the two eldest and their children, however, left the succession of Castile after Isabella's death (1504) to the third, Joan the Mad, and her husband, Philip I (the Handsome)

of Castile, ruler of the Burgundian Netherlands. The Netherlands nobility were delighted to see this enormous accretion of power to their ruler and looked forward to the advantages that they might reap from it. They accompanied him to Castile, where a large section of the high nobility, in their turn, were anxious to acclaim him rather than the redoubtable Ferdinand. Ferdinand was therefore forced to recognize Philip's claims; but this latter died in 1506, and Ferdinand was left as uncontested ruler. His last great success was the annexation of the Spanish part of the Kingdom of Navarre in 1512.

Spain and the New World. While the exploration of the Atlantic coast of Africa had been mainly a Portuguese concern in the 15th century, the Castilians had not been entirely disinterested in such activities and had occupied the Canary Islands (off northwest Africa). In the Treaty of Alcáçovas (1479), when Afonso V of Portugal renounced his claims to the crown of Castile, he also recognized Castilian possession of the Canaries in return for Spanish recognition of Portuguese possession of the Azores (in the Atlantic Ocean west of Portugal), the Cape Verde Islands (off West Africa), and Madeira (north of the Canaries). The conquest of Granada allowed Castile, for the first time, to concentrate major resources and effort on overseas exploration. The support that Columbus received from Isabella was indicative of this new policy. In 1492 Columbus discovered the West Indies, and, in the next half century, the Spaniards conquered huge empires in America and made their first settlements in the Far East. From the beginning there were disputes with the Portuguese, who were conquering their own colonial empire. The Catholic Kings obtained a series of papal bulls (1493) from the Spanish pope Alexander VI and as a result concluded the Treaty of Tordesillas with Portugal (1494) to settle their respective claims. Everything west of an imaginary line 370 leagues (here, the league was just over three nautical miles) to the west of the Cape Verde Islands in the Atlantic was assigned to Spain; everything east went to Portugal. The rest of Europe saw no reason to accept the Pope's decision, and the result was constant and brutal warfare in the overseas colonies, even when the European governments were officially at peace (see also LATIN AMERICA AND THE CARIBBEAN, COLONIAL).

Growing Castilian activity

Colonial policy. Unlike the other European colonists of that age, the Spaniards were vitally concerned with the moral problems of conquest, conversion, and government of heathen peoples. If the great majority of conquistadores ruthlessly pursued gold, power, and status, they took with them Dominican and Franciscan friars who set themselves to convert and educate the American Indians and, sometimes, to protect them from their Spanish masters. The Dominican Bartolomé de Las Casas fought long battles to modify at least the greatest evils of colonial exploitation. His debates with a theologian, Juan Ginés de Sepúlveda, and the writings of Francisco de Vitoria provide the first systematic discussions of the moral and legal problems of conquest and colonial rule. Their importance lay in their effects on Spanish colonial legislation. The Leyes Nuevas ("New Laws of the Indies") of 1542 were based largely on the arguments of Las Casas. While in the colonies these laws were honoured more in the breach than in the observance, yet they provided at least some protection for the Indians, and there was nothing like them in any of the other European overseas colonies of the period. Even Las Casas, however, supported the transatlantic slave trade of black Africans, until, late in his career, he came to recognize its evils.

The Atlantic trade. The crown insisted that all trade with the colonies should be carried on through Seville and should be reserved for Castilians on the argument that it was Castilian money and blood that had built the Spanish overseas empire. This trade was closely regulated by the Casa de Contratación (1503), or the House of Trade, in Seville. The city itself rapidly became one of the greatest trading centres in Europe, and its population rose from 25,000 in 1517 to 90,000 in 1594. Yet Castile was unable to supply all the manufactures that the colonists demanded and for which they paid in solid gold and silver. So far from seeing this trade as an opportunity for Castilian industry, the Cortes actually petitioned the crown in 1548 to prohibit exports to the Indies that, they claimed, were raising prices in Castile. The government did not accept this petition, but Castile had to import much of what its colonists needed from Italy and the Netherlands. The Castilian monopoly of trade with Spanish America in practice had only the effect of giving the rest of Europe the chance to compete on equal terms for the American trade with the monarchy's non-Castilian subjects. The organization and financing of the Spanish Atlantic trade were largely in the hands of Genoese and south German merchants. From the 1540s, when a new method of extracting silver from ore with the use of mercury was discovered, silver mining became a major industry in both Mexico and Peru, and silver shipments in rapidly increasing quantities soon surpassed the earlier gold shipments in value. Precious metal was exported from the Indies to Spain, partly as the crown's right of one-fifth (*quinto real*), but, more important, as payment for imports. The average annual quantities, as registered by the Casa de Contratación (not counting the unknown quantities that were smuggled), rose rapidly from about 1,000,000 pesos in the five-year period 1526–30, to 5,000,000 during 1541–54, and then to the peak of more than 35,000,000 during 1591–95. The growth of overall trade between Seville and the New World followed a very similar pattern, rising until 1550, then stagnating until the early 1560s, and rising again to a peak in the last decade of the 16th century. Prices, especially of agricultural produce, had started to rise in Spain, as in the rest of Europe, long before American silver was imported in considerable quantities. But, whatever the ultimate causes of the price revolution of the 16th century, there can be little doubt that American silver greatly aggravated the inflation in Spain in the second half of the 16th century. The theologians of the university of Salamanca (some 100 miles [160 kilometres] west–northwest to Madrid) in the 1550s were the first to see this connection and to formulate the earliest version of a quantity theory of money (in which money is worth more when scarce than when abundant). Very little of this American treasure seems to have been invested in economic production. Most of it was used for display by the court and ruling circles, to pay for Spanish imports, for the Spanish armies abroad, and to satisfy the government's German, Italian, and Netherlandish creditors. Thus Spain, with all the treasure of the New World at its command, remained a poor country.

Castile's demand for monopoly

The influx of silver from the New World

SPAIN UNDER THE HABSBURGS

Charles I. Ferdinand died on January 23, 1516, and the crowns of the Spanish kingdoms devolved on his grandson, Charles I (1516–56), the ruler of the Netherlands and heir to the Habsburg dominions in Austria and south Germany. This new union had not been planned in Spain, and, at first, it was deeply resented. Cardinal Jiménez, the regent until Charles's arrival in Spain, had to battle against the old antagonisms between nobles and towns that were flaring up again when the magnates took the opportunity of the regency to try to regain their old power. When Jiménez tried to raise a militia, nobles and cities both sabotaged the plan. The old hostilities between the different Spanish kingdoms were as bitter as ever, with the men of Navarre, for instance, claiming that they would rather accept a Turk than an Aragonese as governor of the fortress of Pamplona. Although the court at Brussels had been careful to hold its hand in the distribution of patronage, the Spaniards, nevertheless, accused the Netherlanders of greed and place hunting. It took Charles's Netherlandish ministers a year and a half to settle the Netherlandish government and to make agreements with France and England that would allow the boy-king to take possession of his new kingdom without outside interference. It was a considerable achievement, but for Spain the time was still too long. When Charles arrived in Spain, in September 1517, his supporters were already disillusioned, and the country was apprehensive of the rule of a foreigner. Charles himself, ugly, inex-

perienced, speaking no Spanish, and surrounded by Burgundian councillors and courtiers, did not initially make a good impression. The different Cortes of Castile, Aragon, and Catalonia granted his financial demands but attached to them much pointed advice and criticism.

The comunero movement. On June 28, 1519, Charles was elected Holy Roman emperor as Charles V and prepared to go to Germany. His chancellor, Mercurino Gattinara, summoned the Castilian Cortes to Santiago in northwest Spain (April 1520) to demand more money, even though the former grant had not yet expired. The towns immediately made difficulties. The Toledans refused to appear; the others demanded the discussion of grievances before supply. By a mixture of bribery and concessions, the government finally induced a majority of the delegates (who had transferred from Santiago to La Coruña on the northwest coast of Spain) to vote the new grant. Many of the delegates were immediately disowned in their home towns, and one from Segovia was murdered by an enraged mob. As Charles set sail (May 20, 1520) the Castilian revolution had already begun.

Insurrection against Charles V

The towns, led by Toledo, formed a league and set up a revolutionary government. They claimed—more boldly even than the Third Estate during the French Revolution in 1789—that they were the kingdom and that the Cortes had the right to assemble without a royal summons and to discuss all matters relating to the welfare of the realm. There was talk of dethroning Charles in favour of his mother, Joan the Mad. The *comunero* leader, Juan de Padilla, actually captured the castle of Tordesillas (100 miles northwest of Madrid), where Joan was kept as prisoner; but the Queen, whether out of madness or calculation of the interests of the monarchy, would not commit herself to Padilla's proposals. The *comunero* movement spread rapidly through Castile, and the nobles did nothing to check it. They had not forgiven Charles his quest for the imperial title (which they thought inferior to that of king of Castile) nor his foreign councillors and courtiers. They resented above all his bestowal of the archbishopric of Toledo on a young Burgundian, Guillaume de Croy, and the appointment of his former tutor, Adrian of Utrecht (later Pope Adrian VI), as regent of Castile. Even the appointment of the admiral Fadrique Enríquez and the constable of Castile, Iñigo de Velasco, as Adrian's co-regents did little to mollify the offended grandees. Only when the more radical and popular elements in the cities were gaining control of the *comunero* movement and beginning to spread it to the nobles' estates did the nobles combine to raise an army and defeat the *comunero* forces at Villalar (April 23, 1521).

The power of monarchy was thus restored in Castile, never to be seriously shaken again under the Habsburg kings. The towns kept much of their autonomy, but royal control in the town councils was safeguarded by the appointment of royal officials, the corregidores. The Cortes continued to function; but the deputies of the 18 "royal towns," which alone were summoned, were mostly members of the urban nobility, exempt from direct taxation and therefore not unduly concerned about voting the taxes the government asked for. As to their petitions, the King granted or ignored them as he saw fit. The nobles had won the civil war, but they could no longer break their alliance with the monarchy. The monarchy, now that it could manage the Cortes and afford a standing army, was the stronger partner. But when, in 1538, Charles I proposed a tax from which the nobles should not be exempt, there were immediate rumblings of revolt. Charles had to give way, but he never summoned the nobility again to the meetings of the Cortes. The monarchy had thus won its political victory in Castile only at the cost of letting the nobility contract out of the financial obligations of the state and the empire. The rising burden of taxes fell, therefore, on those least able to bear them and on the only classes whose activities and investments could have developed the Castilian economy.

The crown's expensive political triumph

The nobility. The traditions of the grandees and hidalgos, formed in the centuries of struggle against the Moors, made them even more averse to economic activities than the rest of the European nobility. They invested their money in land, without, however, improving agriculture, and preferred careers in the army, the church, and the civil service to the ignoble occupations of commerce. In the long run, the economic weakness of Spain, aggravated by its social traditions and its system of taxation, proved a serious handicap in Spain's struggle with its western European rivals. After Villalar, however, the Spanish nobility had come to accept Charles I. His championship of Catholic Christianity against the Muslim Turks and German heretics appealed to their own traditions of Christian warfare against the Moors. While Charles kept the grandees out of the central government of Spain itself, he had many prizes to offer in military commands, provincial governorships, and even viceroyalties in Italy and Spanish America. The hidalgos, trained as lawyers at Salamanca or as theologians at Alcalá de Henares (just east of Madrid), could look forward to dazzling careers in the King's councils and in the Spanish church. Even though Charles spent only 16 of the 40 years of his reign in Spain, the Spanish upper classes were beginning to accept and enjoy their monarch's position as the greatest ruler in Europe.

Charles I's foreign policy. Spain as a result, however, became involved in interminable wars. The necessity of defending southern Italy from the Turks brought Charles's empire into collision with the Ottoman Empire, with the central Mediterranean as the chief battle ground. Ferdinand's failure to complete the conquest of North Africa now brought a bitter revenge. The corsair leader Khayr ad-Dīn, known as Barbarossa, had made himself master of Algiers (1529) and acknowledged the suzerainty of the Sultan of Constantinople. Thus, the purely local problem of the Moorish raids on the Spanish south coast became merged into the much more formidable struggle with the Ottoman Empire. In 1535 Charles captured Tunis. It was, perhaps, his most satisfying triumph; for in this enterprise he manifestly appeared in his chosen role of "God's standard bearer," as he said himself. He now seriously considered carrying the war into the eastern Mediterranean, even conquering Constantinople itself. But in 1538 Barbarossa with a Turkish fleet defeated Charles's Genoese admiral, Andrea Doria, at Préveza (west Greece), and in 1541 the Emperor himself failed against Algiers. At the end of the reign, the balance of the two great naval powers in the Mediterranean, the Spanish and the Turkish, was still even.

Problems with the Turkish Empire

Rival Aragonese and Angevin (cousins of the ruling French house) claims to Naples also brought conflict with the French kings, against whom Charles fought four wars. His armies conquered Milan (north Italy) and reduced most of the still independent Italian states to Spanish satellites. An increasing part of the burden of these wars fell on Spain, and especially on Castile. The Spanish *tercios* (infantry regiments) were not only the Emperor's best troops, but it was in Castile that he could raise the largest part of his imperial revenues, and this, moreover, without having to account for the way he spent them, as he had to do with the taxes voted by the States General of the Netherlands. It is therefore not surprising that the empire in Europe with Charles V as head became gradually transformed into a Spanish, or, rather, Castilian, empire of Charles I. In the latter part of his reign, Spaniards and Hispanicized Italians monopolized all high positions in the empire south of the Alps and began to appear in Germany and the Netherlands. More and more they came to interpret the international and Catholic ideals of the Emperor in terms of the political predominance of Spain in Europe and overseas.

Philip II. When Charles abdicated his various lands (1555–56), Philip II (1556–98) succeeded to all his father's dominions except Germany. His empire in Europe, now without the imperial title, was still only a loose union of independent states recognizing the same head. Philip, a great traditionalist, was not the man to inspire his different subjects with a new unifying idea, though he improved the central administration of his empire by the creation of the Council of Italy (1558). But his own Castilian upbringing and preferences increased the tendency toward transforming the empire into a Castilian

empire. Six of the nine viceroys Philip appointed to govern Sicily were Spaniards, as were all those of Naples, with the single exception of one Cardinal Granvelle, and ten out of 13 governors of Milan. In the Spanish viceroyalties of Aragon, Catalonia, Valencia, and Navarre and in those of Mexico and Peru, none but Spaniards, and preferably Castilians, were ever thought of at all. These were the key figures in Philip II's empire, and they were backed by the commanders of the Spanish regiments. Fortresses were nearly always governed by Castilians.

Role of the Castilians in the armies

Only in the Low Countries was it necessary to appoint natives to military commands. When the viceroys and governors were appointed, they were given "secret" instructions—in short, ones not meant for purely propagandistic purposes. These instructions reflected the current commonplaces of Christian government that could be found in scores of "Mirrors of Princes" (handbooks of government popular at the time) published in the 16th century and that Philip had made his own. The governors were to represent the King—not the state or the Spanish Empire—as if he were present in person; it was stressed that they were not appointed for their own benefit but for that of the community they were sent to govern; they were to watch so that the King's subjects might sleep in peace and quiet and to dispense equal justice to rich and poor. Many of the Castilian grandees who were appointed to these high offices undoubtedly strove to live up to these precepts. In practice, however, their success depended largely on the strength of the local opposition they met: this was a great deal in Sicily, which had won the reputation of being "fatal to its viceroys," but very much less in Naples, about which at least one viceroy remarked that no one should wish to be viceroy there because of the pain he would have to suffer when he had to leave that post at the end of his term. A great part of the viceroys' difficulties, however, stemmed from the unreliability of the King himself. Philip was always anxious to maintain the dignity of their office, but he encouraged the local ministers and officials to report on their viceroys behind their backs, and he had no compunction about recalling a viceroy, governor, or minister when it suited him in this way to appease local opposition.

The King kept control over his viceroys and governors by weekly, sometimes daily, correspondence, carried by the excellent postal service that the House of Austria had organized in Europe. All important political decisions were thus taken in Madrid, and there the King relied almost entirely on Spaniards for advice. Only one non-Spaniard, Cardinal Granvelle of Franche-Comté, was ever summoned to Madrid to play a leading role in the King's inner councils (1579–86). It was Granvelle who had earlier, as the King's chief minister in the Netherlands, reminded his master of the international character of his empire. He advised a more international dispensation of royal patronage, as, for instance, the appointment of the Prince of Orange (William I the Silent) to the viceroyalty of Sicily so that Netherlanders and Italians would no longer think that the King regarded only the Spaniards as his "legitimate subjects." But Philip had refused to listen, and the bitter Castilian hostility at court to Granvelle ended by making the Cardinal's ministry in Madrid less and less effective in the last two or three years before his death in 1586.

Philip's refusal of non-Castilian appointments

Finance and imperial policy. Philip II on his accession inherited an unfinished war with France and a debt of some 20,000,000 ducats. While his ally England (to whose queen, Mary Tudor, Philip was married) lost Calais, Philip's own armies won considerable victories, and he was able to conclude the Peace of Cateau-Cambrésis (1559) with France, which confirmed Spanish possessions and hegemony in Italy and which left the frontiers of the Netherlands intact. But the financial position had become irretrievable, and Philip's governments, both in Madrid and in Brussels, had to declare a moratorium on their debts. It was the first of three such moratoriums in Philip II's reign—the other two were declared in 1575 and 1596—and it set the tone for the remainder of Habsburg rule in Spain, marked by growing disparity between the monarchy's imperial policies and the financial resources at its disposal to carry out these policies. For the rest of the 16th century this disparity was still largely masked by the fluctuating, but generally increasing, shipments of silver from the New World. These shipments inspired both the King and his German and Genoese creditors with the perennial hope of new treasure to pay off ever growing debts. But the armies and navies continued to swallow up more than the stream of American silver. In the end the financial burden of empire fell more and more on Castile, and it was this fact that came to determine the course of Spanish history for the next 100 years.

When Philip II returned to Spain, in 1559, he still had a naval war with the Turks on his hands, and, in the following year, his galleys suffered a humiliating and costly defeat at the island of Jarbah (off Tunisia's east coast). In 1566 the steadily deepening crisis of the Netherlands came to a head in an outbreak of image breaking. In that year Sultan Süleyman the Magnificent died, and, for a time, the Turkish danger faded into the background. Philip could therefore risk sending his commander, the Duke of Alba, with his best Spanish and Italian troops to the Netherlands (1567) in order to settle the problems of that dominion once and for all. Alba was to root out heresy, punish those responsible for the rebellion, and impose taxes sufficient to relieve Castile of the need to send any more financial help to the government in Brussels. It was the King's most terrible miscalculation, for rebellion now became revolt and involved Spain in an Eighty Years' War, 500 miles (800 kilometres) from its own borders (1568–1648). It was in the pursuit of this war that the Spanish Empire in Europe eventually foundered.

Repression in the Netherlands

The key to Philip II's and his successors' strategic thinking, however, was always France. This was reasonable; for France was potentially the strongest military power in Europe, and its hostility to Spanish greatness was absolute, despite occasional short periods of rapprochement. But, until 1595, France was paralyzed by a long succession of civil wars. Much as Philip II hated and feared a possible Huguenot (French Protestant) victory in France, he was content to see the civil wars continue, anxious, most often, to intervene on the side of the Catholics yet sometimes covertly offering help to the Huguenots. Until the late 1570s, the threat from the Turks rivalled in importance the problems of the Netherlands. Philip switched his limited resources from the Low Countries to the Mediterranean and back again, unable to achieve a decisive victory in either theatre. It was natural, therefore, that for 20 years after the Peace of Cateau-Cambrésis Spanish foreign policy remained on the defensive. There were, moreover, still formidable internal Iberian problems to be solved.

The Moriscos. The most immediate problem was that of the Moriscos of Granada. The attempt to Christianize and assimilate them had proceeded only very slowly. In the 1560s, the ineptitude and the mutual wrangling of the different public authorities in Andalusia brought government to a virtual standstill. The Captain General of Granada, in charge of defense and internal security, was quarrelling with the municipal council of Granada and with the *audiencia*, the supreme court for Andalusia, over precedence, rights of jurisdiction, and the ownership of some pastures. The *audiencia*, in its turn, quarrelled with the Inquisition over disputed rights of jurisdiction, as did the Captain General. He was supported by the Archbishop of Granada, who was, however, involved in a lawsuit with his cathedral chapter. Such disputes were typical of the Spanish system of government, and it was also characteristic that they became immediately involved in faction fights at Philip II's court. These were therefore rarely settled according to their merits but according to the prevailing political alignment at court. In this case the Governor General, who had usually acted as the protector of the Moriscos against the exploitation of the Christians, lost. The government in Madrid first sent a commission to inquire into titles of land, and this commission confiscated mainly Morisco land. In 1567 a decree was published forbidding the Moriscos the use of

their Moorish names, dresses, and even of their Arabic language. Internal security was transferred from the governor general to the *audiencia*. This was the last straw, for now there was no one to protect the peaceful Morisco farmers from the murderous Morisco bandits of the sierra ("mountains"). On Christmas Day, 1568, they rose against the hated Christians. It took two years of ferocious campaigning, with dreadful atrocities committed by both sides, before the rebellion was put down. The Moriscos of Granada were then deported in small groups to different parts of Castile and settled in a last attempt to achieve assimilation. In the absence of systematic education and in the face of the hostility of the Christian population, this attempt was also doomed to failure.

Portugal and Aragon. There remained the question of the complete unification of the Iberian Peninsula. In the case of Portugal, Philip's opportunity came when his nephew, King Sebastian of Portugal, lost his life and a great Portuguese army in an ill-prepared crusade in Morocco at the Battle of the Three Kings in north Morocco (1578). During the short reign of Sebastian's old uncle, King Henry (1578–80), Philip carefully prepared his ground in Portugal by intrigue and bribery. Nevertheless, when Henry died the opposition to Castile was still so strong in Portugal and the attitude of France and England so threatening that it was necessary for Philip to send the Duke of Alba with an army to conquer Portugal in 1580. Philip respected the laws and privileges of his new subjects and left them to administer their own colonial empire. But the union increased rather than diminished the old hostility between the Castilians and the Portuguese.

Philip II's last action in the peninsula was against Aragon. It was precipitated by a court intrigue that led to the flight (1590) of the King's secretary, Antonio Pérez, to Aragon. Since Pérez was unlikely to be convicted in the *justicia's* court there, the King demanded his transfer to the court of the Inquisition. The populace of Saragossa (some 160 miles [260 kilometres] west of Barcelona) rioted, freed Pérez, and killed the King's special representative (1591). To the Aragonese it meant the defense of their liberties; to Philip it meant open rebellion. A Castilian army marched into Aragon (1591), and Philip made a number of constitutional changes. The *justicia* was, from now on, removable at royal pleasure; the viceroy could be a Castilian, and majority voting was substituted for the principle of unanimity in the Castilian Cortes. These changes gave the crown the ultimate power of decision in Aragon but preserved the kingdom's autonomy.

Aragonese liberties defended

Lepanto. In the Mediterranean the Spanish fleet was inferior to that of the Turks, and Philip had to remain on the defensive, even when the Turks were besieging Malta (1565). Their failure to capture the island from the Knights of St. John, who had leased it from Charles V as emperor, marked the end of their great offensive. Six years later, the combined Spanish, Venetian, and papal fleets—in alliance the numerical equals of the Turks—virtually annihilated the Turkish fleet at Lepanto (1571). The strategic effects of this great victory were negligible, but its moral effects were immense. It confirmed the Spaniards in their chosen role of champions of Christendom and explains much of their continued willingness to support their King's religious and imperial policies, even in the face of ruinous costs and mounting disasters. After Lepanto, however, it became clear that the stalemate in the Mediterranean could not be broken. In 1580 Spain signed a truce with the Porte (Turkish government).

The Armada. From about 1580 the Spanish government became convinced that the rebellion (1568–1609) and heresy in the Netherlands could not be crushed as long as the rebels received help from England and France. These countries, moreover, gave active support to the Portuguese pretender, Antonio, prior of Crato (mid-Portugal), and their privateers committed continual acts of piracy against Spanish trade in the Americas. Philip began to give financial aid to the League, the ultra-Catholic party in France. From 1586 he prepared the invasion of England. The Armada, which set sail from Lisbon in May 1588, numbered 130 ships and nearly 30,000 men, bravely and not at all incompetently commanded by the Duke of Medina-Sidonia. But it had been set an impossible task: that of convoying the army under Alessandro Farnese (*q.v.*), Duque de Parma, from the Netherlands to England in the face of a better armed English fleet and without control of a single deepwater channel port. The defeat of the Armada was inevitable but not dishonourable.

Spanish intervention in France from 1590 was equally doomed to failure. The Duke of Parma, with his Spanish veterans, won great tactical victories, but Spain failed to prevent the succession of Henry of Navarre as Henry IV of France and the collapse of its ally, the League, when Henry became Catholic (1593).

Philip saw his role and that of Spain essentially as that of defender of the Catholic Church against the aggression of the heretics, an aggression that now seemed to have become mainly military and that therefore had to be met by military force. It was therefore essential that the King should safeguard and extend the power of Spain and the just claims of his house, such as those he claimed for his daughter for the throne of France. Every other consideration was subordinated to this obligation, even to the point at which the Spanish ambassador in Rome, the Count of Olivares, intervened in three successive conclaves in order to assure, by a mixture of promises and threats, the election of popes congenial to his master (conclaves of Urban VII, Gregory XIV, and Innocent IX, 1590–91). He just failed in the fourth, but crucial, election of Clement VIII, who was to receive Henry IV back into the Catholic Church (1595).

But, if Philip II could thus justify his aggressive policies to himself, both Spain's enemies and its allies were convinced that they were witnessing the quest for Spanish dominance over Europe. Many Spaniards themselves believed this; but, as the war dragged on and the costs mounted, even the faithful Castilian Cortes began to question the King's policy. After 1580, silver shipments from the New World to Seville reached new record levels, and this undoubtedly helped to persuade Philip II to embark on his grandiose schemes against England and France. Yet they only represented a quarter of his annual revenues. The rest was derived from taxation and from loans for which future revenues were pledged. The Armada campaign was said to have cost 10,000,000 ducats. The combined cost of the continuing naval war against England, the campaigns in the Netherlands, and the military intervention in France was even greater. In 1590 the Cortes accepted the royal demand for a new excise tax that was to raise 8,000,000 ducats in six years and that was appropriately nicknamed the *millones*. But by 1595, a deputy from Seville said bitterly that "the reason why taxes have been raised without noise is because they have not fallen on the rich who are those who have a voice . . . and the sweetness which they find, that is the blood of the poor." A year later, in 1596, Philip II's government declared its third bankruptcy (moratorium), but the *millones* were increased rather than lowered.

Spain had gambled its own prosperity and its American treasure on a decisive victory over the heretics in western Europe and with it its own hegemony over the Continent, and it had failed. Shortly before his death, Philip II concluded the Treaty of Vervins (1598) with France, which substantially re-established the position of 1559. Yet, if Spain failed in its highest ambitions, at the end of the 16th century it was still the greatest power in Europe. It had brought Christianity to millions overseas—and to most contemporaries, if they thought about it at all, it seemed worth the appalling price paid for it in terms of the lives and freedom of non-European peoples—and Protestantism, though not destroyed, had been contained. Spanish monks and mystics had given Catholicism a new content, and Spanish theologians and jurists had created the basis of international law. Spanish literature and art were only now entering their greatest period. Morally and economically there were dark sides to the picture, but to the Spaniards the 16th and early 17th centuries have always been their "Golden Century."

Philip's admission of defeat

Spain in 1600. It is not surprising that the enormous exertions of the last quarter of the 16th century, with its mixture of triumphs, disappointments, and miseries, should have been followed by a general mood of introspection and even disenchantment. This was particularly evident in economic and social thinking. The *arbitristas* (literally, "projectors") were writers who combined an economic analysis of the social ills of Spain with projects for economic recovery and social and moral regeneration. They saw clearly the central weakness of Spain, the attitude of mind that despised productive work and those who engaged in it. Far too many strove to live the life of a hidalgo. The treasures of Mexico and Peru, so far from stimulating investment and industrial production, had only encouraged men to look for shortcuts to riches and to live the life of *rentiers*, investing their money in the *censos*, the government annuities. These *censos* were the greatest plague and perdition of Spain, wrote González de Cellorigo, perhaps the most acute of the *arbitristas* of 1600. "It seems," he concluded, "as if we had wanted to turn these kingdoms into a republic of enchanted men, living outside the natural order."

The positive plans (among many fantasies) advocated by the *arbitristas* included the drastic cutting of government expenditure, the reform of the tax system, the encouragement of immigration into Castile, systematic and extensive irrigation, protection of industry, improvement of transport, and, finally, the sharing of the cost of empire among the constituent kingdoms of the monarchy. These were reasonable proposals, not unlike those put forward by mercantilist writers in the rest of Europe who treated economic activity as a means of increasing the power of the state. But it was not clear that the Castilian ruling classes would be capable and willing to act on them. Its attitudes were varied and often ambivalent, and this ambivalence is also reflected in the imaginative literature of the period.

Proposals for reform

Spain's Golden Age in literature. At one extreme there was the picaresque novel with its implicit satire of a society in which one could make one's way by cleverness and roguery rather than by honest work—that is, if one did not happen to be born a nobleman. Thus, the hidalgo in the *Lazarillo de Tormes* (published 1554), the first of the picaresque novels, is down and out but would rather starve than work, and he expects his servant, the boy Lazarillo, to scrounge for them both. In *Don Quixote* (published 1605 and 1615), the author, Cervantes, raised the picaresque novel to a completely new level of social and psychological insight. It is, among other things, a parable of Cellorigo's "republic of enchanted men," living in a world of illusions and tilting at windmills.

At the other extreme, there was the drama from exponents such as Lope de Vega to Tirso de Molina and Calderón. As with the picaresque novel, the comedy of the "Golden Century" was concerned with the contemporary social scene. The psychological problems faced by its characters arose nearly always directly out of social conflicts. But the social purpose of these plays was essentially conservative: the defense of the highly structured Spanish society of the time. This was achieved by insisting for all social ranks, from the king down to the peasants, on the special dignity and honour of their status. Thus Lope, for the first time, introduced the common people as fully rounded characters on the stage, allowing, for instance, to the daughter of a blacksmith the emotions of love formerly reserved on the stage to aristocratic ladies. Heredity and blood are the principles of a social order that in the comedies may be threatened but that are always reaffirmed in the end. Here may, perhaps, be seen a link with the visual arts of the age and with the Baroque style.

The "Golden Century" in architecture and painting. In the second half of the 16th century, in the more severe artistic climate of the Catholic Counter-Reformation, the playful Plateresque style of buildings fell into disfavour. Philip II preferred the unornamented and monumental classical architecture of Juan de Herrera, the greatest Spanish architect of the century. This could be very effective, as in Philip's monastic palace of El Escorial (20 miles [30 kilometres] northwest of Madrid), which embodied the gloomy and ascetic spirit of the King and also blended with the stark and forbidding landscape of the Sierra de Guadarrama (a range of mountains northwest of Madrid). But only too often the style produced an ugly and pompous monumentality, such as not infrequently afflicts the architecture of countries at the height of their imperial careers. But at the turn of the century this style gave way to the Baroque, which Spanish architects found no difficulty in acclimatizing in their country from Italy. This style could achieve monumentality without being pompous. It could display the grandeur of the church, or the monarchy, or anyone rich enough to build himself a palace. Perhaps most important of all, it was a style that, by its love of ornamentation and its essentially theatrical character, became immensely popular with the mass of the population.

Success of the Baroque style

The painting of the period does not lend itself as easily to a social interpretation; but certain patterns may still be observed. The greatest painter of the Spanish Counter-Reformation, the Cretan El Greco, made his home in Toledo, where the local aristocratic and ecclesiastical society (but not Philip II) seems to have fully appreciated his genius. El Greco's superb portraits, but above all his religious paintings, with their elongated figures rising like so many flames to heaven, seem like the embodiment of the most spiritual aspects of Spanish Catholicism.

El Greco left no school. The painters of the following generation, especially Murillo, had a different religious sensibility, more naturalistic than El Greco, more personal, and more romantic; and again, as did Baroque architecture, they appealed successfully to a popular religiosity. But the greatest of them, Velázquez, was hardly a religious painter at all. His subjects were the King with his family and court and, characteristic for the age and parallel with the drama of the period, the common people. All these he represented with a realism and psychological insight unmatched in the 17th century, except perhaps by Rembrandt.

The reign of Philip III. It was the tragedy of Spain that its ruling classes failed to respond to the social and political problems of the age as creatively as its writers and artists. For this failure there are at least some good reasons. In the first place, the system of royal government, as it was understood at the time, depended ultimately on the king's ability to lead and to make decisions. Philip II's very consciousness of his divinely imposed obligations in this respect, compounded by his almost pathological suspiciousness of the intentions and ambitions of other men, had led him to deprecate independent initiative by his ministers. Philip thus failed to educate an effective ruling class with a tradition of statesmanlike thinking and decision making.

Philip III (died 1621) was a devout, phlegmatic nonentity, totally incapable of carrying on his father's methods of personal government. He therefore had to have a minister who would do all his work for him, a *privado*. His choice, the Duke of Lerma, however, turned out to be a singularly unfortunate one. Amiable, incompetent, and, inevitably, under heavy attack from those who envied his position, Lerma strove to maintain himself by the lavish dispensation of royal patronage to the high nobility. He was not the man to translate the schemes of the *arbitristas* into effective reforms. During the reign of Philip III the government of Spain either became the victim of events that it did not attempt to control or allowed its hand to be forced by outsiders.

Lerma's incompetency

Not all events could have been controlled. In 1599–1600 an epidemic plague claimed some 500,000 victims in Castile. This sudden decimation of the labour force caused a sharp rise in wages that acted as another disincentive to capital investment by Spaniards. Yet the advantages that the labourers had reaped from the rise in wages were quickly offset by renewed inflation. This was the result of the government's decision to solve its perennial financial problems by the massive coinage of the *vellón*, a debased copper coinage. This did not prevent the need for another moratorium on government debts, in 1607, and in 1608

the King had to promise the Cortes of Castile not to issue any more *vellones* for 20 years. But by 1617 he had to ask the Cortes to allow another issue, and yet another one in 1621.

The expulsion of the Moriscos. The most serious social crisis of the reign was, however, entirely man-made. The great majority of the Moriscos lived in the Kingdom of Valencia. Like those of Andalusia, they had been forcibly but ineffectively converted to Christianity. Most of them were relatively poor farmers, agricultural labourers, or small tradesmen and hucksters. They were hated and despised by the poor Christian peasants but protected by the landowners for whom they provided industrious tenants and labourers.

For many years a controversy raged between those who wanted to "solve" the Morisco problem by expulsion and those who pleaded for time and money to achieve their genuine assimilation and Christianization. While the practical, economic aspects of these two views were not neglected, it was characteristic of the Spain of the period that the main emphasis of the debate was on the religious and moral problems involved. In 1609 Lerma's government ordered the expulsion of the Moriscos. By 1614 some 275,000 had been forced to leave Spain. The majority of Spaniards undoubtedly approved of the expulsion. About its economic effects there was at the time and there is still today considerable controversy. In Castile the effects were probably slight. In Aragon and Valencia, where the Moriscos had constituted between 20 and 30 percent of the population, they were certainly much greater. Some but by no means all Morisco land was resettled by "old" Christians. There was a shift from labour-intensive sugar and rice production to mulberry (silk) cultivation and viticulture (vines). The greatest difficulties were caused by the indebtedness of the Morisco peasants and the consequent losses suffered by their urban creditors. An ironic footnote to the expulsion was the plight of the Aragonese and Valencian inquisitions. Once hot for expulsion, they were now left without their major source of income, the composite fines for Moorish practices by which they had formerly milked the Morisco villages.

Effects of the expulsion

Spain and Europe. Neither Philip III nor Lerma were emotionally or intellectually capable of the fundamental reappraisal of foreign policy that Philip II's failures called for. Very few even of the *arbitristas* had seen this need sufficiently clearly. The court, the nobility, and, above all, the clergy and the King's confessors remained caught in the now hardening tradition of Spanish imperialism, simplistically interpreted as the cause of God. Once again, this attitude caused a serious misjudgment of the political forces in England: the absurd hope of placing the infanta Isabella on the English throne when Elizabeth I should die. In 1601 a small Spanish force was disembarked at Kinsale, in Ireland, to cooperate with the Irish rebels. The English army had no difficulty in forcing it to surrender.

Fortunately, the new government of James I was anxious for peace. On the Spanish side, the Treaty of London (1604), which ended 16 years of Anglo-Spanish war, was negotiated on the initiative of Philip II's son-in-law, the archduke Albert, to whom, in his last year, Philip II had handed over the nominal sovereignty of the Spanish Netherlands. It was also Albert and his Genoese general, Ambrogio Spinola, who virtually forced Madrid to negotiate with the Dutch rebels. Between 1604 and 1607, Spain sent unprecedentedly large sums to Flanders. Spinola captured Ostend (on modern Belgium's coast) and won victories in Friesland (north Holland). But it would take 300,000 ducats a month to continue the war successfully, he now wrote to Madrid. After the moratorium of 1607, Philip III was in no position to raise such sums; but still he could not bring himself to recognize the independence of his rebellious and heretical subjects. He compromised by concluding a truce for 12 years, to run from 1609.

In 1610 a new war with France threatened, but Henry IV was assassinated, and once more, for almost 20 years, Spain's most formidable opponent in Europe became preoccupied with its internal problems. The years from 1610 to 1630 were the last period in which Spain clearly dominated Europe. For the first of these two decades Europe enjoyed a kind of Pax Hispanica. Spanish armies controlled Italy, Flanders, and parts of the Rhineland. Spanish and Spanish-inclined Jesuits were confessors at the courts of the Austrian Habsburgs, of Poland, Bavaria, and of some of the minor German and Italian princes. Spanish subsidies, pensions, and bribes made clients even of Protestant politicians in England, Holland, and the Swiss cantons (although much less effectively so than Madrid hoped); and Spanish-paid spies fed the governments of Madrid and Brussels with valuable, if not always accurate, information about its potential enemies in the United Provinces (or Holland), England, and France. Yet, to a much greater degree than most contemporaries realized, this Spanish domination of Europe rested on default: the disunity and temporary weakness of Spain's political and religious opponents. The psychological effects on Spain of this position were wholly disastrous, for it confirmed the Castilian ruling classes in their imperialist attitudes.

While for Philip III and Lerma this attitude led, for reasons both of finance and temperament, to a largely defensive stance, it was quite otherwise for the Spanish representatives abroad. In the absence of an effective lead from Madrid, the Spanish grandees who were the King's viceroys and ambassadors in Europe took it upon themselves to advance Spanish interests as they saw them—that is, in terms of Spanish power. They fortified the route from Milan to the Tirol (now west Austria) through the Valtellina, the vital link with the Austrian Habsburgs; they annexed several small Italian lordships; they inveigled Dalmatian pirates (operating from what is now the Yugoslav coast), the Uskoks, to prey on the trade of Venice, and they even seem to have plotted the complete overthrow of that republic.

More fateful still were their activities in Prague and Brussels. At the courts of the emperors Rudolf II and Matthias, the ambassador Baltazar de Zúñiga organized an effective "Spanish" party. His successor, the Count of Oñate, negotiated the secret Treaty of Graz (1617) by which the Jesuit-educated archduke Ferdinand of Styria (later Emperor Ferdinand II) was designated as heir to Matthias. In return for giving up Philip III's claims to the Austrian succession, which Madrid had never seriously pursued in any case, Oñate obtained the promise of full Spanish sovereignty of the Tirol and Alsace (in modern east France), the two German pillars of the "Spanish Road" between Italy and the Netherlands. At the same time, the "Spanish" party in Prague managed the preelection of Ferdinand as king of Bohemia in case of Matthias' death. Zúñiga and Oñate had undoubtedly strengthened Spain's strategic position in central Europe; but they had also, for the first time since the abdication of Charles V, involved Spain again in the local politics of the Holy Roman Empire. For Philip IV, this involvement turned out to be even more disastrous than it had to Charles V. Spanish leadership, as practiced by the self-willed Castilian grandees abroad, had proved to be energetic and clever; but it was ultimately as devoid of true statesmanship as the slackness of the King and his *privado*.

Spain's position in central European politics

In 1617 Lerma's enemies at court finally managed to overthrow him. Zúñiga returned to Madrid and became the leading advocate of aggressive policies. The Marquis of Bedmar, former Spanish ambassador to Venice and the organizer of the anti-Venetian conspiracy, went as ambassador to Brussels and immediately began to press for the reopening of the war against the United Provinces. In 1621 Philip III died, and with him disappeared the last restraints on the neo-imperialists. Philip IV, a boy of 16, left the effective powers of kingship in the hands of his former gentleman of the chamber, the Count (later Count-Duke) of Olivares. Olivares shared his uncle Zúñiga's political views, and he soon dominated the Council of State.

Philip IV's reign. *Spain and the Thirty Years' War.* In 1620, following the defeat of Frederick V (the elector Palatine, or prince, from the Rhineland who had accept-

ed the crown of Bohemia, now western Czechoslovakia, when offered it in 1618) and the Bohemians, Spanish troops from the Netherlands entered the "Winter King's" hereditary dominions of the Rhine Palatinate. Militarily, Spain was now in a favourable position to restart the war with the United Provinces at the expiration of the truce in 1621. The decision to do so was, however, taken on more general grounds. The Dutch had used the truce only to capture the carrying trade of western Europe and the Baltic with Spain, Zúñiga argued. On the oceans they had never observed the truce but continued their piracies against Spanish and Portuguese shipping. If they were allowed to continue, first the Indies would be lost, then the rest of Flanders, Italy, and, finally, Spain itself, for it would have lost the dominions that had made it great. These were very different grounds for resuming the war from those habitually advanced by Philip II. Little was said about religion or even the King's authority, while the protection of the overseas empire had become the central consideration in Spanish relations with the Dutch "rebels." Olivares dismissed the counter-arguments of the Council of Finance. The young King, content to be told that he was not responsible for the debts of his predecessors, piously declared his intention not to burden his subjects any further. Neither he nor his ministers could foresee that a recent slump in silver shipments from America was not a temporary setback but heralded a rapid, long-term decline. The Dutch, it is true, were equally anxious for war, partly, at least, because of the vain hope that the Belgians would rebel against Spain and join the United Provinces.

Having decided on war, Olivares pursued a perfectly consistent strategy: communications between Spain and the Spanish Netherlands must be kept open at all costs, and the Dutch must be hit wherever they were most vulnerable. The first objective led Spain to cultivate the friendship of James I of England and even to contemplate the restoration of Frederick V to the Palatinate and the marriage of Philip IV's devoutly Catholic sister to the heretic Prince of Wales (later Charles I). It led to very close cooperation with the Austrian branch of the Habsburgs and the need to fight for the control of the Valtellina. The second objective, which followed the advance of the imperial armies under Wallenstein (an adventurer who made himself indispensable to the Habsburgs as a military organizer) to the Baltic, led to grandiose schemes of building an imperial Spanish fleet in the Baltic with Hanseatic (the Hanse towns on the Baltic were independent mercantile organizations) and Danish help in order to destroy the Dutch Baltic trade and with it the economic prosperity of the republic.

However rational and limited these aims and plans seemed in Spain, in the rest of Europe they appeared to show only too clearly the limitless ambitions of the House of Austria. The now habitual talk in Spanish court and military circles of restoring Spain's greatness did not help to persuade Europe otherwise. Spinola's and Wallenstein's victories in the mid-1620s convinced the Spanish Council of State that victory against the Dutch was possible and blinded them to the danger of raising up new and more powerful enemies. Thus, they let slip the last chances of a favourable peace. Yet, despite enormous sums sent annually from Castile to Flanders, the Spanish armies could not break Dutch resistance. They could not even supply their own provisions and ammunition without the covert help of Dutch merchants, who, in their turn, argued that this trade with the mortal enemy brought in the money needed to pay for the troops fighting this enemy. From 1630, when Sweden and France actively intervened in the war, Spain rapidly lost the initiative. Spanish armies could still win tactical victories in Italy and Germany, but the number and seriousness of Spanish reverses, especially at sea, were now steadily mounting.

Improved government under Olivares

The government of Olivares. Olivares was undoubtedly the most able politician directing the Spanish government since Cardinal Granvelle. All contemporaries remarked on the contrast between his energetic and bustling administration and the sleepy regime of Philip III and Lerma. The Catholic Kings, the Emperor, and Philip II had kept the high nobility, to a greater or lesser degree, out of the central government. Lerma had reversed this policy, and Olivares could not go back on this position, although he bitterly lamented the incompetence of his fellow aristocrats and sharply reduced the overgenerous flow of royal patronage to them. He could and did develop the system of committees (juntas) of experts within the councils, which took over a great deal of government business and made its administration more efficient.

In 1623 and 1624 Olivares presented to the King and Council of State a number of memorandums that were nothing less than plans for a far-reaching reform of government and society, on the lines advocated by the *arbitristas*. Like them, Olivares saw the need to change mental attitudes: restraints on the aristocratic love of splendour and display, the need to appreciate the dignity of work and productive economic activity, an end to the economically harmful and morally indefensible mania for *limpieza* (Olivares himself, through his grandmother, had *converso* blood flowing in his veins). On the more immediately practical level, Olivares' memorandums were concerned principally with finance; for, with an annual expenditure of 8,000,000 ducats, there was a deficit of 4,000,000. The Count-Duke proposed the abolition of some of the most harmful taxes, the *millones* and the *alcabala*, the sales tax, and their substitution by other, simpler, and more equitable taxes. Finally, Castile should not be expected to continue to bear almost alone the cost of the war. Like Granvelle, Olivares recognized that the King's non-Castilian dominions could only be expected to share in the burdens of empire if they could also enjoy its advantages, the honours, commands, and control over policy that had been all but completely reserved to the Castilians.

None of these plans was put into practice. The Spaniards were unwilling to change their mode of life and their ingrained beliefs at the behest of a royal favourite. Olivares did manage to arrange loans with a consortium of Portuguese Marrano businessmen, but he was bitterly attacked for this action. Philip IV consulted a committee of theologians about a proposed canalization of the Tagus River, flowing east–west across Spain and Portugal. They forbade it as an interference with God's design. The court itself gaily abandoned a short-lived austerity in the celebrations that followed the arrival of the Prince of Wales in his romantic but abortive quest for a Spanish bride (1623). The financial reforms foundered on the opposition of vested interests to taxation by the Cortes and on the opposition of the whole Castilian ruling class to the plan for the decentralization of the empire. Just as had happened to Granvelle's proposals, there was not even any serious discussion of Olivares' plan. In the 1560s the result of this failure had left Philip II with no alternative but Alba's policy of repression—which caused the revolt of the Netherlands; in the 1620s it left Olivares with no alternative but his Union of Arms—which caused the revolts of Catalonia and Portugal. The Union of Arms was a scheme for the creation of a reserve army of 140,000 men that was to be paid for by the dominions of the Spanish Empire in proportion to their estimated resources. But the non-Castilian dominions disliked this proposal because it infringed their liberties. They also distrusted Castilian intentions, and with some justice; for in 1625 Olivares had advised the King in a secret memorandum to "secretly plan and work to reduce these kingdoms of which Spain is composed to the style and laws of Castile."

Hopelessness of reform

The revolt of Catalonia. Apart from Portugal, Catalonia was the state with the greatest degree of autonomy. Its medieval form of government had not been changed since Ferdinand the Catholic had settled it in 1486. Its countryside, especially on the French border, was infested with smugglers and bandits and riven by local feuds. Its taxes were administered by the Diputació, a self-perpetuating and corrupt committee of the Catalan Corts that functioned during the long intervals between the meetings of that body. The viceroys, hemmed in on all sides by local privileges and without control over the finances of

the province, were virtually powerless. In 1626 Philip IV summoned the Cortes of the realms of the crown of Aragon. Aragon and Valencia reluctantly voted some money but refused conscription of troops. Catalonia refused everything. Nevertheless, Olivares published the royal decree for the Union of Arms. Relations between Madrid and Catalonia deteriorated rapidly.

Increasing financial troubles

As the costs of warfare continued to soar, the government resumed the inflationary minting of *vellones* and had yet to declare another moratorium, in 1627. In 1628 the *vellón* coins were withdrawn, causing a collapse of prices and a business recession. The 1630s added new taxes in Castile and outright confiscations from private individuals, both of income from government annuities and of American silver imported in commercial transactions. Not surprisingly, Madrid was becoming obsessed with what it considered to be the injustice of Catalonia's immunity from taxation. In 1639 Olivares opened a campaign against southern France from Catalonia. It had no rational strategic objective except to pitchfork Catalonia into the war. If the Catalans had to defend their country, Olivares argued, they would have to support the army.

This logic was lost on the Catalans. The peasants, urged on by their clergy, refused to support the troops. During the winter the soldiers were billeted in the countryside. Soon there were clashes with the population, then riots and open rebellion. Too late, Olivares attempted to draw back and conciliate the Catalans. On June 7 the mob murdered the Viceroy in Barcelona. The higher nobility and the urban aristocracies were still anxious for an accommodation; but the countryside was now completely out of control. The Diputació, the only remaining legal authority, was led by a strong-minded cleric, Pau Claris, canon of Urgel, west of Barcelona, who was unwilling to make concessions. In the autumn of 1640 Olivares scraped together the last available troops and sent them against the Catalan rebels. Claris countered by transferring Catalan allegiance to the king of France, "as in the time of Charlemagne" (January 1641). French troops now entered Catalonia. Only when the renewed French civil wars (the Fronde) induced the French to withdraw their army were the Castilians able to reconquer Catalonia (1652). The Catalan upper classes, at least, were relieved, for they had found the French even less congenial masters than the Castilians. For once, Madrid did not repeat its previous mistakes: the liberties and privileges of Catalonia were fully restored.

The revolt of Portugal. The revolt of Catalonia gave the Portuguese their opportunity. The lower classes and the clergy had always hated the Castilians. The Portuguese aristocracy and the commercial classes, previously content with the patronage and the economic opportunities that the union with Spain had provided, had become dissatisfied during the last 20 years. They resented the introduction of Castilians into their government (1634), the ineffectiveness of Spanish naval support in the defence of Brazil against the Dutch, and the growing reaction of the Spanish colonies against Portuguese economic penetration during this period of contracting economic activity. Rather than allow themselves to be sent to fight the Catalan rebels, the Portuguese nobility decided to seize power in Lisbon and proclaimed the Duke of Bragança as King John IV of Portugal (December 1640). Madrid, with an aristocratic conspiracy in Andalusia on its hands (1641), no longer had the means to react.

Portuguese grievances

The last years of Philip IV. The disasters on Spain's periphery were matched by continued mismanagement of Spanish finances at the centre. Once more the government tampered with the *vellón* coinage and then reversed course into a sudden and catastrophic deflation (1641–42). In January 1643 the Castilian grandees were finally able to force Philip IV to dismiss Olivares. The King now decided to run his own government. He dissolved the juntas, and the councils resumed their authority. Soon, control of the government slipped into the hands of Olivares' nephew, Don Luis Méndez de Haro, a clever but colourless politician with neither his uncle's imperial vision nor his panache.

The defeats continued. The Great Condé (the French King's cousin) broke the Spanish *tercios* and their reputation for invincibility in the Battle of Rocroi, northeast France (1643). In 1647, popular revolutions broke out in Naples and Palermo (Sicily), and soon these two cities were in the hands of revolutionary governments. In Naples, at least, it was again the excessive taxation, imposed for Spain's war effort, that had precipitated the rebellion. The Spanish monarchy, wrote the Venetian ambassador to Madrid at the time, "resembled that great colossus that during an earthquake had collapsed in a few moments while everyone hurried along to enrich himself with the fragments."

In fact, Spain survived and even managed to hold on to much of its empire. The revolts of Naples and Sicily, directed as much against the local nobility as against Spain, were put down in 1648. When the Emperor conceded French claims to Alsace and the Rhine bridgeheads, the "Spanish Road" to the Netherlands was irrevocably cut, and the close alliance between the Spanish and the Austrian branch of the House of Habsburg came to an end. With Portugal in revolt and Brazil no longer an issue between the Dutch and the Spaniards, Philip IV drew the only possible conclusion from this situation and rapidly came to terms with the United Provinces, recognizing their full independence and agreeing to the closing of the Scheldt, a river emptying into the North Sea west of Antwerp (Treaty of Münster, January 1648). But Philip IV had not changed his basic policy. He wanted to have his hands free for a final effort against France, even after Catalonia had surrendered. Once again the temporary weakness of France during the Fronde confirmed the Spanish court in its disastrous military policy. Haro passed up the chance of concluding a very favourable peace in 1656.

The war dragged on, with England joining France, capturing Jamaica, and contributing to the Spanish defeat in the Battle of the Dunes on the northern coast of France (1658). The Treaty of the Pyrenees (1659) cost Spain Artois (now northernmost France), Roussillon, and part of Cerdagne. More important than these relatively minor territorial losses was the realization throughout Europe that Spain's pretensions to hegemony had definitely and irremediably failed. The Spaniards themselves were slow to admit it. Philip IV had made concessions to France in order, once again, to have his hands free against the last unforgiven enemy, Portugal. There was no longer any rational basis for his hopes of success. All schemes for financial and tax reforms were still being blocked by vested interests, and the government had declared two more bankruptcies, in 1647 and 1653. Once more the Council of Finance issued a debased coinage to pay for the Portuguese campaign. But the Portuguese routed the last Spanish armies at Ameixial (1663) and at Villaviciosa on the north coast of Spain (1665). In 1668 Spain formally recognized the independence of Portugal.

The Treaty of the Pyrenees

Charles II. For ten years Philip IV's widow, Maria Anna of Austria, acted as regent for the child Charles II (1665–1700). She allowed her government to be dominated by her confessor, the Austrian Jesuit Nithard. He was overthrown by John of Austria, an illegitimate son of Philip IV, who, however, proved quite incapable of providing effective leadership for the country. From then on, the high nobility dominated the government as effectively as it had done in the days of Philip III, playing court intrigues, first with the regent and, later, with the two successive wives of the incapable Charles II. The majority of these aristocrats were self-seeking and incompetent; but some, notably the Count of Oropesa, were men of considerable ability. They finally restored the coinage, in 1680, although not before they had caused another catastrophic deflation. They set up a committee for commerce that pursued orthodox mercantilist policies, encouraging trade and industry. They even took the unprecedented step of investigating the Inquisition and recommending a right of appeal to the secular courts.

Decline of Castile

But these were palliatives. Until the mid-1680s the Castilian economy declined, and this at such a rate that the French ambassador, the Marquis of Villars, claimed to see an appalling deterioration between his two visits, in

The European dominions of the Spanish Habsburgs in 1648.

1668–69 and in 1671–73. In the 1690s the Venetian ambassador characterized the reign of Charles II as "an uninterrupted series of calamities." The population of Castile declined from about 6,500,000 at the end of the 16th century to a low point of under 5,000,000 about 1680. Figures for the whole of Spain followed a similar pattern, from 8,500,000 to about 6,600,000. The reasons for this decline were not so much emigration to the overseas colonies, which averaged 4,000–5,000 a year in the 17th century, as military casualties from all causes, which averaged the frightening figure of 10,000–12,000 a year. More devastating still were the recurrent plagues and, perhaps, the sheer misery of the rural population, who lived on estates that their noble and ecclesiastical owners could not be bothered to manage with even a minimum of efficiency. The shortage of labour, especially skilled labour, and the high wages attracted many foreign workers, perhaps as many as 70,000 Frenchmen. Nevertheless, Castilian industries continued to decline. The nadir was reached in the decade 1677–86, with crop failures, earthquakes, an epidemic that sharply reversed a slight upward trend in population since about 1650, and, on top of these natural disasters, the government's deflation of the coinage.

The French wars. In these circumstances it is not surprising that Spain now became the victim rather than the initiator of aggression. In three successive wars with France (1667–68, 1672–78, 1689–97), Spain lost Franche-Comté (Treaty of Nijmegen, 1678) and some Belgian frontier towns to France but still managed to hold on to the greater part of the southern Netherlands and its Italian dominions. The reason was less Spain's own military efforts, which were puny compared with those of the first half of the century, than the unwillingness of other European powers, especially the United Provinces, to see the Spanish dominions in Europe swallowed up by France. After the last and, for Spain, most disastrous of these wars, the War of the Grand Alliance (1689–97), Louis XIV himself restored Flanders and Catalonia, which his troops had occupied, for he now had his eye on the inheritance of the whole Spanish Empire.

The last years of the childless and evidently dying Charles II were occupied by the manoeuvres of the European powers for the Spanish succession or, alternatively, for the partition of the Spanish Empire. Amid cabals, intrigues, exorcisms of evil spirits, and blood feuds at court, while riots were going on in the streets of Madrid, the rule of the House of Austria came to an end with the death of Charles II, on November 1, 1700.

The decline of Spain. There can be no doubt about the economic and political decline of Spain in the 17th century and especially in its second half. Moreover, Calderón, Valázquez, and Murillo had no successors of remotely comparable stature. It need not be reasonable, however, to speak of decadence, as many non-Spaniards did at the time and later. The term decadence, except perhaps when applied to the person of Charles II, that last unhappy offspring of constant Habsburg intermarriage, does not explain the timing of the decline nor its duration. In the first place, the economic decline was mainly a Castilian phenomenon and did not affect Catalonia and Valencia to anything near the same degree. For Castile, it is perhaps best to see the problem of decline as the *arbitristas* saw it: in the depreciation by Castilians of economic activity, an attitude that was rooted deeply in Castile's past history but that was particularly baleful in a period of general European economic depression, such as the 17th century. To this must be added the aggressive militarism that was central to the Castilian aristocratic tradition and that led to the political hubris (overweening pride) of Spanish imperial policy, from Philip II to Philip IV. The Castilian ruling classes never produced, or perhaps gave no chance to, a leader who could break out of this tradition. Velázquez seems to have known it or felt it instinctively when he painted his "The Surrender of Breda" as the beginning of a hoped-for reconciliation and when, in his portraits of Philip IV, he showed the pathos of a man half aware of his personal inadequacy for the role he is called upon to play. It was the wars that devoured Castile, though they were fought beyond its borders. They do not directly explain the end of the "Golden Century." But it may be suggested that a society that has invested most of its

energies and all its pride in war, even though it be war for an ideal, will not provide a congenial ground for the exercise of creative genius when its ideal has failed and it is left with nothing but a now hollow pride. (H.G.K.)

V. Spain since 1700

THE EARLY BOURBONS, 1700–53

The wars of the 17th century, though they had weakened Spain's power in Europe, had left it still the greatest imperial power in the world. Spain's central problem in the 17th century had been to maintain what remained of its European possessions and control of its American empire. In 1700 both tasks appeared to be beyond the military and economic resources of the monarchy. In the 17th century the greatest threat had come from a land power, France, jealous of Habsburg power in Europe; in the 18th it was to come from a sea power, England, while the Austrian Habsburgs became the main continental enemy of Spain.

The War of the Spanish Succession. In 1700 (by the will of the childless Charles II) the Duc d'Anjou, grandson of Louis XIV of France, became Philip V of Spain. Austria refused to recognize Philip, a Bourbon, and concede the defeat of its hopes of placing an Austrian candidate on the throne of Spain. To England, a Bourbon king in Spain would disrupt the balance of power in Europe in favour of French hegemony.

Louis XIV conceived of Spain under a Bourbon king as a political and commercial appendage of France to be ruled by correspondence from Versailles; he wished to regenerate and strengthen his ally by a modern centralized administration. This task was both complicated and facilitated by the War of the Spanish Succession (1701–14) when the allied armies of Britain and Austria invaded Spain in order to drive out Philip V and establish the "Austrian" candidate, the archduke Charles, on the throne. An efficient administration had to be created in order to extract resources from Spain for the war effort, and thus relieve pressure on the French treasury; at the same time financial shortages imperilled administrative reform while war taxation and war levies drove Catalonia and Aragon to revolt against the demands of the Bourbon dynasty.

Administrative reforms

The instruments of centralizing reform were French civil servants (Jean-Jacques Amelot, Louiv XIV's ambassador, and Jean-Henri-Louis Orry, a financial expert) and a handful of Spanish lawyer-administrators such as Melchor de Macanaz. They were supported by the queen, María Luisa of Savoy, and her friend the 60-year-old Princess of Ursins. The opponents of reform were those who suffered by it: the grandees who had dominated the cumbersome inefficient councils; the councils themselves; the regions like Catalonia, Aragon, and Valencia, in which the establishment of effective royal rule was seen as a Castilian, centralizing, imposition in conflict with the local privileges, or *fueros;* the church, whose position was threatened by the ferocious and doctrinaire regalism of Macanaz, who wished to subject the independent jurisdictions of the church (especially that of the papal nuncios and the Inquisition) to the absolute monarch.

The disaffection of all these elements easily turned to opposition to Philip V as king. Opposition to the new dynasty accentuated the determination of Bourbon civil servants to end special privileges that covered treasonable sympathy with the Austrian and English invaders.

Castile was ferociously loyal to the new dynasty throughout the war, in spite of severe financial difficulties (consequent on the loss of revenues from the Indies). The support of Castile and of France (until 1711) enabled Philip V to survive severe defeats and two occupations of Madrid. In 1705 the archduke Charles landed in Catalonia and took Barcelona. When Philip V tried to attack Catalonia through Aragon, the Aragonese, in the name of their *fueros,* revolted against the passage of Castilian troops.

It was this revolt, backed by the local nobility, that turned the King's advisers resolutely against local privileges and aristocratic treason. After the victory over the archduke Charles at Almansa (April 1707) the *fueros* of the kingdoms of Valencia and Aragon were abolished and the property of rebels confiscated. When the Archbishop of Valencia resisted attempts to make priests of doubtful loyalty appear before civil courts, the regalism of Macanaz was given full course.

This was the last direct triumph of the reformers. With the death of Queen María Luisa in 1714 and the arrival of Philip's new wife, Isabella (Elizabeth Farnese), court support for radical reform disappeared. Macanaz was condemned by the Inquisition, and a less rigid administration, more inclined to compromise with the church and the higher nobility, controlled the country's policy.

The last stages of the war were a Spanish concern. The allies deserted the archduke Charles; the French gave little help to Philip V. In 1714 Philip recaptured the Archduke's capital at Barcelona. By the Decree of Nueva Planta (1716) the *fueros* were abolished and Catalonia was integrated into Spain. Integration, criticized as it was by later generations of Catalans as the destruction of Catalan "nationality," was nevertheless a precondition for industrial revival; it gave Catalonia a domestic market in Spain and later an overseas market in America.

The integration of Catalonia into Spain

Paradoxically, a disastrous war had for the first time created a unitary Spanish state: except for the Basque Provinces and Navarre, Spain was under direct royal administration.

It was in its possessions outside Spain that Spain paid the price of defeat: the treaties of Maastricht and Utrecht (1713) stripped the country of its European possessions (Belgium, Luxembourg, Milan, Sardinia, and Naples) and gave Britain Gibraltar and the right to send one ship a year to trade with Spanish America.

"American" and "Italian" policies. Two tendencies can be discerned in Spanish policy until 1748: a desire for revenge and recovery in Italy, and an "Atlantic" policy; *i.e.,* the protection of America from British incursions and the revivification of Spanish colonial rule. Both policies demanded a strong army and navy. The "Italian" tendency is connected with Philip V's second wife, Isabella, and her desire to get Italian thrones for her sons. The instruments of her ambitions were two foreigners: the Italian cardinal Julio Alberoni, the exiled son of an Italian gardener, and the Dutch-born adventurer Juan Guillermo Riperdá. The attempt to recover its possessions in Italy involved Spain in an unsuccessful war with Austria, now the great power in Italy. Spain suffered a serious naval defeat at Capo Passero in 1718. Nevertheless, Isabella's persistence was rewarded when her son, the future Charles III, became the duke of Parma in 1731 and king of Naples in 1733, relinquishing his claims to Parma.

The American–Atlantic tendency was the work of Spanish ministers with a particular interest in the navy and foreign trade—José Patiño, Marqués de la Ensenada, and José de Carvajal y Lancáster. The "Italian" and "Atlantic" tendencies existed side by side in the late years of Philip V's reign. Atlantic rivalries in the form of a dispute over the interpretation of British trading privileges in Spanish America granted at Utrecht brought on the War of Jenkins' Ear (1739–43), during which the British sacked Porto Bello in the Caribbean. The Spanish fleet nevertheless was surprisingly effective and worsted Adm. Edward Vernon at Cartagena. The Italian–Mediterranean policy led directly to Spanish involvement in the War of the Austrian Succession (1740–48). It made possible an alliance of France and Spain against Austria, now the dominant power in Italy, giving Isabella the opportunity to settle her second son, Philip, in an Italian duchy. Spanish troops entered Milan (1745). Ferdinand VI (reigned 1746–59) was concerned with the domestic recovery of Spain rather than the extension of its power in Europe. He hoped to recover Gibraltar at the general peace that ended the War of the Austrian Succession. But the Anglo-French rapprochement made recovery of Gibraltar an impossibility at the Treaty of Aix-la-Chapelle (1748); the treaty merely strengthened Spain's position in Italy when Philip became duke of Parma, Piacenza, and Gustalla.

With Ferdinand VI the Atlantic tendency became dom-

inant. Since Britain was Spain's great enemy in the Americas (as Austria had been in Italy) its "natural" ally was France as Ensenada and Carvajal had seen (hence a series of family pacts with France in 1733 and 1743). It was only in the last years of his reign that Ferdinand's minister, Ricardo Wall, attempted a policy of strict neutrality as the best means of saving Spain from the hostility of Britain, Austria, or France.

This American interest was reflected in increased trade (the old system of convoyed fleets was abandoned for individual sailings), the founding of privileged trading companies (1725), and the founding of new naval arsenals at Ferrod and Cartagena (1726). But the central weakness of Spain as an imperial power remained. The Spanish economy could not supply America with the consumer goods it needed in return for its increased exports. These were supplied either by British merchants through the "legitimate" trade from Cádiz or by smuggling. The Spanish navy, in spite of considerable efforts, could not suppress a contraband trade that, from the colonists' point of view, was a necessity.

The ministers of Ferdinand VI revived the reforming traditions weakened during the latter years of Philip V, whose lethargy deepened into chronic melancholia.

One of the most important imitations from French administrative practice was the use after 1749 of crown officers, or intendants, to rule in the provinces. The intendants strengthened royal control over local government, especially in its financial aspects; together with the captains general (set up by Philip V), they were responsible for a renewal of provincial public works. Carvajal reorganized the postal system; Ensenada, at one time the all-powerful minister of Ferdinand VI, was a great road builder; he opened the Seville tobacco factory, botanical gardens, and observatories; above all, he increased royal receipts by rationalization of the tax structure. The reforms of Ferdinand's successor, Charles III, though more dramatic, were a continuation of those of Ferdinand VI.

THE REIGN OF CHARLES III, 1759–88

Two features distinguished the Caroline reforms from those of the early Bourbons. First, Charles III was a "reformer's king" in that he consistently supported reforming ministers. This was surprising in a monarch who had no great intellectual gifts, was obsessed by hunting, and turned his court into the most boring society in Europe. Second, the civil servants were distinguished from their predecessors by their adherence to a philosophy of government derived from the commonplaces of the European Enlightenment.

Penetration of Enlightenment ideas

Nevertheless, there were sharp differences among the civil servants. The Conde de Aranda and Pablo de Olavide y Jáuregui were influenced by the French Philosophes; Gaspar Melchor de Jovellanos y Ramírez was a disciple of Adam Smith; Pedro Rodríguez Campomanes drew more directly on such Spanish reformers as Macanaz; José Moñino Floridablanca was a professional administrator. All would have taken as their slogan *Felicidad* ("Felicity")—a well-ordered monarchy based directly on the productivity of people who are made happy by the intelligent application of the principles of political economy. There were, however, impediments (*estorbos*), such as traditional privileges (*e.g.*, grazing rights held by a sheep breeders' corporation, the Mesta) or attitudes (*e.g.*, the prejudice of the nobility against the "mechanical trades"); they could not be allowed to stand in the way of greater prosperity and, therefore, of a higher tax income for the state.

Economic revival. The years after 1714 had seen a gradual economic recovery, quite marked in the last half of the 18th century. How much of this revival of the last half of the century was the work of conscious but often confused government policy must remain doubtful. Thus the famous decree (1783) "ennobling" the mechanical trades had little practical result; the attempt to establish government factories and replace religious charity by the productive employment of the poor was a relative failure. Government policy had little to do with the growth of population, which rose during the century from 8,000,000 to 12,000,000. The increased demand for food and the consequent sharp rise in prices encouraged agriculture, benefitting the large landowners of the south and the small farmers near growing towns such as Barcelona. The most remarkable feature of this economic revival was the emergence in Catalonia after 1745 of a modern textile industry, based on cotton. The industry benefitted from a protected market in Spain and the colonies. In the Basque Provinces the archaic iron industry began a slow process of modernization. In Galicia, Catalan immigrants established a flourishing fishing fleet. The brandy trade brought sudden prosperity to the ports of Catalonia and their hinterland.

Nevertheless, the financial reforms of the earlier years and the abolition of internal customs duties removed obstacles to the expansion of the internal market, and the opening of the American trade (see below) acted as a strong stimulant.

One important feature of these developments was that they took place not in the old Castilian core of the monarchy but in the peripheral regions; not in the countryside but in the towns. It was on the periphery that price rises were steepest, outstripping wages in Barcelona and thus creating the beginnings of a social problem. The role of Catalans in the economic revival lies at the origins of the Castilian stereotype of the Catalans as selfish, thrusting businessmen, indifferent to traditional values and exploiting their fellow Spaniards.

Imperial problems. To Charles III the key to prosperity lay in the Indies, for a prosperous Spain demanded an American market. He saw clearly that Spain alone could not preserve an overseas market closed to the outside world against Britain. Ricardo Wall's policy of strict neutrality had allowed Britain to make gains in Canada that must weaken France—the only other anti-British power in America. If Britain would respect Spain's possessions, or if Charles could mediate between France and Britain in such a way as to preserve the balance between them in America, then to commit Spain to the French alliance was a dynastic luxury. Once it was clear to Charles that British terms were non-negotiable, then the Family Compact with France of 1761 was a piece of realpolitik. It was signed by the "anglophile" Ricardo Wall.

The Seven Years' War

The consequence of such an alliance was involvement in the Seven Years' War (*q.v.*)—too late to save France. In 1762 the British occupied Havana—the greatest single blow sustained by Spain in the war. Spain theoretically allowed no foreigners to share directly in the colonial trade: the effect of this had been to starve the colonies of necessary imports and to encourage smuggling. In 1762, 15 ships entered the port of Havana; during the 11 months of British occupation, 700. This was a dramatic indication to the colonists of the drawbacks of the Spanish monopoly, especially when that monopoly was exercised by what was, in European terms, an underdeveloped nation.

The Treaty of Paris (1763) concluding the Seven Years' War destroyed France as an American power. Spain lost the territory between Florida and the Mississippi, in return gaining Louisiana from France. Spain also had to recognize Portuguese advances in the Río de la Plata (the fort of Sacramento) and the British right to cut mahogany in Central America. The Family Compact was therefore an immediate military failure, and it was only the revolt of the American colonies against Britain that enabled Spain to recover the ground it had lost; the successful alliance with France to aid the colonists resulted in the Treaty of Versailles (1783), which gave back Sacramento, the two Floridas, and Minorca. Not until later did it become apparent that an alliance of revenge with colonial insurgents is a short-sighted policy for an imperial power.

Reform of imperial administration

The problems of imperial defense were thus temporarily solved by British weakness after 1765. The positive side of Charles III's imperial policy was an attempt to create an efficiently administered colonial empire that would provide the crown with increased revenues and with a closed market for the exports of an expanding Spanish economy.

The rationalization of the administration of the Indies had started before Charles III with the creation of a new viceroyalty at Santa Fe de Bogotá (now Bogotá) in 1717. To protect the south against the British and against Portuguese incursions from Brazil, the Viceroyalty of La Plata was created in 1776. The centrepiece of Caroline reform was the introduction of the intendant system in the colonies to tighten up local administration. Most dramatic of all was the abolition of the monopoly of Cádiz, by which all trade to the colonies had to go through that port. Beginning in 1778 non-Castilian ports could trade directly with the colonies.

The new policies brought some immediate and striking results. Energetic viceroys and ministers and ruthless intendants doubled or tripled imperial revenues. The volume of Spanish goods in the American trade increased tenfold in ten years, so that Britain became seriously concerned at the Spanish revival. But imperial free trade would not satisfy the growing demand from Creole producers for free trade with all nations. Nor did the colonial oligarchs desire efficient government and higher taxation; they preferred bad government that let them control their own affairs. They showed their discontent in a series of revolts in the 1780s; only the fear of the native Indians drove them back to allegiance to the Spanish crown.

Domestic reforms. The domestic reforms of Charles III are more interesting for what they intended than for what they accomplished. They were not directed, as has often been maintained, at fostering a "bourgeois revolution." The middle classes were too weak, in a predominantly agrarian country, for the role of a modernizing elite; nor did Charles III contemplate a frontal attack on the traditional nobility. The purpose of reform was to remove what seemed to civil servants to be "traditional" constrictions on economic growth and administrative anachronisms that prevented the efficient exercise of royal power.

Reorganizations of the machinery of central government made for greater executive efficiency, but complete rationalization was never achieved; the old machinery of the councils persisted, with the Council of Castile as the ultimate decision-making body. An attempt to establish royal control of municipalities (without which, reforms could not get past the oligarchic councils) was likewise only a partial success. Most of the public works that characterized the late 18th century were the achievement of vigorous captains general. The extensive civil functions of these military officials was the first sign of a hybrid military–civilian government that, in another form, was to be developed in the 19th century.

Nor was the economic structure of agrarian Spain modified. All the chief reformers believed that the great and extensively cultivated estates, especially in Andalusia and Extremadura, constituted the greatest bar to agricultural prosperity. The landless underemployed proletariat who worked the large estates began to alarm reformers. "Why in our villages and towns are these men without land and in the countryside land without men? Bring them together and all will be served." Property should be more widely distributed, it was felt; there should be a free market in land. Yet none of the reformers was radical enough to push through a wholesale assault on private property or on the civil entail (the juridical instrument by which the *latifundios*, or large estates, were preserved intact). Acts such as the limitation of future entail, which preserved great estate intact over generations (1789), the limitation of the privileges of the Mesta (1779), and the right to enclose olive groves and irrigated land (1788) showed that the reformers believed primarily in the right of private individuals to do what they liked with their own; the unrestricted pursuit of private profit, they believed, would bring public prosperity. *Corporate* property was the enemy: hence the proposal that common lands owned by municipalities and the crown should be sold for individual cultivation and hence the proposals to end ecclesiastical entail (mortmain).

The attack on the privileges of the greatest corporation in Spain, the church, was less radical than has sometimes been maintained. Charles III himself was a devoted Catholic—he dedicated Spain to the Immaculate Conception. Some of his servants were fashionable anticlericals. Most were regalists; that is, they asserted the right of the crown to control over the church in civil matters. In the extreme regalists' view, the state should take care of charity and education; it should subject priests to civil jurisdiction for civil crimes and assert the traditional rights of the crown over church appointments.

The regalist attack on the church

The main attack of the regalists fell on the Jesuit order. In 1766 a serious riot in Madrid revealed some of the difficulties confronting the reformers. The abolition of fixed wheat prices during a bad harvest (a step that reflected the reformers' belief in the virtues of a free market) and an attempt to reform outlandish fashions in popular dress brought out the mob in Madrid. The Jesuits were alleged to have fostered the riot and were expelled from both Spain and America in 1767. The importance of this expulsion has been overestimated. Already expelled from France and Portugal, the Jesuits were bitterly criticized by rival orders and by the secular clergy: 42 of the 56 bishops approved of the expulsion. Again the expulsion was a *negative* achievement; more ambitious plans to set up a state university system and a state welfare organization failed.

The question arises of the extent to which the policies of Charles III resulted from the acceptance by his servant of the precepts of the Enlightenment. Certainly Aranda, the "Hammer of the Jesuits," and Olavide, whose flippant anti-clericalism was to be his undoing at the hands of the Inquisition, were what were called *esprits forts* (*i.e.*, French-influenced radicals); their views gave a sharp edge to traditional regalism. Jovellanos was a disciple of Adam Smith. Although his famous *Informe sobre la ley agraria* ("Report on the Agrarian Law") contains not a single original thought, the book is significant in that it attempts to apply dogmatic laissez-faire ideology to Spanish conditions. Here was one of the foundations of Spanish liberalism.

One of the aims of the Enlightenment was to produce a bourgeois society in which no traditional prejudices or traditional institutions should limit the pursuit of private profit—the foundation of national prosperity. But in Spain the social base was too narrow. In spite of economic changes over the century, the bourgeoisie was limited to the coastal towns, Barcelona and Cádiz in particular, with branches in Saragossa and the Basque country. Patriotic societies, organized with government encouragement from 1765 onward, were meant to provide the provincial basis for a progressive society and to familiarize Spaniards with European advances in technology and agriculture. They did not get much beyond the status of local reading rooms and debating societies.

Traditional Catholic society was still strong, if under attack from a minority of intellectuals and civil servants. As the reaction of the countryside after 1808 was to show, the church was still a great social power. The Duke of Wellington observed that "the real power in Spain is in the clergy. They kept the people right against France." To most of the clergy the new ideas of the Enlightenment were "foreign" and dangerous, and there could be no such thing as moderate progress encouraged by the king himself—the notion of a "revolution from above" that was to haunt subsequent Spanish history. Voltaire, Locke, and Rousseau were quite simply dangerous heretics, though the Inquisition proved powerless to prevent the clandestine circulation of their works. It was the clerical attacks on heretics as much as the subversive works themselves that familiarized a narrow stratum of society with new ideas. When the French Revolution exposed the dangers of progressive thought, the traditionalist cause was immensely strengthened and the Inquisition appeared to the crown itself to be a useful instrument to control the spread of dangerous ideas.

CHARLES IV AND THE FRENCH REVOLUTION

In 1788 Charles III, who had been the "nerve" of reform in the sense that he loyally supported able ministers, was succeeded by his son, Charles IV, a weak, amiable man dominated by a lascivious wife, María Luisa. Spain was

ruled after 1792 by her favourite, Manuel de Godoy, a handsome, plump officer from the lower nobility. It was not merely that Godoy was incompetent and self-seeking; the French Revolutionary and Napoleonic Wars (*q.v.*) put unbearable pressures on a weak power. Reform was now dangerous. Neutrality was impossible; alliance with either France or the anti-Revolutionary coalitions engineered by Britain proved equally disastrous.

The influence of Godoy

Floridablanca, the prime minister, disliked both the internal effects of the Revolution (the spread of radical as opposed to government guided reform) and its external consequences (the weakening of the anti-British alliance). His hostility to France was the cause of his dismissal. Aranda, a friend of France, was discredited by the excesses of the Revolution (1792). Godoy became prime minister at age 25 because the old ministers of Charles III had failed to devise a foreign policy. In domestic affairs, Godoy supported a mild version of the enlightened reformism of his predecessors; but, like them, he failed to find a satisfactory place for Spain in the Europe of the French Revolutionary and Napoleonic Wars (1800–15).

Spain had no alternative but to declare war on France after the execution of Louis XVI (1793). The war was popular but disastrous; in 1794 the French armies invaded Spain, taking Bilbao, San Sebastián, and Figueras. Godoy feared the spread of revolutionary propaganda in the wake of the French armies in Catalonia and the north (there was a republican conspiracy in 1795). Above all, he was convinced that Britain was the true enemy of Spain. Thus the Treaty of San Ildefonso (1796) represented a deliberate choice: the French alliance, irrespective of the nature of the French regime, as the only policy for a weak imperial power.

The consequences of this choice were disastrous. War with Britain became inevitable and cut off Spain from America, opening its colonial markets to Britain and the United States; Godoy invaded Portugal with success in the War of Oranges (1801) but the defeat of the Franco-Spanish fleet by the British at Trafalgar in 1805 and the "selfishness" of Napoleon caused him to seek a rapprochement with the allies. Had Napoleon lost the Battle of Jena (1806) against the Prussians, Godoy would have joined the Fourth Coalition against him.

Godoy's position was now extremely weak. He was unpopular at home. The court aristocracy disliked him as an upstart; severe inflation produced great hardship among the poorer classes; a campaign of gossip was mounted against him by those intellectuals whom he did not patronize. He now hoped, with French help, to dismember Portugal and to secure personal salvation in a principality. This curious hope was the basis of the Treaty of Fontainebleau (1807) by which Napoleon and the Spanish government agreed upon the conquest and partition of Portugal. When French troops on the way to Portugal occupied the fortresses of northern and central Spain and when Napoleon demanded territorial gains in Spain itself, Godoy's policy was bankrupt. It was obvious that Napoleon had lost all faith in Godoy and Spain as an ally: the "dirty intrigues" of the heir to the throne, Ferdinand, prince of Asturias, against his father and Godoy led Napoleon to think of drastic intervention in Spanish affairs.

Appointment of Joseph Bonaparte

The opportunity for direct intervention by Napoleon was given by the Revolt of Aranjuez (March 17, 1808), in which the partisans of Ferdinand (an alliance of discontented aristocrats and others opposed to Godoy) impelled the abdication of Charles IV and the dismissal of the favourite. Napoleon summoned both the old king and Ferdinand VII to Bayonne, where both were impelled to abdicate. The Spanish throne was offered to Napoleon's brother Joseph.

THE FRENCH INVASION AND THE WAR OF INDEPENDENCE, 1804–14

Joseph could count on the support of cautious, legalistic administrators and soldiers, of those who believed resistance to French power impossible, and of those who considered that Napoleon might "regenerate" Spain by modern reforms. These groups became convinced *afrancesados*, as members of the pro-French party were called. Relying on their support, Napoleon entirely underestimated the possibility of popular resistance to the occupation of Spain by French armies. Although the rising of May 2 in Madrid was suppressed, local risings against the French were successful wherever French military power was weak.

The War of Independence. After the deposition of King Ferdinand, "patriot" Spain outside the control of the French armies split into a number of autonomous provinces. Resistance centred in provincial committees (juntas) that organized armies. A Central Junta at Aranjuez sought to control this nascent federalism and the local levies, and Spanish regular troops defeated a French army of inferior, ill-supplied troops under Dupont at Bailén in July 1808. The French retired from Madrid. Napoleon himself invaded Spain and by 1809 was in control of most of the peninsula. The Spanish regular army, led by incompetent generals, suffered defeat after defeat.

The War of Independence, or, as the English call it, the Peninsular War, became for Napoleon the "Spanish ulcer," and he attributed his defeat in Europe to its requirements for men and money. He was defeated not by the inefficient Spanish regular army but by British troops under Wellington advancing from Portugal with the aid of Spanish guerrillas. The guerrillas represented popular resistance as against the supposed pro-French proclivities of the "possessing classes." As the main battles—Talavera (July 1809) and Vitoria (June 1813)—were fought by Wellington, the guerrillas pinned down French garrisons, intercepted dispatches, and isolated convoys.

The Constitution of Cádiz. The significance of the war years lies in the re-creation of a patriotic spirit to cover the bare bones of Bourbon administrative centralism and in the explicit formulation of a liberal ideology that was to be a dynamic factor in Spanish history.

The Central Junta and its successor, the Regency, were compelled to summon a Cortes (Parliament) in order to legitimize the situation created by the absence of Ferdinand VII, who was in France. Conservatives conceived of its task as the mere supply of the sinews of war on behalf of an absent king. The Cortes, when it met at Cádiz in 1810, was dominated by liberals who wished to go beyond the mere support of the war effort and establish a constitution that would make impossible the revival of rule by a favourite like Godoy. The Constitution of 1812 was to become the "sacred codex" of Latin liberalism.

The Constitution of Cádiz gave Spain a strictly limited monarchy (the king must work through his responsible ministers), a single-chamber Parliament with no special representation for the church or the nobility, and a modern centralized administrative system based on provinces and municipalities. All this had little basis in the medieval precedents quoted in the debates and was inspired by the constitutions of revolutionary France. Bourgeois individualism inspired legislation against entail, favouring instead the sale of common lands and the individual's right to dispose of his property as he might wish. The abolition of the Inquisition represented a mixture of historic regalism and modern anti-clericalism. This measure produced a conservative reaction, as did all liberal anti-clericalism through to the Second Republic in the 1930s. This reaction gave a popular underpinning to Ferdinand VII's destruction of liberalism and all its works in 1814 (see below).

Abolition of the Inquisition

In addition to initiating a liberal tradition, the War of Independence bequeathed two problems: first, generals chafed at control by civilian juntas and on occasion overthrew them, thus initiating the phenomenon of the pronunciamento, or military revolution; second, the *afrancesados*, often men of liberal inclinations but tarred with the accusation of collaborationism with the French, were left as an indigestible element within liberalism itself.

FERDINAND VII, 1814–33

With the help of an army corps and of conservative sentiment that had been outraged by the liberalism of 1812, Ferdinand returned from exile in France to rule Spain as

an absolute monarch. In 1820 he was forced by military sedition to return to constitutionalism (1820–23). For the last "ominous" decade of his reign he returned to a relatively enlightened form of ministerial despotism. The years 1814–20 were dominated by the attempt to re-establish Spanish rule in America and by the problem of maintaining an inflated wartime army with a permanent economic deficit.

The failure of liberalism. The solution of the Cádiz liberals to the imperial problem had been to make the colonies constitutionally part of metropolitan Spain by giving them representation in the Cortes. This did not stop the revolt of the colonies, where the Creoles wanted local self-government and free trade rather than liberal centralization. In 1814 it was not clear that the rebels under Simón Bolívar in the north and San Martín in the south would succeed; but all of Ferdinand's efforts to assemble a large army and a fleet to send to America failed. In 1820 the army that was to subdue the colonies revolted against the king in a pronunciamento organized by Major Riego Nuñez and supported by the local liberals organized in Masonic lodges.

The Revolution of 1820

The Revolution of 1820 brought into power the "jail birds"—liberals of the 1812 vintage who had been persecuted by Ferdinand VII. The Constitution of 1812 was re-established together with other liberal legislation, including the sale of monastic property.

The liberal system failed once more because it was a minority creed sustained by a section of the army—the military radicals such as Riego—against a mounting conservative reaction that had been fed once more by an attack on the church, especially the monasteries. The liberals themselves split. The more conservative wing (led by Martínez de la Rosa, a dramatist) wished for a more moderate constitution, based on the French Charter of 1814, which would give better representation to the upper classes and would not be totally unacceptable to the King, as was the "prison" of the Constitution of 1812. The King gave no support whatsoever to this movement and, in a cowardly fashion, disowned a rising of the guards' regiments that backed it. Thus the extreme radicals (*exaltados*) gained control by means of demonstrations in the streets, organized by clubs run on the lines of the Jacobins of the French Revolution.

The conservative reaction developed in the north around the regency set up at Seo de Urgel. Without French help, the movement would not have been successful, but when Louis XVIII sent French troops (the "Hundred Thousand Sons of St. Louis"), the liberal armies disintegrated and the liberal system fell.

Once more revolution at home favoured revolution in the colonies. Mexican conservatives, who had no desire to be ruled by Spanish anti-clericals, successfully established an independent Mexico under Agustín de Iturbide (1822). Spanish military power in South America finally foundered on the decisive Battle of Ayacucho (1824). Of Spain's far-flung empire, only the islands of Cuba, Puerto Rico, and the Philippines remained.

The "ominous decade," 1823–33. The "ominous decade", as it was called by the persecuted liberals, began with a severe purge of liberals; but in its later stages the regime became increasingly unacceptable to extreme conservatives, who looked to the King's reactionary brother, Don Carlos. Ferdinand had to rely either on inefficient traditionalists who could raise no money on the European money markets or on the more liberal ministers who were able financiers. Ministers such as Luis López Ballesteros, a friend of the *afrancesados*, set the tone with a serious attempt at a government-fostered economic revival.

The Carlists

This return to 18th-century "ministerial despotism" did not satisfy the liberal exiles, who mounted ineffective invasions in 1824 and 1830. More important, the conservatives of Don Carlos' court faction accepted Ferdinand VII's rule only on condition that Don Carlos would inherit the crown. In 1829, Ferdinand married his niece María Cristina of Naples, who realized that her influence depended on the elimination of that of Don Carlos. In March 1830, her faction at court persuaded the King to exclude Don Carlos from the succession even if María Cristina produced a female heir. This attack on the rights of Don Carlos was the origin of the Carlist party and of the Carlist Wars, which were for over a half century to be a disrupting influence in Spain. After the defeat of an attempt to force María Cristina to recognize Don Carlos' rights during Ferdinand's illness (September 1832), María Cristina's faction was dominant at court. She succeeded in securing all important military commands in the hands of supporters of the claims of her daughter, Isabella. When, on September 29, 1833, Ferdinand died, Isabella was proclaimed queen, with María Cristina as regent. The First Carlist War (1833–39) broke out almost immediately.

ISABELLA II, 1833–68

The Carlist Wars. The dynastic war between Isabelline liberalism and Carlism was a savage civil war between urban liberalism and rural traditionalism, between the poorly paid and equipped regular army of the liberal governments, supporting Isabella, and the semi-guerrilla forces of the Carlists. The Carlist strength lay in the north, especially in the Basque Provinces and Navarre, where there was strong support for the *fueros* against liberal centralism and for the traditional Catholic order represented by the religious bigotry of Don Carlos and his circle. But the Carlists could not break out of their bases in the north to capture an important city. The great Carlist leader Tomás Zumalacárregui y de Imaz was killed in an attempt to capture Bilbao, and Don Carlos' expedition to Madrid failed (1837). In 1839 the Carlist commander staged a mutiny against the clerical court of Don Carlos and came to terms with Baldomero Espartero, the most successful of Isabella's generals.

María Cristina allied with liberalism out of military necessity, not from conviction. She would have preferred to grant administrative reforms rather than consent that her daughter should become a constitutional monarch. But the liberals alone could save her daughter's throne from the Carlists, and the minimum demand of all liberals was a constitution. As regent from 1833 to 1840, she therefore consistently supported conservative liberals against the radicals. The Royal Statute (1834) represented this alliance between respectable upper-middle-class liberals and the crown.

This conservative constitution, with its property franchise and the great powers it gave the crown in the choice of ministers, could not stop the drift toward the left implicit in liberalism itself. The radicals, who were the heirs of the *exaltados* of 1820–23, were installed in power first by a series of provincial town risings in 1835 and later, after a short-lived conservative reaction, by an army mutiny that forced María Cristina to accept the Constitution of 1812. The radical politicians, however, accepted a more moderate compromise constitution—that of 1837. Of more enduring importance was the sale of church lands to finance the war. The great disentailment carried out by Prime Minister Juan Alvarez Mendizábal and his successors altered profoundly the social structure of Spain by putting on the market large quantities of land, most of which was bought by large landowners or prosperous peasants.

Moderates, progressives, and the generals. The Carlist Wars left civilian politicians discredited, and generals became the arbiters of politics not, as in 1814–20, as intruders but as part of the political machinery. They became the "swords" of the two main political groups. The *moderados*, who were upper-middle-class oligarchic liberals fearful of democratic violence and upholders of the prerogatives of the crown, represented the conservative stream in liberalism. Their rivals, the *progresistas*, were the heirs of the *exaltados* and represented a lower stratum of the middle class; the *progresistas* were prepared to use the discontent of the urban masses in order to bring pressure on the crown to give them office. Their instrument was the Urban Militia. Espartero used his military faction and his supporters among the younger *progresista* politicians and their artisan followers in the great cities to oust María Cristina and establish himself as regent

(1841–43). Espartero proved a disappointment to the radical *progresistas*, who now allied with his conservative opponents under his military and political rival, Ramón María Narváez. In 1843 Espartero was thrown out by a pronunciamento.

The pronunciamento of Narváez

Narváez jettisoned his *progresista* allies through a court intrigue, and between 1844 and 1854 he and his fellow generals dominated domestic politics as representatives of the *moderados*. Their administrative, educational, and financial measures and the formation of the Civil Guard were lasting achievements; but the generals could not stabilize their rule on the basis of their constitution of 1845, a conservative revision of 1837. The period was disturbed by a series of *progresista* military risings.

To the left of the *progresistas*, who were prepared to accept the monarchy if it gave them office, a Democratic Party developed; it was prepared to dethrone Isabella II, who was declared of age to rule in 1843. Never strong in numbers outside the towns, the Democrats radicalized politics. Orthodox *progresista* politicians were embarrassed by their extremist attitudes but could not neglect their potential role as urban revolutionaries.

It was not the Democrats but a group of discontented generals led by Leopoldo O'Donnell who successfully revolted in 1854. They were prepared to sacrifice the dynasty because the Queen and her mother favoured a rigid court conservatism that effectively excluded them from influence.

The rebellious military oligarchs were forced to call in civilian and radical support. This turned their pronunciamento into a mild revolution. Isabella survived only through Espartero's political timidity. Unprepared to accept the backing of the Democrats as the "George Washington of Spain," he accepted an alliance with O'Donnell, who was determined to arrest the drift to radicalism. In 1856 he broke with Espartero, defeated a demonstration in his favour, and dissolved the National Militia, the instrument of the left-wing Progressives. The radical thrust was thus defeated.

Economic expansion. The "revolutionary" period of 1854–56 saw no important constitutional change; but the further extension of disentailment and the new law for limited companies provided the legal structure for a rapid expansion of the economy. To promote this expansion, there were new injections of foreign credit—particularly French—and new banks. This capital made it possible to begin the railroad network that was to provide the transport infrastructure for a national market. The textile industry of Catalonia flourished, as a modern wool manufacture grew up; in the Basque Country, the second pole of an industrial economy developed slowly around iron. Agriculture, still a dominant sector of the economy, expanded as the church and common lands provided new fields for the easiest of cash crops—wheat; the growth of such towns as Barcelona created a market for vegetables, wines, and fruit.

Expansion resulted in the classic expression of 19th-century liberalism—the haute bourgeoisie of finance and industry. Members of this new class ranged from solid Catalan manufacturers demanding protective tariffs to safeguard their gains, to daring speculators such as the railway financier Marqués de Salamanca, who took an active part in political life and the urbanization of Madrid. It also included successful generals ready to forget their humble origins. Together with the large landowners, these groups formed the oligarchy of liberalism.

The government that presided over this prosperity was O'Donnell's Liberal Union—an attempt to fuse all dynastic parties in a broad-based coalition. It provided a long period of stable government (1856–63), and had the Progressive politicians been less afraid of losing their left wing to the Democrats and had the Queen been willing to grant Progressives power, the dynasty might have survived. Instead, she excluded the Progressives and forced them, first to withdraw formally from political life, then to contemplate revolution. Their "sword," General Prim y Prats (a chemist's son and a striking example of the social mobility of the liberal army), was a resolute conspirator and the ablest of the political generals of the 19th century. When Isabella's court ministers alienated O'Donnell's followers, a powerful coalition was formed, and Prim dropped his alliance with the Democrats. A slump caused by bad harvests, a series of mediocre ultra-conservative governments, and a growth in democratic agitation among university intellectuals (whose main concern was the hold of the church over education) gave wide support to the military rising against Isabella. Her armies would not defend her, and she was forced to leave for France in September 1868.

O'Donnell's Liberal Union

THE REVOLUTION OF 1868 AND THE REPUBLIC OF 1873

The revolution that led to the dethronement of Isabella was the work of army oligarchs led by Francisco Serrano y Domínguez and Progressive conspirators behind Prim. The Democrats became active in setting up juntas after the revolution: for the most part they rapidly became Federal Republicans under the influence of the theories of the French anarchist Pierre-Joseph Proudhon as presented by their leader, Pí y Margall. The Democratic intellectuals' main contribution was to add a radical democratic content to the demands of the military oligarchy.

The generals were determined to keep the leadership of the revolution in their own hands by channelling it into a constitutional monarchy. Although they had to concede universal suffrage in the Constitution of 1869, they ruthlessly suppressed republican risings in the summer of that year. Their problem was to find a constitutional monarch. Prim's attempt to persuade a Hohenzollern to accept the throne was opposed by France and set off the Franco-German War in 1870. In November 1870, Amadeus, duke of Aosta, was elected king, and Prim, the kingmaker, was assassinated the day Amadeus entered Madrid.

Amadeus, duke of Aosta

Amadeus attempted to rule as a constitutional monarch. Opposed both by Republicans and by Carlists, he could form no stable government from the "September coalition" of former conservative Liberal Unionists, the ex-Progressives, and the moderate Democrats—now called Radicals. Once Amadeus called the Radicals to power, the conservatives deserted the dynasty. Amadeus abdicated after an attack by the Radicals on the army in February 1873. The Cortes proclaimed Spain a republic.

The Republic of 1873 came into existence to fill the political vacuum created by Amadeus' abdication. The Republican Party was neither strong nor united. When the Republican leaders, on legal scruples, refused to declare for a *federal* republic, the provincial Federal extremists revolted.

This Cantonalist revolt was serious in Cartagena, Alcoy, and Málaga. The Republican leaders had allowed attacks on the army that had reduced it to impotence. To conservatives and men of order, the country seemed on the verge of total dissolution; the Carlists were immensely strengthened by the "excesses" of Cantonalists. Too late, Emilio Castelar y Ripoll, the last president of the republic, tried to recapture the loyalty of the army. In January 1874, Gen. Manuel Pavia y Rodríguez de Alburquerque drove the Republican deputies from the Cortes building in the hope of creating a government of order. Pavia turned power over to Gen. Francisco Serrano to form a coalition government.

General Serrano took over as president of a unitary republic. His main task was victory over the Carlists, now a strong force in northern Spain. In this he failed, and on December 29, 1874, a young brigadier, Arsenio Martínez Campos, "declared" for Alfonso XII, the son of Isabella.

There was no resistance. The extreme threat of anarchy in 1873 had resulted in a strong conservative reaction, strengthened by the religious policies pursued since 1868. The Constitution of 1869 for the first time had allowed complete freedom of religion. In spite of a total failure to create political stability, the Revolution of 1868 bequeathed to Spain the model of a modern secular state based on universal suffrage. On the extreme left these years saw the effective penetration of anarchism, especially in rural Andalusia and in industrial Catalonia, where the lower classes deserted a long tradition of political action via the Democratic and Republican parties and

moderate unionism. Though anarchists were persecuted after 1873, the movement was kept alive by small groups of enthusiasts.

The Cuban revolt

The worst problem of the years 1868–75 was posed by the independence movement in Cuba, which, with Puerto Rico, was the last possession of Spain in America. Cubans had long resented the failure to reform rule by captains general, to grant some autonomy, and to ease the economic sacrifices imposed by the Spanish tariff system. The revolt that began in October 1868 made great demands on Spain in men (100,000 by 1870) and money. The Ten Years' War (1868–78) made difficulties for all governments in power in Spain after 1868 and forced abandonment of the most popular of the pledges made by the rebels in 1868: the abolition of the arbitrary and socially selective recruitment system. Like the Carlist wars, the Cuban War favoured the monarchical reaction.

THE RESTORED MONARCHY, 1875–1923

Once the Carlists had been defeated and the Cubans had accepted the peace settlement of El Zanjón (1878), the restored monarchy provided the most stable government Spain had known since 1833. This stability was sustained by respectable economic growth.

Stability, 1875–98. The architect of the restoration itself and of the Constitution of 1876 was Cánovas del Castillo. A superb politician, Cánovas had hoped for a civilian restoration; he accepted Martínez Campos' coup but used the young Alfonso XII to keep the military out of politics.

The Canovite system

The Canovite system was artificial in that it required the contrived rotation in office (*turno pacífico*) of a Liberal and a Conservative party; this in turn demanded governmental control of elections, which were run by caciques, or local political bosses, who controlled votes in their districts. Only in this way could the government selected by the king and the politicians in Madrid obtain a parliamentary majority; extensive corruption and the use of administrative pressures on electors were perhaps the only ways to make the parliamentary system work in an underdeveloped society. This system survived the death of Alfonso XII (1885) and only began to falter in the 1890s, toward the end of his wife's regency. The Carlist threat weakened with defeat, and the majority of Republicans in Spain were domesticated and reconciled to the use of "legal" means.

"Without being a rich country," wrote an economist in the early 1880s, "Spain has become comfortably off." This prosperity, untroubled by the claims of organized labour, was the result of the demand for iron ore after the invention of the Bessemer process (England and France invested heavily in mineral production), of the demand for Spanish wine after the devastations by phylloxera in France, and of the resumption of railway construction. The third largest wool industry in Europe grew up beside the older cotton mills in Catalonia. The boom did not break until the late 1880s, when an agricultural depression set in. A wave of economic pessimism preceded the political and intellectual reaction of 1898.

The loss of Cuba, Puerto Rico, and the Philippines in 1898 exposed the political system to severe criticism. No fiscal and political reform sufficient to satisfy Cuban demands could be effected within the framework of the monarchy, partly because of the pressure of the Spanish loyalist party in Cuba. A revolt of 1895 set off another costly war against Cuban guerrillas. The intervention of the United States could not be staved off by a last-minute grant of autonomy. Their humiliating and total naval defeat in 1898 became known to Spaniards as "the Disaster." Spain now lost all of its American possessions and the Philippines at the very time when the great European powers were building their overseas empires.

War with the United States

Opposition movements, 1898–1923. Criticism of the restoration monarchy came from the Catalan and Basque regionalists, from a revived Republican Party, from the proletarian parties, from the army, from the more forward looking politicians, and from the intellectuals.

Basque regionalism, though more akin in its ideas to extreme nationalist movements, was less a challenge than Catalan regionalism, which dominated Spanish politics until 1923. With its own Catalan language and a revived cultural tradition, it moved from a demand for protection of Catalan industry against "Castilian" free trade to a demand for political autonomy. The *Lliga Regionalista* (founded 1901), dominated by the Catalan industrialist Francisco Cambó de Asís and the theoretician of Catalan nationalism, Prat de la Riba, demanded the end of the *turno* and a revival of regionalism within a genuine party system. Cambó wished to solve the Catalan question "within Spain"—*i.e.*, by legal means and in cooperation with monarchical politicians. The revival of Catalanism, however, set off a "Castilian" reaction in which moderate Catalans were accused of selfishness or of hiding separatist aims under "respectable" regionalism. In the 1907 election the united Catalan front, Solidaridad Catalana, defeated the parties of the system but then divided into a right (which accepted a solution within the monarchy) and a left (which was to drift to Republicanism). Cambó's cooperation with Madrid brought Catalonia no tangible concessions.

Republicanism, which had degenerated into local politicking and lived on its memories of 1873, was revived by the remarkable oratorical and organizational talents of Alejandro Lerroux, whose Radical Republican Party offered a program that appealed to the alienated working class voter of Barcelona.

Here he was competing with a slow revival of anarchism, which veered between terrorism and educational propaganda and union activity; the anarcho-syndicalist union, the Confederación Nacional del Trabajo (CNT), was founded in 1910. The Socialist movement with its union (the Unión General de Trabajadores, or UGT, founded 1888) was relatively weak except in the mining districts of the north and in Madrid, where it was dominated by its French-influenced founder, Pablo Iglesias. In 1909 the Socialists abandoned their boycott of "bourgeois" politics and allied with the Republicans. This alliance was to give the party a political leverage in excess of its voting strength.

The "Generation of 1898"

The intellectuals' protest embraced the writers of widely differing ideas collectively known as the "Generation of 1898." Joaquín Costa y Martínez, a voluminous writer, was an especially harsh critic of *caciquismo*; he wanted a revived, effectively democratic, modernized Spain. His attempt to create a coalition of the "productive classes" against the political drones in the Unión Nacional failed. Miguel de Unamuno y Jugo saw regeneration in terms of a return to "pure" Spanish values. All of the Generation of 1898 distrusted politics as managed by professional politicians who were out of touch with the "real" Spain.

Among the politicians themselves, the conservative leaders Francisco Silvela and Antonio Maura and the democratic liberal José Canalejas sought to regenerate the system by widening the degree of political participation through "sincere" elections. They were opposed by the cratic liberal José Canalejas sought to regenerate the system by widening the degree of political participaty. This exposed Alfonso XIII (who succeeded in 1902) to the charge of political interference in a constitutional monarchy in which "opinion" did not provide the king with a choice between two strong parties. The danger of "sincere" elections to the political establishment was revealed by the Republican victories in 1903.

Revolt in Morocco

The call up of troops for Morocco, where Spanish troops were engaged in operations protecting the Spanish coastal possessions, set off the Tragic Week of 1909 in Barcelona. Public order collapsed; anarchists and Radical Republicans burned churches and convents. Maura was driven from office because Alfonso XIII (who had succeeded in 1902) accepted the Liberals' estimate of the harm Maura's firm repression would inflict on the monarchy. Rather than resist a Liberal Party that had allied with the "sewer" (the Republican parties), the King held that the Liberals were a useful "lightning conductor," protecting the monarchy from the threat on the left. Ever since Maura's fall, the King's diagnosis had been challenged by conservatives.

World War I produced increased strains. Real wages fell, making the unions restive, and in 1917, junior officers formed juntas and struck for better conditions. The ensuing crisis was exploited by Catalan politicians, increasingly pressing for autonomy. The revolutionary coalition split up, and a general strike frightened Cambó and the Catalans, who threatened to call a national convention that would unite all critics of the monarchy. The formation of a national government under Maura ended the last serious attempt to regenerate the political system and to make it respond to reformist and Catalan demands. No subsequent government was strong enough to face the anarchist agitation in Catalonia and the Moroccan War.

Spain had been granted a protectorate in Morocco in 1912. In the effort to pacify it, economizing politicians were ready for compromise with the tribes, but the generals saw conquest as the only solution. A bid by Gen. Fernández Silvestre, reputedly backed by Alfonso XIII, for a crowning victory ended in the terrible massacre of Spanish troops at Annual in 1921. Opposition politicians were determined to expose the King's action and criticize the army.

Anarchist influences

World War I had given the anarcho-syndicalist movement great power. At the same time there grew a terrorist fringe, which the leaders of the CNT could not control. These leaders (Salvador Sequí and Angel Pestaña), though they shared the anarchist contempt for political action, wished to build unions powerful enough to challenge the employers by direct action. They mistrusted the libertarian tradition of spontaneous revolution as a means of toppling the bourgeois state. The great Barcelona strike of 1919 was the most impressive in Spanish history. When the employers' violent reaction discredited the moderates in the Confederación Nacional del Trabajo, it was followed by a wave of assassinations by gangsters employed by both the anarchists and the employers.

Thus, when Gen. Primo de Rivera staged his pronunciamento in September 1923, he could count on the support of the conservative classes fearful for social order. The Lliga, for instance, became more concerned about suppressing strikes than about Catalan autonomy, for which it had campaigned from 1915 to 1918. He could also count on the tacit alliance of Alfonso XIII, who was tired of politicians who could not provide him with effective governments.

PRIMO DE RIVERA (1923–30) AND THE SECOND REPUBLIC (1931–36)

Primo de Rivera. Primo de Rivera was a political improviser who believed his mission was to save Spain from the old politicians and to hand over government (after an interval of personal rule) to "clean" patriots. He failed to complete the process because his rule became increasingly unpopular, especially among the intellectuals and Catalans. The September 1923 coup by which he had gained power had been widely welcomed in Catalonia, where, as captain general, Primo had listened sympathetically to Catalan demands. Soon afterward, however, Primo became a Spanish patriot and permitted an "anti-Catalan crusade." His followers' attempts to build up a political party (the Patriotic Union) to run a regenerated Spain and to provide it with an ideology collapsed.

At first he ruled via the army. In spite of initial quarrels with the African commanders, whom he forced to retreat in Morocco, the Military Directory was responsible for final victory in the protectorate. The Spanish, collaborating for the first time with the French, landed at Alhucemas (al-Hoceima) in September 1925 and defeated the most successful tribal leader, Abd el-Krim. By 1927 the whole of the protectorate was successfully occupied.

The Civil Directory (1925–30) was responsible for a thorough overhaul of local government and for an ambitious public works program to increase irrigation, hydraulic power, and road building. Primo's economic nationalism entailed strict protectionist policies and an attack on foreign oil monopolies. The complicated bureaucratic control of industry did not endear him to capitalists after 1926; on the other hand he collaborated successfully with the UGT while suppressing the CNT. The Civil Directory failed in its main task: to win sufficient political support in the National Assembly summoned for 1928 to facilitate a return to quasi-constitutional government.

Throughout his early years Primo was favoured by an economic expansion based on favourable terms of trade for Spanish exports. By 1929 the peseta began to fall in value in spite of desperate measures to save it. Economic recession alone would not have ruined the dictator, but he lost the support of both the army and the King. The army turned against him as a result of his attempts to abolish the privileges of the artillery and engineer corps. The King believed that student protests, the growing discontent in Catalonia, and the increasing conspiracies of the "old" politicians imperilled the dynasty. On January 28, 1930, he forced Primo's resignation.

Alfonso acted too late. His earlier support of the dictatorship ruined him in the eyes of the politicians and public. The weak governments of Gen. Dámaso Berenguer and Adm. Juan Bautista Aznar could barely keep order. At San Sebastián (August 17, 1930) an alliance of former liberal monarchists, Catalan politicians, and Republicans agreed to overthrow the monarchy. The failure of a Republican military rising at Jaca (December 12, 1930) saved them from establishing a republic by force. The municipal elections of April 12, 1931, proved that the great cities were overwhelmingly Republican. Rather than face civil war and street demonstrations in Madrid, Alfonso XIII left Spain.

Abdication of Alfonso XIII

The Second Republic. The history of the Second Republic falls into four distinct phases: (1) the Provisional Government, which lasted until the religious issue forced its resignation in October 1931; (2) the governments of the Left Republicans and Socialists, which ruled from October 1931 and were defeated in the elections of November 1933; (3) the conservative government of the Radical Republicans and the Catholic right from November 1933 to February 1936, punctuated by the revolution of October 1934, and that ended with the electoral victory of the Popular Front in February 1936; and (4) the government of the Popular Front and "the descent into violence" that culminated in the military rising of July 1936.

The Provisional Government was a coalition government, presided over by Alcalá Zamora, whose Catholicism reassured moderate opinion. The coalition included all the groups represented at San Sebastian: Lerroux's Radicals, the Catalan left, the Socialists, and the Left Republicans dominated by Manuel Azaña y Diaz.

The elections to the Constitutent Cortes strengthened the Socialists and Left Republicans and thus upset the parliamentary balance between moderate Catholic Republicans and the left. It was the left that imprinted its views on the constitution, especially its religious clauses. The historically conditioned anti-clericalism had led the government to tolerate an outburst of church burning (May 1931). The Socialists and Left Republicans inserted in the constitution an attack on religious education and the regular orders, which forced the resignation of Alcalá Zamora and Miguel Maura, his minister of the interior.

This direct and, it would seem, ill-advised clash with Catholic sentiment was to provide a base for the construction of a party of the right devoted to the reversal of the church settlement. This party, the creation of the Catholic politician Gil Robles y Quiñones, became Acción Popular; it was to become the main component of the right-wing electoral grouping, the Confederación Española de Derechas Autónomas (CEDA). To the left its "accidentalism" (the doctrine that forms of government were irrelevant provided the church could fulfill its mission) was suspect.

The Acción Popular

From October 1931 the government, with Azaña as premier, was in the hands of Left Republicans and Socialists, with the Catholic right, the Basque Catholics, the Navarrese Carlists, and Lerroux's Radicals in opposition. Azaña aimed to create a modern democracy; labour legislation would be the work of the Socialists, with the UGT leader, Largo Caballero, as minister of labour.

In April 1931 there was a danger that Catalonia might

declare its independence within a federal state. Azaña's greatest achievement was the settlement of the Catalan question. He overcame conservative Republican opposition to limited home rule under the Generalidad, which was controlled by the Catalan left (Esquerra) under Luis Companys. Largo Caballero's legislation provided labour with a strong negotiating position but could not, in itself, mitigate the mounting unemployment, which was particularly serious in the *latifundios* of the southwest. Since new machinery for the settlement of labour disputes was dominated by the UGT, it was opposed by the CNT, now influenced by the extreme revolutionary apoliticism of an anarchist group, the Federación Anarquista Ibérica (FAI). Violent strikes were frequent.

Sedition from the right came to a head in General Sanjurjo's pronunciamento in Seville (August 10, 1932). A fiasco, it reflected the army's resentment at Azaña's military reforms, which were intended to create an efficient army by pensioning off superfluous officers; though the reforms were necessary, they were carried out with what Gen. Emilio Mola called a "vindictive spirit" that made them resented. Politically more dangerous than Sanjurjo's abortive coup were the steady growth of Gil Robles' Acción Popular and the Socialists' desertion of the Azaña coalition, as Largo Caballero wearied of cooperation with "bourgeois" parties. In the elections of November 1933, therefore, the left was divided and the right relatively united in the electoral union of the CEDA. Given an electoral law that favoured electoral coalitions, the CEDA and Lerroux's Radicals, now a respectable middle class party, triumphed.

Conservative reaction

In spite of substantial achievements, the first two years of the republic dissatisfied important groups. The Socialists believed they could extract no further gains for labour from the "bourgeois" republic. A limited agrarian reform did little to ease chronic underemployment in the southwest. At the same time half-hearted Socialism alienated capitalists. Perhaps the most serious failure was in the realm of public order. The sedition of the extreme right was parallelled on the left by the strikes of the CNT against what it called "the republic of hangmen." The Law of Public Order and the government's sharp repression failed to control outbreaks and laid it open to the accusation of dictatorship.

The newly elected Cortes was dominated by Lerroux's Radicals and the CEDA. Lerroux could not govern without the support of Gil Robles. With power within sight, Gil Robles accentuated his legalism, to the distaste of the militant monarchists among his supporters. Nevertheless, his party was regarded by the Left Republicans and Socialists as a Catholic brand of the Fascist trends now winning out in western Europe.

When CEDA entered Lerroux's government the Socialists staged a revolution, which the Left Republicans did not disown. Revolutionary councils were set up in the mining districts of Asturias, where there was considerable destruction of property. In Barcelona the revolution was the work of Catalan nationalists, who believed autonomy was imperilled by the actions of the Madrid government in overruling an agrarian law passed by the Generalidad. Unsupported by the CNT, it was quickly suppressed.

The October Revolution of 1934 is the dividing point in the Second Republic. The Socialists, fearing the fate of their Austrian and German brothers, had revolted against a legal government and thereby established in the minds of the right the fear of "Red" rebellion. In the subsequent repression by the army lay the emotional origins of the Popular Front against "Fascism"—a re-creation of the Azaña coalition of Left Republicans and Socialists in order to fight the elections of February 1936.

The Popular Front

The Popular Front won the election of February 1936 by a narrow majority. Spain had become polarized, and the division was to intensify.

The Popular Front government was exclusively Republican, though it was supported in the Cortes by the Socialists. Under Largo Caballero, the left Socialists put increasing pressure on the government, using revolutionary language if not intending revolution. Largo Caballero's revolutionary rhetoric concealed his hope that the orthodox Republicans could be eased from power, leaving the field open to a pure Socialist government, which his followers chose to call, in Leninist language, the "dictatorship of the proletariat."

Just as the fears of the "Fascism" of the right justified the defensive reaction of the Socialists, so the right argued that the Republican government was a prisoner of the revolutionary left (they could point to a rapid growth of Communist influence). The Falange, founded by José Antonio Primo de Rivera, the son of the dictator, was a nationalist anti-Marxist grouping appealing to youth ready to engage in street affrays with the Socialist Youth. Conservatives rallied behind the right-wing National Front, which openly appealed to the military to save Spain from Marxism.

The army was the key factor; by the early summer a young officers' conspiracy was backed by Mola, Manuel Goded, and, finally, Francisco Franco. The murder of Calvo Sotelo with the connivance of government security forces was the final outrage for the right and the army.

THE CIVIL WAR

The rising of the military started in Morocco on July 17, 1936, and spread to the garrisons of metropolitan Spain in the following days. The Civil War took place because the rising was successful only in Old Castile, in Navarre, where Carlist support was decisive, and, of the larger towns, in Saragossa, Seville, Córdoba, Valladolid, and Cádiz. Galicia soon went over to the Nationalists, as did most of Andalusia. Catalonia and the Basque Provinces were loyal to the government because the Republic guaranteed their autonomy. In Madrid and Barcelona, the security forces, helped by the workers who were armed belatedly by the government, defeated the officers. Thus, in broadest terms, the Republic held the centre, the Levant, Catalonia, and the Basque industrial zones; the Nationalists held the food-producing areas. One consequence was to be an increasingly acute food shortage in the Republican zone.

The role of the workers in defeating the rising made their organizations the power in the Republican zone. The legal government was by-passed or totally supplanted by local committees and trade unions; the workers' militia replaced the dissolved army. In many parts of Spain a social revolution took place in July 1936: factories and farms were collectivized. The English novelist George Orwell described Barcelona, where the CNT was all-powerful, as "a town where the working class was in the saddle." The success of working class control, in terms of increased production, is difficult to estimate.

This revolution was distasteful to the Left Republicans and to the Communist Party, which rapidly grew in number and in political influence because it controlled the supply of arms from the Soviet Union. In the name of an efficient war effort and the preservation of "bourgeois" elements in the Popular Front, the Communists pressed for a popular army and central government control. In September–November 1936, the CNT was brought into the government of Catalonia and into Largo Caballero's ministry in Madrid—an astonishing step for a movement that had consistently rejected "bourgeois" politics. The CNT militants did not approve the leaders' "surrender" and the dismantling of the militia-backed revolution.

A small Marxist revolutionary party, the Partido Obrero de Unificación Marxista (POUM), which rejected the Popular Front in favour of a workers' government, set off a rebellion in Barcelona in May 1937. The Communists, Republicans, and anti-Caballero Socialists used this as an excuse to oust Largo Caballero, who proved insufficiently pliable to Communist demands. The government led by the Socialist doctor Juan Negrín was a Republican–Socialist–Communist concern. The great unions, the UGT and CNT, were replaced by the political parties.

The Communists were correct in arguing that the committee–militia system was militarily ineffective. General Franco's army, ferried over from Morocco, cut through the militia and arrived before Madrid by November 1936. The successful resistance of the city, which was stiffened by the arrival of the International Brigades and

Soviet arms, meant that the Civil War would be prolonged for two years.

Victory would go to the side with the best army, with unified political control, and with adequate arms supply. The core of the Nationalist army was the African army commanded by General Franco. Abundantly supplied with generals, the troops and junior officers of the Nationalist armies were well trained. Given the confused political control in Republican Spain, the secure military and political command of Franco (from October 1936) was decisive. In April 1937 he ruthlessly incorporated the Falange into a unified movement under his leadership.

Both sides sought help from abroad. The Republic consistently hoped that France and Great Britain would allow them to acquire arms. Partly because of fear of a general war, partly because of domestic pressures, both powers backed non-intervention (*i.e.*, self-imposed restriction of arms supply by all powers). General Franco appealed immediately to Hitler in Germany and to Mussolini in Italy, which supplied aircraft early in the war. The Germans, in return for mineral concessions, supplied the Condor Legion (100 combat planes), and the Italians sent ground troops; both supplied tanks and artillery.

The Western democracies protested but did nothing. The Soviet Union alone responded to the breakdown of non-intervention by supplying arms to the Republican side. Soviet supplies were of great importance (tanks, aircraft, and a military mission) after October 1936. The Communist International also organized the International Brigades. In 1938, Soviet supplies dropped off, and the balance of arms supply was decisively in favour of the Nationalists.

Once the Popular Army replaced the militia (which was held to be responsible for the easy advance on Madrid and the fall of Málaga to Italian troops in February 1937) the Republic held Madrid and defeated two flanking attacks in the battles of Jarama (February 1937) and Guadalajara (March 1937), where the International Brigades decisively defeated a motorized Italian corps.

After his failure at Madrid, General Franco transferred his effort to the north, where the bombing of Guérnica, on April 26, 1937, by German planes outraged public opinion in the democracies: by October 1937, General Franco had captured the industrial zone, shortened his front, and won a decisive advantage. Diversionary battles at Brunete and in Aragon were costly and revealed the great weakness of the Republican Popular Army: its incapacity to sustain an initially successful offensive.

When General Franco concentrated again on Madrid the Republican army staged its most effective offensive in the winter Battle of Teruel (launched December 15, 1937). General Franco recovered Teruel, drove to the sea and committed his one strategic error in deciding on the difficult attack on Valencia rather than turning against Catalonia. To relieve Valencia the Republicans attacked across the Ebro (July 24, 1938); once more they failed to exploit the breakthrough, and the bloody battle exhausted the Popular Army.

The final Nationalist campaign in Catalonia was relatively easy. On the Republican side, the feasibility of continued resistance, which was supported by the Communists and Negrín, caused acute political divisions. On March 7, 1939, a civil war broke out in Madrid between Communists and anti-Communists. On March 28 the Nationalist forces entered a starving capital.

Capture of Madrid

FRANCO'S SPAIN, 1939 TO PRESENT

The first decade of General Franco's government was harsh. As a result of the Civil War roughly 1,000,000 Spaniards were dead or had emigrated. Fierce political repression was matched by economic hardship. General Franco's alliance with the Axis powers brought diplomatic isolation from the Western democracies. After 1950, growing foreign investment and change in economic policy brought an increase in material prosperity and a diminution of opposition activities.

Recovery after 1939 was made difficult by the destruction caused by the Civil War (especially of railway rolling stock), by a severe loss of skilled labour, by a series of bad droughts (especially 1949), by restrictions on the import of capital goods imposed by the European war, and by misguided attempts at state-controlled industrial development within a protected economy. The national income dropped back to the levels of 1900, and real wages fell to half of those of 1936. These were the years of near famine, of the black market, and of rural misery and flight to the towns.

General Franco's sympathies (and, even more so, those of his foreign minister, Serrano Súñer) lay openly with Germany and Italy, to whom he gave moral and material support. He nevertheless demanded a high price for his military cooperation against the Western Allies, on whom he was dependent for food and oil imports. He consistently maintained his mission against world Communism, however, sending the Blue Division against the Soviet Union (1941–43).

Franco's relations with the democracies

When it appeared likely that the Allies would win the war, in 1943, General Franco declared Spain's neutrality, but this late change earned no reward from them. Though Britain's Winston Churchill recognized the value of Spanish neutrality, the Allies were unwilling to desert the Soviet alliance; to the American and Soviet leaders, Roosevelt and Stalin, General Franco was a "Fascist." With Churchill's defeat by the Labour Party in Great Britain in 1945, the three great powers all declared their hostility to General Franco's government as undemocratic.

The declared hostility of the dominant great powers and the exclusion of Spain from the United Nations gave the opposition in Spain new life. Don Juan, the heir of Alfonso XIII, presented himself as a democratic alternative, and agreements were negotiated between the liberal monarchists and the opposition in exile, excluding the Communists, in 1947. Valiant but futile guerrilla activities, inspired largely by the CNT and the Communist Party (1944–48), were easily suppressed.

General Franco met these difficulties, the most severe of his regime, with confidence. The Fuero de los Españoles (July 1945), guaranteeing personal freedoms (provided no attack was made on the government), was an attempt to establish a more democratic image. More significant was his alliance with the church, which was given control of education, and his reduction of the Falange (which had supplied a national Fascist ideology) to a mere appendage of his government. The ostracism of Spain by the United Nations and the consequent withdrawal of ambassadors from its member nations was skillfully turned into a means of rallying support for General Franco in the name of national unity.

General Franco's confidence came from his divination that, with the Cold War between the Western democracies and the Communist states, the United States could not sustain its hostility to Spain and that the Allies, while declaring for the democratic opposition, would not directly intervene to overthrow his regime. Hence the hopes of the opposition came to nothing; once more the monarchists and Republicans split, and the "internal" and "external" oppositions drew apart. In 1953 an agreement with the United States gave General Franco considerable financial advantages in return for the establishment of four United States bases in Spain. "At last," he could declare as the ally of a great power, "I have won the Civil War."

Establishment of United States air and naval bases

Thus by 1953, Spain appeared to be a stable state. Internal political control remained in General Franco's hands, ensured by his mastery of the army and his ability to play off the groups that supported him against each other. In these ministerial changes the Falange steadily lost power to the technocrats of the Opus Dei (a lay Catholic organization), which broke with the economic nationalism of the Falange in favour of a "normal" capitalist system, with market mechanisms replacing state control.

The new policies seemed justified by their economic success, which was aided by a rapid growth of tourism and foreign investment. As in many countries that have seen an economic miracle, spectacular expansion (a growth rate of 7.4 percent between 1962 and 1966) brought problems of inflation and a wages–cost spiral.

Investment went mainly into industry and some spectacular irrigation projects; the Spanish countryside remained poor and its productivity low. The rural poor of the south emigrated to the factories of Europe or to the cities of Spain.

While the new prosperity brought a degree of social mobility that was novel to Spanish society and satisfied the middle classes, rising prices entailed a revival of labour troubles. The workers became disillusioned with the "official" syndicates run by the Falange. They set up workers' commissions outside the official framework, and there were serious strikes, in spite of legislation that forbade them.

Sections of the church were sensitive to these discontents. While the episcopate, on the whole, held to the view that the church should support the state, younger priests saw the long-term dangers of such an alliance. Thus they were sympathetic to the workers' commissions.

An even more intractable problem was that of Basque nationalism, and, again, some of the Basque lower clergy were sympathetic to the nationalists. The nationalist movement developed an extremist wing that supported violent action.

The most serious problem was the failure of the system to provide a safety valve for discontents. In 1966 a new Organic Law of the State reintroduced a measure of direct election of a proportion of members of the Cortes by heads of families and their wives. But clearly this was not intended to reintroduce political parties: they remained, in General Franco's words, a symptom of the "particular furies" that had so often destroyed Spain. The trade unions were freed from Falangist control. Press censorship was replaced by a press law, which, though it left publishers open to prosecution by the state, nevertheless allowed a freedom of expression unknown since 1939. It looked as if gradual liberalization was under way.

The Organic Law of 1966

This prospect was clouded by student troubles and labour unrest. Just as the workers distrusted official unionism, so the students disliked official students' syndicates. They had protested violently as far back as 1956, and in 1968 their protests forced a closing of the universities. The students' grievances against the educational system were largely justified; but their political aims were ill-considered and their alliance with the workers tenuous. Student violence in Madrid and Barcelona alarmed the government, and in early 1969 a state of emergency lasted two months. This action took place against a background of rumours about General Franco's health and brought the problem of the succession to the forefront.

Since Spain was legally a monarchy, the choice lay between Don Juan, the son of Alfonso XIII, and Don Juan's son Juan Carlos. A choice of Don Juan, a critic of Franco, would lead to a parliamentary monarchy and give political life to Franco's enemies. Juan Carlos, who was close to Franco, was declared legal heir in 1969. In 1972 Franco decreed that at his death he be succeeded by Juan Carlos as chief of state and by the vice president, Luis Cerrero Blanco, as chief of government.

In the early 1970s Franco's government seemed to gain in strength. Spain made attempts to improve relations with eastern Europe and Latin America; a trade pact was signed with the Soviet Union in September 1972.

(R.Ca.)

BIBLIOGRAPHY. The principal bibliographical guide to Spanish history is BENITO SANCHEZ ALONSO, *Fuentes de la historia española e hispanoamericana*, 3rd ed., 3 vol. (1952). LUIS G. DE VALDEAVELLANO, *Historia de España*, vol. 1 (1952), is the best general history, but it extends so far only to 1212. FERRAN SOLDEVILA, *Historia de España*, 3 vol. (1952–54), is beautifully illustrated, but it sees the history of Spain from the Catalan point of view. The most comprehensive work eventually will be the collaborative *Historia de España* under the editorial direction of RAMON MENENDEZ PIDAL, of which five volumes have thus far appeared. JAIME VICENS VIVES is the editor of another collaborative work, the *Historia social y económica de España y América*, 5 vol. (1957–59). Among the most important interpretive works is AMERICO CASTRO, *España en su historia* (1948; Eng. trans., *The Spaniards: An Introduction to Their History*, rev. ed., 1971), the most recent statement of his thesis emphasizing the medieval interaction of Christians, Muslims, and Jews. CLAUDIO SANCHEZ-ALBORNOZ has taken sharp issue with him in his *España, un enigma histórico*, 2 vol. (1956). RAMON MENENDEZ PIDAL, *Historia de España*, vol. 1 (1947; Eng. trans., *The Spaniards in Their History*, 1950), is a judicious essay on the formation of the Spanish character. A highly readable and provocative overview of the trends of Spanish history is given by JAIME VICENS VIVES in his *Aproximación a la historia de España*, 5th ed. (1962; Eng. trans., *Approaches to the History of Spain*, 2nd ed. rev., 1970).

Ancient Spain: For prehistoric Spain, see LUIS PERICOT GARCIA, *La España primitiva* (1950); or ANTONIO GARCIA Y BELLIDO, *La península ibérica en los comienzos de su historia* (1953). GARCIA Y BELLIDO is also the author of works on the Carthaginians and Greeks in Spain: *Fenicios y Carthagineses en occidente* (1942) and *Hispania Graeca*, 3 vol. (1948). A useful work in English on the Roman period is C.H.V. SUTHERLAND, *The Romans in Spain, 217 B.C.–A.D. 117* (1939).

Medieval Christian Spain: In addition to the general works cited above, the following may be helpful: LUIS G. DE VALDEAVELLANO, *Curso de historia de las instituciones españolas. De los orígines al final de la edad media* (1968), an excellent survey of medieval institutions; ALFONSO GARCIA GALLO, *Manual de historia del derecho español*, 3rd ed. rev., 2 vol. (1967), especially valuable for its collection of documents relating to government and law. The most up-to-date work on its subject is JAIME VICENS VIVES, *Manuel de historia económica de España*, 5th ed. (1967; Eng. trans., *An Economic History of Spain*, 1969). E.A. THOMPSON, *The Goths in Spain* (1969), is the most recent work on the Visigothic kingdom. YITZHAK BAER, *A History of the Jews in Christian Spain*, 2 vol. (1961; orig. pub. in Hebrew, 1959), treats one of the principal elements in medieval society and makes use of a wealth of sources. A classic work delineating the life of the Cid and placing him in the context of the 11th century is RAMON MENENDEZ PIDAL, *El Cid en la historia* (1921; Eng. trans., *The Cid and His Spain*, 1934). ROBERT I. BURNS, *The Crusader Kingdom of Valencia*, 2 vol. (1967), is a useful study of the settlement of Valencia after the Christian reconquest.

Muslim Spain: The best work in English is W. MONTGOMERY WATT, *A History of Islamic Spain* (1965); see also E. LEVI-PROVENCAL, *Histoire de l'Espagne musulmane*, 2nd ed., 3 vol. (1950), and *L'Espagne musulmane au X^e siècle* (1932).

1479–1700: JOHN H. ELLIOTT, *Imperial Spain, 1469–1716* (1963), is the only single work covering precisely this period, and it is perhaps the best modern synthesis in any language. JOHN LYNCH, *Spain Under the Habsburgs*, 2 vol. (1964–69), is based on the latest research, especially in economic history. It has useful up-to-date bibliographies. ROGER B. MERRIMAN, *The Rise of the Spanish Empire in the Old World and in the New*, vol. 2–4 (1918–34), covers the period from the Catholic Kings to Philip II. It is still useful as the most detailed political history of the period. The last volume, on Philip II, is especially good. ANTONIO DOMINGUEZ ORTIZ, *Crisis y decadencia de la España de los Austrias* (1969; Eng. trans., *The Golden Age of Spain, 1516–1659*, 1971), is a synthesis by one of the most distinguished contemporary Spanish scholars. HELMUT G. KOENIGSBERGER, *The Habsburgs and Europe, 1516–1660* (1971), attempts to see Spanish history in the perspective of European history. It consists of chapters from *The New Cambridge Modern History*, vol. 2 and 3, and from *The Age of Expansion*, ed. by H.R. TREVOR-ROPER (1968). This latter volume also contains a fine short chapter by H. KAMEN, "Spain's Dominion," on the reigns of Philip II and Philip III. FERNAND BRAUDEL, *La Méditerranée et le monde méditerranéen à l'époque de Philippe II*, 2nd ed., 2 vol. (1966; Eng. trans. of vol. 1, *The Mediterranean and the Mediterranean World in the Age of Philip II*, 1972), is a large-scale economic and historical geography of the Mediterranean basin during the 16th century, in which Spain plays a central role. This book has become a classic since it first appeared (1949) and has been the basis for all further work on the period and area. EARL J. HAMILTON, *American Treasure and the Price Revolution in Spain, 1501–1650* (1934), is a pioneering study whose price series have not been superseded; however, its statistical methods and interpretations are open to criticism, and the tables should be used with caution. WILLIAM H. PRESCOTT, *History of the Reign of Ferdinand and Isabella the Catholic*, 3 vol. (1838, many later editions), is still the fullest and most readable account in English. J.M. BATISTA I ROCA, "The Hispanic Kingdoms and the Catholic Kings," *The New Cambridge Modern History*, vol. 1 (1957), is an excellent short modern account. HENRY C. LEA, *A History of the Inquisition of Spain*, 4 vol. (1906–07), is still the fullest, and a very fair, account. PAUL J. HAUBEN (ed.), *The Spanish In-*

quisition (1969), prints short extracts from authors with different viewpoints on this very controversial subject. JOSEPH PEREZ, *La Révolution des "comunidades" de Castile, 1520–1521* (1970), is the most detailed account of both the events and the social and political background of the Comunero revolt. GARRETT MATTINGLY, *The Defeat of the Spanish Armada* (U.S. title, *The Armada;* 1959), is outstanding both for its scholarship and for its readability. JOHN H. ELLIOTT, *The Revolt of the Catalans: A Study in the Decline of Spain, 1598–1640* (1963), is the definitive work on this subject. JOHN H. PARRY, *The Spanish Seaborne Empire* (1966), is an excellent introduction to this subject.

Spain since 1700: The best general introduction to the problems of modern Spain remains GERALD BRENAN, *The Spanish Labyrinth*, 2nd ed. (1950). For a general outline of political, economic, and social developments, see RAYMOND CARR, *Spain: 1808–1939* (1966). SALVADOR DE MADARIAGA, *Spain* (1958), is a stimulating general study by a liberal Spaniard. For the War of the Spanish Succession, see HENRY KAMEN, *The War of Succession in Spain, 1700–15* (1969). The internal history of the reign of Charles III is well covered by RICHARD HERR, in *The Eighteenth Century Revolution in Spain* (1958). PIERRE VILAR, *La Catalogne dans l'Espagne moderne*, 3 vol. (1962), is a masterly treatment of the late-18th-century social and economic history of Catalonia. EARL J. HAMILTON, *War and Prices in Spain, 1651–1800* (1947), is a basic study of the economy. ROBERT SOUTHEY, *History of the Peninsular War*, 3 vol. (1823–32), is still useful. The military history of the war (from the British point of view) is covered in CHARLES OMAN, *A History of the Peninsular War*, 7 vol. (1902–30). Napoleon's policy in Spain is studied in detail in ANDRE FUGIER, *Napoléon et l'Espagne, 1799–1808*, 2 vol. (1930). For the intervention of the army in politics, see ERIC CHRISTIANSEN, *The Origins of Military Power in Spain, 1800–1854* (1967); and STANLEY G. PAYNE, *Politics and the Military in Modern Spain* (1967). For midcentury politics see V.G. KIERNAN, *The Revolution of 1854 in Spanish History* (1966); and for the history of the republic, see C.A.M. HENNESSY, *The Federal Republic in Spain* (1962). There is no adequate study of Restoration Spain in English. ANTONIO RAMOS OLIVEIRA, *Politics, Economics and Men of Modern Spain, 1808–1946* (1946), is a useful guide. The best introduction is contained in M. FERNANDEZ ALMAGRO, *Historia política de la España contemporánea* (1956). A Centre Left account of the republic is GABRIEL JACKSON, *The Spanish Republic and the Civil War, 1931–39* (1965). An excellent study of the politics of the Right is RICHARD ROBINSON, *The Origins of Franco's Spain* (1970). The history of the Civil War is fully treated in HUGH THOMAS, *The Spanish Civil War* (1961). For the internal history of the republic, BURNETT BOLLOTEN, *The Grand Camouflage* (1968), is excellent. FRANZ BORKENAU, *The Spanish Cockpit* (1937); and GEORGE ORWELL, *Homage to Catalonia* (1938, reprinted 1969), are splendid contemporary accounts. The politics of Nationalist Spain are treated in STANLEY G. PAYNE, *Falange* (1961). For the development of the Franco régime see J.W.D. TRYTHALL, *Franco* (1970); and GEORGE HILLS, *Franco* (1967).

Spallanzani, Lazzaro

One of the great 18th-century physiologists, Lazzaro Spallanzani made important contributions to the experimental study of sense organs, regeneration, digestion, respiration, and animal reproduction. His investigations into the development of microscopic life in nutrient culture solutions paved the way for the research of Louis Pasteur. He also found time to make studies of physical phenomena, such as volcanoes, springs, the weather, and the depth of Lake Ventasso.

Spallanzani was born on January 12, 1729, at Scandiano, Modena. His father, a distinguished lawyer, sent him to the Jesuit college at Reggio, at which he received a sound education in the classics and philosophy. He was invited to join the order, but, although he was eventually ordained (in 1757), he declined this offer and went to Bologna to study law. Under the influence of his kinswoman Laura Bassi, a professor of mathematics, he became interested in science. In 1754 Spallanzani was appointed professor of logic, metaphysics, and Greek at Reggio College and in 1760 professor of physics at the University of Modena.

Although Spallanzani published in 1760 an article critical of a new translation of the *Iliad,* all of his leisure was being devoted to scientific research. In 1766 he published a monograph on the mechanics of stones that bounce when thrown obliquely across water. His first biological work, published in 1767, was an attack on the biological theory suggested by Georges Buffon and John Turberville Needham, who believed that all living things contain, in addition to inanimate matter, special "vital atoms" that are responsible for all physiological activities. They postulated that, after death, the "vital atoms" escape into the soil and are again taken up by plants. The two men claimed that the small moving objects seen in pond water and in infusions of plant and animal matter are not living organisms but merely "vital atoms" escaping from the organic material. Spallanzani studied various forms of microscopic life and confirmed the view of Antonie van Leeuwenhoek that such forms are living organisms. In a series of experiments he showed that gravy, when boiled, did not produce these forms if placed in phials that were immediately sealed by fusing the glass. As a result of this work, he concluded that the objects in pond water and other preparations were living organisms introduced from the air and that Buffon's views were without foundation.

Spallanzani, oil painting by an unknown artist, probably early 18th century. In the collection of the Università degli Studi di Pavia, Italy.

Experiments on spontaneous generation

The range of Spallanzani's experimental interest expanded. In 1768 he published the results of his regeneration and transplantation experiments. He studied regeneration in a wide range of animals including planarians, snails, and amphibians and reached a number of general conclusions: the lower animals have greater regenerative power than the higher; young individuals have a greater capacity for regeneration than the adults of the same species; and, except in the simplest animals, it is the superficial parts not the internal organs that can regenerate. His transplantation experiments showed great experimental skill and included the successful transplant of the head of one snail onto the body of another. In 1773 he investigated the circulation of the blood through the lungs and other organs and did an important series of experiments on digestion, in which he obtained evidence that digestive juice contains special chemicals that are suited to particular foods. At the request of his friend Charles Bonnet, Spallanzani investigated the male contribution to generation. Although the spermatozoa had first been seen in the 17th century, their function was not understood until some 30 years after the formulation of the cell theory in 1839. As a result of his earlier investigations into simple animals, Spallanzani supported the prevailing view that the spermatozoa were parasites within the semen. Both Bonnet and Spallanzani accepted

Experiments on regeneration, transplantation, and digestion

Preformation and the male contribution to reproduction

the Preformation theory. According to their version of this theory, the germs of all living things were created by God in the beginning and were encapsulated within the first female of each species. Thus, the new individual present in each egg was not formed *de novo* but developed as the result of an expansion of parts the delineation of which had been laid down within the germ by God at the Creation. It was assumed that the semen provided a stimulus for this expansion, but it was not known if contact was essential nor if all the parts of the semen were required. Using amphibians, Spallanzani showed that actual contact between egg and semen is essential for the development of a new animal and that filtered semen becomes less and less effective as filtration becomes more and more complete. He noted that the residue on the filter paper retained all its original power if it were immediately added to the water containing the eggs. Spallanzani concluded that it was the solid parts of the secretion, proteinaceous and fatty substances that form the bulk of the semen, that were essential, and he continued to regard the spermatzoa as inessential parasites. Despite this error, Spallanzani performed some of the first successful artificial insemination experiments on lower animals and on a dog.

As Spallanzani's fame grew, he became a fellow of most of the scientific societies in Europe. In 1769 he accepted a chair at the University of Pavia, where, despite other offers, he remained for the rest of his life. He was popular with students and colleagues. Once a small group, jealous of his success, accused him of malpractice in association with the museum that he controlled, but he was soon vindicated. Spallanzani took every opportunity to travel, to study new phenomena, and to meet other scientists. The accounts of his journeys to Constantinople and Sicily still provide interesting reading. Toward the end of his life he conducted further research on microscopic animals and plants that he had started early in his career; he also began studies on the electric charge of the torpedo fish and sense organs in bats. In his last set of experiments, published posthumously, he attempted to show that the conversion of oxygen to carbon dioxide must occur in tissues, not in the lungs (as Antoine-Laurent Lavoisier had suggested in 1787). He died in Pavia in 1799.

BIBLIOGRAPHY. Most general histories of biology have a short section on Spallanzani. MICHAEL FOSTER, *Lectures on the History of Physiology During the Sixteenth, Seventeenth and Eighteenth Centuries* (1901, reprinted 1924), deals with Spallanzani's work on digestion and respiration. Two books by ELIZABETH B. GASKING are *Investigations into Generation, 1651–1828* (1967), which discusses Spallanzani's researches into regeneration, infusions, and his experiments on fertilization, and *The Rise of Experimental Embryology* (1970), a general history, with an account of Spallanzani's experiments and comments on the Preformation theory. Spallanzani's own works in translation are *Tracts on the Natural History of Animals and Vegetables*, trans. by J. DALYELL (1803); and *An Essay upon Animal Reproductions*, trans. by M. MATY (1769).

(E.B.G.)

Special-Interest Groups

In its widest definition, the term special-interest group (or its synonym interest group) refers to any aggregate of individuals that, on the basis of one or more shared concerns or wants, makes claims upon other groups in society or upon society in general in order to maintain or promote its position or objectives. Special-interest groups can be more specifically described and classified in terms of motivation, structure, and political activity.

Promotional groups

Categories defined by motivation. Within the broad definition of special-interest groups, two polar types are recognizable: first, interest groups proper, such as trade unions, farmers' unions, and employers' associations, which have as their primary purpose the enhancement of the advantage of their members; and, second, promotional groups, such as the societies for the prevention of cruelty to children or various voluntary relief agencies, which exist primarily or entirely to enhance the advantage not of their own members but of the population, even perhaps to the discomfort or disadvantage of their own members. Some of these, such as churches or various evangelizing groups, exist to promulgate a distinctive set of values to be applied to society as a whole. The distinction between interest groups proper and promotional groups is not sharp for two reasons. In the first place, most interest groups proper sincerely believe that in furthering their own material advantage they are also serving that of society as a whole—by promoting "free enterprise" or a healthy and wealthy body of farmers or a well-paid and enthusiastic corps of school teachers. But the propagation of such beliefs is certainly not the primary purpose of such organizations, thus distinguishing them from promotional groups. The second reason is that some groups—for instance, organized churches—fall between the two types; they can simultaneously pursue advantages for their own sect and seek to inculcate a distinctive set of values in a whole society.

Natural and associational groups

Categories defined by structure. In primitive or developing societies, the most prominent type of interest group is the natural (*i.e.*, primordial or communal) one—that is, one based on kinship, lineage, neighbourhood, or religious confession. In Western, industrialized societies, though such groups do sometimes retain influence (as do the nationalities in Yugoslavia or Czechoslovakia), the most prominent interest group is the associational (*i.e.*, secondary or factitious) type, like the trade union or Campaign for Nuclear Disarmament, which is deliberately created to serve defined purposes. Often, associational (or factitious) groups are created for the sake of the specialized purposes of the first type; the Indian Workers Union, for instance, was created from the community of Indian persons in Britain.

Within the class of associational groups, further qualifications must be made:

1. Not all associational groups possess formal structure. "Wall Street" in the United States, or the "City" in London, though consisting of a loose network of persons or functions, may nevertheless exert powerful collective pressures.
2. Some associational groups are collectivities; but others are single, discreet organizations. Thus General Motors Corporation exerts its own strong influence vis-à-vis the U.S. government irrespective of the influence of the more general employers' organization to which it possibly belongs, like the National Association of Manufacturers.
3. Some associational groups are temporary or *ad hoc*. Such are the so-called anomic groups, such as enraged French farmers who come together briefly to put logs across roads in order to draw governmental attention to their grievances.
4. Some associational groups are "latent." There may be a common interest among certain members of the public even though these individuals may not have combined into a formal or informal organization. The individuals may be unaware that they have a common interest or, if aware, see no reason to defend or promote it. Or, even if the members consciously wish to defend or promote an interest, the laws may restrict or control their ability to associate for such a purpose.

Pressure groups

Categories defined by political activity. If or when any interest group tries to influence the government in the pursuit of its aims, it becomes a "pressure group." Not all interest groups proper try to exert influence on governments; many (such as businesses and trade unions) do so only as a part of their more general activities of promoting their own interests. Promotional groups, on the other hand, spend much or all their time precisely in trying to influence the government to favour their aims. Groups such as an anglers' association may, therefore, turn into pressure groups for a time—the time when they seek to influence the government for one of their purposes—and then revert to simple interest-group status. A pressure group is therefore definable as "any interest group that is not a part of the government and does not itself seek to govern the country in its own name, but does seek to influence that government for its own purposes."

Two difficulties arise. First, some groups are neither a

governmental agency nor entirely a private group. In autocratic states, Communist or otherwise, for instance, trade unions are often controlled by the government or the governing party. In the Western liberal democracies, again, agencies like the Tennessee Valley Authority (in the U.S.) or the British Broadcasting Corporation, though subject to the overriding control of the government, enjoy substantial autonomy in certain brand areas.

The second difficulty lies in distinguishing a pressure group from a political party. The most fruitful approach is to stipulate that, whereas a party puts up candidates for election to public office and has a structure and carries out activities to secure their election, a pressure group seeks to influence both the government and the parties. The Catholic interest in Italy, for instance, is served both by the Christian Democratic Party and also by the Catholic Action Society. The first is unquestionably a party with its own program, mode of operation, and structures; and the second is unquestionably a pressure group. Again the "natural" group of Swedes in Finland serves itself by the Swedish People's Party; this is clearly a special-interest group, yet it puts up candidates and is represented in the legislature because it thinks its members' interest is best served by exerting pressure as part of a governmental coalition.

Thus, it may be that what begins as a pressure group winds up as a political party. The British Labour Party had its origins in 1900, when a collection of trade unionists formed a Labour Representation Committee in order to secure the election of working-class MP's to Parliament; later it broadened its membership and program to become the Labour Party of today. Again, in France, Pierre Poujade's pressure group, the Union of Small Shopkeepers, was involved in the 1956 elections and won over 40 seats, thus becoming a political party before retiring from the electoral arena in 1958 and reverting to pressure-group status. The reverse process can also occur, as when a political party engenders pressure groups; thus, the Communist parties in France and Italy have set up interest groups for women, youth, workers, and the like.

CHARACTERISTICS OF PRESSURE GROUPS

Power elements. Even in the most pluralistic of the Western liberal democratic states, it is wrong to picture public policy as simply the result of a parallelogram of group forces. The groups are themselves restrained by institutions, procedures, and public beliefs. Among the *institutions*, the most important are the public bureaucracy, the political parties, and the independent branches of the government (the executive, legislature, and judiciary —or some combination of these, depending on the structure of government). To the extent that each or all of these institutions have strong traditions, no interest group supplants them but instead has to deal with them. The governmental procedures in force also affect groups' performance. To the extent that public issues are traditionally subject to publicity and wide discussion, groups are limited in the kind of activities that they can pursue. They are constrained by public *beliefs* as to what is in "the public interest," by what is a proper or improper procedure, or by what causes are respectable and what are not. If any of these three entities—institutions, procedures, or public beliefs—become feeble, interest groups can intrude into them. By allying with or gaining power over the parties, the legislature, or the bureaucracy, for instance, groups can tend to substitute themselves for such organs in the decision-making process.

Inside every country the power that pressure groups wield against the government and that each group wields relative to its rivals depends on a combination of the following variables, some of which are mutually dependent:

1. Density is the ratio of actual membership to potential membership. The higher the density, the more "representative" is the group of all the people whose interests it purports to represent and the greater will be the inclination for governments to recognize and consult it. On the other hand, too wide a membership brings with it internal cleavages, so that on certain issues the organization may not be able to tender clear-cut advice or, indeed, may have to refrain from offering advice altogether.
2. Wealth not only helps a group to develop a skilled management and bureaucracy but also enables it to propagandize and to finance political parties.
3. Prestige lends a group the ability to get a favourable initial hearing from government and public, even though its numbers may be small and its wealth meagre.
4. Organization consists notably of the ability to brief legislators and administrators well and quickly, to mobilize members and the public rapidly, and to receive advance intelligence of likely trends in policy.
5. Socioeconomic leverage is strong among some groups (such as trade unions) that can disrupt social life and low among others (such as consumers associations).
6. Militancy consists of making an effective nuisance of oneself, so that, hopefully, governments will be willing to "buy" time or peace.
7. Specialized information and skills add the weight of authority.
8. Electoral strength refers to the power of some groups that, though poorly organized or having a low density, nevertheless command wide support in the electorate and so find themselves courted by rival political parties.

Strategy and tactics. Although all groups seek out the most influential agencies of government, the most influential may not be accessible; and resort must be had to the next most influential organ that *is* accessible. Because the Communist trade unions in Italy, for instance, are not welcome at the Roman Catholic controlled Ministry of Labour, they try to penetrate the legislature through political election. Indeed, in any system the influence of the various organs of government varies. In France the president and bureaucracy are more influential than the majority party and Parliament; in the United States, the president and Congress balance each other, with control of the bureaucracy shared between the two. Strategy, for an interest group, consists of determining and going to the most influential organ that is accessible.

Tactics to affect the executive

The tactics of an interest group range from the constitutional to the unconstitutional (or "direct action"), the legal to the illegal—all subject, as noted above, to the restraints of institutions, public procedures, and public beliefs. When the target of the tactics is the executive and the governmental bureaucracy, the following are the prime methods: *Constitutional operations* include (1) advice via advisory bodies attached to the ministries (as in Britain and France), (2) official hearings outside the ministries (as in Royal Commissions in the U.K. and presidential commissions in the U.S.) or inside the ministries (as in Germany or Sweden), and (3) ad hoc consultations and cooperation. *Semiconstitutional operations* include (1) recruitment of state civil servants into the private bureaucracies of the interest groups, or vice versa, and (2) bribery and favours, which need not necessarily mean passing of money but can take the form of providing entertainment, gifts, or meals. *Semidirect operations* include such measures as refusing to provide information or to cooperate in administering legislation and thus generally withdrawing from advisory functions. *Direct action* includes such measures as the withdrawal of labour (the British Medical Association, for instance, advised its members to withdraw from the state medical service in 1965 unless its demands were met) or even violence such as the roadblocking activities of enraged French farmers in the 1960s).

Tactics to affect the legislative

When the target is the legislature, the following are the chief kinds of tactics used by interest groups: *Constitutional operations* include (1) testimony before legislative committee hearings (extremely important in the U.S. and somewhat important in Sweden, the German Federal Republic, Japan, and Italy); (2) direct representation in the legislature, which involves having individual businessmen, financiers, farmers, school teachers, journalists, and other professionals representing the larger interests of their profession or sponsoring group (in Great Britain in 1955 some 30 percent of Labour's MP's were trade-union sponsored); and (3) lobbying, which refers to the activities of salaried or nonsalaried persons who try to promote their interest groups' aims by seeking personal contacts with

legislators, by sending communications or information to legislators or persuading others to do so, and by rendering campaign assistance to favoured legislators. (In the U.S., lobbying is conducted not only by private interest groups but also by certain members of the executive branch and the bureaucracy.) *Semiconstitutional operations* include subvention or payment of retainers as well as providing campaign contributions, secretarial help, office accommodations, and the like, which are restricted but not forbidden by law. *Semidirect action* includes mass lobbying, such as promoting mass demonstrations before legislators, ostensibly to relate grievances but in fact to impress public opinion. *Direct action* includes threatening legislators with a withdrawal of financial assistance, with physical violence, or with riots (as in Japan, where snake dances and riots become a means of protest).

When political parties are powerful, they may prove a highly preferred target. Tactics in such cases include the following: *Constitutional operations*, such as, (1) exacting election pledges, which is most important and fruitful in countries (such as the U.S.) where there is relatively little national-party discipline, where representatives owe a certain allegiance to local-party groups and constituents, and where, most important, representatives do possess legislative power; (2) financing the party, which in all systems is perhaps the most effective operation and which in most Western parliaments—and in Western-style parliaments like Japan's—is systematically done by trade unions, employers associations, and individual firms; and (3) lobbying the party machinery, a method that is virtually nonexistent in the United States but is significant in such countries as Great Britain and Germany.

Tactics to affect political parties

A final target of interest groups is public opinion. The general opinion of the public at large can be of importance in issues where questions of "fairness" or "justice" arise (on which most people feel they can pronounce). These questions involve such matters as capital punishment, the use of nuclear weapons, or certain wars, about which large numbers of people feel very strongly.

ROLE OF INTEREST GROUPS IN VARIOUS POLITICAL SYSTEMS

The Anglo-American and Swedish patterns. In the United States, Great Britain, and Sweden, the general population is not irreparably divided on ideological or cultural lines. Although there arise from time to time some small extremist groups, the population at large is not split into irreconcilable blocks. Given this situation, the most influential and prominent groups are "secondary" associations that have highly specialized objectives, form freely without the requirement of prior governmental permission, and carry out their activities autonomously. With the exception of the affiliation of the trade-union movement to the Labour Party in Britain and in Sweden, the groups are politically neutral; and even the alignment of British and Swedish trade unions and cooperatives does not prevent them from cooperating with other parties nor hinder their free access to government departments. Latent groups are few, since freedom of speech and association and the right to petition the government permit most interests to organize, while good communication media facilitate such organization. Public participation in such groups is, by world standards, high. The pressure groups play highly specialized roles and are sharply differentiated from the political parties.

National differences

Although American and British means of influencing the executive are similar (by advisory committees, special inquiries, and day-to-day consultation and mutual assistance), these relations are more insitutionalized in Britain than in the U.S. British groups seek to influence the parties by affiliation or by securing their members' nomination as candidates, neither mode being employed in the U.S., and by financial assistance, which occurs in both states but in quite different ways owing to the very different legislation on this matter in the two countries. British groups seek to influence the legislature by securing direct representation through participation in party caucuses and by promoting amendments in the committee stage. In the U.S. the methods employed consist of lobbying influential congressmen and appearing at committee hearings, which are far more important in Congress than in the House of Commons. In influencing public opinion, American groups spend far more than their British counterparts—one reason being that purchase of time on radio and television networks is permissible in the U.S., whereas in Britain it is not. In addition, access to the presidency can prove decisive in the U.S.; and some groups such as the National Association for the Advancement of Colored People have scored notable successes by seeking court action.

In Sweden the tactics are somewhat different, owing to three factors: the existence of a multiparty system and the existence of coalition cabinets, the structure of the bureaucracy, and the much greater institutionalization of pressure groups. Sweden, Denmark, and Norway each possess a multiparty system; but when coalitions are formed, they are highly stable. Consensus is achieved in a three-tier operation—first at interparty (electoral) level, then at the interparty-coalition (legislative) level, and finally at the bureaucratic level. In Sweden groups seek to influence the parties by affiliation (the trade unions being affiliated to the Labour Party), by financing them (trade unions giving to the Labour Party, employers groups to the antisocialist parties), and by securing direct representation through the nomination of members as parliamentary candidates. The parties respond by trying to compose a balanced ticket of the spectrum of interests. Hence the groups can affect the legislature through their representatives inside each of the parties and may, on occasion, form a cross-party legislative pressure group in defense of their common interest; and they also seek access to the party caucus and influence the committee stage of legislation. In the latter case they are assisted by the standard Swedish procedure by which the "comments" of outside interests are attached to the government's bill, even if they contradict the bill's purposes. Groups have ready access to the legislature in the same ways that Anglo-American groups do, except that the procedure is highly institutionalized; the "Royal Commission" with representatives of the bureaucracy, the parties, and the interest groups seek to reach initial agreement on a bill to be presented to the legislature; and when this device is not used, "comments" appended to the bill serve to put the measure in the context of the avowed interests of various groups.

Not unlike the system in Britain, the U.S., and Sweden is the system in Japan, which, despite sharp ideological divisions, has a strong and stable two-party arrangement. This has led to the emergence of a pattern of highly institutionalized pressure groups of the "secondary" type, the most influential of these being business and organized labour. Business, on the whole, is aligned with the conservative Liberal-Democratic party, supplies the bulk of its funds, and has a large say in policy formation. Organized labour constitutes a powerful element within the Japanese Socialist Party. In an earlier day, rural farm groups carried considerable political weight—for the conservatives—but the increasing industrialization and urbanization of the country have tended to reduce its importance.

The French and Italian patterns. In France and Italy the political pattern is characterized by deep ideological cleavages. The Roman Catholic Church, for example, operates through both its own political party and its own interest groups, such as the Catholic Action Society and Catholic youth and women's group. By the same token, the highly ideological and sectarian Commmunist Party establishes its own pressure groups, such as trade unions, farmers associations, and youth movements. Several rival groups thus compete for the same clientele aligned or affiliated with rival political parties.

Under France's Fifth Republic, the executive branch currently controls the majority party in the legislature, and the role of the legislature has been reduced; whereas, under Italy's current system, feeble and fragile coalition cabinets have weakened executive leadership of the legislature, and the legislature itself is highly fragmented among numerous parties. Because contacts between interest groups on the one hand and the parties, civil service departments, and legislature on the other are poorly insti-

tutionalized, semidirect action or even direct action against the executive and the legislature are more common, and lawless activities of crowds and violent organizations have proved more widespread.

The means of influencing the chosen targets also vary. In France attention has shifted from the legislature (under the Fourth Republic) to the president and bureaucracy (under the Fifth); interest groups now act through the numerous advisory bodies, private contacts, and such official institutions as the Economic and Social Council. Interest groups secure contacts by putting former civil servants on their own payrolls. The fact that many civil servants and business executives come from the same schools facilitates private collusion.

In Italy interest groups direct their attention mainly to three targets. First, the bureaucracy, even though it is highly fragmented and provides few formal advisory channels of communication, is open to ad hoc and personal consultations (except to groups deemed ideologically distasteful, such as the Communists). Second, the parties are often twinned to interest groups, as noted earlier; and thus the groups seek and achieve direct representation in the legislature. Third, the legislature, because it is composed of interest groups, is heavily influenced in specialized legislative committees. In general, therefore, interest groups have tended to "intrude" into the organs of government, forming close alliances with certain departments and legislative commissions and inserting themselves into others via their membership in political parties. In short, interest groups are not "contained" as they are in Anglo-American and Scandinavian countries—political institutions are fragmented and weak, procedures are irregular or personal and not formal, and public beliefs are polarized into uncompromising ideologies.

Patterns in developing countries. Although there is no one typical pattern for all underdeveloped countries, which of course embrace over two-thirds of the world's sovereign states, there are a few common characteristics that can be suggested. First, political culture in each of these countries is fragmented, sometimes because of ideological differences, sometimes because of the mutual hostility of "natural" groupings based on kinship, lineage, tribe, or language. Second, nascent interest groups representing new modernizing and industrializing forces tend to range against rural natural groupings. The modernizers have defined and specialized objectives, whereas the traditionalists usually represent a spectrum of attitudes, beliefs, values, and interests. Both, in any case, tend to sponsor or generate their own political parties. Third, during preindependence days in some countries, trade unions and other movements (such as the Somali Youth League) carried on activities that would otherwise have been carried on by political parties; when independence came, these groups continued such activities, thus blurring the functional distinctions between parties and interest groups. Fourth, associations in these countries tend to have low membership densities; and in most of these countries the principal "interest"—that is, the peasantry—is hardly organized at all. Attempts to develop widely represented peasant movements have had only limited success. Fifth, although organization and established procedures may be poor, latent interest is usually high. In a particularly divisive and administratively feeble country, this interest latency may reveal itself in lawless and violent group activity—such as strikes, riots, guerrilla movements, and assassinations.

Countries with one-party or military governments

In some countries "parties" in elections are not really parties but simply electoral coalitions of various interest groups—the most influential groups consisting of cliques of landlords; leaders of religious, ethnic, or linguistic groups; and the like. Legislatures tend to reflect these divisions and temporary arrangements in society and so enjoy only feeble authority.

In countries with single-party regimes, such as Kenya, Tanzania, and Tunisia, the parties tend to lose their mass following and fairly well-defined organization in the years following independence. (A notable exception, however, is India with its Congress Party.) To enhance their authority, the party leaders try to limit or abolish the autonomy of such factitious interest groups as trade unions, cooperative movements, and youth and women movements and try to turn these groups into ancillaries of the party.

In some countries the military has taken over, either alone or with civilian elements, and imposed an authoritarian rule. In such cases, the most prominent groups are governmental—the military and the executive. Unless factitious interest groups enjoy a long history of organization (as does the Catholic hierarchy in Latin America), they are often turned into governmental ancillaries or suppressed. In these countries ruled by the military or single parties, the political process turns into a highly informal medley of pressures and personal contacts between the government, the military forces, the various "natural" groups, and some of the more strategically placed factitious groups (such as the church hierarchy or private industry). The "system" is constantly threatened with government coercion or violent outbreaks by sections of the population.

Patterns in Communist states. Like Western states, but unlike developing countries, Communist countries contain various associational groups (trade unions, cooperatives, and the like) but few, if any, promotional groups. In addition, such countries as the U.S.S.R., Czechoslovakia, Yugoslavia, Romania, and the People's Republic of China contain many ethnic groups; and Poland, Hungary, and East Germany contain influential organized churches. But unlike the Western states and like a good many of the developing countries, Communist countries grant such groups very little autonomy. The government is firmly controlled by a single party, is highly centralized, and tries to control a great deal of life. The Communist Party may allow other parties to exist in coalition under conditions that the party itself lays down; in Poland, for instance, the controlling party is the (Communist) United Polish Workers' Party, and it permits the peasant interest to be represented by the minor United Peasant Party and the professions by the even smaller Democratic Party. The leading party assures its power, however, by controlling the nomination (in all but minor cases tantamount to election) of the leadership of all minor parties and interest groups, and the only great interest group that is excluded is the leadership of the Catholic Church. In any event, no interest group or party can be legally constituted in a Communist country without the express permission of the authorities. And even when an interest is allowed to formally organize, it rarely can exert any influence on the government, for governmental leaders, having been nominated by the Communist Party, are responsible to the party alone, not to various interests.

One consequence of these restrictions is a high degree of interest latency in certain sectors; this latency is attested by the fact that within six months of the fall of Antonín Novotný in Czechoslovakia in January 1968 over 70 groups were petitioning the government for legalization.

In the U.S.S.R.

In the U.S.S.R. there exist large trade unions, cooperative associations, and professional societies; many scientific, defense, and sports societies, as well as some 100,000 house committees, sanitary teams, parent-teacher associations, and the like. All are party led and controlled; and they purportedly serve, in Stalin's words, as "transmission belts from the party to the masses." One must not infer, however, that such associations are entirely without other significance. In the first place, the party is not identical with the state bureaucracy, though it controls the latter; hence divergences and collisions can occur between an interest group (such as the trade unions) and a concerned ministry regarding the interpretation or implementation of a party's directive. The result often is a triangular meeting of interest group, officials, and party functionaries, with the latter mediating. Second, the constitution provides that these so-called mass organizations should be consulted on selected issues, as they indeed were in regard to the education act of 1958.

In other Communist states

Poland's groups include such economic interests as the trade unions and the Peasant Self-Aid and such professional ones as the General Technical Organization and the Writers' Union, as well as the Socialist Youth League; the Rural Youth League; the Women's League; and vari-

ous cultural-ethnic associations for Ukrainian, Lithuanian, or German minorities. In all of them, party leadership is assured (with minor exceptions), and they have relations with the bureaucracy and party mediators similar to those in the U.S.S.R. In Poland, however, there is the exceptional role of the Catholic Church, which has established some kind of equipoise with the party and has its own press, organizations, and clubs, even though its electoral freedom is severely restricted (only certain pro-Socialist Catholics are allowed to form "parties," such as the Znak, Pax, and the Christian Socialist Association, which participate in elections on the joint list with the Communist and other parties).

Yugoslavia has gone furthest in recognizing interest groups. The society contains many conflicting interests—nationalities; religious communities; a free-enterprise peasant sector; a decentralized network of workers' councils; and a large number of cultural, economic, and professional associations. The 1963 constitution gives institutional expression to these groups: in the five-chamber legislature, legislation is processed through the Federal Chamber, representing the population at large and individual republics; the Politico-Economic Chamber, representing management agencies and sociopolitical organizations; and the Chambers of Economics, of Education, and of Social Welfare and Health, representing their respective fields. The current factionalism inside the ruling "National Alliance," the centrifugal pulls of the peasant sector and the workers' councils, and the rivalry of the nationalities have combined to make these legal provisions much more than a formality.

Species and Speciation

Species are groups of organisms sharing many traits, or characteristics, in common; some are obvious, others subtle. Species come into being through the process of speciation. Most people recognize the distinctness of at least a few of the birds, fishes, insects, and plants that inhabit their immediate environment, and such knowledge is often extensive among so-called primitive peoples, who may be familiar with hundreds of kinds of plants and animals upon which they depend for food, drugs, and clothing or which they learn to avoid because of their stings, poisons, or distastefulness. The seemingly universal ability to recognize different species of organisms strongly suggests the reality of species distinctions.

THE DISTINCTIVENESS OF SPECIES

The readily observable distinctiveness of most species results from the fact that individuals belonging to different species seldom mate with one another, and the characteristics of one species are, therefore, seldom transferred to another. At the same time, the characteristics of each species result from the fact that the young inherit from their parents genes that determine their characteristics. Offspring differ in many ways from their parents because there are many ways in which the parental genes can be shuffled, or recombined, in the offspring. Characteristics essential to the survival of the individual, however, vary little between parent and offspring. In any event, the differences by which species are distinguished are generally characteristics common to all members of one species but not shared by individuals of a related or similar species. Common differences between species of birds may involve the shape of the feet or bill or the form of the wings. The advantage of a given shape is often obvious from the role played by the bird in its environment—a foot suitable for attacking and grasping prey may not be suitable for swimming or wading. Similarly, a bill useful for crushing plant seeds may be useless in extracting insect larvae from a tree. But not all differences between species are so obviously adaptive. Certain species of lizards are distinguished by the presence of enlarged scales along the back. The reason such scales should be advantageous to members of one species but not to those of another is not immediately clear. Apparently trivial differences often are discovered to be important for the species; for example, differences between the colours of the iris of the eyes in some species of gulls ensures that mating takes place only between members of the same species.

Many seemingly unimportant characteristics are readily observed in plants. Species may differ in texture, shape, or size of leaves. Some species produce seeds surrounded by a heavy, fleshy fruit; others shed seeds light enough to be blown by the wind. Many of these differences are understandable as adaptations that better ensure the survival and reproduction of the individual in a particular habitat.

A fuller understanding of the nature and origin of species is a focal point of research in systematic biology. It is also the considerable task of systematists to discover, name, and classify the multitude of plant and animal species. For some groups, such as birds, the task is by now essentially complete, and systematists speak with assurance about the total numbers of species in the world; in other groups, such as the insects, there may yet be thousands of unnamed species.

The task of naming species

In order to handle the task of naming and classifying species, a relatively simple system of nomenclature has gradually developed and has been agreed upon internationally. Under this system each new species is described in a publication in a standard manner and given a name consisting of two parts—a generic name, which encompasses a number of closely related species, and a species name, which narrows the identification to one species. The name of the Gila monster, a poisonous lizard of the southwestern United States, for example, is *Heloderma suspectum*. A systematist in another part of the world, even with no knowledge of the English language, would readily recognize that this species is a close relative of the beaded lizard of Mexico, *Heloderma horridum*. In a similar fashion, genera that share a number of characteristics are placed in the same family, related families in the same order, orders in classes, and classes in phyla (or divisions; see CLASSIFICATION, BIOLOGICAL).

Species in nature are complex. Some may evolve very slowly, others rapidly. Some may interbreed and produce hybrid offspring, others at least show no evidence of interbreeding. Some may be quite different in one part of their range in comparison with another part, others remarkably similar over their entire range. Before considering these and other phenomena based upon the modern knowledge of species and speciation, it is well to review briefly the history of species concepts in order to place the subject and theory in perspective.

SPECIES CONCEPTS

Historical background. Historically, man's preoccupation with the recognition of species may be almost as old as man himself. Originally, as now, it was important to know which species were useful for what purpose.

An informal basis for recognition of species was sufficient for small regions or small groups of people; but as

scientists began to attempt the naming and classifying of all living and fossil species, it became clear that a more universal system was necessary. An agreed upon system of naming species was essential for communication among scientists, as was a system of classification based upon the relationships between species.

One of the first persons to suggest a formal arrangement of species, John Ray, a 17th-century English naturalist, proposed that species be recognized on the basis of the differences in structure that are transmitted from generation to generation. A great Swedish naturalist, Carolus Linnaeus (Carl von Linné), developed a simple system for naming plants and animals; with modifications, it is still in use today. It features a generic and a specific name for each organism and is therefore called binary (or binomial).

Linnaeus believed that species are fixed, or unchanging, and that each is the result of a separate act of creation. To him, therefore, a single individual organism could characterize an entire species. In describing species of snakes, for example, he might have recognized a species with 180 belly scales, another with 160. But the simple system began to break down with the discovery that the number of scales is variable even within one species. Nevertheless, Linnaeus' system of naming and grouping organisms into categories has been able to handle an enormous number of species discovered since his time.

It is important to note that the term related species had an entirely different meaning to biologists of the 17th and 18th centuries than it does in the 20th. At that time "related" meant simply sharing characteristics. Thus, limbless animals (sharing the characteristic of "no limbs")—entirely unrelated in an evolutionary sense—might have been grouped together. With the publication (1859) of Charles Darwin's *Origin of Species*, the term related acquired exact meaning: descent from a common ancestor, as a result of which many characteristics are shared. Species thus are related because they look alike, and they look alike because they share many genetic traits.

Darwin's view of species

With the publication of Darwin's work, which occurred before anything was known about heredity, it became necessary for man to change his view of species, most of all, of his own, for if species evolved as Darwin insisted, then they should be found to exist in varying intermediate stages in a continuous process of speciation. Furthermore, if they evolved by natural selection, variability must exist between individuals; for it is on variability that selection acts, and natural selection was the central core of Darwin's theories.

Darwin's research turned the attention of biologists to a detailed comparison of species for the purpose of determining their evolutionary relationship. The sharing of features by different species acquired new meaning and significance. Detailed studies of many species showed clearly that they are variable and, in fact, that some of the most important characteristics separating species are behavioral and physiological rather than anatomical.

The rediscovery (1900) of Gregor Johann Mendel's pioneering work on the heredity of peas clearly had implications for the species concept. Species differences came to be understood as inherited characteristics, and the genetic mechanism by which the presence or absence of a certain trait is manifested in a plant or animal came to be understood in a general way.

Currently, a species is recognized as a population of organisms that share a number of traits because, through interbreeding, such traits, as expressions of genes, appear in the offspring of matings between individuals of that species. Since the thousands of genes carried by each parent individual can be recombined in countless ways in the offspring, no two individuals will be genetically identical (except for those of identical multiple births, such as twins, triplets, etc.). Though each human individual is sufficiently different to be recognized as distinct, it is still easy to recognize that all human beings are members of a species because of the numerous common traits that exist between individuals. Outside a particular species, individuals have fewer genes in common and, therefore, resemble each other less. The sharing of many genes by individuals within a species, coupled with some degree of reproductive isolation from individuals of another species, is the basis of the concept of biological species that has resulted from a synthesis of genetics, systematics, and ecology.

Major concepts of the species. *The typological species.* Linnaeus and other early naturalists, who assumed that species are invariable in space and time, characterized the species by a single type or "normal" set of characteristics. Today a range of variation of distinctive characteristics within a species is recognized—such as four to eight spines per fin or 17 to 25 bristles per antenna. Strict adherence to a typological concept would require the recognition of many "species" within a single population of interbreeding members.

The morphological species. The concept of morphological species requires that one population must differ in some morphological characteristic from another population in order to be described as a new species. That the majority of species can probably be described in this way is evidenced by the fact that species named on the basis of morphological differences also fit the biological species concept (see below). The concept of typological species, while it is based on morphological differences, is distinct in denying variability within species. The morphological concept holds, instead, that variability is the rule rather than the exception.

Similarity of morphological and typological concepts

The nondimensional species. The idea of a nondimensional species differs from the morphological concept in emphasizing all differences between species at a given time and place. It is, accordingly, the working definition of the local naturalist. A species in a single area may differ in colour, structure, and behaviour from the same species in other areas. Each species, however, lacks the dimensions of space and time; in other words, there is no recognition in the concept that the same species at another locality may show differences in habitat and life history. The nondimensional species concept involves a particular population, or local group of individuals, of a species; the entire species range may encompass hundreds of such local populations.

The biological species. The biological species is what most biologists have in mind when they speak of species. This multidimensional concept recognizes that a species may be spread over a wide area and that in different areas it may be dissimilar in appearance, may breed at different times, or, in the case of migratory species, may leave and arrive at different times. The central concern is with what it is that produces and maintains the distinctiveness of each species over its range. Attention is therefore focussed on the mechanisms that thwart successful interbreeding. Although the biological species concept is difficult to apply to all species, it seems to be the most suitable way of regarding species. Throughout the remainder of this article, the term species refers, unless otherwise stated, to the biological species.

APPLICATION OF THE BIOLOGICAL SPECIES CONCEPT

The biological species concept has wide application to the majority of organisms. It focusses attention on the really important criterion of reproductive isolation, which is the mechanism by which species integrity is maintained. Because reproductive isolation is often brought about as a result of differences in behaviour, ecology, and genetics, much attention has been given to these characteristics; this has resulted in enrichment of the field of systematic biology and a better understanding of the nature of species.

It is useful to present the exceptions—examples of situations in which the concept is difficult to apply—for these have been the objects of intense study and have resulted in much new biological information.

Allopatric species. The biological species concept is difficult to apply to allopatric species—*i.e.*, populations that appear to be closely related but differ in enough characteristics to be called different species and are geographically isolated from one another. The barrier of geography prevents natural interbreeding, but sometimes

the two problematic groups can be artificially bred in the laboratory by taking eggs from the female of one "species" and fertilizing them with sperm from the male of another "species." Normal development of the hybrid offspring is justification for stating that the two "species" are closely related but does not provide enough evidence for considering them a single species. Even if they came into contact naturally, they might still behave as two species and not interbreed because of reproductive isolation, as a result of differences that preclude the production of normal offspring. Similar experiments with plants, in which one species is pollinated with pollen from the flower of another species, suggest little about the natural forces that might prevent cross-pollination or discourage germination of the hybrid seed.

The decision as to whether to consider two allopatric populations as species often can be made on a fairly reasonable basis. If two such populations are as different from one another as related species that are known not to interbreed, then they may be considered separate species.

Evidence from experiments

The failure of artificial crossing would be further confirmation of the presumption that the species are distinct; the two populations have indeed reached a point at which interbreeding would not be possible even if their ranges were rejoined. Similarly, if the two allopatric populations differ in characteristics that would make mating difficult should their ranges meet, they may be considered separate biological species. Differences in time of flowering, in mating calls, or in soil requirement might prohibit or greatly restrict interbreeding. Generally then, the biological species concept has been extended to allopatric populations by emphasizing that a species is a group of populations that actually—or potentially—exchange genes and that are reproductively isolated from other groups of populations.

Hybridization. Hybridization between populations that are considered on all other grounds to be a species is a common occurrence in some frogs and toads, some freshwater fishes, and many plants. In some instances the hybrids that result are abnormal and soon die. In some cases the hybrid matures but is sterile, or incapable of reproduction. In still other instances the hybrid may mature and reproduce, but subsequent breeding with either parental species results in "hybrid breakdown," in which later generations of hybrids rather than the first suffer from gene incompatibility. In these instances of hybrid inviability, sterility, or breakdown there is effective reproductive isolation: little or no transfer of genes occurs between the parental types, and they are therefore distinct species even though interbreeding occurs.

There are instances, however, of interbreeding between organisms that are generally considered to be separate species and in which there appears to be fairly free gene exchange in the area of species overlap. In these cases the gene flow is limited to a narrow geographic band or is associated with unnatural disturbances that dissolve the barriers to interbreeding or provide habitats in which hybrids can survive; nevertheless, the entities still maintain their distinctiveness as two species over the vast majority of their ranges.

Speciation is a dynamic process, and there exist populations in all stages of becoming species. Some populations are completely isolated reproductively in zones of overlap, and there is no question about the status of these as species. Others hybridize but produce unsuccessful offspring, again raising no doubts about their status as species. Others interbreed rather freely in some areas but not in others, perhaps because the process of speciation has not been completed.

Variants within a single species. Variations within a species are common in both animals and plants. In some instances there may be distinct colour or pattern differences within a single population with no intermediates between the types. Such instances are called polymorphisms. Males and females of some species are so different in appearance that they were originally described as separate species. Other polymorphisms are not so evident and may involve such characteristics as chromosome structure and number. If such differences pose no barrier to successful interbreeding, then they offer no real difficulty to the application of the biological species concept.

Polymorphism

In many species, striking differences occur between populations in different parts of the geographic range. At the boundaries between these geographic groups—called races or subspecies in animals and varieties in plants—are zones of intergradation in which the characteristics of one group are replaced by those of another. In some instances it may be difficult to decide whether there is sufficient restriction of interbreeding in these intergradation zones to call the populations involved species.

Asexual species. If a species is defined as a group of organisms reproductively isolated from other groups but with freely interbreeding individual members, then every individual of an asexual species is potentially a new species. Asexual species of animals usually produce only females; in such species as bees the males are produced asexually, the females sexually. In other species there may be alternation between sexual and asexual stages of reproduction in the life cycle. Such an alternation of generations is the rule among plants.

Among plants, many types of asexual reproduction are grouped under the term apomixis. This category includes vegetative reproduction by the rooting of broken stems or specialized buds, self-pollination of a flower by pollen from the same flower, or development of the egg without fertilization. All such mechanisms tend to restrict recombination of genes to a greater or lesser extent, and the resulting offspring resemble the parent more closely than is true in unrestricted sexual reproduction.

The biological species concept cannot really be applied to organisms that reproduce asexually. In such cases comparative morphology of such species is relied upon to reach a decision concerning its status. Fortunately, most such species have characteristics that are shared by the majority of individuals within the species and are different from those of other asexual species.

Fossil species. It is difficult to apply the biological concept to species that have a time dimension. Living species exemplify various points in the evolutionary process. It is relatively easy, for example, to discern three separate living species; however, the distinctions between these species become fewer and fewer as the fossil record approaches the common ancestor from which they arose. They begin to lose their separate identities.

It is difficult to apply the biological species concept to fossil species in general. Often the species is represented only by fragments, but even given complete fossil material the species can be defined only on a morphological basis. If fossil species show striking structural differences, however, it is generally a safe presumption that they were incapable of interbreeding. Were this not the case it is unlikely that the differences would have been maintained through the course of evolution.

THE PROPERTIES OF SPECIES

Distinctiveness. The ability of sexes to recognize mates within their own species and to distinguish them from sexes of another species is exceedingly important; an error may produce sterile or defective offspring.

The importance of mate recognition

Isolating mechanisms are employed to decrease the likelihood of such untoward events. Fireflies use the flash as a means of species identification; different species differ in the timing of the flash signal produced. In frogs and toads, the distinctive call of the males attracts the females to the proper mate. In some animals, such as moths, mate attraction depends upon volatile scents produced by another individual of the same species. In some fishes, the pattern of movements made by the male during courtship allows the female to discriminate between a male of her own species and one of another.

Isolating mechanisms in plants are less obvious. Differences in flower structure between related species, however, may serve the same function as do differences in mating behaviour between animal species. Insect pollinators transfer pollen grains from the male reproductive organs of one plant to the female organs of another plant of the same species. Differences between related plant species in flower colour, shape, and fragrance may result

in the attraction of different pollinators and reduce the possiblity that an insect may carry pollen to the "wrong species." Even if such unproductive transfers of pollen do occur, the reproductive organs differ sufficiently between the two plant species to preclude pollen germination.

Great emphasis has been placed on the necessity that the female discriminate between potential mates. Correct species identification is not usually equally important for the male. He generally can produce enormous numbers of sperm, and thus he loses little as a result of occasional mismatings if, in the process, he also fertilizes a number of females of his own species. The female, however, generally expends a great deal of energy on the production of a relatively small number of nutrient-packed eggs. If she errs in her choice of a mate, she may lose an entire year's —or even a lifetime's—production of young.

Isolating mechanisms are often grouped into classes such as premating and postmating. For practical purposes, premating (or prezygotic) mechanisms serve to prevent interbreeding or at least to prevent cross-fertilization between species. These mechanisms include differences in habitat preference of species that occur in the same area, differences in time at which mating occurs, differences in various aspects of the mating process, physical incompatibility of the reproductive organs, or failure of fertilization.

Postmating (or postzygotic) mechanisms interfere with the successful exchange of genes between species even though mating is possible. These include deficiency of the hybrid young, sterility of the hybrids, or hybrid breakdown.

Gene flow. Many species are spread over thousands of square miles and may look somewhat different in one part of their range than they do in another. But they still possess certain common characteristics by which their single species status can be recognized throughout the range. The maintenance of these features in common over vast areas may be the result of a cohesive force known as gene flow. Offspring produced from a mating are likely to move some distance away from their parents, and the genes they received will move with them. In the next generation the reproductive process will result in a similar "flow" of genes from one place to another. Certain species characteristics are essential regardless of the environment in which the species occurs; such traits spread easily because of gene flow and will be maintained throughout the population because of their survival value to the individual possessing them. It has not yet been possible, however, for biologists to state with certainty the relative roles played by gene flow and by selection in maintaining species characteristics over large areas.

The movement of genes through populations

Variability. *Genetic variation.* As already indicated, there is a great deal of variation between individuals in a species. These may be differences in colour patterns, in structural details, or in body chemistry. It is apparent that all human beings belong to the same species because interbreeding between them is demonstratably possible. Humans also share many characteristics in common, including a relatively large brain, longer legs than arms, the same number and shape of teeth, and the ability to communicate by symbols. In other characteristics, however, individual humans differ considerably; they may have different blood types, skin colour, hair colour, tolerance to cold or heat, and so forth. Sexual reproduction provides a great opportunity for shuffling genes at each generation, so that the offspring produced are never identical to the parents or, for that matter, to other individuals of the family or the species. Differences in blood type are but one familiar example of the fact that many important gene differences are unnoticeable. These "hidden" variations offer significant alternatives upon which selection can act.

In most animal species there are striking genetic differences between the sexes, and individuals are clearly male or female in some characteristics while sharing most of their other characteristics. Other differences, as in colour, shape, or life stage, may simply be polymorphic variations.

Finally, there is a genetic variability between populations of most species. This becomes obvious when it involves characteristics such as colour; for example, rodents that live on lava flows may have darker fur than individuals of the same species living on the pale soils and sand surrounding the lava flows. The genes that produce dark coat colour in the animals on the lava flows are favoured there because they render the rodents carrying these genes less subject to predators. On the paler ground, genes producing paler coloration are favoured for the same reason. Such variations present in the species will be acted upon by the selection to favour different series of phenotypes (obvious variants) in different parts of the range.

Environmental and age-related variations. It is often difficult to separate variations produced by genes from those produced by the environment, since most characteristics of organisms are a result of the interaction between a gene and its environment. Although genes control skin colour in man, for example, exposure to sunlight also has an effect. Thus, the distinction between which aspects of a trait are the result of differences in genes and which are the result of differences in environment is sometimes nebulous. Generally, when a certain characteristic is said to be environmentally produced, it is meant that most of the variability in that characteristic is produced by the environment.

Relative influence of nature and nurture

In many plants certain differences in colour and leaf shape are caused primarily by the conditions under which the individual plant grows. If it is shaded, its leaves may be larger to provide greater surface area for sunlight. Plants that grow in areas of poor soil and high wind velocity may be dwarfed and bent compared to individual plants growing in richer soil and a protected situation.

Among animals, differences in size may simply reflect the adequacy of diet, which varies depending upon the habitat. Similarly, the number of eggs laid by the female may reflect the adequacy of the diet available to her. Fish grown under crowded conditions but with adequate food may be stunted.

The aging process also produces obvious differences between individuals. In wild, hoofed mammals, defective joints are more common in old than they are in young individuals. In turtles, the edges of the shell often show a ragged appearance in old animals, and the distinct lines between the scales on the shell, very regular in young animals, may be quite erratic in older individuals. Some of the most obvious effects of aging are seen in man.

Many of these characteristics are probably primarily under direct genetic control. A common North American snake, the blue racer, shows a distinctly blotched pattern when young; the adult, however, shows no pattern at all. The timing of appearance of the difference is probably under genetic control. Similar features include the change in pattern of deer from the spotted fawn to the uniform colour of the adult, the development of horns or antlers in older animals, and the different stages in the life cycle of insects and frogs.

To the extent that any trait has some genetic variability, it can evolve, or change, in time as certain genes in given environments are either favoured or not favoured by natural selection. An athlete with large, firm muscles and a large chest capacity does not pass such characteristics on to his offspring, but if there is a genetic variability in the capacity of muscles and lungs to respond to stress, then such traits may be more easily developed through exercise in the offspring of outstanding athletes than in the offspring of less exceptional individuals.

Geographic variation in species. As already has been stated, many wide-ranging animal species show distinctly different characteristics in one part of the range than in another. Each variant type occurs over a fairly discrete geographic area, but at certain places in the range many intermediate types are found. Such areas, called zones of intergradation, represent subspecies boundaries. These intergradation zones indicate that there is no restriction to interbreeding between the variants. The presence of subspecies, called races among animals, confirms that there are stages in the speciation process that can readily be observed in most wide-ranging species. In many cases

such geographic variants were called different species before their true status was determined. Such geographic races are common in plants as well, but they are generally called varieties by botanists. The problems presented by these populations are the same in plant as in animal species.

Sibling, or cryptic, species. Species that look remarkably similar but nevertheless possess all of the characteristics of biological species are spoken of as sibling, or cryptic, species. For some reason, the genetic differences that exist between them are not manifested in their appearance. Detailed studies, however, have often revealed subtle morphological differences between sibling species.

Several related and similar-appearing species of frog have long been called leopard frog. Crosses between these species often result in young that are abnormal or have quite different mating calls. The species may differ in certain details of internal anatomy as well as in the number of external spots, though superficially they may look quite similar. Even more similar species are known among insects. Two common species of fruit fly (*Drosophila*) are exceedingly difficult to distinguish; their behaviour, however, is so different that there is little or no mismating between them under natural conditions.

THE EVOLUTION OF SPECIES

The process of species formation—speciation—evidently takes a very long time. Consequently, the origin of a new species cannot be observed. Changes that occur within a species, however, can be observed, as in the case of industrial melanism of the peppered moths (see EVOLUTION). The process of speciation has been deduced from data gathered by comparative examination of evidence and not by experiment. Speciation can conveniently be divided into species formation through geographical isolation, or allopatric speciation, and species formation in the absence of geographic isolation, or sympatric speciation.

Allopatric speciation. In the process of allopatric speciation, the range of a species becomes fragmented so that some populations are geographically isolated from others. This geographical isolation comes about in different ways. One obvious method, the invasion of islands by some individuals of a species, often happens when individuals are rafted on flood-borne debris; the castaways are then effectively isolated from others of their species. The cutting of large canyons over geological time spans disrupts the ranges of some species, as do changes in climate. The development of grasslands where once there were forests, encroachments by the sea, the reduction of a stream to a series of isolated pools, and the formation of caves may result in the isolation of some populations of a species. During the history of the earth, such disruptions of the ranges of species have been occurring continuously. Regardless of the manner in which geographic isolation actually occurs, the process of allopatric speciation begins with some degree of geographic isolation of populations within a single species.

The degree of geographic separation required to isolate a population depends upon the species concerned. A change sufficient to isolate small spring-dwelling salamanders would be of less significance to a flying insect, bird, or mammal. Plants with effective seed-dispersal or pollen-drift mechanisms will not be easily isolated by narrow disruptions of their ranges.

The significance of isolation

The evolutionary significance of geographic isolation is that populations, when separated, evolve independently. Natural populations cannot become highly specialized to their particular environment as long as there is a free flow of genes from adjacent populations. The gene flow is stopped or enormously reduced by geographic isolation, but this stoppage of gene flow does not explain why differences arise between the now-isolated populations.

Differences between isolated populations may arise in several ways. First, differences may arise by chance. Perhaps an island that is invaded and eventually populated by a few individuals of a species may not be reinvaded by others of that species for a long time. The small number of founders cannot possibly carry all the genes found in the large parental population from which they came. Consequently, there will be some chance differences between island and mainland populations. Second, differences may arise because of differences in the environments of isolated populations. As a result, selection may favour slightly different gene arrangements in one population than in another. The soils may be of different composition, predators may be different or may be present in different proportions, or competing species may be different; all these environmental variables affect the way in which selection acts. Thirdly, differences may arise by the process of mutation, which changes the arrangement or structure of genes. Finally, genetic differences may already have existed between the populations prior to their isolation.

Differences between isolated populations increase with the passage of time. One of the facts that struck Darwin was the enormous differences between breeds of domestic animals produced by deliberate selection on the part of man if such selection was consistently applied over several generations. Natural selection has the same effect but over longer periods of time in isolated populations.

Just as populations become isolated in time, they also can become reunited. Changes in the environment can permit formerly isolated populations to come into contact; their individuals then may freely interbreed, thereby tending to break down the differences accumulated during isolation. Some characteristics, however, may still be preserved as differences between overlapping populations, which are then recognized as subspecies. If the genetic differences accumulated during isolation are sufficiently great or if the differences affect important characteristics such as mating or embryological development, then interbreeding between the reunited populations may not occur at all or may occur and result in inferior offspring. If the two formerly isolated populations are effectively isolated by such genetic barriers and their differences are irreversible, speciation has occurred: two biological species have evolved from an original single species.

The geographic distribution of closely related species often shows that they are allopatric or that their ranges only partially overlap; both types of data suggest that isolation or former isolation was important in the formation of such species. Furthermore, it is often found that entirely unrelated animals, such as mammals and reptiles or insects and plants, contain pairs of species with similar ranges, suggesting that their isolation and subsequent speciation was the result of a common geographic barrier.

The selection of isolating mechanisms

It is important to recognize that isolating mechanisms are not favoured by natural selection because they prevent interbreeding, for if such mechanisms evolve in isolated populations there would be no chance for interbreeding, anyway. Even if two formerly isolated populations are reunited, selection may yet act to reduce the interbreeding between these populations. Earlier it was said that isolating mechanisms are generally divided into prezygotic mechanisms, which prevent fertilization, and postzygotic mechanisms, which operate against the offspring resulting from crosses between species. Clearly natural selection cannot usually favour postzygotic isolating mechanisms in zones of overlap between species. If, for example, the offspring between two species are sterile, there is no way for selection to strengthen the infertility. If the offspring die, selection cannot favour "increased" death. This is because the advantage will be to those offspring that are the least liable to die (for they will survive in greater numbers) and to those hybrids that are the least sterile (for they will produce more offspring). Thus, selection would tend to reduce rather than enhance the effectiveness of postzygotic isolating mechanisms.

It is, however, possible for selection to favour prezygotic mechanisms and to enhance the strength of such isolating mechanisms in zones of overlap. In time, a prezygotic mechanism could be produced in the zone of overlap that would be effective in reducing interbreeding and thus avoiding the waste of energy in the production of inferior hybrid offspring. In other words, reinforcement of reproductive isolation has occurred in the zone of overlap. It is

unlikely that such reinforcement could occur if there were no pre-existing postzygotic incompatibility between the two populations; otherwise there would be no disadvantage to interbreeding and thus no opportunity for reinforcing selection. The two populations would be subspecies or less. Such examples of reinforcement of isolating mechanisms are extremely rare, a fact that constitutes a weakness in speciation theory.

It may be questioned whether or not distinct geographic races, or subspecies, are stages in the speciation process. If differences accumulating in allopatry do not interfere with reproduction between individuals of different populations when the populations are reunited, then speciation has not occurred. This does not mean, however, that differences cannot be recognized between the populations. If, for example, the area in which the populations were rejoined was along a forest–grassland border, then the colour patterns best suited to animal species of the grassland might not be the ones best suited to species of the forest. Although interbreeding between the populations occurs, the movement, or flow, of genes affecting body colour may be interrupted along the border. This may occur with no incompatibility between the populations, so that speciation will not take place. Instead, there exist populations that can be recognized as subspecies with perhaps a narrow zone of intergradation between them in which there is considerable variability in body colour or pattern. This intergradation zone may persist over a long period of time.

Subspecies in general, therefore, are not stages in speciation because the process will go no further. On the other hand, some populations—particularly allopatric ones—that are recognized as subspecies have the potential for becoming different species. Such subspecies may very well be stages in the speciation process.

Sympatric speciation. Speciation that occurs without geographic isolation and while populations are in continuous contact with one another is called sympatric speciation. There has been considerable controversy over whether sympatric speciation is possible at all and, if so, how important it has been in the formation of species.

Advocates of the theory of sympatric speciation must explain in a plausible way how a single population can differentiate into different species without some barrier to gene exchange between them. A few examples will suggest how such differentiation may happen. Thus, a species of moth in Britain lays eggs on apple trees and hawthorn trees, and the larvae hatching from these eggs feed on these two trees. There is a tendency for moths reared on apple trees to mate with other moths reared on apple trees and to lay their eggs there. A similar predisposition affects the moths reared on hawthorn trees. Despite these habitat differences, the moths look alike and can interbreed; they represent a single biological species. At the same time, however, they suggest a mechanism by which sympatric speciation might occur in time. Genes that promote the success of moths on apple trees can increase in frequency because these moths tend to breed with other moths reared on apple trees; such is also the case with the hawthorns and their moths. In time, interbreeding between apple moths and hawthorn moths might result in offspring less capable of utilizing either food plant.

Disruptive selection

Then selection would be spoken of as disruptive—favouring either an apple specialist or a hawthorn specialist but not an intermediate type. This disruptive selection coupled with nonrandom mating—*i.e.*, a tendency to mate mostly with individuals reared on the same food plant—would result in reproductive isolation. Increased genetic divergence and speciation could then possibly occur just as if the moths were geographically isolated.

Sympatric speciation has been suggested for two North American field crickets with nearly, but not quite, congruent ranges. These two species differ primarily in their life cycles. In one, the adults breed in the spring; the other breeds in the fall. Because the adults are short-lived, there can be little or no interbreeding between them. It has been suggested that an ancestral species of cricket had both spring and fall breeders in a single population (such crickets are known among the relatives of those under consideration). A series of harsh winters could have resulted in the death of all but the resistant eggs and nymphs, effectively dividing the ancestral population into fall-breeding and spring-breeding strains between which there was essentially no genetic difference at the outset; however, there was opportunity for such differences to evolve because of reproductive isolation.

It is possible to construct theoretical models of ways in which sympatric speciation might occur, and it is also possible to promote genetic divergence sympatrically in laboratory populations with appropriate selective forces. Furthermore, there are species in nature whose characteristics and ranges suggest no history of geographic isolation. For these reasons sympatric speciation is not impossible or even improbable in some instances.

Sympatric speciation initiated by hybridization has evidently been of major importance in plant speciation. A similar process has occurred in animals but is far less common, presumably because hybridization between animal species is seldom successful. Most examples of hybridization seem to be associated with a disturbance of the habitat, the breaking down of some of the barriers to interbreeding, and provision of new sorts of habitats in which hybrid young may flourish.

Flooding by rivers, fires in forests or prairies, lava flows, and soil erosion have always altered plant environments.

How hybrids survive

The offspring produced by hybridization, if they manage to survive, are most likely to cross with one or the other parental species, a process known as backcrossing. This occurs because the parental types greatly outnumber the hybrids. Offspring from a backcross will contain predominantly parental types, which are already adapted to a particular environment; for this reason, backcrossing hybrids are more likely to be successful than the hybrid at producing viable offspring. Through backcrossing, at least some of the characteristics of one parent species will be transferred by way of the hybrid into the other species. This process, called introgression, is widespread in plants and occurs in a few animals. Introgression introduces new gene combinations into both parental species, providing new material upon which selection can act. Since the new combinations are enormous compared with the small number introduced by mutation, introgression can be of considerable importance in the evolution of some species.

One common problem in hybrids between species is sterility of the hybrids resulting from failure of the chromosomes to pair properly, a critically important process in the formation of sex cells. Plant species have often circumvented this problem by a process called polyploidy, in which the chromosome number in hybrids is altered. In some hybrid plants, a doubling of the chromosome number has occurred to produce a polyploid hybrid in which pairing between the identical duplicated chromosomes allows normal sex-cell formation and successful reproduction. The hybrid, however, must breed with other hybrids like itself; backcrosses to either parent species are unsuccessful. Thus, polyploid hybrids are reproductively isolated from either parental species, and speciation has occurred sympatrically. Comparative study of closely related species of plants indicates that many close relatives differ by multiples of some chromosome number, indicating that polyploidy has occurred in the evolutionary history of many of the species. It has been estimated that more than one-fourth of the flowering plants may be polyploid species.

In recent years polyploidy has been discovered in the vertebrate animals. At least one frog and several lizards are known to be polyploid species. The lizards are particularly interesting because, for the most part, they are triploids, meaning that they have one set of chromosomes derived from one parent species and two sets from the other. The triploid species are parthenogenetic; *i.e.*, only females are produced, and the eggs are able to undergo development without fertilization.

Stasipatric speciation. This relatively new concept in speciation theory was proposed to account for the distribution of various "species" of Australian grasshoppers.

Stasipatric speciation contains aspects of both allopatric and sympatric speciation. The grasshoppers concerned differ from one another in chromosome structure. In one type there evidently has been fusion of chromosomes. In other types there have been translocations of parts of chromosomes. These chromosome differences presumably arose by mutation, but it is difficult to understand how they spread, since the mutant containing one of each chromosome type would have been at a disadvantage. In quite small populations within the range of the grasshoppers, however, the new chromosome might become established in the population by chance, a process known as genetic drift. Once the new chromosome was present as the only type in one of these populations, it could spread through the parental species. Stasipatric speciation thus is visualized as a process by which differences arise in isolated populations within the range of a species and, once established, spread and displace the ancestral type in part of its range. It results in a number of closely related species with ranges that abut on one another or overlap only slightly.

The role of chance in spreading chromosomal differences

There seems little doubt that such a model of speciation is possible, but how different it is from allopatric or sympatric models is not clear. The grasshoppers just mentioned evidently have limited powers of movement and prefer specific habitats, so it is not difficult to accept the possibility that one population in a favourable patch of habitat might be geographically isolated from another even if it were in the centre of the range of the species. Thus, the differences between these species actually develop in allopatry. It is also possible that the chromosomal differences arise in isolated peripheral populations at the edge of the range of a species. Again, in this instance, allopatry serves to explain the situation.

THE RELATIONSHIP BETWEEN SPECIES AND OTHER TAXONOMIC CATEGORIES

The artificiality of higher taxa

The evolutionary relationship between species and subspecies or varieties has already been dealt with, but little consideration has been given to the relationships between species and genera or families, the higher taxonomic categories. All of the upper categories of taxonomy have been constructed in an attempt to show evolutionary relationships between species, between genera, between families, and so forth. All of these more inclusive levels of classification originated because of a speciation event at some time in the distant past.

Two closely related living species are distinct points in a continuous evolutionary process from a single ancestral species. With the passage of long periods of time—millions of years—these two species in turn may have given rise to several descendant species. Two groups clustering similar species constitute two genera. Since both genera had a remote common ancestor, they are placed in a common family.

There exists no complete record of any species through time to confirm the systematists' notions of relationships. Nevertheless, it reasonably can be assumed that species sharing a large number of characters in common are closely related and should be placed in a genus distinct from another group of related but significantly different species. Without direct knowledge of the history of the evolution of species, errors in the placement of species into higher categories are bound to occur. The category of species, however, appears to be the most stable and universal of all taxa. Beginning with the species that comprise the vast assemblage of organisms now on earth, systematists attempt to place them into genera, families, orders, classes, and phyla (or divisions) in a way that reflects the latest conception of their evolutionary history; for example, snakes and lizards are both considered orders in the class Reptilia, a grouping that implies that the two orders shared a common ancestor in the past; it in no way means that any living snake evolved recently from any living lizard. The speciation event that split these animals into different lines occurred millions of years ago; the animals are the end points from which the evolutionary history of the group is deduced. It is upon this history that a system of classification is imposed.

Spectroscopy, Principles of

Spectroscopy is the study of the absorption and emission of light and other radiation, as related to the wavelength of the radiation. Light from natural sources (such as the Sun, stars, fireflies, flames, and lightning) and from man-made sources (such as incandescent lamps, arcs, lasers, and fluorescent lamps) is generally composed of many colours. This composite nature of light, discovered in 1666 by the English physical scientist Sir Isaac Newton, is not usually evident to the casual observer, but it can be shown by passing light through a prism or other device that splits it into its constituent colours. A display or description of these colours emitted by a source of light is called the spectrum (plural: spectra) of the source (see Figure 1).

Spectroscopy is the science that deals with the sources, measurements, analyses, and uses of spectra. It has practical application in almost every technical field, especially for identifying constituents and processes in any source that emits light. With spectroscopic methods, one can analyze in the laboratory, for example, the composition of a small amount of material with an accuracy and speed that cannot be achieved by chemical processes. Samples can be compared to test their identity. A continuous flow of products can be monitored for variations or pollutants. Apparatus to measure temperatures in controlled thermonuclear fusion (the uniting of certain atoms so that part of their mass is converted to energy) is another special application of spectroscopy. Still another type of spectroscopic observation makes possible detailed studies of atomic and molecular structures. In astronomy, solar magnetic storms can be predicted and the chemical constitution of stars can be analyzed by spectroscopy.

GENERAL PRINCIPLES

Basic features of light. The term electromagnetic radiation describes the transfer of energy through space by electric and magnetic fields without the transfer of matter. Light is properly designated as that range of electromagnetic radiation visible to the human eye, although the term sometimes includes regions which are invisible.

Light, as well as other electromagnetic radiation, has a wave character, and specification by wavelength (distance between successive crests of a light wave) can be made far more precisely than specification by colour. In early spectrometers, each wavelength absorbed or emitted by a source was displayed as the image of a slit, with images side by side for many wavelengths; such images are called lines, and so each line represents a wavelength or frequency, and the series of lines is called a spectrum. Some modern spectrometers use electrical devices for detectors, and the spectrum is displayed as a series of peaks on a graph of line intensity versus wavelength; these peaks by convention are also called lines.

Meaning of spectral lines

Because the shortest wavelengths of electromagnetic radiation are on the order of atomic diameters, special units are employed to specify them. The angstrom unit, symbolized by Å, named after a Swedish physicist, Anders Jonas Ångström, is equal to 10^{-10} metre; and one nanometre, abbreviated nm, is equal to 10^{-9} metre. The micrometre, symbolized by the Greek letter mu, μ, is equal to 10^{-6} metre (equal to 10,000 Å or 1,000 nm) and is frequently used in the infrared region. Visible light has a wavelength range of about 400 nanometres (violet) to 700 nanometres (deep red).

It is often convenient to specify an electromagnetic wave by the frequency at which it oscillates, or vibrates, rather than by wavelength. Frequency (ν) and wavelength, symbolized by the Greek letter lambda, λ, are inversely proportional to one another, and their product is equal to a constant ($\nu\lambda = c$), in which ν is frequency or number of oscillations per second, usually expressed in hertz (Hz), one hertz being one cycle per second, or megahertz (1,000,000 Hz). The constant, c, is equal to the speed of light *in vacuo*, 2.997925×10^8 metres per second. Electromagnetic phenomena with their approximate wavelength and frequency ranges are shown in Table 1.

Basic properties of atoms. An isolated atom can exist as a stable structure only in certain discrete (distinct) states, called energy states or stationary states, and a measurement of the energy of the atom will result in one of the values characteristic of that atom. In principle, the so-called allowed states for any atom can be found from the laws of quantum mechanics. Under ordinary conditions, an atom is almost always in its lowest possible energy state (its ground state, in which it possesses the minimum possible energy). Energy can be added only in

those amounts that will just raise the energy to one of the other allowed values. The atom will not absorb an amount of energy that would make its final energy some intermediate value. An atom that has absorbed energy and is in one of its higher states is said to be in an excited state. The energy levels are identical for identical atoms; allowed energies of a particular atom of silver are the same as those for any other atom of the same isotope of silver (isotopes are all atoms of an element that have unequal mass but the same atomic number.

Table 1: Electromagnetic Phenomena

	approximate wavelength range (metres)	approximate frequency range (hertz)
Radio waves	10–1,000	3×10^5–3×10^7
Television waves	1–10	3×10^7–3×10^8
Microwaves, radar	1×10^{-3}–1	3×10^8–3×10^{11}
Infrared	8×10^{-7}–1×10^{-3}	3×10^{11}–4×10^{14}
Visible light	4×10^{-7}–7×10^{-7}	4×10^{14}–7×10^{14}
Ultraviolet	1×10^{-8}–4×10^{-7}	7×10^{14}–3×10^{16}
X-rays	5×10^{-12}–1×10^{-8}	3×10^{16}–6×10^{19}
Gamma rays (γ rays)	1×10^{-13}–5×10^{-12}	6×10^{19}–3×10^{21}
Cosmic rays	less than 1×10^{-13}	greater than 3×10^{21}

Other small systems, including molecules, ions (charged atoms or molecules), atomic nuclei, and elementary (subatomic) particles, have discrete allowed energies.

If an atom in its ground state is given some amount of energy so that it then exists in an excited state, it will give off that extra energy spontaneously as it moves back into lower states, ending in the ground state again. The energy is often emitted as electromagnetic radiation, hence it appears as light if the wavelength is appropriate. In the process of a single transition from some upper state to a particular lower state the energy given off is found from the combination principle: emitted energy (E) equals upper state energy minus lower state energy; this energy is usually carried by a single group of light waves (a photon) having a frequency (ν) in which photon energy (E) is equal to a constant times the frequency, or, $E = h\nu$, in which h is Planck's constant, a unit of action (work times time), 6.6256×10^{-34} joule second. This relationship determines frequencies (and wavelengths because $\lambda = c/\nu$) of light emitted by atoms if the energies of the states are known; conversely, the relationship allows finding the energy states of an atom from measurements on the spectrum of that atom. The allowed energies of an atom are discrete and therefore its spectrum consists of discrete wavelengths. Because of the appearance of a given wavelength when seen through a prism or grating spectroscope, these discrete emitted (or absorbed) wavelengths are called spectral lines (see Figures 1 and 5).

Historical survey. The basis for spectroscopic research and for analytical spectroscopy is the discovery, made by a German physicist, Gustave Kirchhoff, in 1859, that each pure substance has its own characteristic spectrum. Another German physicist, Joseph von Fraunhofer, repeating more carefully an earlier experiment by an English scientist, William Hyde Wollaston, had shown in 1814 that the spectrum of the Sun does not grade smoothly from one colour to the next but is crossed by many dark lines, indicating that light is missing at certain wavelengths because of absorption (see Figure 1 above; see also the Plate in the article LIGHT). These lines are still called Fraunhofer lines, and the spectrum containing them is called a darkline, or absorption, spectrum. The spectra of some metals and compounds when heated in flames and the spectra obtained from electric discharges in gases were studied by many scientists during the 18th and 19th centuries; these spectra were seen to be composed of numerous bright discrete lines indicating that only certain wavelengths were present in the emitted light. These are called brightline, or emission, spectra. Although the possibility of the existence of characteristic spectra, a spectrum unique for each chemical element, had been considered by numerous investigators, the early studies were hampered by the difficulty of obtaining rela-

The combination principle

tively pure substances and the fact that even slightly impure substances could yield many spectra simultaneously. By using carefully purified substances, Kirchhoff demonstrated characteristic spectra and initiated the technique of spectroscopic analysis of the chemical composition of matter. The technique was applied by Kirchhoff and his colleague Robert Bunsen in 1861 to the analysis of the solar spectrum and the identification of the chemical elements in the Sun.

Before the 20th century, there was no theory that could explain satisfactorily how spectra are formed or why different elements have different spectra. Some of the principal discoveries leading to present understanding of spectra were: the discovery of infrared radiation by an English astronomer, William Herschel, in 1800 and of ultraviolet radiation by a German physicist, Johann Wilhelm Ritter, in 1801; the recognition of a series in the spectrum of hydrogen in 1885 by a Swiss scientist, Johann Jakob Balmer; the discovery of the electron, the basic negatively charged constituent of atoms, by a British physicist, J.J. Thomson, in 1897; the beginnings of quantum theory by a physicist in Germany, Max Planck, in 1900; the formulation of the combination principle; the experimental proof that atoms are composed of tiny, massive positively charged nuclei surrounded by electrons, by a British physicist, Ernest Rutherford, in 1911; the first theoretical calculations of the discrete energy states of atoms and the wavelengths of light given off by atoms, by the Danish physicist Niels Bohr in 1913. Quantum mechanics was developed by the physicists Erwin Schrödinger and Werner Karl Heisenberg of Germany to describe the detailed properties of atoms. This theory, extended by the physicists Wolfgang Pauli of Austria and P.A.M. Dirac of England, and others, now provides methods for calculating energy states and spectral lines emitted by atoms, ions, and simple molecules.

Applications. In chemistry and physics, spectroscopy is used as a tool for studying the structures of atoms and molecules. The large number of wavelengths emitted by these systems makes it possible to check theories of their structure in detail.

Use of spectroscopy as an analytical tool

Spectroscopy provides a precise analytical method for finding the constituents in material having unknown chemical composition; in typical analyses, a concentration of a few parts per million of a trace element in a material can be detected when the material is vaporized and caused to emit light (as in an electric arc) to produce an emission spectrum, the bright lines that identify the element causing the spectrum. The absorption spectra of solutions containing inorganic or organic chemicals show dark lines and bands (close groups of lines) characteristic of the molecules, radicals (molecular fragments), and ions present in the solution. Emission and absorption spectra of the atmosphere are thus used for monitoring trace elements and compounds (*e.g.*, mercury or the compound dichlorodiphenyltrichloroethane [DDT]) in pollution control, the sensitivity of these techniques sometimes approaching a few parts per 1,000,000 in concentration.

In astronomy, the spectra of the Sun and other stars show lines characteristic of the atoms, ions, and radicals in them, plus lines characteristic of materials in the nearby empty space between the source and the Earth, and materials in the Earth's atmosphere. Spectra of the light reflected from planets other than the Earth show, in addition, lines caused by absorption by their atmospheres. Thus chemical analyses can be made of these distant objects.

Data on spectroscopic properties of atoms, ions, and molecules are used in the design of lasers (devices that operate on the principle of stimulating the emission of stored energy in atoms), which have wide scientific, industrial, and military application. Fluorescent lamps make practical use of the absorption of ultraviolet radiation with subsequent emission of visible light. High-purity spectral lines are used in metrology (the science of measurement), particularly for measurement of fundamental physical constants, such as the electron's charge and mass; the fundamental metric unit of length, the metre, is in fact defined as 1,650,763.73 wavelengths of a particular unperturbed line in the spectrum of krypton gas. Spectroscopic analyses are used in criminology, archaeology, medicine, agriculture, the biological sciences, and engineering.

PRACTICAL CONSIDERATIONS

General methods of spectroscopy. Production and analysis of a spectrum usually require four components: (1) a source of light (or other electromagnetic radiation), (2) a disperser to transmit different wavelengths differently, (3) a detector to sense the presence of light where it appears after dispersion, and (4) a recorder to make a spectrogram, a temporary or permanent copy of the spectrum.

An apparatus intended to accept light, separate it into its component wavelengths, and detect the spectrum is called a spectrometer; a spectrograph is a spectrometer that also records spectra. A spectroscope is a combination of disperser and associated optics for visual observation of spectra. A monochromator consists of a disperser and associated optical components arranged to accept light from an external source and transmit only a small range of wavelengths. A spectrophotometer is a spectrometer used to record quantitatively the amount of light emitted or absorbed by a sample of material according to the wavelength.

Processes in spectral sources and types of spectra. Two kinds of spectra can be distinguished: emission spectra, which show bright lines or bands on a dark background, and absorption spectra, which have a continuously bright background except for dark lines (Figure 1).

A spectral line is emitted when atoms (or other particles) are excited by some means to the upper energy state responsible for the transition and then decay to the lower energy state. The required initial excitation can be produced in a variety of ways. A collision between an electron with high energy (energetic electron) and an atom can give energy to the atom to raise it to an excited state. Electron impact is the principal basis for excitation in electric discharges (see below *Laboratory sources of spectra*). Excitation of atomic states can also be accomplished by irradiating atoms with electromagnetic radiation that they can absorb. Fluorescence spectra are produced when atoms become excited by absorbing radiation (often in the ultraviolet region) and then emit radiation as the atoms decay to lower states. Impacts on atoms by energetic atomic nuclei, ions, and molecules produce excited atomic states in special applications.

Electron excitation

An incandescent liquid or solid, such as a lamp filament, emits a broad, continuous range of wavelengths. In these sources, the atoms may be excited both by electron and by atom impact. Because the atoms are packed closely, their individual energy levels merge together into overlapping levels; the emitted lines then overlap and merge into a continuous—*i.e.*, nondiscrete—spectrum. Similar phenomena occur in the interiors of stars and in high-pressure arcs, in which broadening of spectral lines occurs because of the high collision rates.

So-called bound–free or free–free transitions occur, with resulting emission of radiation, when an electron makes a transition in its energy level to an unbound state from a bound or from another unbound state. These transitions also give rise to continuous spectra.

Before radiation reaches an observer, it may pass through a medium, usually consisting of a vapour of unexcited atoms (or ions or molecules), in which specific wavelengths are absorbed; these absorbed waves correspond to transitions by the vapour atoms from their ground states to higher states. As a result, the absorbed wavelengths are missing in the spectrum of radiation transmitted through the vapour. This phenomenon is the origin of the Fraunhofer lines in the solar spectrum; light emitted by the hotter, deeper layers within the Sun is partially absorbed by atoms in the cooler, outer layers before it reaches Earth. Flames are often used as sources of spectra. Temperature and composition vary throughout a flame; hence flames can be used as absorption sources or as emission sources.

An emitting atom moving toward an observer (or in-

strument) compresses the light waves emitted in that direction. The light then has shorter wavelengths than it would have if the emitter were at rest; *i.e.*, its spectrum is shifted toward the blue. Similarly, light emitted by atoms moving away from the observer has longer wavelengths, hence appears redder. This phenomenon is called the Doppler effect. As a result, light that would have a well-defined wavelength if emitted by atoms at rest has a spread or broadening caused by their ordinary random thermal motion toward and away from the observer. This Doppler broadening restricts the useful resolving power (ability to distinguish between two adjacent lines) of spectroscopic instruments. The average speeds of atoms in a source increase with temperature; so the widths of spectral lines indicate the temperature of the source. The shifts of spectra with relative velocities of source and observer are sometimes used to measure velocities of sources, especially in astronomical spectra.

Laboratory sources of spectra. In atomic spectroscopy, a few sources of spectral emission lines serve for most purposes. These sources are: the hollow cathode; the Geissler tube invented by Heinrich Geissler, a German physicist; carbon arc; sparks; electrodeless lamps; and flames (see Figure 3).

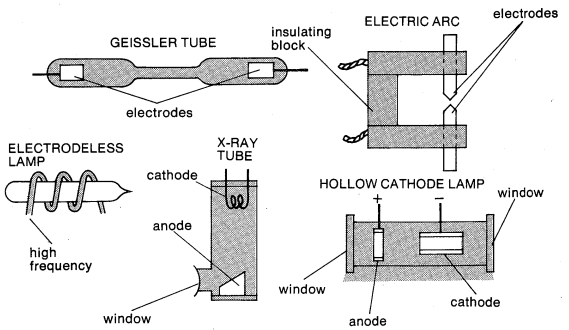

Figure 3: *Sources of laboratory spectra.*
All of these sources, except for the X-ray tube, generate visible and ultraviolet light.

The hollow cathode discharge lamp

The hollow cathode discharge lamp (Schüler tube after Hermann Schüler, a German physicist) consists of two electrodes mounted inside a glass or ceramic envelope. The cathode (negative electrode) is usually formed as a cup or hollow cylinder constructed of, or coated with, the material the spectrum of which is to be investigated. The gas within the envelope is usually one of the inert gases —helium, neon, or argon—at a pressure of roughly 1 torr (the torr is a unit commonly used in specifying gas pressures; sea-level atmospheric pressure is approximately 760 torr). A direct electric current, typically one to 100 milliamperes, at several hundred volts, is passed through the tube; the spectrum appears most brightly within the cathode.

The Geissler discharge tube, the archetype of the neon signs used extensively in advertising, consists of a glass tube having an electrode at each end and filled with a gas at pressure typically 0.1–10 torr. Often a portion of the glass tube is constricted to provide greater current density (hence greater brightness) in that region. Transformers operating typically at voltages from 1,500–10,000 volts and currents from 10–50 milliamperes, alternating current (ac), power these tubes. A modification of the Geissler tube is used to provide the metric standard of length.

Electrodeless lamps consist of glass tubes, usually about one centimetre in diameter and a few centimetres long, filled with a gas at 0.1–10 torr pressure. Spectra of materials other than gases can be obtained by adding to the gas a few milligrams of a volatile compound containing the element of interest; *e.g.*, uranium chloride for the spectrum of uranium. The power source is a high-frequency oscillator, typically 25–2,500 megahertz. (Current within the lamp may be induced by wrapping wires leading from the oscillator around the lamp or by placing the lamp inside an appropriate resonant cavity connected to the oscillator.)

For rapid spectroscopic processing and analysis of solid materials, arcs are convenient sources. Graphite and copper are typical electrode materials. A small amount of the material of interest may be powdered, mixed with powdered electrode material, and pressed into a shape convenient for use as one electrode of an arc. Other methods can be used to incorporate the material within an electrode. Arcs can be run with a wide range of voltages (perhaps 10–100 volts) and currents in the range of 1 to 100 amperes, in an atmosphere of air or some other gas. Usually the current is direct current (dc), with the powdered material in the cathode. Effective temperatures in arcs often range from 3,500° to 5,000° C (6,300° to 9,000° F). At such temperatures, little ionization of the atoms occurs, and mainly the spectra called the first, or neutral, spectra of elements are observed.

Spark sources are often used when higher excitation is required than is available in an arc. The simplest spark source consists of the discharge of a strong current at a potential of around 5,000 volts across a gap between two electrodes. Effective temperatures for these sources can range into the tens of thousands of degrees Celsius; the materials within the spark are often ionized, sometimes highly so, and the dominant spectra are the second (II, singly ionized, or one electron missing from each atom), third (III, doubly ionized, or two electrons missing from each atom), etc., depending upon the power released in the spark, the materials and spacings of the electrodes, and the surrounding atmosphere.

The first man-made spectroscopic sources consisted of flames to which small amounts of substances were added, to be vaporized and excited by collisions with the constituents of the flame. Flame sources are used extensively in analytical chemistry; in these, the materials are formed into an aerosol so that they can be injected into the flame conveniently at a controlled rate.

Transparent chambers or containers with windows at both ends serve as absorption cells for the production of absorption spectra. Light having a continuous distribution of wavelength is passed through the cell. When a gas or vapour is introduced into the cell, the change in the transmitted spectrum can be interpreted as the absorption spectrum of the gas. Often, absorption cells are enclosed in ovens because many materials of spectroscopic interest vaporize significantly only at high temperatures.

Methods for dispersing spectra. *Refraction.* Historically, glass prisms were first used to break up or disperse light into its component colours. The path of a light ray bends (refracts) when it passes from one transparent medium to another; *e.g.*, from air to glass. Different colours (wavelengths) of light are bent through different angles; hence a ray leaves a prism in a direction depending upon its colour (see Figure 4). The amount of

The refracting prism

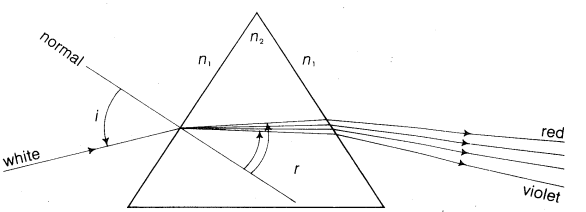

Figure 4: Refraction of light by a prism having index n_2 immersed in a medium having refractive index n_1. The angles i and r that the rays make with the normal are the angles of incidence and refraction. Because n_2 depends upon wavelength, the incident white ray separates into its constituent colours upon refraction, with deviation of the red ray the least and the violet ray the most.

bending of a ray at each interface can be found from Snell's law (Willebrord van Roijen Snell of Holland, *c.* 1600), which states that if n_1 and n_2 are the refractive indices of the medium outside the prism and of the prism, respectively, and the angles i and r are the angles that the ray of a given wavelength makes with a line at right angles to the prism face, as shown in Figure 4, then the equation $n_1 \sin i = n_2 \sin r$ is obtained for all rays. The refractive index of a medium, indicated by the sym-

bol n, is defined as equal to the speed of light *in vacuo* divided by the speed of light in the medium. Typical values for n range from 1.0003 for air at 0° C (32° F) and atmospheric pressure, to 2.3 for thin layers of zinc sulfide.

For typical optical glasses, the refractive index is in the neighbourhood of 1.5–1.9 and varies by 2 to 4 percent across the visible spectrum, with the refractive index greater for violet light than for red light. Because the variation of the refractive index is small, the spectrum is spread over a relatively small range of angles; thus prism instruments are generally used in applications for which low spectral resolution (ability to separate wavelengths) is sufficient.

In order for a prism to produce a large number of exit light beams having different, well-defined wavelengths, it is necessary that the incident light beam composed of these same wavelengths falls upon the prism as a set of parallel rays. This condition is conveniently accomplished by a collimator, a combination of lens and aperture (in this case a slit). Light rays from the source pass through the slit at the focus of the collimator lens, which then renders the rays nearly parallel (see Figure 5). After

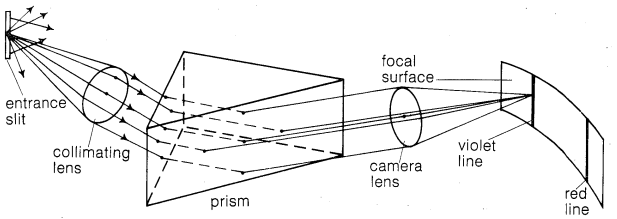

Figure 5: *Principles of a prism spectrograph.*
Light from a point on entrance slit (illuminated by a light source) is formed into parallel rays by the collimating lens. The light is refracted by the prism, then focussed by the camera lens. Violet light from the point is brought to focus; the slit is imaged as a line at the focal surface. Red light from slit is imaged as a different line. A spectrum thus appears at the focal surface.

the light is refracted by the prism, it is focussed by a lens, usually called the camera lens; if a viewing screen is placed at the focus, an image of the slit is seen for each wavelength of light present. Because the image of a slit is a line, each wavelength forms its own line. The lines can be observed by the eye or by placing photographic or photoelectric detectors at the focal position.

There are other devices besides prism instruments that can be used to break up light into its constituents. A collimated beam of light may be considered as a collection of parallel wave fronts advancing in the direction of travel of the light. Just as a water wave breaks up into ripples moving in all directions when it strikes a barrier, a light wave breaks up into waves travelling in all directions when it meets a barrier. This is the phenomenon of diffraction. Where the sizes of optical components approach the wavelength of light, diffraction phenomena become predominant.

Diffraction. Diffraction gratings are composed of closely spaced transmitting slits on a flat surface (transmission gratings) or alternate reflecting and nonreflecting grooves on a flat or curved surface (reflection gratings). A typical grating might be ruled on an aluminum coating on a piece of glass having dimensions from 2 × 2 centimetres (0.8 × 0.8 inches) up to 15 × 30 centimetres (6 × 12 inches) and consist of equally spaced parallel lines, as few as 100 lines per millimetre of width or as many as 6,000 lines per millimetre. The close spacing of lines requires that the wave picture of light be used to describe the interaction of light with a grating.

Secondary waves

If collimated light falls upon a transmission grating, the wave fronts, or crests, successively pass through and spread out as secondary waves from the transparent parts of the grating. Most of these secondary waves, when they meet along a common path, interfere with each other destructively, so that light does not leave the grating at all angles. At some exit angles, however, secondary waves from adjacent slits of the grating are delayed by exactly one wavelength, and these waves reinforce each other when they meet; that is, the crests of one fall on top of the other. In this case, constructive interference takes place and light can leave the grating. Constructive interference occurs also for delays of 0, 2, 3, 4 . . . wavelengths. The grating equation describes this phenomenon for both the transmission and reflection grating and gives the relationship between the incident angle, i; exit, or reflection angle, r; spacing between grating slits, d; wavelength, λ; and the integer, m (usually called the order of interference): the product of order and wavelength is equal to the product of slit spacing and the difference between the sines of the angle of incidence and exit; *i.e.*, $m\lambda = d(\sin i - \sin r)$. If light having several constituent wavelengths falls upon a grating at a fixed angle, i, different wavelengths are diffracted in slightly different directions and can be observed and recorded separately. Each wavelength is also diffracted into several orders (or groupings); gratings are usually blazed (engraved) so that a particular order will be the brightest. A lens or concave mirror can then be used to produce images of the spectral lines.

A simplification is obtained when a concave grating is used as a disperser. This device is formed by ruling on a concave mirror parallel lines equally spaced along a geometrical chord of the surface. Because a concave mirror has focussing properties, it can replace both collimator and camera lens (see Figure 6). Henry Augustus Rowland, a physicist in the United States, showed (1882) that if entrance slit, grating, and photographic plate lie on a circle the diameter of which is equal to the radius of curvature of the grating, all spectral lines can be made to focus. Many large, high-resolution grating spectrographs have been built on the basis of the Rowland circle, and most tabulated data on wavelengths have been obtained with such instruments.

The Rowland mount

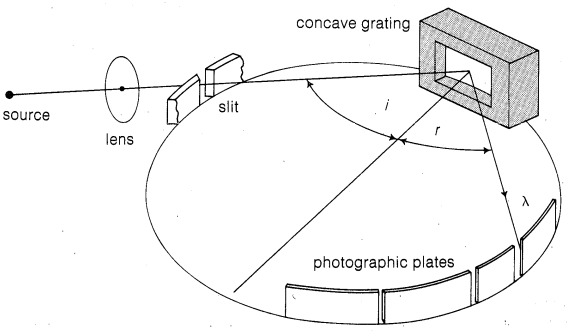

Figure 6: *Essentials of a concave-grating spectrograph based on the Rowland circle.*
Light from source is imaged onto the entrance slit by the lens. Light having wavelength λ will be diffracted by the concave grating shown in its holder, at angles r fixed by the grating equation and imaged on the photographic plates arranged in an arc around the circle to accept one of the various orders.

In any grating spectrometer, if a slit aperture is moved along the surface where the spectral lines are focussed, the lines are transmitted successively through the aperture. A detector placed behind the aperture then responds to the spectrum, line by line; the output of such a detector can then be amplified and recorded. These scanning techniques have some advantages over photographic recording: because the detection efficiencies of some electrical detectors (see below *Detectors*) are greater than efficiencies of photographic detectors, the method provides greater sensitivity and greater speed. Many photoelectric detectors respond nearly linearly—*i.e.*, with response proportional to the amount of light received—so the recorded brightness is simply related to the characteristics of the source.

In some arrangements, it is more convenient to tilt the grating (or prism) about its axis that is parallel to the slit than to move the slit. Typically, the grating may be rotated so that the angles of incidence and diffraction change, hence changing the wavelength of light reaching the fixed exit slit.

Interference. A third class of devices for dispersing spectra consists of interferometers, which divide a wave front by semitransparent surfaces, allow the beams thus produced to travel different paths, and then recombine

the beams. Variants of this method are used in testing of optical components. In spectroscopy, the principal interferometers are those developed by a United States physicist, A. A. Michelson (1881), in an attempt to find the luminiferous ether—a hypothetical medium then thought to pervade all space—and by two French physicists, Charles Fabry and Alfred Pérot (1897), specifically for high-resolution spectroscopy (see Figure 7).

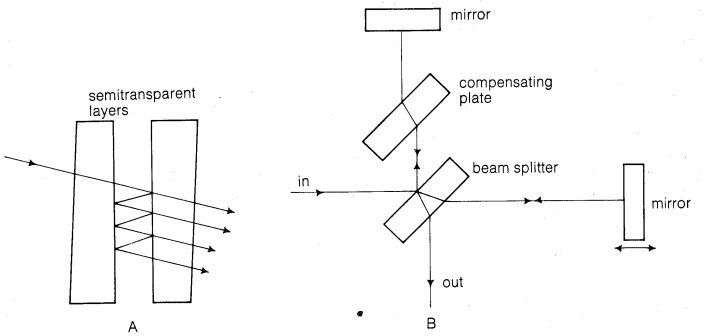

Figure 7: *Interferometers often used in spectroscopy.* (A) Fabry–Pérot interferometer; the plates are wedged to aid in the removal of spurious reflections. (B) Michelson interferometer, showing the path of a light ray through a beam splitter, which transmits and reflects approximately equal amounts of light, and a compensating plate to make the paths in glass equal for both arms of the instrument.

In the Michelson interferometer, an incident beam of light strikes a tilted semitransparent mirror and divides, weaker waves being reflected and transmitted. These continue to their respective mirrors, are reflected, and return to the semitransparent mirror. The two waves finally moving toward the observer have travelled different path lengths, hence interfere and are transmitted preferentially only if their path difference is 0, 1, 2, 3, . . . wavelengths. This device then acts as a filter that transmits preferentially certain wavelengths and reflects others back to the light source, resulting in a visible interference pattern. The Fabry–Pérot interferometer (Figure 7A) consists of two parallel glass plates coated with highly reflecting, slightly transparent films on their inner faces. When the interferometer is placed in a beam of light from a spectrometer, multiple reflections take place between the two faces, producing concentric interference rings. Even if there are two spectral lines so close together that they cannot be resolved by an ordinary spectroscope, the Fabry–Pérot interferometer will produce rings of slightly different radii, depending on the wavelengths of the two lines, which can be distinguished from one another.

Instruments for obtaining high resolving power often use interferometers in series with grating instruments. The grating preselects the line or lines of interest, which are further analyzed by the interferometer.

Multiplex spectrometers

Beginning about 1960, instruments known as multiplex spectrometers found considerable use, especially in recording astronomical infrared spectra. The prototype of this kind of instrument is the Michelson interferometer (Figure 7B), with one mirror mounted upon a carriage so that length of the light path in that branch of the light path can be varied. A spectrum is obtained by recording photoelectrically the light intensity of the interference pattern as the carriage is moved. Little preselection of wavelength is done, and so the resulting signals, containing information simultaneously about many wavelengths, are complicated. A mathematical transformation (called a Fourier transform) must be performed on the data to yield the spectrum (see OPTICS, PRINCIPLES OF). The principal advantage of this method is that the entire spectrum is recorded simultaneously with one detector. With the use of these Fourier spectrometers and other types of multiplex spectrometers, the spectra obtained are less affected by electronic noise originating in the detectors than are the spectra obtained by conventional scanning spectrometers.

Detectors. The principal detection methods used in spectroscopy, to be described below, are: photographic (plates and films), photoemissive (photodiodes, photomultipliers, image tubes), radiometric (bolometer, thermocouple, thermopile, Golay cell), and semiconductor (photoconductive and photovoltaic cells).

In most investigations before about 1940, and in many current applications, a strip of photographic film or a photographic plate records the pattern of spectral lines. This method has several advantages over other methods of recording: the source brightness need not be constant; information over the entire spectrum is recorded simultaneously; a permanent record results, detailed studies of which can be made later.

Photoemissive detectors have replaced photographic plates and films in many applications. When a photon (quantum of light) having sufficient energy strikes a metal surface, it can cause the ejection of an electron from the surface. A stream of photons releases a series of electrons, hence produces an electric current. A photoemissive diode (photodiode) consists of a surface (the cathode) appropriately treated to permit the ejection of electrons and a separate electrode (the anode) on which electrons are collected, both often sealed within an evacuated glass envelope. A photomultiplier (or multiplier phototube) has a cathode, a series of electrodes (dynodes), and an anode sealed within a common evacuated envelope. Some photoemissive detectors use continuous-strip or continuous-tube dynode structures. Appropriate voltages applied to the cathodes, dynodes, and anode cause electrons that are ejected from the cathode to make collisions with the dynodes in succession, knocking out more electrons upon each collision. The current is thus multiplied by the tube and is then more easily amplified and recorded. A single photon ejecting a single electron from the cathode can be detected as a pulse of 100,000 to 10,000,000 electrons at the anode; for some applications, these single pulses are counted directly. Photomultipliers are useful primarily in the wavelength range 1,050–12,000 angstroms, from far ultraviolet to near infrared; the lower wavelength limit is set by light-transmission properties of optical materials, whereas the upper limit is set by the requirement that the photon must have enough energy to eject an electron from the cathode.

Image intensifier tubes contain a sensitive photocathode and provision for accelerating the ejected photoelectrons so that they strike a phosphor screen, causing many photons to be emitted; alternatively, the electron may pass through a thin film, ejecting more electrons, which are accelerated in turn and detected, or may strike a photographic plate, causing its exposure. Such devices are often used in night-vision devices. They have found some application in spectroscopy because they maintain to some extent the sensitivity of photoelectric detection while preserving the information about the location at which the initial photon arrived.

A bolometer is a device the electrical resistance of which changes when it becomes warmer as a result of its absorbing light. A thermocouple junction is a junction between dissimilar metals. If an electrical circuit is made using two dissimilar metals, and if the junctions are at different temperatures, current flows in the circuit. A junction that absorbs light can thus be used as a detector, because its temperature generally increases when it absorbs light. A thermopile is a set of thermocouples mounted in series in order to obtain sensitivity greater than that obtained with a single junction. Golay cells detect light by the expansion of a gas when it is warmed by incident radiation. The four detectors described here have the common characteristic of responding to incoming energy of any wavelength; hence they can be used for detection in the far infrared where photographic and photoemissive detectors are insensitive.

Photoconductive cells contain thin semiconductor layers in which electrical resistance varies with illumination. Geiger–Müller tubes, proportional counters, and ionization chambers that depend on the release of electrons by incoming photons are used for detecting radiation from far ultraviolet to gamma rays (see below *X-ray detectors*).

When detection of spectra is done photographically, the

Recording of spectra

spectrogram serves also to record the results. In order to produce a nonphotographic permanent record, as with a scanned spectrum, the output signal current or voltage from the detector may be amplified and fed into an auxiliary output device. The simplest such device is a galvanometer that deflects an amount proportional to the input signal; a chart recorder can be used to draw an ink record of deflection versus wavelength on a moving strip of paper, or the amplified signal may be digitized and printed or recorded on magnetic tape, paper tape, or punched cards for later handling by computer.

II. Foundations of atomic spectra

BASIC ATOMIC STRUCTURE

Because the emission of spectral lines depends on the electron structure of atoms, it is apropos here to show how the periodic table of elements is organized. This will require definitions of the following quantum numbers: principal, orbital, spin, and magnetic. An atom, the smallest stable particle of neutral matter, has a diameter of approximately 2×10^{-10} metre. It consists of a core, or nucleus, which contains most of the mass of the atom, and a collection of electrons surrounding the nucleus. The nucleus contains a certain number (Z) of protons and a generally different number (N) of neutrons; the diameter of a nucleus depends upon the number of protons and neutrons and is typically in the range 1.5 to 10 $\times 10^{-15}$ metre (.000015 to .0001 angstrom); *i.e.*, much less than an atomic diameter. Each proton has one unit of positive electric charge ($+e$). Because each electron carries the basic unit of negative electric charge, and because opposite charges attract one another, in a neutral atom the total charge of the nucleus, $+Ze$, is balanced by Z electrons surrounding the nucleus. An atomic ion is an atom having either more or fewer electrons than protons (*i.e.*, more or fewer than Z electrons); an ion thus has a net negative or positive electric charge.

The chemical and spectroscopic properties of atoms and ions are primarily determined by their electronic structures; *i.e.*, by the numbers and arrangements of electrons surrounding their nuclei. Typical energies of electrons within an atom range from a few electron volts (eV) to a few thousand electron volts. (One electron volt, equal to 1.60×10^{-19} joule, is the kinetic energy gained by an electron when it is accelerated by a one-volt potential difference.) Chemical reactions and other processes occurring in spectroscopic sources usually involve energy exchanges of this order of magnitude. Processes that occur within nuclei to produce electromagnetic radiation and other forms of radioactivity typically involve energies ranging from thousands to millions of electron volts; hence nuclei are nearly unaffected by the usual processes occurring in chemical reactions, light absorption, and light sources.

The forces holding an atom together are primarily electrostatic—*i.e.*, the mutual attractive electric force between the positive charges in the nucleus and the negative charge of each electron. Because like charges repel one another, there is a significant amount of electrical repulsion of each electron by the others. Also, two principles not usually apparent in the macroscopic world of everyday experience become important in atomic phenomena. The Pauli exclusion principle (1925) states that no two electrons can exist in the same energy state. The Heisenberg uncertainty principle (1925) predicts that it is impossible to measure accurately both the position and momentum of an electron simultaneously. A more useful approximate picture of an atom is that of a massive nucleus concentrated at a point surrounded by an electron mist or cloud, the density of which is proportional to the probability that an electron can be found there.

To a rough approximation, the electrons within an atom or ion move independently of one another. It is often possible first to calculate the properties of an atom on the basis of independent motions of the electrons rather than to make corrections for the correlations in electron motion caused by their forces on each other. Calculations begin with finding the possible states of atoms (and ions) that have just one electron outside a closed shell (see below *The periodic table*)—*i.e.*, hydrogen-like atoms and ions. The electron states in a complex atom are built up of electrons in these "one electron" states, and then corrections are made for the interelectronic forces.

HYDROGEN ATOM STATES

Principal quantum number. A hydrogen atom is composed of a nucleus (a proton) and a single external electron. The electron has wave properties in addition to particle properties. (Experiments show that atoms, molecules, and other microscopic particles also have wave properties.) Its wavelength is specified by the de Broglie relation (1924): particle wavelength, symbolized by the Greek letter lambda, λ, is equal to Planck's constant, h, divided by momentum (mass times velocity), or $\lambda = h/p$, in which p is the momentum of the particle. This wave then travels around the nucleus of the atom. In order that the wave not cancel itself, it must travel at the appropriate distance from the nucleus so that the circumference of the orbit is equal to n times the electron wavelength, in which n is a positive integer equal to 1, 2, 3, ... The electron wave will then be stable. The motion of the electron is also limited by the requirement that the force on the electron is equal to the electron's mass times its acceleration (Newton's second law). The result is that the electron can exist stably only at certain average distances from the nucleus, and these distances are specified by giving n, the integer mentioned above. The electron's average distance from the nucleus is equal to the square of this integer times a constant, or n^2a_0, in which a_0 (equal to .525 angstrom) is known as the first Bohr radius (because Niels Bohr first calculated it on the bases outlined here). The number n is usually called the principal quantum number for the orbit. The energy of an electron in a hydrogen-like atom or ion is equal to minus the atomic number (Z) squared times Planck's constant (h) times the speed of light (c) times a constant divided by the principal quantum number squared—*i.e.*, $-Z^2hcR/n^2$. The constant R is called the Rydberg constant, and its product with Planck's constant and the speed of light (hcR) is approximately 13.6 electron volts. The energy is negative, indicating that the electron is bound to the nucleus. The algebraic value of the energy increases as n increases; hence the principal quantum number n equals one for the ground state of hydrogen. As the integer n takes on larger values toward infinity, the energy approaches zero. As this happens, the electron's average distance from the nucleus increases without limit and the atom becomes more nearly ionized (an ion approaches further ionization). The energy that is added to an atom or ion in its ground state just to cause the removal of an electron is called the ionization potential.

De Broglie waves

The first Bohr radius and the Rydberg constant

The combination principle suggests that the energies, frequencies (ν), and wavelengths (λ) of photons emitted by hydrogen atoms ($Z = 1$) should be expressed by $E = hf = hcR(1/n_1^2 - 1/n_2^2)$ and $1/\lambda = R(1/n_1^2 - 1/n_2^2)$, in which n_1 and n_2 take on the values of the principal quantum number for the final and initial states, respectively. The latter formula (with $n_1 = 2$) was found empirically by Balmer in 1885 to fit the wavelengths of the visible spectrum in hydrogen if $n_2 = 3, 4, 5, \ldots$. This was the first discovery of a spectral series. It was found in 1890 by the Swedish physicist Johannes Robert Rydberg that numerous data for the other spectra of atoms could be fitted by series formulas that are a slight modification of Balmer's formula, $1/\lambda = R[1/(n_1 - a)^2 - 1/(n_2 - b)^2]$, in which n_1 is held fixed for each series, n_2 takes on integer values greater than n_1, and a and b are nearly constant numbers for a given series and are called quantum defects. In each series, as n_2 becomes much larger than n_1, the wavelength approaches the series limit given by the wave number, $1/\lambda$, equal to $R/(n_1 - a)^2$.

Orbital quantum number. The second quantum number to be considered is the orbital quantum number. Although classically an electron's orbit may be elliptical with any ratio of major to minor axes, solution of the quantum mechanical equations shows that only certain distributions of the electron cloud exist in space and these depend on the angular momentum of the electron. Angu-

lar momentum is a concept applied to a body that is moving in an orbit or rotating on its own axis; it depends on the angular velocity and distribution of mass about an axis; it has the property of direction, being at right angles to the plane of motion. The orbital angular momentum of the atom is equal to the square root of a positive integer times the next successive integer, multiplied by the quantity Planck's constant divided by two pi—*i.e.*, $\sqrt{l(l+1)}(h/2\pi)$, in which l is a positive integer and h is Planck's constant. The number l, called the orbital quantum number, is restricted to be less than the principal quantum number; so if n is equal to one, l can only be zero, and hence the orbital angular momentum is equal to zero. If $n = 2$, l can be 0 or 1, yielding orbital angular momentum $= 0$ or $\sqrt{2}(h/2\pi)$. If $n = 3$, l can be 0, 1, or 2, etc.

Magnetic quantum number. The third quantum number is the magnetic quantum number. The tilt of an electron's distribution will be restricted to certain values when it is surrounded by a magnetic field. This phenomenon, the restriction of allowed directions for the atomic angular momentum, is known as space quantization and was first demonstrated in 1922 by two German physicists, Otto Stern and Walther Gerlach. The component (value) of the angular momentum of the atom along any given direction is equal to integral units of a quantity, Planck's constant divided by 2π—that is, $m_l(h/2\pi)$, in which m_l is another integer, being positive or negative so long as its magnitude does not exceed l. For instance, if $l = 1$, m_l can have the values $+1$, 0, or -1. The number m_l is usually called the magnetic quantum number.

Space quantization

Spin quantum number. The fourth quantum number is concerned with the spin of electrons. Experiments show that an electron has a further characteristic, its spin, which affects its motion and hence its possible energies. The electron behaves as if it were a spinning top, with its own intrinsic angular momentum having magnitude that can be obtained from the expression for orbital angular momentum by substituting ½ for l—*i.e.*, $\sqrt{(\frac{1}{2})(\frac{1}{2}+1)}(h/2\pi) = \sqrt{\frac{3}{4}}(h/2\pi)$—one says that the electron has spin $s = \frac{1}{2}$. Whether this angular momentum is directed toward or opposite a particular direction is indicated by giving the component of s along that direction. The allowed values are equal to $m_s(h/2\pi)$, in which m_s is either $+\frac{1}{2}$ or $-\frac{1}{2}$.

Spin–orbit interaction. These four quantum numbers, n, l, m_l, m_s, specify the state of a single electron completely; each number implies a particular wave function (equation) describing that aspect of the electron's motion. The description of an electron's motion can be done entirely mathematically using these numbers and the functions they represent.

The energies of the electron in a hydrogen-like atom or ion are fixed primarily by the mutual electrostatic attraction of the electron and the nucleus; there are, however, significant magnetic effects affecting the energies. An electron has an intrinsic magnetic dipole moment; that is to say, it behaves in some ways as a small bar magnet aligned along its spin axis. Also, because of its orbital motion within the atom, the electron creates a magnetic field in its vicinity. The interaction of the electron's magnetic moment with the magnetic field created by its motion (the spin–orbit interaction) modifies its energy to depend upon n, the principal quantum number, and another quantum number, j, representing a combination of its orbital-angular-momentum quantum number, l, and its spin-angular-momentum quantum number, s. In keeping with the requirement that energy and angular momenta can have only discrete values within an atom, the quantum number, j, can take on positive values only between $l + s$ and $l - s$ in integer steps; because s is ½ for the single electron in a hydrogen-like atom, j is ½ for $l = 0$ states, $j = \frac{1}{2}$ or $\frac{3}{2}$ for $l = 1$ states, $j = \frac{3}{2}$ or $\frac{5}{2}$ for $l = 2$ states, etc. The magnitude of the total angular momentum of the atom, then, can be expressed in the same form as for the orbital and spin momenta: $\sqrt{j(j+1)}(h/2\pi)$, and the component of angular momentum along any direction is a multiple of Planck's constant divided by 2π, namely, $m_j(h/2\pi)$, in which m_j can have any value between $+j$ and $-j$ in integer steps (*e.g.*, $\frac{5}{2}$, $\frac{3}{2}$, $\frac{1}{2}$, $-\frac{1}{2}$, $-\frac{3}{2}$, $-\frac{5}{2}$). The quantum numbers n, l, j, m_j are often used to specify a state in the hydrogen atom. Small differences in energies of levels because of the spin–orbit interaction sometimes cause complexities in spectral lines that are known as the fine structure of spectral lines.

Fine structure

THE PERIODIC TABLE

Although there seems to be no simple justification for the fact, it is found that in any atom no two electrons have the same set of quantum numbers n, l, m_l, m_s (or n, l, j, m_j), defined above. Even when interactions between the electrons occur, and when magnetic interactions between an electron's spin and its orbital motion occur so that a new state of an electron is specified by a different set of four quantum numbers, no two electrons in an atom have the same set. This is the Pauli exclusion principle; its most direct application involves the explanation of the periodic table of the elements first developed by two chemists, Dmitry Ivanovich Mendeleyev of Russia and Lothar Meyer of Germany (*c.* 1869). This table (see Figure 8) lists the elements in rows in order of increasing atomic number Z; it is found that the elements in the same column have similar chemical properties.

Figure 8: Periodic table of the elements. Left column indicates the subshells that are being filled as atomic number Z increases. The body of the table shows element symbols and Z. Elements with equal numbers of valence electrons—and hence similar spectroscopic and chemical behaviour—lie in columns. In the interior of the table, where different subshells have nearly the same energies and hence compete for electrons, similarities often extend laterally as well as vertically.

To see how elements fit into the periodic table, it is helpful to start with a hydrogen atom—a singly charged atomic nucleus and one electron—then add exterior electrons and positive charges to the nucleus one by one for successive elements. Each electron will make transitions to its lowest possible energy state. For hydrogen, this is the state with $n = 1$, $l = 0$, $m_l = 0$, $m_s = \frac{1}{2}$ or $-\frac{1}{2}$; these numbers specify the resulting configuration, or arrangement, of electrons of a hydrogen atom in its ground state. If a positive charge is added to the nucleus and a second external electron is added, it too will go to its lowest state, again $n = 1$, $l = 0$, $m_l = 0$, and with m_s different from that of the first electron (otherwise both electrons would have the same set of quantum numbers n, l, m_l, m_s and this would violate the Pauli exclusion principle). The resulting configuration is that of helium in its ground state. There are only two possible electron states with $n = 1$, and these are now occupied by electrons. It is said that the $n = 1$ shell (or orbital) is filled or closed. This closed shell is relatively stable and difficult to excite; helium is the first of the inert, or noble, gases.

The helium configuration

If a third electron is added (to make a lithium-like atom), it cannot occupy the $n = 1$, $l = 0$ shell with the others, because its quantum numbers would then be identical with those of one of the other electrons. This electron has its lowest possible state with $n = 2$. For this value of n, the orbital quantum number l can be either 0 or 1; a state for $l = 0$ has slightly lower energy. The quantum numbers of this electron are then $n = 2$, $l = 0$, $m_l = 0$, $m_s = +\frac{1}{2}$, or $-\frac{1}{2}$. The inner $n = 1$ shell is

relatively stable and remains inert in chemical processes; the chemical and spectroscopic behaviour of this atom is similar in many ways to that of hydrogen, since lithium and hydrogen both have one external electron free to move (valence electron).

Addition of the next electron to produce a beryllium atom completes the partial shell or subshell $n = 2, l = 0$. A subshell consists of all electrons of the same principal and orbital quantum numbers. The atom is analogous to helium in that both atoms have two outer electrons. The $n = 2$ shell is not filled, however, because an electron with $n = 2$ can have $l = 1$. Outside the inner shell $n = 1$, there are six possible electron states with $l = 1$ because an electron can have any combination of $m = 1$, 0, or -1, and $m_s = +½$ or $-½$. As successive electrons are added to yield boron, carbon, nitrogen, oxygen, fluorine, and neon, the electrons take quantum numbers $n = 2$, $l = 1$, and all possible different combinations of m_l and m_s, until a total of six with $n = 2$, $l = 1$ have been added. This completes the $n = 2$ shell, having a total of eight electrons in two subshells. The resulting atom is neon, the second of the noble gases.

When the next (11th) electron is added, it cannot go into any state with $n = 1$ or $n = 2$ because these are already filled by electrons. The lowest available state is now $n = 3$, $l = 0$, $m_l = 0$, $m_s = ½$ or $-½$. This atom is sodium; its outer structure is analogous to those of lithium and hydrogen, and so it has similar spectroscopic and chemical properties. Addition of another electron, which takes quantum numbers $n = 3$, $l = 0$, $m_l = 0$, $m_s = ½$ or $-½$ (m_s opposite to that of the 11th electron) yields magnesium, similar in structure and properties to beryllium, which lies above it in the periodic table. Addition of another electron yields aluminum, similar to boron. As more electrons are added, the elements silicon, phosphorus, sulfur, chlorine, and argon are produced. The spectra, structures, and chemical behaviour of these are similar to those of the elements carbon through neon, respectively, because the numbers of outer (valence) electrons are the same. In a similar fashion, the remainder of the periodic table is constructed, with some irregularities caused by different subshells having nearly the same energies (see Table 2).

Electron nomenclature

As a shorthand method of indicating the electron configurations of atoms and ions, the letters *s, p, d, f, g, h,* . . . are used to denote electrons having, respectively, $l =$ 0, 1, 2, 3, 4, 5, ... (The letters *s, p, d, f* originate from spectral series that had the designations sharp, principal, diffuse, and fundamental before their origins were fully understood.) A number prefixed to the letters gives the value for n, and a superscript to the right of each letter indicates the number of electrons with those values of n and l. The configuration $2s^1$ represents a single electron with $n = 2$, $l = 0$ (the superscript 1 is usually omitted). The configuration $1s^22s^22p^3$ represents two electrons with $n = 1$, $l = 0$, two electrons with $n = 2$, $l = 0$, and three electrons with $n = 2$, $l = 1$. The ground state configurations for the known atoms are given in Table 2.

For the atoms in the first third of the periodic table, one can often specify both the total orbital angular momentum and the total spin angular momentum in a given state. The total orbital angular momentum is the sum of the orbital angular momenta from all the electrons, taking into account their quantized values and their signs (plus or minus); it has magnitude $\sqrt{L(L+1)}(h/2\pi)$, in which L is an integer. The possible values for L depend upon the individual l values and the orientations of their orbits for all the electrons comprising the atom. The total spin momentum has magnitude $\sqrt{S(S+1)}(h/2\pi)$, in which S is an integer or half an odd integer depending on whether the number of electrons is even or odd. The possible value of the total spin angular momentum can be found from consideration of all the possible orientations of electrons within the atom. (Usually, in taking the L and S values, only the valence, or outer shell, electrons are considered, because in a closed subshell, there are as many electrons quantized in one direction as there are in the opposite direction, with the result that their orbital and spin momenta add up to zero. Thus only the valence electrons contribute angular momenta to the whole atom.) The total of orbital plus spin angular momentum has the magnitude $\sqrt{J(J+1)}(h/2\pi)$, in which J can take any positive value from $L+S$ to $L-S$ in integer steps; *i.e.*, if $L=1$ and $S=\frac{3}{2}$, J can be $\frac{5}{2}$, $\frac{3}{2}$, or $\frac{1}{2}$. The remaining quantum number, m_J, specifies the orientation of the atom as a whole; m_J can take any value from $+J$ to $-J$ in integer steps. A term is the set of all states with given configuration, L, S, and J. If this specification can be made, it is called LS, or Russell–Saunders coupling (1925), after an astronomer, Henry Norris Russell, and a physicist, Frederick A. Saunders, of the United States. Energy levels are plotted as bars on a vertical energy scale. Atomic levels are labelled S, P, D, F for $L=0$, 1, 2, 3, ... The designation of such a level is written as ^{2S+1}L; *i.e.*, the level $^3D_1$ has $S=1$, $L=2$, $J=1$. Sometimes the term is preceded by the principal quantum number to indicate in which shell the state occurs—*e.g.*, $5\,^3D_1$. A multiplet is the set of all transitions between two terms.

For heavier atoms, magnetic interactions among the electrons often contrive to make L and S poorly defined, although J and m_J still remain constant quantities for a given state of an atom, a coupling scheme known as j–j coupling.

Principle governing internal structures

A simple unifying principle underlies all the internal structures of atoms: atoms or ions having the same number of electrons outside the same, closed electron shell, called an isoelectronic sequence, have quite similar spectra. This similarity is illustrated in Figure 9, which shows drawings to scale of some of the energy levels of one electron near the ground states of a hydrogen nucleus ($Z=1$), a helium nucleus ($Z=2$), and a calcium nucleus ($Z=20$). Similarities in spectra for ions having the same number of electrons are sufficiently close that the spectral lines from a highly ionized (multiple loss of electrons) element can often be identified by extrapolation from known isoelectronic spectra.

TRANSITIONS

An isolated atom or ion in some excited state spontaneously transfers to a lower state with the emission of one or more photons, thus ultimately going into its ground state. The time required for such a transition varies greatly according to the wavelength of the photon to be emitted; for a transition in which a photon of visible light (wavelength typically 500 nanometres or 0.5 micrometre) is emitted, a characteristic average emission time is 1–10 nanoseconds ($1\text{–}10\times10^{-9}$ second). The emission time is proportional, approximately, to the cube of the wavelength; *i.e.*, a transition giving rise to a photon having wavelength 5 micrometres will occur in a time characteristically 1–10 microseconds.

Not all conceivable transitions, however, are possible within an atom. Theoretical and empirical selection rules restrict the kinds of transitions that may occur. The first selection rule found (1924, by Otto Laporte, then a physicist of Germany) states that all states of an atom can be divided into two sets: odd and even. A transition may take place from an odd to an even state or vice versa, but not between states in the same set.

Another selection rule states that during a transition, only one electron changes values of n and l. Other selection rules state that J can change only by unity or zero in a transition, and that if L and S are well defined within the atom, L can change by not more than unity ($\Delta L=0,\pm1$) and S cannot change at all during a transition.

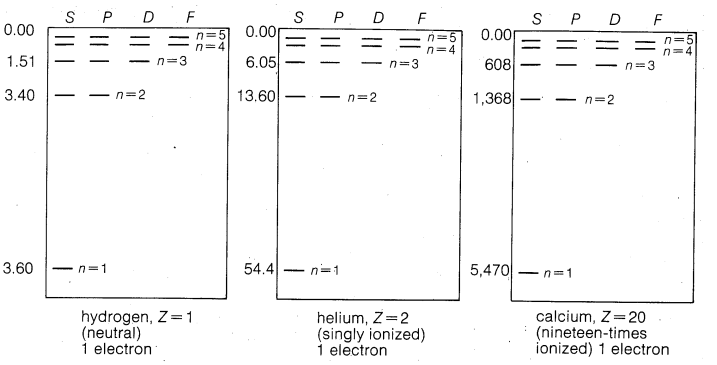

Figure 9: Level diagrams (Grotrian diagrams) for isoelectronic atom and ions, showing similarities in their level structure. The values for the principal quantum number n are for the electron in each case. The numbers at the left of the levels are the binding energies for the outermost electron, in electron volts; the electron is freed from the atom (or ion) at binding energy=zero.

Although these rules are not exact, and violations of them occur, the corresponding transitions for the violations are usually relatively slow and the spectral lines resulting are relatively weak. Such transitions are called forbidden transitions. For atoms in about the first third of the periodic table, the L and S selection rules provide useful criteria for the classification of unknown spectral lines. In heavier atoms, greater magnetic interactions among electrons cause L and S to be poorly defined, and these selection rules are less applicable. Occasionally, excited states are found that have lifetimes much longer than the average, because selection rules prohibit all transitions between levels. Such states are called metastable.

Metastable states

The transition rates from one state to another in all but the hydrogen-like atoms can be calculated only with difficulty. Accurate theoretical values can be obtained only with sophisticated computer routines, paying careful attention to the detailed structure of the atom. Experimental values for state lifetimes are of great importance in checking the accuracy of atomic theory.

PERTURBATIONS OF LEVELS

The energies of atomic levels are affected by external magnetic and electric fields in which atoms may be situated. The effect of a magnetic field (the Zeeman effect, after Pieter Zeeman, a Dutch physicist) is to cause an atomic level to split into its states of different m_J, each with slightly different energy. The result is that each spectral line separates into several closely spaced lines. The number and spacing of such lines depend upon the J values for the levels involved; hence the Zeeman effect is often used to identify the J values of levels in complex spectra. The required magnetic field is usually provided by a massive electromagnet that nearly surrounds the light source.

The corresponding effect of line splitting caused by the application of a strong electric field is known as the Stark effect (after Johannes Stark, a German physicist).

Small modifications to electronic energy levels arise because of the finite mass and nonzero volume of the atomic nucleus and the distribution of charges and currents within the nucleus. The resulting small energy changes, called hyperfine structure, are used to obtain information about the properties of nuclei and the distribution of the electron clouds near nuclei. Systematic changes in level positions are seen as the number of neutrons, N, in a nucleus is increased; these effects are known as isotope shifts. The principal isotope effects are: for light atoms (Z less than about 20), increased binding of electrons to

nuclei occurs, and decreased effects are seen caused by correlations in electron motion as the number of neutrons increases. For heavier atoms, a decreased binding of the electrons to the nucleus results as the neutron number increases, because the nuclear volume increases. The isotopic effects are so small that they are of no concern in molecular spectroscopy. The nucleus may behave as a small magnet because of circulating currents within; the magnetic fields produced in this way may affect the levels slightly. If the electric field outside the nucleus differs from that which would exist if the nucleus were concentrated at a point, this difference also can affect the energy levels of the surrounding electrons (see section V).

(J.O.S.Jr.)

III. Molecular spectra

The principal divisions of molecular spectroscopy are nuclear quadrupole resonance, nuclear magnetic resonance (NMR), electron paramagnetic resonance (EPR), gas phase microwave spectroscopy, electron spectroscopy, Raman spectroscopy, and infrared, visible, and near and far ultraviolet spectroscopy. The first three divisions are discussed in the article MAGNETIC RESONANCE, and the remainder are covered in the text below.

EXPERIMENTAL PRINCIPLES

The experimental arrangements for observing absorption spectra will normally involve a source of radiation; a device for selecting a narrow wavelength range, unless the source itself is monochromatic—*i.e.*, emits a single wavelength that can be changed at will; a cell for containing the sample of matter to be studied; and a radiation detector for measuring and recording the amount of radiation transmitted, both with the matter present and with it removed.

In the different spectral ranges, the sources of radiation for absorption spectroscopy will vary as will the detectors. In the microwave and radio-frequency regions, powerful monochromatic sources of controllable frequency have been available for some time. With the advent of the tunable laser (a monochromatic source of variable frequency in the optical regions), such sources became available in the early 1970s for the production of infrared, visible, and near ultraviolet. Otherwise, sources having a natural broad range of wavelengths combined with some optical device for selecting the desired monochromatic wavelengths, such as a prism or diffraction grating, are needed.

The photographic plate, the eye, photocells and photomultipliers, thermal detectors, and silicon rectifier crystals are among the detectors employed.

The molecular spectra of various substances are observed under a variety of conditions. Depending in part on the type of spectroscopy, the substances may be studied as gases, liquids, or solids, or in liquid or solid solutions, as single crystals, polycrystals, glasses, or as solid mixtures with other crystals. Similarly, circumstances make it advantageous to work in certain temperature ranges, sometimes at extremely low temperatures. Interesting work has been done with materials in unusual, possibly transient states, such as, for example, molecules that are ionized, parts of molecules that have been broken (*i.e.*, free radicals), highly reactive species trapped and preserved at low temperatures in inert, unreactive media such as frozen argon, special impurity centres in crystals, and molecules passing through a vacuum as a molecular beam. Each of these special circumstances confers advantages in particular cases.

THEORY OF MOLECULAR SPECTRA

Origins of molecular spectra. The spectra emitted by molecules can be much more complicated than those emitted by atoms because there are not only energy contributions from the electrons but also from the relative motions of the atomic nuclei. Molecules are made up of two or more atoms and hence consist of atomic nuclei surrounded by clouds of electrons. The moving electrons are attracted by the nuclei and thereby bind the latter together.

The energy of a molecule can be usefully divided into parts. The electrons have kinetic energy of motion and potential energy because of their attraction to the nuclei and repulsion by each other. Another potential energy originates in the mutual repulsions of the positive nuclei. These parts together constitute the electronic energy of the molecule, energy that is changed under electron or molecular impact, or when X-rays, ultraviolet, or visible light is absorbed, processes called excitation. X-rays primarily affect the inner atomic electrons; visible light or impact energy mainly excites the outer, so-called valence electrons.

Electronic energy of a molecule

The nuclei also can move, particularly in a back and forth vibrational motion with respect to one another. A molecule with several nuclei can display various patterns of vibration. Radiation in the infrared region may excite some of these vibrations.

Molecules also rotate about their centres of mass and thus possess rotational energy, at least when the substance exists in the gas phase. Finally, in a gas they are normally moving about as a whole—*i.e.*, executing translational motion.

The magnitude of these energies can be ordered, with the electronic energy of the inner electrons the greatest, that of the outer electrons next, followed by changes in vibrational energy, and, finally, by those in rotational energy. Changes in translational energy usually are not involved in spectra except for certain effects connected with the breadth of spectral lines.

There are some interactions, or interdependence, between these different kinds of energies, but the separation into kinds of energy, or energy parts, is nevertheless a concept of great practical importance. It is also true that changes in the smaller energy terms usually accompany changes in the larger ones. Thus, absorption of ultraviolet or visible light will normally change the vibrational and rotational energies as well as the electronic energy of a molecule. Similarly, in gases at least, rotational changes usually accompany vibrational changes brought about by absorption of infrared radiation.

Quantization of molecular energy. One consequence of quantum mechanics is that the energies of a molecule (except the translational energy) are quantized; *i.e.*, a molecule is not allowed by nature to possess an arbitrary amount of electronic, vibrational, or rotational energy; instead, only certain restricted discrete values of the energy are allowed.

Figure 10 shows the allowed values—that is, the energy levels—of the vibrational energy of a molecule composed of two atoms. The lower levels, designated as E_v, are nearly equally spaced as is predicted by quantum mechanics for a hypothetical case in which the force between the atoms of a molecule increases linearly (at a constant rate) with the increase in internuclear distance. For such a vibrating molecular system, called a harmonic oscillator, theory gives an energy for each level equal to a factor of some integer plus ½ (by substituting for v its values 0, 1, 2, etc., one gets ½, 3/2, 5/2, etc.) times a constant (ν_0), the vibration frequency calculated according to ordinary or classical mechanics and Planck's universal constant (h): $E_v = (v + ½)h\nu_0$, $v = 0, 1, 2, \ldots$, in which v, an integer, is called the vibrational quantum number. The actual levels converge upon one another as this quantum number increases, because the chemical bond (the force holding the molecule together) weakens and ultimately breaks when it is stretched sufficiently—*i.e.*, the constituent atoms are separated. Beyond the dissociation energy, when the bond breaks, all values of the relative translational kinetic energy of the atoms are allowed without any restriction from quantum mechanics.

Allowed energies for a harmonic oscillator

When a molecule is exposed to radiation, it is found from both theory and experiment that it will not efficiently absorb radiation and thereby undergo a transition from one energy level to another unless the energy of a quantum of radiation (which has the value $h\nu$, the product of the frequency of radiation ν, and Planck's constant h) matches the energy difference between the energy level initially occupied by the molecule and some higher level. If, on the other hand, the value of $h\nu$

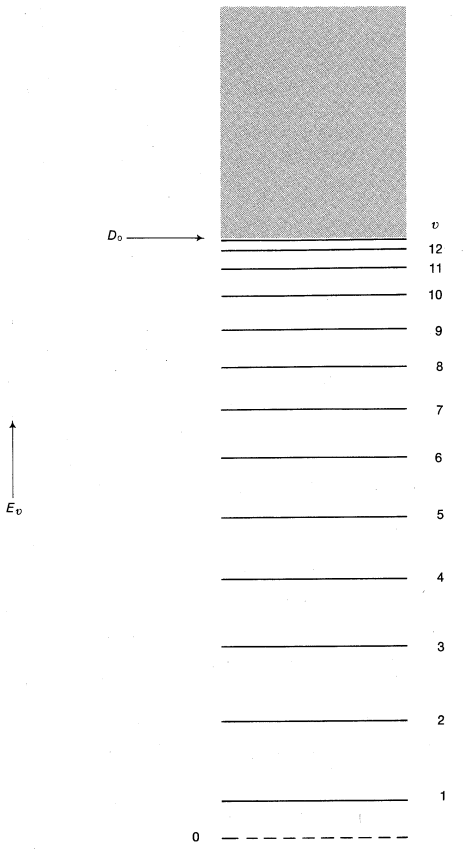

Figure 10: Allowed values of the vibrational energy E_v of a diatomic molecule. Levels are labelled with the quantum $v = 0, 1, 2, \ldots$. The zero energy (dashed line) is not an allowed value. The point D_0 is the dissociation limit, above which the molecule breaks into two separate atoms.

matches the energy difference to a lower energy level, the molecule may be caused to emit the frequency ν. This phenomenon is called induced emission.

Selection rules

Not only must energy be conserved (*i.e.*, $\pm h\nu = E_{\text{final}} - E_{\text{initial}}$) but also there may be additional restrictions, called selection rules, on what changes of energy level may occur. Thus for a polar diatomic molecule (a molecule with an unsymmetric charge distribution), vibrational transitions from one energy level to the adjacent level symbolized as $\Delta v = 1$ are much more probable than changes in the quantum number v by 2, 3, etc. These rules have a sound theoretical foundation, and often it is possible to make firm predictions regarding selection rules and intensities.

APPLICATIONS

The most obvious application of many of the branches of molecular spectroscopy is for characterizing and identifying specific chemical species—*i.e.*, for chemical analysis, either qualitative or quantitative. The infrared spectra of materials in the gaseous, liquid, or solid state at moderate resolution are highly characteristic of individual species—a sort of molecular fingerprint that, once taken, usually permits the same substance to be identified if encountered again. Raman spectra (after Sir Chandrasekhara Venkata Raman, a physicist of India) are similar in their utility. Pure rotational spectra (microwave spectra) are even more characteristic but are obtainable for far fewer species. Visible and ultraviolet spectra are usually considerably less structured than infrared spectra but are easy to observe, quantitatively measurable, often obtainable on tiny samples, and have been of great importance in chemistry. In a similar way, the closely related fluorescence spectra are of wide utility for analysis. X-ray spectra are mostly useful for identifying the atoms that are present. One of the most useful branches for these chemical applications is that of nuclear magnetic-resonance spectroscopy, which is discussed in the article MAGNETIC RESONANCE.

Besides these important analytical uses—important in controlling manufacturing processes as well as in the laboratory—spectroscopy has been one of the major sources of scientific information about the geometry of molecular structure, including much of the data on the way electrons are distributed in molecules and how they bring about chemical binding of the atoms. Some of these applications will be discussed below.

FIELDS OF MOLECULAR SPECTROSCOPY

Microwave spectroscopy. (See also section V.) Microwave radiation is electromagnetic radiation with wavelengths of a few millimetres to several centimetres (see Table 1). The region is differentiated from its neighbours (the far infrared at shorter wavelengths, ultrahigh frequency radio at longer wavelengths) only by the practical techniques of generation, transmission, and detection used. Microwaves can be generated by special electronic vacuum tubes—*e.g.*, klystrons—or by backward wave oscillators, and more recently by certain solid-state devices such as the Gunn effect diode. These sources can be made highly monochromatic.

Microwaves can be transmitted through hollow metal tubes, often of rectangular cross section (wave guides, see ELECTROMAGNETIC RADIATION) and can be detected by a silicon diode rectifier crystal connected to a suitable amplifier and recording or display device.

If a wave guide with mica windows at the ends is arranged to form an absorption cell and then evacuated and filled to a low pressure (perhaps one hundred thousandth of atmospheric pressure) with a suitable gas, such as carbonyl sulfide (COS), certain frequencies in the microwave region are weakly but sharply absorbed by the gas. Figure 11 shows the signal strength versus frequency of *p*-bromotoluene. In practice, some form of modulation of the absorption is generally used in order to increase the

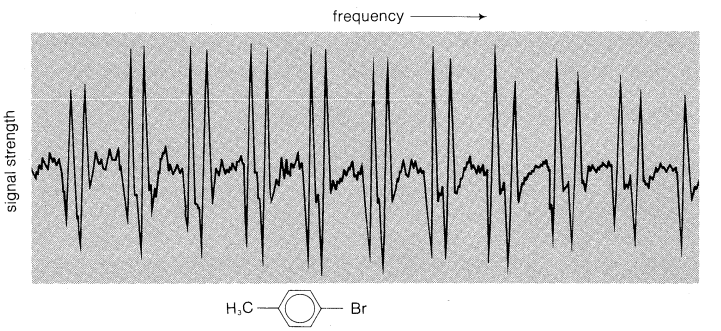

Figure 11: Microwave spectrum of *p*-bromotoluene at low resolution. Signal strength in absence of electric field is upward, in presence of field downward. Note pairs of peaks arising from two isotopes of bromine.

sensitivity. In almost all such cases, the molecule absorbs a photon or quantum of microwave energy and converts it to increased molecular-rotational energy; *i.e.*, the molecule undergoes a transition from one specific, quantized discrete rotational level to another.

Rotational levels

In order to display a sharp microwave spectrum, a substance normally must have a nonvanishing, permanent electrical dipole moment (an electric dipole moment means that the electric charge is not symmetrically distributed over the molecule); it must be in the vapour state at a low pressure; and its molecules must not be too large and complicated. Many thousands of kinds of molecules have already been found suitable for producing microwave spectra.

Detailed information about individual molecules that can be obtained from microwave spectroscopy includes quantitative molecular structures, electrical dipole moments, magnetic moments, nuclear-electrical quadrupole moments that measure the deviation of the nuclear charge from sphericity, nuclear spins, low vibration frequencies, barriers to internal rotation, molecular quadrupole moments, and information about chemical bonds. The

spectra are highly characteristic of each kind of molecule and hence can be used for analysis. Some transient species, such as the free radicals hydroxyl (OH), sulfur monoxide (SO), bromine monoxide (BrO), and others, have been studied.

Astronomers have used special radio telescopes to discover the presence in interstellar space of certain molecules—hydroxyl, water, ammonia, formaldehyde, and others—by means of characteristic, recognizable microwave lines.

A simple example of how structures can be obtained is provided by diatomic molecules, consisting of two atomic nuclei and linear molecules, for which an adequate model is provided by the linear-rigid rotor—a rotating rigid body made up of a set of mass points (each representing a nucleus) arranged in a straight line. The orientation is measured with the two polar angles of the axis, and the only parameter, or characteristic quantity, required is the moment of inertia (I) specified as a sum of terms, each of which is equal to the mass of a nucleus (electrons are not considered because of their relatively negligible mass) times the square of its distance along the axis from the centre of mass; *i.e.*, $I = m_1z_1^2 + m_2z_2^2$, in which m_1 and m_2 are the masses and z_1 and z_2 are their distances. For this model system, quantum mechanics leads to the result that the energy is inversely proportional to the moment of inertia (I) and dependent on a quantum number (J) that takes on integral values; *i.e.*, $E_J = J(J + 1)\ (h^2/8\pi^2I)$, in which $J = 0, 1, 2, \ldots$ for the allowed values of the rotational energy E_J. Here h is Planck's constant.

Although this system provides a good model for the rotational energy levels of diatomic and linear molecules, it is not perfect; for example, molecules are not really rigid but stretch because of the centrifugal force of the rotation. This characteristic and other interactions of rotation and vibration are observable but not large. In addition, electrons contribute a small amount to the moment of inertia.

From A.P. Cox and J.M. Riveros, *The Journal of Chemical Physics*, vol. 42, p. 3109 (1965)

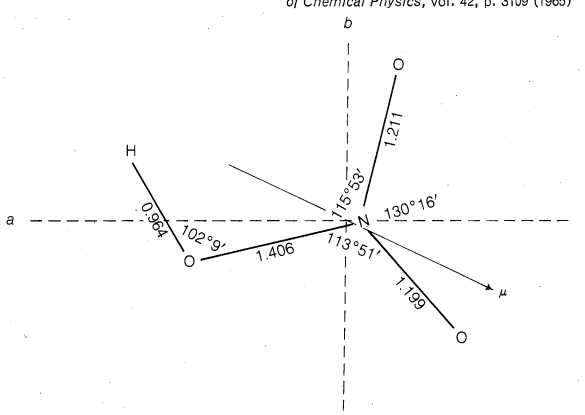

Figure 12: Structure of nitric acid molecule, determined by microwave spectroscopy. Principal axes *a* and *b*, and direction of dipole moment μ are also shown. Interatomic distances are in units of 10^{-8} centimetre (see text).

Quantum mechanics also provides selection rules (*i.e.*, prescribes the energy levels involved) for transitions in this case. If the molecule has a permanent dipole moment, emission or absorption of radiation can occur between adjacent levels; that is, the selection rule is obeyed by a difference in quantum numbers $\Delta J = 1$ for a pure rotational transition. Consequently, the spectrum should consist of a series of lines, equally spaced in frequency ν_J, which follows from the energy equation and selection rule: $h\nu_J = E_{J+1} - E_J = [(J + 1)\ (J + 2) - J\ (J + 1)]\ h^2/8\pi^2I = 2\ (J + 1)\ h^2/8\pi^2I$, in which the term $(J + 1)$ takes on the values 1, 2, 3, etc. This equation means that the transitions have frequency spacings $2h/8\pi^2I$. From a measured frequency of known quantum number J, the moment of inertia, I, for the particular kind of molecule can be obtained. For a diatomic molecule consisting of two nuclei of masses, m_1 and m_2, with internuclear distance r, the moment of inertia expression reduces to the product of the masses times the separation squared, divided by the sum of the masses, or, $I = m_1m_2\ r^2/(m_1 + m_2)$; so that a knowledge of the moment of inertia obtained from spectral measurements leads to a value for the internuclear separation. For nonlinear molecules, molecules having their nuclei arrayed other than in a straight line, the expressions for the rotational energy levels and transitions in terms of the moments of inertia are more complicated, but they have been developed and are widely applied.

Nonlinear molecules

For molecules with more atoms, the structure involves more parameters (internuclear distances) and the information from one microwave spectrum is not sufficient. The internuclear distances of molecules that differ only in that one or more nuclei are replaced by other isotopes are found to change but slightly, however, so that the microwave spectra of a number of such isotopic species can be used in order to provide sufficient information for the complete structure of a simple molecule. Figure 12 shows an example.

Infrared spectroscopy. Infrared radiation has a range of wavelengths from about 8×10^{-4} millimetre (.8 micron) to about 10^{-1} millimetre (100 microns)—*i.e.*, from visible light to microwaves. It is customary to divide the infrared region into near, medium, and far infrared domains. Photography can still be used out to about .0012 millimetre (1.2 microns) wavelength (the near infrared), and various special photoconductive detectors are available for part of the medium region, but at longer wavelengths one must use much less sensitive thermal detectors, such as thermocouples, bolometers, or Golay-cell detectors, all of which use the radiation to produce a temperature rise in some temperature-sensitive element.

Heated objects were the primary sources of infrared radiation before the discovery of lasers. The latter became available in the early 1970s for many specific sharp frequencies (narrow lines), whereas the thermal sources used theretofore gave radiation spread continuously over a broad range of wavelengths.

Present-day infrared spectrometers still use thermal sources, a prism of special material or a diffraction grating to select out narrow ranges of wavelength, mirrors instead of lenses for focussing the radiation, and either photoconducting or thermal detectors. Depending on the wavelength range, prisms and windows may be made of rock salt (sodium chloride), potassium bromide, quartz, or other materials chosen because they are transparent to the desired rays. Glass does not transmit except in the visible and adjacent infrared. The difficulty of finding suitable transparent materials for the remainder of the infrared region explains the use of concave mirrors instead of lenses and also favours the use of gratings over prisms. Grating instruments are commonly used in infrared studies (see *Methods for dispersing spectra*).

A different type of spectrometer than those employing prisms and gratings uses the interferometric principle and has the advantage of large aperture; *i.e.*, it accepts a large cone of light from the source and hence is particularly advantageous in the infrared where sources are weak and detectors are of low sensitivity.

Lasers are highly promising sources, and some spectroscopy is being done with them, but lasers tunable over an adequate range became feasible only in the early 1970s.

The main impact of infrared spectroscopy is probably in the medium region, say from 0.003 millimetre to perhaps 0.025 millimetre (or 3 to 25 microns), because most of the vibration frequencies of not too complicated molecules fall in this range.

The vibrational behaviour of a molecule is quite well simulated by a model consisting of point masses (the atomic nuclei) held together by weightless springs (representing the chemical-valence bonds). These binding forces are really caused by the electrons, which, being many thousands of times lighter than the nuclei, can be treated as approximately massless. If a macroscopic, mechanical model of a molecule made of steel balls (nuclei) and springs (bonds) is vibrated at a slowly increasing frequency, it will display a series of resonances (*i.e.*,

Resonant frequencies

certain frequencies at which the model will respond fairly sharply and vibrate in a particular way) with specific ratios of the amplitudes of motion of the different balls. Each resonance involves a different pattern of motion, these patterns being the normal modes of motion, each with its own frequency (see Figure 13).

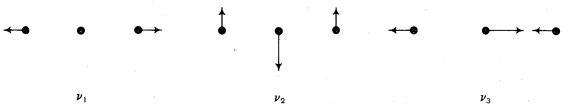

Figure 13: Normal modes of vibration (ν_1, ν_2, ν_3) of the linear molecule carbon dioxide, CO_2. Arrows represent the relative displacements of the three atoms in each of the modes.

Such mechanical models are not actually used, because classical mechanics permits the ready calculation of the frequencies and modes of motion of an idealized model with point masses and weightless springs. A molecule is much closer to this idealization than any achievable mechanical model. Actually, of course, a molecule obeys quantum mechanics and not classical mechanics. Fortunately, the quantum-mechanical results for the molecular model are closely related to the classical ones. Calculations for the infrared spectrum show absorptions only at frequencies equal to certain of the classical resonant frequencies discussed above. The frequencies that can appear are those for which the electrical dipole moment of the molecule changes during the normal mode of motion.

Further refinement of the calculations shows that other frequencies may occur weakly, for example, at twice those of certain classical frequencies. In addition, these infrared absorptions are not extremely sharp and for light gases under high resolution are seen to consist of bands of many sharp lines. This fine structure arises from simultaneous changes in rotational energy.

The infrared spectrum of a molecule is highly characteristic and hence is widely used by chemists to identify substances by comparing the substance to be identified with an authentic sample (see Figure 14). Moreover, it is found that certain groups within the molecule, such as the hydroxyl (OH), lead to the appearance of frequencies that are rather constant from one molecule to another and hence can be used to indicate the presence of the group in the molecule. Other groups that show their own frequencies include carbon–hydrogen (CH), sulfur–hydrogen (SH), double bonded carbon–oxygen C = O, and carbon–carbon double bond C = C. A great deal of empirical information of this nature has been accumulated.

From L. Bellamy, *The Infrared Spectra of Complex Molecules*, 2nd ed. (1958); Barnes & Noble Publishers, New York, and Methuen & Co. Ltd.

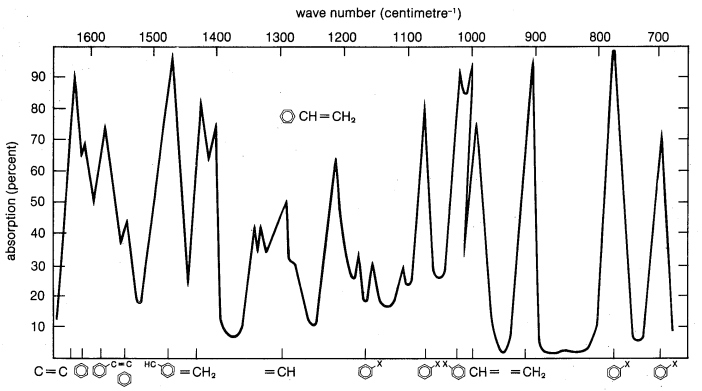

Figure 14: Vibrational infrared spectrum of styrene. The individual peaks are characteristic of the various structural features of the styrene molecule shown along the bottom edge of the figure. The hexagons represent the benzene ring of six carbon atoms present in the structure; X represents the entire group of carbon and hydrogen atoms attached to the benzene ring.

From a more theoretical viewpoint, infrared vibrational frequencies can be used to determine the forces between the atoms within a molecule, and they can also provide information about molecular symmetry.

The rotational fine structure, when observable, provides much the same kind of structural information as does the pure rotational spectra studied in the microwave region. The frequency resolving power in the infrared region is a great deal lower than in the microwave regions at present; on the other hand, nonpolar (uniform-charge distribution) molecules can be studied.

Raman spectroscopy. Raman spectroscopy makes use of the fact that photons can be scattered by molecules (whether in the gaseous, liquid, or solid state), with or without a change in frequency—*i.e.*, loss or gain in energy. Most scattered photons continue on with the same energy; a small percent lose some of their energy to the scattering molecule as additional vibrational or rotational energy; the remainder of the photons gain energy at the expense of the vibrational or rotational energy of the scattering molecule. Because the vibrational energy of a molecule is quantized (as is the rotational energy of a gas molecule), the changes in energy or frequency that occur are limited to a few discrete values. When using photons initially of a single frequency, the scattered radiation contains a small number of discrete frequencies corresponding to energies that have been shifted by rotational or vibrational energy intervals.

Laser beams for Raman scattering

Experimentally, modern Raman spectrometers use a strong monochromatic, visible laser beam to illuminate the sample, which can be quite small. The light scattered, usually at right angles to the incident beam, is passed into a spectrometer (normally of a grating type) that is scanned over the desired spectral range, and the spectral output is detected with a phototube and recorded as a function of frequency and intensity (see Figure 15).

If a Raman line has frequency ν resulting from incident radiation of frequency ν_0, the frequency shift $\nu - \nu_0$ (or $\nu_0 - \nu$ if ν is less than ν_0) is the frequency of a transition, usually vibrational, in the sample. The Raman effect therefore provides information about vibration frequencies, as does infrared spectroscopy. If the scattering molecule has any symmetry, however, the selection rules for the Raman and infrared transitions may differ.

Pure rotational Raman spectra have been observed in gases for small molecules and have provided structural information. For the Raman effect, the molecule can be polar or nonpolar.

Visible and ultraviolet spectra. Coloured substances absorb radiation having frequencies in the visible portion of the spectrum. Thus a solution that looks blue when viewed by transmitted white light does so because the material absorbs yellow light from it. Other materials may be transparent in the visible region but may or may not absorb in the near ultraviolet region. More and more substances show absorption bands as the region considered is moved farther into the ultraviolet.

These particular absorptions are almost always due to the excitation of electrons. As in atoms, the electronic energy in a molecule is quantized, so that certain discrete values are allowed. If the quantum of radiation is energetic enough to remove an electron or an atom from the molecule, however, the resulting system can have any relative translational energy (nonquantized) so that part of the spectrum can show regions of continuous absorption.

An approximate way of describing the behaviour of the electrons in a molecule has been found to be useful, though not exact. Whereas each electron is actually influenced in its motion by the instantaneous position of every other electron, an approximation is made by replacing this complicated interaction by an interaction that has been averaged over the motions of the other electrons. In this way, it is possible to treat the complex problem in a certain sense as if the electrons acted independently of each other. In quantum mechanics, the location of an electron in a molecule is determined by specifying the probability of its presence at any point. Thus a plot of the probability would have the appearance of a cloud. This probability distribution in space of a particular electron in the present approximation is then governed by a single-electron function called a molecular orbital (see CHEMICAL BONDING). For a given molecule there exists a whole set of these molecular orbitals (of various cloud-

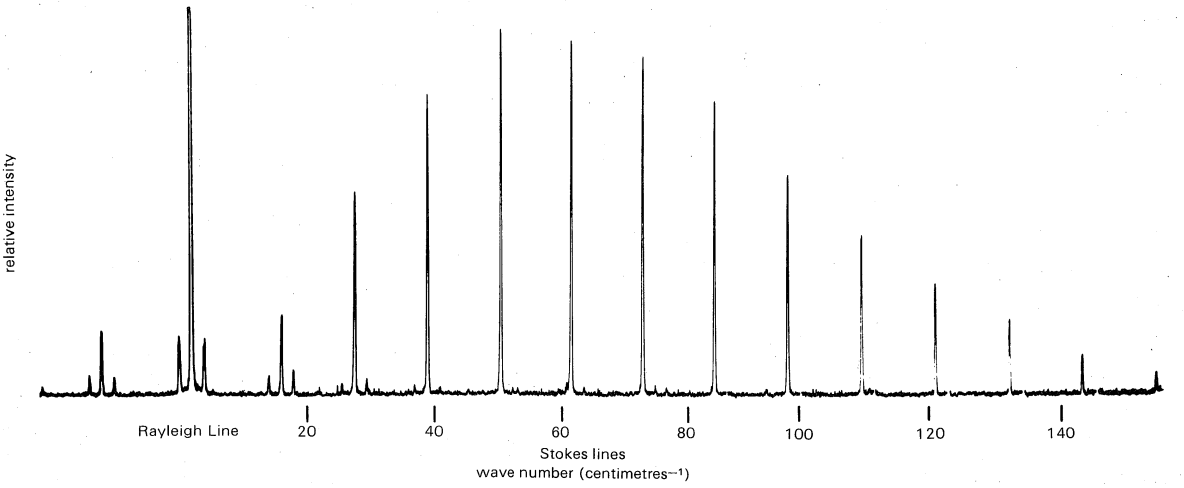

Figure 15: Pure rotational Raman spectrum of gaseous oxygen, O_2. Rayleigh line is light scattered without change of rotational or vibrational energy. Stokes lines involve an increase in rotational energy of the molecules.

like shapes); and for the state of lowest energy for the whole molecule (called the ground state), the electrons are assigned to the molecular orbitals of lowest energy, two at a time. Two electrons can occupy a single molecular orbital if the two electrons have opposite electron spin orientations; the Pauli exclusion principle forbids occupancy of an orbital by more than two. In the simplest form of the theory, the electronic energy is then considered to be twice the sum of the energies of these occupied molecular orbitals.

Besides the filled molecular orbitals, there are others that are not filled when the molecule is in its ground state. A molecule, however, may be raised to an excited electronic state by absorption of radiation or by a collision. The excited states can be approximately described by assigning one or more electrons to previously unfilled molecular orbitals (MO's) of higher energy, leaving a corresponding number of holes among the previously fully occupied lower MO's. The transition of lowest frequency would involve transferring one electron from the highest MO occupied in the ground state to the lowest empty MO. See Figure 16.

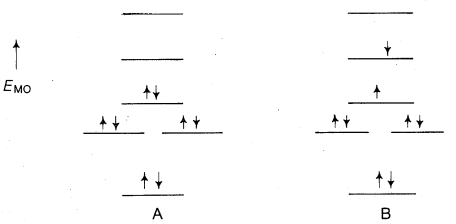

Figure 16: Example of an energy occupancy diagram for molecular orbitals (MO's). (A) For ground electronic state; each lower MO is occupied by a pair of electrons with opposite spins (arrows). (B) For lowest excited singlet state, in which an electron has been excited to a previously empty MO. Vertical position of bars indicates energy, E_{MO}, of individual MO's. Second level shows two MO's of same energy (degeneracy).

This method of labelling and classifying excited states and electronic transitions is of enormous value, but the mathematical approximations related to it do not always give good quantitative results. The missing energy correction, called the correlation energy, arises from the difference between the actual instantaneous repulsions of the electrons and the averaged interaction, and this energy can be large.

Correlation energy

Frequently, the additional approximation is made by describing a molecular orbital as a combination of two or more atomic orbitals from different atoms of the same molecule. The electronic orbitals of lowest energy are usually in fact describable as essentially pure inner-shell atomic orbitals. On the other hand, the highest occupied molecular orbitals, in a covalently bound molecule (each atom contributes one electron to the mutual bond) at least, will involve outer-atomic orbitals of more than one atom. Some of the MO's are largely responsible for the chemical binding energy of the molecule because they have lower energy than the atomic orbitals into which they transform when the atoms separate.

Molecules with simple, covalent electron-pair bonds with all inner-electron orbitals fully occupied tend to be transparent to visible radiation. In other words, there is a fairly large energy gap between the completely filled MO's and the lowest unfilled one.

There are two classes of molecules, on the other hand, that tend to be coloured (*i.e.*, to absorb in the visible region). One class consists of compounds of such transition-group metals as iron, nickel, platinum; that is, those with partially filled atomic orbitals. In many cases, electrons can undergo transitions to low-lying (inner-electron) orbitals of the same shell. (When the probability distributions in space of all the electrons of an atom in the ground state are considered, it is found that the electrons are grouped more or less in shells around the nucleus.) Another class contains molecules for which the simple bonding diagrams are inadequate; but there are several alternate ways of drawing in the lines representing chemical bonds, and the more correct representation (called conjugation or resonance) is a kind of quantum-mechanical superposition of the several bond structures. The two classic Kekule structures of benzene (Figure 17) provide a good example of resonance. The six carbon atoms of the molecule form a closed, six-sided structure that has six-fold symmetry (all sides equal, all angles equal) with all carbon–carbon bonds identical and with properties intermediate between those of double and single bonds. Theory shows that molecules displaying resonance should have low-lying empty MO's and therefore

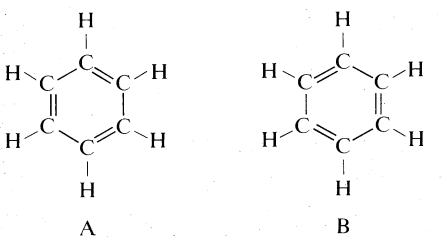

Figure 17: Two classic Kekule structures for benzene, C_6H_6, which show two equivalent ways of drawing alternate single and double bonds between neighbouring pairs of carbon atoms. In the actual molecule all six bonds are equivalent and the bonding is approximately the average of the two Kekule structures.

the possibility of visible or near-ultraviolet absorption bands. Organic dyes are in this category. Sometimes the MO's responsible for absorption are quite localized in part of the molecule. Such groups of atoms are called chromophores.

The fact that an electron is endowed with an intrinsic angular momentum (spin) that can display only two orientations, roughly speaking, in space gives rise to a number of spectroscopically interesting effects. The Pauli exclusion principle requires that if two electrons are in the same molecular (or atomic) orbital, they must have opposite spin orientations, cancelling their spin angular momenta, so that a majority of molecules exist in ground states with the electron spins completely paired. If one of these electrons is excited to another orbital that happens to have a vacancy, the atom or molecule will be excited to one of four energy states, grouped as a singlet state or a triplet level. The singlet state arises when the excited electron and its original partner are antiparallel (that is, have spins in the opposite direction); the triplet level, on the other hand, results when the excited electron and its original partner are parallel, having spins in the same direction. The combined two spins can have any one of three overall orientations, or more correctly, three possible values of the component of spin-angular momentum, versus only two for a single electron spin. There are many orbitals to which an excited electron may be raised, and consequently there exists a series each of singlet and triplet levels; an atom or molecule will thus lose energy by radiation by making transitions either from one singlet state to another singlet state or from one triplet set to another triplet set, transitions between singlet and triplet states being forbidden.

Singlet and triplet states

Many organic molecules, mostly so-called aromatic molecules, absorb in the visible or near ultraviolet and return rapidly to the ground state with the emission of nearly the same frequency as was absorbed. This phenomenon is fluorescence. The efficiency may be quite high; *i.e.*, nearly all the radiation absorbed is rapidly (in about 10^{-8} second) reradiated. Much of fluorescent light is of somewhat lower frequency than that absorbed, because the molecule can return, not only to the lowest state but also to one or another of the excited vibrational levels of the ground electronic state (see Figure 18). In some cases, this phenomenon leads to a fluorescence spectrum with a vibrational pattern that is approximately a mirror image of the pattern of the absorption spectrum.

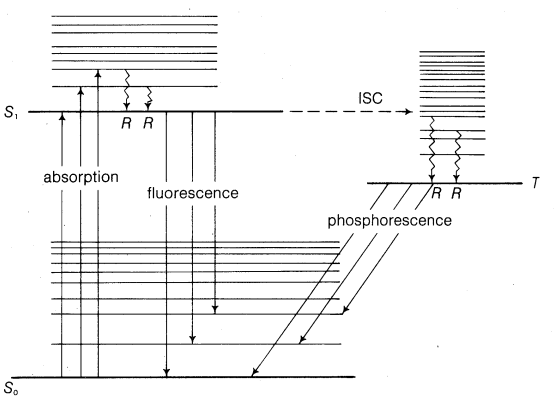

Figure 18: Lower vibrational and electronic energy levels of a complex molecule, showing ground electronic level S_0, the lowest excited singlet electronic state S_1, the lowest triplet electronic level T, plus associated vibrational levels for each. Zigzag arrows R show nonradiative loss of vibrational energy by collisions. ISC represents an intersystem crossing.

With some molecules another process competes with fluorescence. Absorption raises the molecule to an excited singlet state, perhaps with some vibrational excitation also. Collisions cause a rapid loss of vibrational energy but not of electronic energy. The molecule then has a certain probability of intersystem crossing—*i.e.*, of undergoing a transition, without radiation—to a highly excited vibrational state of the triplet manifold. Collisions again remove this vibrational energy, leaving the molecule in the triplet electronic state. From there it can return to the ground state either by radiation—*i.e.*, phosphorescence—or by another intersystem crossing to a high vibrational state of the ground, singlet, electronic manifold, with subsequent loss of vibrational energy. In various molecules, one or another of these pathways is used.

Triplet states generally have much longer lifetimes than singlet states, especially in solid glassy media at low temperatures, because the radiative transition to the ground singlet state is a forbidden one. Its occurrence is explained in terms of certain small interactions, in particular that between the magnetic moments of the electron spin and electronic orbital motion.

These phenomena are of chemical interest, for some compounds undergo different reactions in their excited states depending upon whether they are in the excited-singlet or excited-triplet state. Furthermore, these excitation energies can in suitable circumstances be transferred from one molecule to another, of the same or of different species.

One important application of visible and ultraviolet spectra is to the accurate determination of the energy required to dissociate a diatomic molecule into its constituent atoms. The energy-level pattern for the ground electronic state consists of a sequence of vibrational states, the lower members of which are approximately equally spaced (see equation in section above on quantization of molecular energy). As the vibrational energy is increased, the energy levels are more and more closely spaced and ultimately converge to a limit, which is the maximum vibrational energy possible without actually tearing apart the molecule into two atoms (see Figure 19).

Sequence of vibrational states

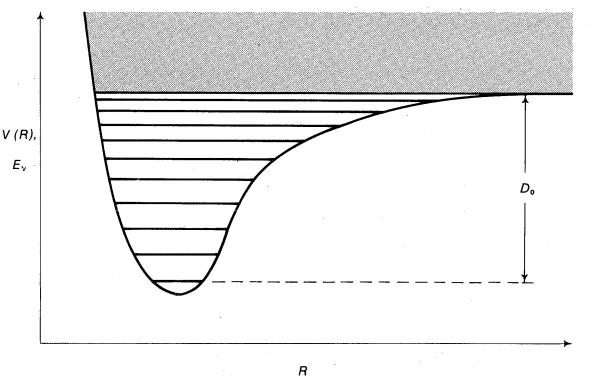

Figure 19: Potential energy function $V(R)$ and vibrational energy levels (E_V) for a diatomic molecule, showing dissociation limit at energy D_0 above lowest vibrational level.

In favourable cases, it is possible to observe an emission spectrum consisting of a series of lines that converges to a limit in the high-frequency direction. These lines are transitions from an excited electronic state to the various vibrational levels of the ground electronic state, as shown in the Figure. Planck's constant (h) times the difference in frequency between that of the limit and that of the transition to the lowest vibrational level is the energy of dissociation (D_0) and can sometimes be obtained with great accuracy. It is naturally necessary to know the states of the resulting atoms, because they need not be in their lowest states.

Electron spectroscopy. In most forms of spectroscopy, the fractions of the radiation for various wavelengths absorbed by the sample are measured. These data are then often used to determine the energy levels of the matter. There are other ways, however, of obtaining the same or similar information. In one of these, monochromatic radiation of quite high energy—in the X-ray or ultraviolet regions—is passed into the matter. Because of its high energy, it can cause the complete removal of an electron from the irradiated molecule, leaving the latter in the form of a positive ion (*i.e.*, an electrically charged molecule). The ejected electron will carry away as kinetic energy the excess energy, and this kinetic energy can then

be rather accurately measured by recently improved instruments. For example, Planck's constant (h) times the frequency (ν_0) of the incident photon is its energy ($h\nu_0$); if E_{elec} is the kinetic energy of the ejected electron, then the energy of the resulting ion, relative to the initial state of the neutral molecule, is equal to their differences, or $E_{ion} = h\nu_0 - E_{elec}$, by conservation of energy. In a typical experiment to determine an ionization energy, a gas may be irradiated by the 585-angstrom line of a helium discharge and the velocities of the electrons measured to give E_{elec}. Normally there will be several peaks in a curve plotted to show numbers of electrons versus energies. Each peak will represent one quantum state of the ion (provided that all the molecules were initially in their lowest energy level). Consequently, this method provides information about the states of the ion.

The ionic states can be approximately described in terms of the molecular orbital, now empty, from which the electron came. With ultraviolet excitation only outer electrons can be removed.

With X-ray excitation, electrons from the inner atomic shells (K or L electrons) can be ejected. The energies of these electrons are primarily characteristic of the particular atom involved; but there are small shifts from one molecule to another molecule, especially for molecules in which the chemical binding or environment of the particular atom differs markedly. These electron spectra (giving E_{elec} in the above equation) are therefore of use in identifying the atoms present and in obtaining some information about their environment. These two versions of electron spectroscopy were in the development stage in the 1970s, but these versions appeared likely to become quite important.

Related to electron spectroscopy are various experiments in which energy levels and other types of information are obtained by collisions between the molecule of interest and beams of electrons, neutrons, ions, or other particles. Various quantities can be measured, such as the energy loss of the stream of particles, or the angular and velocity dependence of this loss. One advantage of some of these collisional techniques is that they can sometimes detect transitions forbidden in optical spectroscopy, so that energy levels that are difficult to locate by conventional methods can be found.

Forbidden transitions

Molecular-beam spectroscopy. In the long-wavelength regions, the minimal width of a spectral line, and hence the achievable resolving power, is often limited by collisions between molecules, or between molecules and a wall of the container, or by the effect of the motion of the molecules along the direction of propagation of the radiation (Doppler effect). All of these effects can be largely eliminated by examining the molecules in the form of a narrow stream moving through an evacuated chamber in a direction at right angles to the direction of propagation of the radiation. Such a stream is called a molecular beam and can be produced by allowing a gas to flow through a small opening into an evacuated vessel.

In principle, extremely narrow spectral lines are thereby made possible, but the difficulty is that there are so few molecules in the path of the radiation that it is difficult to detect the absorption. A physicist, Isidor Rabi of the United States, solved this problem by reversing the usual procedure; instead of measuring the photons absorbed from the radiation beam by the molecules, he devised a scheme for measuring the number of molecules that have absorbed or emitted a photon. Figure 20 is a schematic diagram of a typical molecular-beam spectrometer, showing a source, s, from which the beam of molecules (or atoms) issues and a device, D_1, that deflects molecules in different quantum states by different amounts so that only those in one state (or sometimes one group of states) passes through the slit, S_2 into the central region. In this region, the molecules are exposed to radiation, the frequency of which can be varied; usually in the same region there is a constant magnetic or electric field as well. The beam then enters a second state selector, D_2, that passes on to the detector, d, only those molecules still in the quantum state selected by D_1. In operation, the radiation frequency is varied until its energy, $h\nu$, is

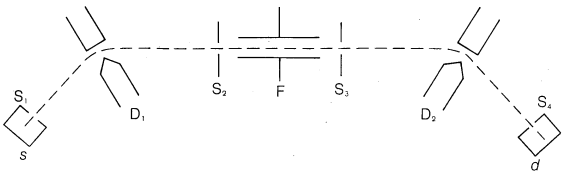

Figure 20: *Molecular beam spectrometer.*
Beam molecules (dashed line) originate in source s; S_1, S_2, S_3, S_4 are slits; D_1 and D_2 produce an inhomogeneous magnetic or electric field, which deflects molecules in different states by different amounts; F is the central region where molecules are subjected to oscillating electrical and magnetic fields; d is the molecule detector. Molecules that undergo a transition in F do not reach the detector.

equal to the energy transition (up or down) from the selected state of the molecules to some other state. If a transition to this other state is allowed, some of the molecules will then absorb or emit energy and thus be changed from their original state. Such molecules will not pass through the second state selector, D_2. The detector output will therefore show a minimum at this resonance frequency.

The heart of the device is clearly the state selectors D_1 and D_2. Several varieties are available. Small polar molecules, especially diatomic molecules, can often be separated according to their rotation–space orientation quantum numbers by an inhomogeneous (nonuniform) electric field. Molecules having sufficient rotational magnetic moments, even if they have no electrical dipole moment, may sometimes be state selected by an inhomogeneous magnetic field.

This method has been mostly used to observe transitions between different space-quantized states of the same rotational–vibrational level split apart in energy by an electrical or magnetic field, but transitions between different rotational states are also observed. The main application of the molecular-beam technique is to the study of hyperfine structures of transitions arising from tiny effects, such as interaction of the magnetic moments of nuclei with the magnetic moments generated by molecular rotation.

The molecular-beam method has been used to measure molecular electric dipole moments with great accuracy so that the small changes that occur from one vibrational state to another are easily measurable. These quantities are useful for testing theories of chemical binding. For example, a reasonably satisfactory and quite simple model for highly ionic molecules such as sodium chloride (in the vapour phase at high temperatures) attributes the chemical bond to the attraction of the oppositely charged ions balanced by the repulsion resulting from the interpenetration of the electron clouds of the ions. This picture can be made quantitative in a way that accounts for much molecular-beam data on ionic molecules.

Test of binding theories

Double and multiple photon effects. The interaction between matter and an electromagnetic field of radiation can usually be treated as a small effect that causes the matter to undergo occasional transitions with the absorption (or emission) of a single photon. With stronger radiation fields, however, transitions from one energy level to another can occur with the involvement of two (or even more) photons. Two photons can be absorbed simultaneously by the same molecule or one may be absorbed and one of a different frequency emitted (as in the Raman effect). Double photon absorption permits two different types of spectroscopy to be combined. For example, there can be simultaneous absorption of an infrared and a microwave photon. The development of lasers has provided sources of infrared and visible radiation strong enough to make these multiple-photon effects readily observable.

These various phenomena have extended the range of techniques available to the spectroscopist and have been most useful, therefore, for assisting in the analysis of complex spectra.

This brief discussion necessarily omits many topics, such as Mössbauer spectroscopy (see MOSSBAUER EFFECT), the effects of electric and magnetic fields, and

information obtainable from intensities and line widths. Molecular spectroscopy is a broad and growing field, continually developing new techniques and new capabilities for obtaining valuable information about molecules.

(E.B.W.)

IV. X-ray spectroscopy

Discovery of X-rays

A penetrating, electrically uncharged radiation was discovered in 1895 by a German physicist, Wilhelm Conrad Röntgen, and named X-radiation because its origin was unknown. This radiation was produced when electrons (cathode rays) struck glass or metal surfaces in high-voltage evacuated tubes, and was detected by the fluorescent glow of coated screens and by the exposure of photographic plates and films. The medical applications of this radiation that penetrated flesh more easily than bone were recognized immediately, and X-rays were in medical use in Vienna within three months of their discovery.

Initially, vain attempts were made to deflect the rays by means of electric and magnetic fields, on the assumption that they were composed of charged particles. Classical mechanics of the day showed that charged particles, such as cathode rays in an X-ray tube, when decelerated quickly from high to low speed in their collision with matter, should give off electromagnetic radiation (bremsstrahlung, or braking radiation), which in turn should show a wave character. Tests made to show the wave character of X-rays by diffraction were inconclusive, however, indicating that the wavelengths must be shorter than about 1×10^{-10} metre if X-rays were indeed waves. The first clear demonstrations of the wave nature of X-rays were provided in 1912 when X-rays were diffracted by the closely spaced atomic planes in a crystal of zinc blende (zinc sulfide). Because the details of the diffraction patterns depended upon the wavelength of radiation, these experiments set the stage for the spectroscopy of X-rays. The first spectrographs for this radiation were devised in 1912–13 by two British physicists—father and son—William Henry and Lawrence Bragg, who showed that not only did there exist continuum X-ray spectra, to be expected from processes involving the stopping of charged particles, but also discrete characteristic spectra, indicating that the details of atomic structure determine some X-ray properties (see Figure 2). The systematic increase of characteristic X-ray energies with atomic number was shown by Moseley in 1913 to be explainable on the basis of the Bohr theory of atomic structure.

Wavelengths for X-rays range from about 0.05 angstrom to 100 angstroms, with the range 10–100Å, known as soft X-rays, overlapping the far ultraviolet. A convenient unit of wavelength is the X-unit or X.U., defined so that approximately 1,000 X.U. = 1Å (the actual value is 1,000 X.U. = 1.00203 Å). The X-ray wavelength range is then approximately 50–100,000 X-units.

Relation to atomic structure. Short wavelength radiation can be produced by isolated atoms and ions by two related processes. If two or more electrons are removed from an atom, the remaining outer electrons are more tightly bound to the nucleus by its unbalanced charge, and transitions of these electrons from one level to another can result in photon wavelengths of 100 angstroms or less. The resulting spectra can be observed in spark sources. An alternate process occurs when in a neutral atom an electron is removed from an inner shell. This removal can be accomplished by bombarding the atom with electrons, protons, or other particles at sufficiently high energy and also by irradiation of the atom by sufficiently energetic X-rays. Almost immediately, the remaining electrons in the atom readjust, making transitions to fill the "hole" left by the removed electron, and X-rays are given off in these transitions. The latter process occurs in an ordinary X-ray tube, and the resultant X-ray lines, the characteristic spectrum, is superimposed on a spectrum of continuous radiation resulting from decelerated electrons.

The shells in an atom, labelled by $n = 1, 2, 3, 4, 5$, by the optical spectroscopist, are labelled *K, L, M, N, O,* . . . by the X-ray spectroscopist.

In many ways the vacancy, or "hole," remaining when an electron is removed from one of these shells, behaves as a positively charged electron; *e.g.*, if after an electron is removed from the *K* shell of an atom, an *L*-shell electron makes a transition to the *K* shell, the net result is the transfer of a single "hole" from the *K* to the *L* shell. The possible energies of such a vacancy thus can be labelled by the hydrogenic quantum numbers, *n, l, j, m*; because the production of a vacancy is equivalent to cancelling the negative charge at a region within the atom (*i.e.*, adding positive charge there), however, the energy of a vacancy is highest at the *K* shell, lowest in the outermost shell, and X-ray energy levels by convention are inverted compared to those of atoms having single outer electrons.

Inverted energy levels

Within a shell, there are some differences in vacancy energy according to whether or not an *s, p, d,* etc., electron has been removed and according to the total angular momentum of the electrons. The subshells are labelled by Roman numerals according to their energies. Figure 21 shows an X-ray energy-level diagram for uranium (*Z*, atomic number 92), including the allowed transitions.

From F.K. Richtmyer and E.H. Kennard, *Introduction to Modern Physics*, copyright (1947); used with permission of McGraw-Hill Book Company

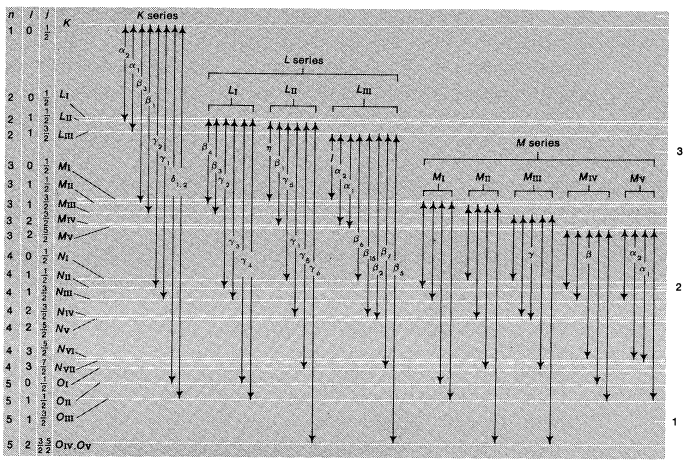

Figure 21: X-ray levels in uranium, showing transitions allowed by the selection rules $\Delta l = \pm 1$, and $\Delta j = \pm 1,0$. The ordinate scale is logarithmic. Since an X-ray level occurs when there is vacancy rather than an electron in a shell, the levels are inverted relative to hydrogenic levels.

If the continuous spectrum from an X-ray tube is passed through a pure absorbing material, it is found that the absorption coefficient changes suddenly at X-ray wavelengths corresponding to the *K, L, M,* etc., shell energies. The sudden increases of absorption coefficients (or absorption) as the wavelength is reduced past these shell energies are called absorption edges and serve as useful reference wavelengths that can be precisely determined (see Figure 2). Wavelengths of absorption edges range from 247.92 angstroms for the L_{II} edge in magnesium to below 0.1 angstrom for the *K* edges of elements heavier than plutonium ($Z \geq 94$).

The X-ray fluorescence radiation of materials is of considerable practical interest. Atoms irradiated by X-rays having sufficient energies, which may consist of either characteristic or continuous rays or both, lose electrons and as a result emit X-rays characteristic of their own structures. Such sources are weak; they have, however, an advantage over primary sources, such as X-ray tubes, in that there is little or no background caused by bremsstrahlung; the emitted spectrum is then nearly a pure-line spectrum. Such methods are used in the analyses of mixtures of unknown composition.

Production methods. An X-ray tube consists of a source of electrons (usually a heated filament) and a massive anode, mounted within an evacuated chamber or envelope (see Figure 3). A potential difference of 10–100 kilovolts is maintained between cathode (the negative electrode) and anode (the positive electrode), and typical power inputs range from 100 to several thousand watts. At the higher power levels, it is often necessary to cool the anode with circulating fluid. The anode materi-

al of an X-ray tube determines the range of wavelength for the discrete spectra, with the shortest discrete wavelengths produced by materials having highest atomic number. Bremsstrahlung, the continuous part of an X-ray spectrum, extends to a minimum wavelength (λ_0). It is found that this wavelength diminishes as the accelerating potential (V) is increased across the X-ray tube; in fact, the minimum wavelength and X-ray voltage are related by the Duane-Hunt law stating that electronic charge times voltage is equal to Planck's constant times speed of light divided by minimum wavelength—*i.e.*, $eV = hc/\lambda_0$.

If the X-ray fluorescence spectrum of some element is desired, a sample of the element is placed near the anode, usually outside the window of the tube where it is accessible. The potential voltage, of course, must be sufficiently high to release electrons from an inner shell (*e.g.*, at least 70 kilovolts to produce the characteristic K lines of tungsten). Baffles are placed in and around the tube to reduce the amount of primary radiation escaping from the tube other than through the exit window. Great care must always be taken in the operation of X-ray machines to avoid excessive exposure of any part of the body to the radiation.

Analysis. In the soft (10–100 angstroms) X-ray-wavelength region, it is possible to use grating spectrometers for analyzing spectra. Optical materials do not transmit radiation in this wavelength range, and they reflect this radiation inefficiently. It is necessary to use gratings at grazing incidence; that is, with the incident and reflected radiation moving nearly parallel to the grating.

Use of crystal spectrometers

For shorter wavelengths, crystal spectrometers are used. X-ray radiation falling on a set of geometrically aligned atoms is diffracted only in certain directions set by the requirement of constructive interference. A crystal spectrometer consists typically of an entrance slit, a bent crystal, and a detector, in a geometrical arrangement similar to that of a concave grating spectrometer. In such an instrument, the so-called bent crystal is a crystal of mica, quartz, germanium, or gold a few square centimetres in area and a millimetre or so thick, curved to a radius of a metre or more. The lattice spacing for the crystal is accurately known, and the observed angles of diffraction are used to measure and identify the wavelengths entering the spectrometer.

A source of X-rays of known wavelength can also be used to find the lattice spacing, crystal orientation, and crystal structure of an unknown crystalline material. The crystalline material is placed in a well-collimated beam of X-rays, and the angles of diffraction are recorded as a series of spots on photographic film. This method, known as the Laue method after a German physicist, Max Theodor Felix von Laue, is effective for studying crystals having dimensions of the order of a millimetre (0.04 inch) or larger. If microcrystalline materials (powdered crystals) are placed in the X-ray beam (Debye–Scherrer method, after Peter Debye and Paul Scherrer, chemists in Holland), the pattern observed is a series of concentric rings the diameters and intensities of which depend upon the lattice spacings of the crystal and its structure.

X-ray detectors. The most universally used detectors for X-ray spectroscopy are photographic plates and films and semiconductors (crystals that become conductive when irradiated).

For electrical recording of X-ray intensities, scintillators and ionization chambers are often used. A scintillator is a material that emits light when X-rays are absorbed. It is used in conjunction with a photomultiplier to provide an electrical signal, the intensity of which is proportional to the X-ray flux. An ionization chamber contains a positive and a negative electrode; when an X-ray photon enters the chamber through a thin window, it ionizes the gas inside and an ion current flows in the electrical circuit connected to the electrodes. The window is often beryllium, chosen for mechanical strength and relative transparency to X-rays. The gas is chosen to absorb strongly (*i.e.*, it gives a copious supply of ions) in the desired wavelength region. With increased voltage on the electrodes, the ionization chamber becomes a proportional counter, which gives out an amplified electrical pulse when an X-ray photon is absorbed within it. At still higher voltages, absorption of an X-ray photon with consequent ionization of many atoms in the gas initiates a discharge breakdown of the gas and causes a large electrical pulse output. This device is known as a Geiger–Müller tube (after two German physicists, Klaus Wilhelm Geiger, and Alex Müller) and forms the basis for radiation detectors known as Geiger counters.

Semiconductors

Semiconductor analyzer–detector combinations have replaced many of the other detectors. A semiconductor can serve as a detector because an X-ray photon passing through it creates electron-hole pairs, allowing charge to flow in the circuit attached to the semiconductor junction. The amount of charge can be proportional to the photon energy if the entire energy is absorbed in the junction; thus this device serves both as an energy analyzer and a detector of lines in an X-ray spectrum. Connected to a multichannel analyzer, the combination can record the number of photons per unit of energy and display them as a curve. In more sophisticated equipment, these data are automatically fed into a computer for analysis.

Applications. X-ray fluorescence and location of absorption edges can be used to identify quantitatively the elements present in animal tissues, paint, industrial chemicals, and many other substances. Emission of X-rays from high-temperature laboratory plasmas (a fourth state of matter, consisting of almost equal numbers of fast-moving particles of negative and positive charges) is used to probe the conditions within them. In the temperature range 10^{6}° K to 10^{7}° K, plasmas emit X-rays strongly; X-ray spectral measurements show both composition and temperature of a source. Similar measurements have been made on astronomical sources, such as the Sun. Because X-rays are absorbed by the Earth's atmosphere, such measurements are made above the atmosphere by apparatus carried by balloons, rockets, or satellites (see X-RAYS).

V. Radio-frequency spectra

The energy states of atoms, ions, molecules, and other particles are determined mostly by the mutual attraction of the electrons and the nucleus and by the mutual repulsion of the electrons. Electrons and nuclei have magnetic properties in addition to these electrostatic properties. The spin–orbit interaction has been discussed in the section on hydrogen-atom states. Other (usually weaker) magnetic interactions within the atom exist between the magnetic moments of different electrons and between the magnetic moment of each electron and the orbital motions of others. Separations between levels having different energies because of these magnetic interactions vary from less than 10^{8} hertz to greater than 10^{13} hertz, being generally greater for heavy atoms.

Origins. Nuclei of atoms often have intrinsic angular momentum, or nuclear spin, and magnetic moments because of the motions and intrinsic magnetic moments of their constituents; the interactions of nuclei with the magnetic fields of the circulating electrons change slightly the energies of the states in the atom. As a result, an atomic level that consists of several states having the same energy when the nucleus is nonmagnetic may be split into several closely spaced levels when the nucleus is one that has a magnetic moment. The levels will have different energies depending on the relative orientation of the nucleus and the magnetic field produced by the surrounding electrons. This additional structure of an atom's levels or of spectral lines caused by the magnetic properties of its nucleus is called magnetic hyperfine structure. The nuclear angular momentum is added to the orbital and electron-spin angular momenta to give the total angular momentum (F), the magnitude of which is $\sqrt{F(F+1)}\,(h/2\pi)$, in which h is Planck's constant, and the projection of which along the magnetic-field direction is $m_F h/2\pi$ in analogy with the quantum numbers J and m_J. Separations between levels differing only in the relative orientation of the magnetic field of the nucleus and electron range typically from 10^{6} hertz to 10^{10} hertz.

Hyperfine structure

Because of the motions and the intrinsic magnetic moments of its constituent electrons, an atom generally has a

total magnetic moment. The atom then has different energies when aligned in different ways in an applied magnetic field (Zeeman effect).

Atoms, ions, and molecules can make transitions from one state to another state that differ in energy because of one or more of these magnetic effects. Molecules also undergo transitions between rotational and vibrational states. Such transitions can be either spontaneous or can be induced by the application of appropriate external electric or magnetic fields at resonant frequencies. Transitions also can occur in atoms, molecules, and ions between high-lying electronic states near the ionization limit. The resulting spectra are known as radio-frequency (rf) spectra, or microwave spectra; they are observed typically in the frequency range from 10^6 to 10^{11} hertz.

The spontaneous-transition rate as an atom goes from an excited level to a lower one varies roughly as the cube of the frequency of the transition. Thus radio-frequency and microwave transitions occur spontaneously much less rapidly than do transitions at visible and ultraviolet frequencies. Because of this, most radio-frequency and microwave spectroscopy is done by forcing a sample of atoms to absorb radiation instead of waiting for it to emit radiation. These methods are facilitated by the availability of powerful electronic oscillators throughout this frequency range. The principal exception occurs in the field of radio astronomy; there emission spectra of astronomical sources, (*e.g.*, stars, galaxies, nebulae) are collected by large antennas and are amplified and detected by cooled, low-noise electronic devices.

Methods. The first measurements of the absorption spectra of molecules for the purpose of finding magnetic moments were made in 1940 by Rabi and his collaborators, using molecular and atomic beams (see above *Molecular-beam spectroscopy*). A beam focussed by magnets when no radio-frequency field was present was defocussed and lost when a frequency corresponding to one of the atomic absorption frequencies was applied to the coil, resulting in the atoms making transitions to other states. A spectrum then comprised a graph of the number of atoms coming through the magnets versus the frequency applied to the coil; the number of dips in this curve and the frequencies at which they occurred could be used to find the magnetic moment and angular momentum of the nucleus of the atom under investigation.

One of the most famous laboratory experiments with radio-frequency spectra was performed by two physicists, Willis E. Lamb, Jr. and Robert Curtis Retherford of the United States, in 1947. Their experiment involved a measurement of the energy difference between two almost-coincident levels in hydrogen, designated as $2^2S_{1/2}$ and $2^2P_{1/2}$. Although optical measurements had indicated that these levels might differ in energy, the measurements were difficult and were open to alternative interpretations. Atomic theory suggested that those levels should have exactly the same energy. Lamb and Retherford showed that hydrogen atoms in the $2^2S_{1/2}$ level would undergo a transition to the $2^2P_{1/2}$ level when subjected to radiation at about 1,058 megahertz; hence the levels did not have the same energy and the theory was incomplete. This energy separation in hydrogen (corresponding to a frequency of about 1,058 megahertz) is now known as the Lamb shift.

Radio-frequency measurements of intervals in ground levels and excited levels of atoms can be made by placing a sample of atoms (usually a vapour in a glass cell) within the coil of an oscillator and tuning the oscillator until a change is seen in the absorption of energy from the oscillator by the atoms. An alternative method is known as optical double resonance; here optical radiation corresponding to a transition in the atom of interest is passed through the cell and its intensity is monitored. If radio-frequency radiation is absorbed by the atoms in either of the levels involved, the intensity, polarization, or direction of reradiation of the absorbed light may be changed. In this way a sensitive optical measurement indicates whether or not a radio-frequency interval in the atom matches the frequency applied by the oscillator.

Optical double resonance

The operation of a maser (a type of microwave amplifier) depends upon the production of more atoms in the upper of two atomic levels separated by typically several hundred to several thousand megahertz. If such atoms are fed into a cavity that is tuned to the transition frequency, the atoms give off their excess energy to set up an oscillation in the cavity. Thus an oscillator is formed that resonates at the atomic frequency; this frequency can often be measured with extraordinary precision and can serve as a standard for time interval, called an atomic clock. The primary standard of time in the metric system is based on such an oscillator, which uses cesium vapour and oscillates at 9,192, 631, 770 hertz.

In those atoms in which the nucleus has a magnetic moment, the energies of the electrons depend slightly upon the orientation of the nucleus relative to the magnetic field produced by the electrons at the centre of the atom. The magnetic field at the nucleus depends somewhat upon the environment in which the atom is found, which in turn depends upon the atoms nearby. Thus the radio-frequency spectrum of a substance indicates both the constituents and the forms of chemical binding in the substance. Spectra resulting when the nucleus changes orientation are known as nuclear magnetic-resonance spectra, or NMR spectra, and are of considerable utility in identification of organic compounds (see MAGNETIC RESONANCE).

Radio-frequency transitions have been observed in astronomy in the frequency range from about 400 megahertz to about 9,000 megahertz (.75- to .033-metre wavelength). The earliest observation was of the 21-centimetre (1,420-megahertz) transition that occurs in the ground level of hydrogen as the proton spontaneously flips its spin direction relative to the electron from parallel ($F = 1$ states) to antiparallel ($F = 0$ states). Observations on this transition have provided much information about the temperature and density of hydrogen in the Earth's galaxy. Observation of the hydroxyl OH emission at 1,665 megahertz and other frequencies and of water emission at 2,220 megahertz indicates chemical composition and temperature for the regions in which they are observed. Transitions have been observed for which hydrogen atoms go from principal quantum numbers as high as n from 253 to 252, down to a transition as low as n from 91 to 90. Such atoms are presumably formed when protons capture electrons in large orbits; the spectra yield details of the local temperature and electric and magnetic fields. Lines caused by helium and possibly carbon have also been observed.

VI. Spectral analyses

The simplest method of analysis involves observation of a spectrum through a spectroscope. The advantages of this method are flexibility and speed; quantitative properties of a spectrum can be followed easily. Such observations, limited to the visible region, are useful for checking light sources for the presence of major constituents, because prominent, easily recognized lines or patterns can be found in the arc spectra of most elements. The transmitted spectrum of a solution can indicate the presence or absence of chemical substances.

ANALYSES OF PHOTOGRAPHIC DATA

Two principal classes of experiments in which photographic recording has found wide use are composition analysis and studies of the structure of atoms and ions.

In the simplest form of composition analysis, the spectrum of a source, consisting of a direct-current electric arc between two electrodes, is recorded and compared to spectra of pure elements by direct superposition. If the spectrograph possesses sufficiently high resolving power, the presence of an element in the source is indicated by coinciding lines on the two spectrograms. When quantitative determination is important, relative intensities may be compared. To do this, measured quantities of the sample the composition of which is being investigated may be mixed in several ratios with much larger quantities of graphite, copper, or other carrier material (called a matrix), and placed one at a time in the tip of the graphite or copper negative electrode of the arc. Several spectra of

Composition analysis

the sample material are thus obtained, in each of which one such electrode and a pure positive electrode (not of the element under observation) are used for the source. Comparison-arc spectra, each taken with the negative electrode of graphite or copper containing a small known amount of a pure element, are then compared with the spectra of the unknown material. If the operating characteristics of each of the arcs and of the spectrometer are maintained constant, and care is taken that all of the photographic films or plates are processed in the same way, it is possible to determine approximate amounts of many elements in concentrations ranging from greater than 50 percent down to a few parts per million.

As the admixture of any element in an arc is reduced, the weaker lines in its spectrum disappear first. The last lines to disappear are the most sensitive indicators of the presence of that element and are known as the persistent lines of the element.

If comparison spectra are not readily available for the element the presence of which is being investigated, it may be necessary for the investigator to measure wavelengths in the spectrum of the unknown material and compare these wavelengths with those tabulated for the suspected element. In order to facilitate measurement of wavelengths, a known reference spectrum (*e.g.*, that of iron) is usually exposed onto the same film without changing the spectrometer setting so that the known and unknown spectra are superimposed; wavelengths in the unknown spectrum are then calculated by interpolation between lines in the reference spectrum.

Study of the structure of a given atom or ion by means of its spectrum proceeds in a different manner. In such cases, it is necessary to make accurate measurements of wavelengths over as great a range as can be obtained. Reference wavelengths are again included on the photographic record of the spectrum of interest; if the greatest accuracy is desired, the reference wavelengths must have been measured in terms of the fundamental standard of length, the line of krypton-86 at about 6,057 angstroms, in terms of which the metre is defined. Determination of wavelengths in the spectrum of the atom of interest is again accomplished by interpolation between known reference lines, correcting where necessary for nonlinearity of the spectrograph.

After the wavelengths have been obtained, their wave numbers, proportional to the photon energies emitted by the atom, are calculated with correction for the index of refraction of air. Next, all sums and differences of wave numbers are calculated, and from recurring values of these quantities, relative positions of energy levels within the atom can be obtained. The levels are then classified according to their probable quantum numbers with the help of comparisons with isoelectronic spectra (atoms with the same number of electrons outside the last closed shell have similar spectra), application of selection rules, and study of the Zeeman effect in the spectrum.

For an element such as a rare earth or actinide, which may have a complex spectrum involving many thousands of lines, much of the analysis is automated. The photographic plate with its line spectrum is placed in a microdensitometer, which takes successive reading of the line positions across the plate and feeds these numbers directly into a digital computer. The numerical manipulations required for the analysis are then carried out electronically.

ANALYSES WITH SCANNED SPECTRA

The development of scanning spectrometers that use linear-response photoelectric detectors has revolutionized the study of details in the structures of spectral lines from laboratory and astrophysical sources. For example, changes amounting to only a few percent in the intensity of the Fraunhofer *D* lines, caused by the presence of sodium in the Earth's atmosphere, can be detected photoelectrically without difficulty but are difficult to observe photographically because of the nonlinear response of the photographic process. Changes of several percent in the widths (the measure of the spread in wavelength) of spectral lines from plasma sources can be followed if photoelectric detectors are used but not with photographic detectors; such changes may show changes in pressure or free-electron density within the discharge. In cases where two spectral lines overlap or blend, careful numerical analysis of data obtained by a photoelectric detector can often permit identification of positions and relative intensities of both lines; this analysis is far more difficult to do if the lines are recorded photographically and data are obtained by a microdensitometer.

Spectral widths

The quantum efficiency, the ratio of the number of incident photons to the number of recorded bits of information, can approach unity for photomultiplier detectors in the ultraviolet and visible regions, but the corresponding efficiency for photographic detectors is only about one part in 1,000; hence measurements with photoelectric detection are possible at lower light levels than with photographic detection. This sensitivity has made possible the recording of spectra from sources that send less than one photon per second into the spectrometer. Examples of studies in which low light levels are the rule include analyses of positions and profiles (*i.e.*, intensity changes across line widths) of spectral lines in weak discharges in a lamp at low temperatures to identify the details of processes leading to excitation, study of the spectra of fast ion beams excited by collisions with gases or thin foils, and high-resolution studies of absorption spectra of planetary atmospheres to identify their constituents.

In the production of a spark or in the initiation of a glow discharge, the effective temperature of the gas, the amount of ionization, and the relative excitations of different atomic levels change significantly within times of the order of microseconds. The details of such variations can be followed by photomultiplier detectors; in fact, photomultiplier detectors can be designed to follow changes occurring in less than a nanosecond (1×10^{-9} second). Time-resolved spectroscopy of sources is accomplished by arranging an electronic switch to operate the source repetitively, perhaps at line frequency of 50–60 times per second. A second switch, triggered by the first, sensitizes the detector photomultiplier for a brief interval at the desired time after the excitation pulses. The signals recorded by this photomultiplier depend on the spectrum only at that particular time after excitation. (J.O.S.Jr.)

Speech, Physiology of

Communication, though it may be defined in many ways, is, in essence, the transmission of information, questions, and intentions among creatures; in human communication the message includes thoughts and abstract ideas. Human communication by language emerged as man evolved from the other primates. Most animals communicate by acoustical, optical, and tactile means of transmission. Thus, most mammals have a laryngeal voice (from vocal cords); many lower vertebrates use simpler forms of respiratory generation of sound waves; and various insects possess some sound-generating apparatus on their legs, wings, or body to produce audible vibrations in the manner of crickets, cicadas, and grasshoppers.

Animal communication. Animal communication systems vary greatly in the complexity of the codes used in transmission and thus in the amount of information that can be processed at one time. Stridulating insects have but a small repertory of stereotyped sounds that vary only in rhythmical pattern. With evolution, the number of vocal patterns increases. The chicken produces a number of cries, each expressing a specific message: the cock's crow, the announcement that an egg has just been laid, the incessant clucking of the mother hen to keep the chicks together, the subdued warning that a preying bird has been sighted, the excited shrieks when the corn basket shows up, the contented cooing while resting in warm sand. All these vocal patterns are directed by chemical (hormonal) influences within the chicken's body; the rooster, for example, loses his crow after castration. The considerable variability of vocalization is well known among cats and dogs. Anger and joy, fear and fury, hunger and satiation, submission and aggression, rejection and welcome, and the love calls in particular are species specific, but they also remain stereotyped. Animals cannot learn calls beyond their inherited potentials. Each call is controlled by specific brain mechanisms under the influence of various hormones regulated by the pituitary gland and the brain. All of the systems of audible communication presuppose some kind of receiving organ; *e.g.*, the mammalian ear.

Human communication. While many animals possess voices of various types and inflections, man has learned to modulate his voice by articulating the laryngeal tone into audible oral speech. The terms speech and voice are by no means interchangeable: voice is the result of laryngeal sound production (phonation); speech is the superposition of oral and nasal resonances through movement of the oral articulators (see Figure 1). Articulation in itself is meaningless, until the conventional codes of a language have been learned, ordinarily first from the mother, then from other family members, and finally in school. "Sick," for example, means "ill" in English, while *sic* means "so" or "thus" in Latin. The difference between speech and language is one of application. Speech is the oral, audible expression of human language while talking. Writing and reading represent the use of human language through graphic symbols. The Morse code, naval flag signals, smoke signals of American Indians, African drum languages, and the almost extinct whistle language of the Pyrenees are all examples of special language usage without the need for oral speech. Each of these language systems has its own mode of transmission (electronic equipment, light, and air) and each is limited by darkness, distance, obstacles, etc.

Speech and language differentiated

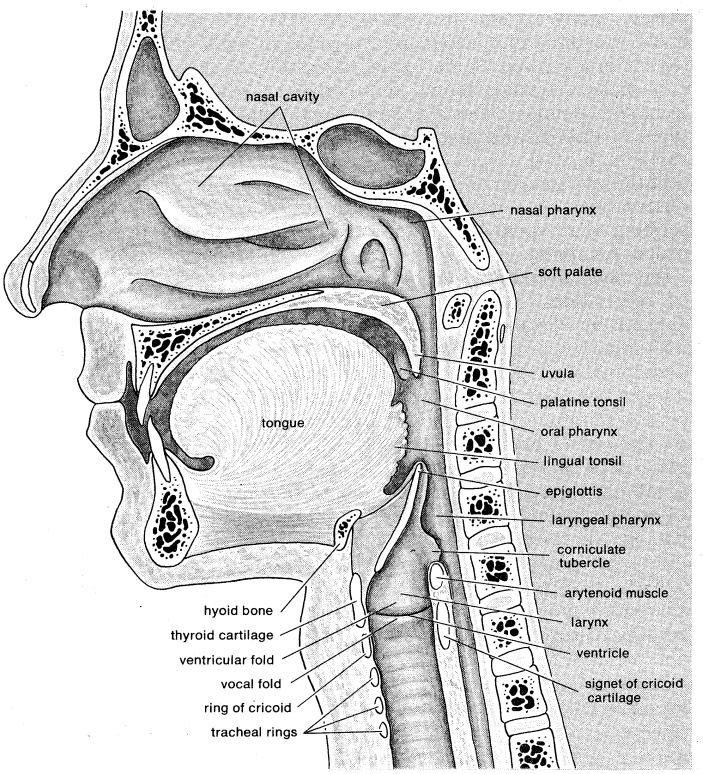

Figure 1: Sagittal section of head and neck.

Man became characteristically human when he learned to speak, perhaps 1,000,000 or more years ago, although the exact time will probably never be known. The ability to use symbolic and abstract spoken language is so far specifically human, though psychologists who have investigated the possibility of teaching spoken language to chimpanzees raised like human children in the family home have had results that, while limited, suggested that great affection and intensive training can teach a nonhuman some primitive beginnings of symbolic verbal behaviour (*e.g.*, sounds resembling "mama").

Man differs from the higher animals in several respects: he makes no mechanical use of his mouth in food gathering or tool making, and thus has freed his oral cavity for such activities as verbal articulation. He developed manual dexterity, the preferred use of one leading and dominant hand for skilled manipulation, drawing, and (later) writing. Preferred laterality (left or right) of hand, foot, eye, face muscles, tongue, and even ears is linked to the development of a distinctively human (known in no other animal) dominance of one brain hemisphere over the other in speech learning. Many nerve pathways from either side of the brain cross to the other side of the body. Thus, the human brain became ready for specialized language function in the dominant side of the brain, usually on the left side. It may be inferred that language had such precursors as tool making and cerebral dominance. Conversely, it would seem that prehistoric relics of fire, tools, weapons, and utensils indicate that the makers of such artifacts must have possessed some language. All human culture (and its propagation) appears to depend on some form of language to serve as the vehicle for teaching, persuasion, and tradition. Indeed, cultural impoverishment is seen in those with little or no language and speech: deaf-mutes, the mentally retarded, or the abnormally isolated. Without special instruction, learning is greatly impeded in deaf children, although the potential for great intelligence may be present.

Communication systems. Some social insects, such as the bees and ants, have a fairly complex system of communication. Biologists have described the stereotyped dancing movements used by bees to transmit specific information regarding food gathering, temperature control in the hive, dangers, etc. Observation of an anthill shows how the ants "trill" on each other's antennae to organize the various activities, albeit with seemingly senseless redundancy of effort.

Most creatures rely on the transmission of information through some coded system of communication. All of these systems are based on an elementary triad: an encoding sender (*e.g.*, the bodily structures that produce sound), a transmitting medium (*e.g.*, air), and a decoding receiver (*e.g.*, the ear and associated structures). At both ends of the chain, some kind of nervous system functions in the processes of encoding and decoding. The mechanical function of emitting and receiving the coded information is carried out by various types of impulse

Common features of communication systems

generators (*e.g.*, vocal cords) and stimulus receptors such as the ear. The connecting medium must simply be present, such as air or water for sound (vibration), open space for light, metal for electricity, etc.

The role of the nervous system. The perfection of human language thus depends on the learning potential of the nervous system, particularly the human brain. Some species have evolved highly specialized sensing systems. Bats produce laryngeal impulses in the ultrasonic range near 200,000 cycles per second; they are called ultrasonic to indicate that man cannot hear them. The reflections of these high-frequency waves from the irregular walls in dark caves, or from the body of a flying insect, are received by the bat's ears during flight and serve as a precise means of orientation by echo localization. Some mammals, such as mice and dogs, are known to hear in the ultrasonic range and surpass humans in this respect. Despite their frequently remarkable sensory talents, most animals are typically unable to learn human spoken language; their brains are not sufficiently specialized; for example, signs of cerebral dominance have not been found. Animals cannot learn to speak because their sound generators (parts of the mouth and throat) are not sufficiently flexible mechanically or sufficiently free from concentrating on the task of food getting.

Primary and secondary function. Bodily organs all function primarily to maintain life. The human larynx, for example, evolved as a valve that prevents the aspiration of fluids or solids into the lungs. Various reflexes (coughing, gagging, vomiting, sneezing, etc.) are inborn and thus neurologically predetermined as a further protective device. A normal baby at birth exhibits such basic reflexes; these are governed by specific centres in the brain. Sucking, swallowing, breathing, and other built-in (nonlearned) vital functions proceed automatically and usually beyond voluntary control.

Secondary, superimposed, learned functions also depend on brain mechanisms and the bodily organs they control. The articulated movements of speech have evolved from inborn reflexes serving food intake and breathing. Producing voice by phonation is a modification of exhaling. Voice without language is a reflex, possessed by many animals including the normal human baby, which cries out with the first breath of life. But speech is a superimposed, secondary function that each infant must learn from someone else.

The distinction between primary and secondary functions is helpful in understanding the frequent occurrence of disorders of voice and speech despite the presence of seemingly normal organs for their production. Inborn reflexes seem to have emerged early in animal evolution; such primary functions are thus said to be phylogenetically ancient, having appeared in lower animals many millions of years ago. The superimposed secondary functions, which have been learned by man and must be learned anew by each infant, are phylogenetically very recent. Many examples in medicine suggest that the old primary functions are more resistant to disease and derangement than are the secondary. In cases of human emotional disorder, speech may be severely distorted or totally absent, while the reflex functions of the person's throat and larynx remain perfectly intact.

Production of voice sounds and articulated speech

Respiratory mechanisms

Human speech is served by a bellows-like respiratory activator, which furnishes the driving energy; a phonating sound generator in the larynx (low in the throat) to transform the energy; a sound-molding resonator in the pharynx (higher in the throat), where the individual voice pattern is shaped; and a speech-forming articulator in the oral cavity (mouth). Normally, but not necessarily, the four structures function in close coordination. Audible speech without any voice is possible during toneless whisper; there can be phonation without oral articulation as in some aspects of yodeling that depend on pharyngeal and laryngeal changes. Silent articulation without breath and voice may be used for lipreading. While the anatomy and physiology of respiration are discussed in the articles RESPIRATION, HUMAN; RESPIRATORY SYSTEM, HUMAN, a few comments on phonic breathing are in order here.

Differences between quiet breathing and phonic respiration

An early achievement in experimental phonetics at about the end of the 19th century was a description of the differences between quiet breathing and phonic (speaking) respiration. One typically breathes approximately 18 to 20 times per minute during rest and much more frequently under strenuous effort. Quiet respiration at rest as well as deep respiration in physical effort are characterized by symmetry and synchrony of inhalation (inspiration) and exhalation (expiration). Inspiration and expiration are equally long, equally deep, and transport the same amount of air during the same period of time, approximately one pint of air per breath at rest. Recordings (with a device called a pneumograph) of respiratory movements during rest depict a curve in which peaks are followed by valleys in fairly regular alternation.

Phonic respiration is different; inhalation is much deeper than it is during rest and much more rapid. After one takes this deep breath (one or two quarts of air), phonic exhalation proceeds slowly and fairly regularly for as long as the spoken utterance lasts. Trained speakers and singers are able to phonate on one breath for at least 30 seconds, often for as much as 45 seconds, and exceptionally up to one minute. The period during which one can hold a tone on one breath with moderate effort is called his maximum phonation time; it depends on such factors as body physiology, state of health, age, body size, physical training, and the competence of the laryngeal voice generator—that is, the ability of the glottis (the vocal cords and the opening between them) to convert the moving energy of the breath stream into audible sound. Phonation time is markedly reduced in all the laryngeal diseases and disorders that weaken the precision of glottal closure, in which the cords (vocal folds) come close together, for phonation.

Repiratory movements when one is awake and asleep, at rest and at work, silent and speaking are under constant regulation by the nervous system. Specific respiratory centres within the brain stem regulate the details of respiratory mechanics according to the body needs of the moment. Conversely, the impact of emotions is heard immediately in the manner in which respiration drives the phonic generator; the timid voice of fear, the barking voice of fury, the feeble monotony of melancholy, or the raucous vehemence during agitation are examples. Conversely, many organic diseases of the nervous system or of the breathing mechanism are projected in the sound of the sufferer's voice. Some forms of nervous system disease make the voice sound tremulous; the voice of the asthmatic sounds laboured and short winded; certain types of disease affecting a part of the brain called the cerebellum cause respiration to be forced and strained so that the voice becomes extremely low and grunting. Such observations have led to the traditional practice of prescribing that vocal education begin with exercises in proper breathing.

Types of breathing

The mechanism of phonic breathing involves three types of respiration: (1) predominantly pectoral breathing (chiefly by elevation of the chest), (2) predominantly abdominal breathing (through marked movements of the abdominal wall), (3) optimal combination of both (with widening of the lower chest). The female uses upper chest respiration predominantly, the male relies primarily on abdominal breathing. Many voice coaches stress the ideal of a mixture of pectoral (chest) and abdominal breathing for economy of movement. Any exaggeration of one particular breathing habit is impractical and may damage the voice.

LARYNGEAL ANATOMY

The morphology (structure) of the larynx is studied according to the cartilages, muscles, nerves, blood vessels, and membranes of which it is composed.

Cartilages of the larynx. The frame or skeleton of the larynx is composed of several cartilages, three single and three pairs (see RESPIRATION, HUMAN). Single cartilages are the shield-shaped thyroid in front, whose prominence forms the "Adam's apple" in the male; the cricoid carti-

lage below, which resembles a signet ring and connects the thyroid to the trachea or windpipe; and the leaf-shaped epiglottis, or laryngeal lid, on top. Among the paired cartilages are the two arytenoids, which ride on the cricoid plate and move the vocal cords sideways; the two corniculate cartilages of Santorini on top of the arytenoids; and the two cuneiform cartilages of Wrisberg. The cartilages are held together by ligaments and membranes, particularly around their joints. The larynx is connected below to the uppermost ring of the trachea (see Figure 1 again), while above it is connected by the thyrohyoid ligaments to the hyoid bone beneath the tongue. Most of the laryngeal cartilages ossify (turn to bone) to variable degrees with age under the influence of masculinizing hormones. This fact is an important sign in the X-ray diagnosis of certain vocal disorders. If a man shows less ossification than is normal for his age, he may be deficient in male hormones; this may also account for an effeminate sound in his voice. Conversely, when a woman shows increased laryngeal ossification, she may suffer from virilizing hormones, which might also explain any lowering and roughening in her voice.

Laryngeal muscles. There are two types of laryngeal muscles, the external (extrinsic) ones, which move the larynx as a whole, and the internal (intrinsic) ones, which move the vocal folds to shape the glottis. It is helpful to remember that the anatomical names of most such muscles are derived from their origin on one structure to their insertion on another.

The extrinsic muscles comprise the thyropharyngeus, extending from the posterior border of the thyroid cartilage to the pharyngeal constrictor muscle, and the cricopharyngeus, from the cricoid cartilage to the lower portion of the pharynx and the opening of the esophagus (the food tube connecting the mouth and stomach). This cricopharyngeus muscle aids in the closing of the esophagus whenever it is not open for swallowing. Under the influence of emotional tension, the cricopharyngeus muscle may go into a spasm, which leads to a painful sensation of tightening in the throat, usually described as a "lump in the throat." A disorder of this sort (previously referred to as globus hystericus) is now believed to be a sensation of cricopharyngeus spasm from emotional tension or imbalance via excessive activity of the autonomic (involuntary) nervous system.

"Lump in the throat"

Extrinsic muscles. Although it is situated outside the laryngeal cartilages, the short cricothyroid muscle, a triangular muscle between the respective two cartilages, is traditionally discussed among the intrinsic (internal) muscles. Whenever this muscle contracts, the cricoid and thyroid cartilages are brought together anteriorly. This moves the anterior (forward) insertion of the vocal cords inside the thyroid wing forward, while their posterior (backward) insertion on the arytenoid cartilages is shifted backward. From this rotation results a marked elongation of the vocal folds clearly visible on X-ray films. This stretching action is the chief mechanism for raising the pitch of the sound generated and thus for the differentiation of vocal registers (*e.g.*, chest voice, falsetto). For embryologic reasons, the cricothyroid is the only laryngeal muscle that has its own nerve supply from the superior laryngeal nerve, a high branch of the vagus nerve (which issues from the brainstem). All other laryngeal muscles are innervated by the recurrent or inferior (low) laryngeal nerve, a low branch of the vagus nerve. This fact is important in the diagnosis of laryngeal paralysis because the resulting immobilization of the vocal cord and the remaining vocal function depend on the type of paralysis; *i.e.*, whether only the high or the low nerve or both of the laryngeal nerves are paralyzed on one side.

Intrinsic muscles. The intrinsic muscles include all of the following. The thyroarytenoid muscle extends from the inside of the anterior edge of the thyroid cartilage to the anterior vocal process of the arytenoid cartilage. This muscle may be separated into two portions, an internal part within the vocal cord and an external part between the vocal cord and the wing of the thyroid cartilage. For the most part, the fibres run parallel with the vocal cord. When they contract, they shorten the cord, make it thick, and round its edge. The external portion assists in bringing the vocal cords together, thus making glottal closure more tight.

The cricoarytenoid muscles

The cricoarytenoids are two muscle pairs: one lateral pair (to the side) and one posterior pair (backward). These two pairs of muscles have an antagonistic (opposing) action. The posterior cricoarytenoids are the muscles of inspiration that open the glottis. They arise from the posterior surface of the cricoid plate and are attached, in an upward, forward, and outward direction, to the lateral muscular process of the arytenoid cartilage. When these muscles contract, they rotate the arytenoid outward, thus opening the glottis. The lateral cricoarytenoids belong among the muscles of expiration, the adductor group. They arise from the lateral ring of the cricoid cartilage and insert into the muscular process of the arytenoid in an upward and backward direction. Contraction of the lateral cricoarytenoids rotates the arytenoid cartilages inward so that the vocal folds are brought together.

The two sides of the interarytenoid muscle are blended into one single mass, which extends from the muscular process of one arytenoid to that of the other. The action of this muscle is to pull together the posterior aspect of the arytenoid cartilages, thus closing the posterior portion of the cartilaginous glottis between the vocal processes of the arytenoids.

A fold from the top of the arytenoid to the lateral margin of the epiglottis on each side is supported by a bilateral band of muscle, the aryepiglotticus muscle. This semicircular structure aids in narrowing the laryngeal vestibule by pulling the arytenoids together and the epiglottis down. This is another example of the sphincter action ("valve" function) of all adducting laryngeal muscles that bring the vocal cords together. This sphincter action, by tightening of its closure, is the basis for all laryngeal protection. When this primitive sphincter mechanism intrudes into the refined coordination of phonation, it constricts the voice and causes the throaty quality of retracted resonance. This primitive, protective mechanism is at the root of many functional voice disorders. Moreover, the constricting sphincter action by many muscles is very strong because it is opposed by only one muscle, the abducting posterior cricoarytenoid.

Vocal cords. The two true vocal cords (or folds) represent the chief mechanism of the larynx in its function as a valve for opening the airway for breathing and to close it during swallowing (see Figure 2). The vocal cords are

From Lederer and Hollender, Basic Otolaryngology (1956); F. A. Davis Company

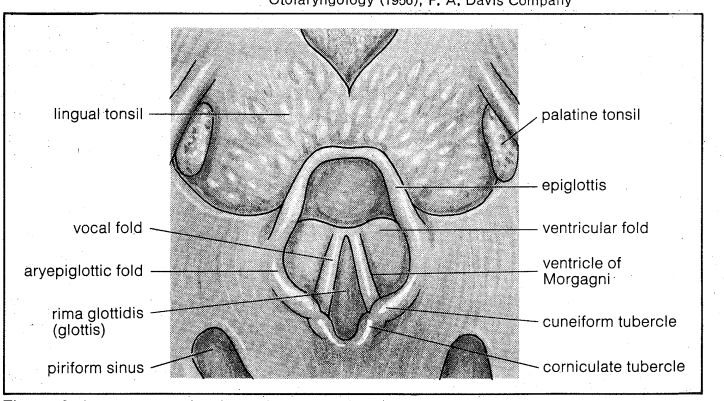

Figure 2: Laryngoscopic view of glottis and vocal cords (folds).

supported by the thyroarytenoid ligaments, which extend from the vocal process of the arytenoid cartilages forward to the inside angle of the thyroid wings. This anterior insertion occurs on two closely adjacent points, the anterior commissure. The thyroarytenoid ligament is composed of elastic fibres that support the medial or free margin of the vocal cords.

The inner cavity of the larynx is covered by a continuous mucous membrane, which closely follows the outlines of all structures. Immediately above and slightly

lateral to the vocal cords, the membrane expands into lateral excavations, one ventricle of Morgagni on each side. This recess opens anteriorly into a still smaller cavity, the laryngeal saccule or appendix. As the mucous membrane emerges again from the upper surface of each ventricle, it creates a second fold on each side—the ventricular fold, or false cord. These two ventricular folds are parallel to the vocal cords but slightly lateral to them so that the vocal cords remain uncovered when inspected with a mirror. The false cords close tightly during each sphincter action for swallowing; when this primitive mechanism is used for phonation, it causes the severe hoarseness of false-cord voice (ventricular dysphonia).

False vocal cords

The mucous membrane ascends on each side from the margins of the ventricular folds of the upper border of the laryngeal vestibule, forming the aryepiglottic folds. These folds extend from the apex of the arytenoids to the lateral margin of the epiglottis. Laterally from this ring enclosing the laryngeal vestibule, the mucous membrane descends downward to cover the upper-outer aspects of the larynx where the mucous membrane blends with the mucous lining of the piriform sinus of each side. These pear-shaped recesses mark the beginning of the entrance of the pharyngeal foodway into the esophagus.

The mucous membrane of the larynx consists of respiratory epithelium made up of ciliated columnar cells. Ciliated cells are so named because they bear hairlike projections that continuously undulate upward toward the oral cavity, moving mucus and polluting substances out of the airways. The true vocal cords, however, are exceptional in that they are covered by stratified squamous epithelium (squamous cells are flat or scalelike) as found in the alimentary tract. The arrangement is functional, since the vocal cords have to bear considerable mechanical strain during their rapid vibration for phonation, which occurs during many hours of the day. The transition from the respiratory to the stratified epithelium above and below the vocal cords is marked by superior and inferior arcuate (arched) lines. Unfortunately, such transitional epithelium also has the drawback of being easily disturbed by chronic irritation, which is one reason why the large majority of laryngeal cancers begin on the vocal cords. The mucous membrane of the larynx contains numerous mucous glands in all areas covered by respiratory epithelium, excepting again the vocal cords. These glands are especially numerous over the epiglottis and in the ventricles of Morgagni. The mucus secreted by these glands serves as a lubricant for the mucous membrane and prevents its drying in the constant airstream.

The vocal cords also mark the division of the larynx into an upper and lower compartment. These divisions reflect the development of the larynx from several embryonal components called branchial arches. The supraglottic portion differs from the one beneath the vocal cords in that the upper portion is innervated sensorially by the superior laryngeal nerve and the lower (infraglottic) portion by the recurrent (or inferior) laryngeal nerve. The lymphatics (*i.e.*, the vessels for the lymph flow) from the upper portion drain in an upward lateral direction, while the lower lymphatics drain in a lateral downward direction.

The space between the vocal cords is called rima glottidis, glottal chink, or simply glottis (Greek for tongue). When the vocal cords are separated (abducted) for respiration, the glottis assumes a triangular shape with the apex at the anterior commissure. During phonation, the vocal cords are brought together (adducted or approximated), so that they lie more or less parallel to each other. The glottis is the origin of voice, although not in the form of a "fluttering tongue" as the Greeks believed.

Dimensions of the vocal cords

The vocal cords vary greatly in dimension, the variance depending on the size of the entire larynx, which in turn depends on age, sex, body size, and body type. Before puberty, the larynx of boys and girls is about equally small. During puberty, the male larynx grows considerably under the influence of the male hormones so that eventually it is approximately one-third larger than the female larynx. The larynx and the vocal cords thus reflect body size. In tall, heavy males the vocal cords may be as long as 25 millimetres (one inch), representing the low-pitched instrument of a bass voice. A high-pitched tenor voice is produced by vocal cords of the same length as in a low-voiced female contralto. The highest female voices are produced by the shortest vocal cords (14 millimetres), which are not much longer than the infantile vocal cords before puberty (10–12 millimetres). The larynx is, among other things, a musical instrument that follows the physical laws of acoustics fairly closely.

LARYNGEAL FUNCTION

The physiology of the larynx has been investigated for many years. The first laryngeal mirror was invented in 1829, but its value was not recognized. Almost 30 years later, a Spanish singing teacher used a dental mirror to observe his own larynx during his study of artistic singing. Soon after, the art of laryngoscopy was introduced into clinical practice; the medical specialty of laryngology was born. During the remainder of the 19th century and early in the 20th century, many important discoveries were made by numerous German, French, and Italian laryngologists, physiologists, and phoneticians.

Theory of voice production. The physical production of voice has been explained for a long time by the myoelastic or aerodynamic theory, as follows: when the vocal cords are brought into the closed position of phonation by the adducting muscles, a coordinated expiratory effort sets in. Air in the lungs, compressed by the expiratory effort, is driven upward through the trachea against the undersurface of the vocal cords. As soon as the subglottic pressure has risen sufficiently to overcome the closing effort of the vocal cords, the glottis is burst open, a puff of air escapes, the subglottic pressure is reduced, and the elasticity of the glottis together with the effect of the moving air causes the adducted cords to snap shut. The subglottic pressure rises again and the entire cycle is repeated. These cycles of exploding air puffs occur as frequently as the physical interaction of the subglottic pressure with the glottic resistance permits. The latter is determined by the tension of the vocal cords and their closing force. The number of these cycles per second is small for tones of low pitch and much greater for high tones, as will be explained later. The resulting laryngeal fundamental tone thus varies greatly in audible pitch.

According to the myoelastic theory, the production of laryngeal voice is a mechanical phenomenon directed by aerodynamic principles and muscular coordination. The vocal cords vibrate purely passively in the blowing airstream and are merely maintained in their position of phonation by the adducting muscles as these are activated by the laryngeal nerves. This vibration is not an active phenomenon like the whirring of the wings of a flying insect. Evidence for the myoelastic theory can be demonstrated in various ways. High-speed motion pictures of the vocal cords have been made, photographing their vibration at the rate of 4,000 or more frames per second. When such a picture is then projected at regular film speeds of 16 or 24 frames per second, the available film length is greatly extended in duration so that each of the hundreds of vocal-cord vibrations per second can be seen in ultraslow motion. A tone of 250 cycles per second (cps or Hz), for example, filmed at 4,000 frames and played back at 16 frames per second will permit each of the 250 vibrations to be seen for one second. Other evidence supporting the myoelastic theory is found in observations such as the fact that a nearly normal voice can be produced despite bilateral (on both sides) vocal-cord paralysis.

Vocal registers. *The basic registers.* For many centuries the so-called vocal registers were well known to the classical masters of the bel canto style of singing, the basic registers being called chest voice, midvoice, and head voice. These terms are derived from observations, for example, that in the low-chest register the resonances are felt chiefly over the chest. When sitting on a wooden bench with a large male, one can feel the vibrations of his low voice being transmitted through the back of the bench. In the high head voice, the vibrations are felt chiefly over the skull. The practice of singing is based on

Table 1: Laryngeal Activity in Chest and Falsetto Register of the Male

	chest register	falsetto register
Position of larynx	low	elevated
Shape of cords	rounded, full	sharp-edged, thin
Length of cords	short	elongated
Tension of cords	low isotonic inner tension	great isometric outer tension
Ventricular folds	adducted	abducted
Ventricles	narrow	wide
Glottal closure	complete in each cycle	open oval slit
Length of glottis	full length of cords	short, anterior
Vibrations	broad, entire surface	narrow, marginal
Amplitude of vibration	wide	small
Frequency of vibration	low	high
Vocal pitch	low	high
Epiglottis	lowered	elevated
Supraglottic space	narrow	widened
Thyroarytenoid	very active	inactive
Cricothyroid	inactive below 150 Hz	very active
Harmonics	prominent higher harmonics	fundamental almost sinusoidal
Vocal timbre	full, resonant, loud	thin, weak, soft
Perceptual characteristic	masculine	juvenile, feminine
Function	speaking voice	special artistic effects

several artistic subdivisions in both sexes, depending on factors as discussed below. Other vocal phenomena may be heard below and above normal register limits, such as extra low tones, the "vocal fry."

Transition between vocal registers

The natural transition between two adjacent registers may be compared to the gearshift of a car. The same absolute vehicle speed can be maintained by driving either with the engine turning fast while in low gear or with fewer engine revolutions in the next higher gear. The register mechanism of the human voice is quite similar in this respect. Where the registers overlap, a series of transitional tones may be sung with either of the adjacent registers. These tones of the same fundamental frequency, sound level, and basic sound category in different vocal registers have recently been defined as isoparametric tones. In the untrained male voice, the transition between the midvoice and the high falsetto sounds abrupt; this so-called register break is similar to the noisy gearshift in a run-down truck. One aim of vocal education is to teach smoothly equalized register transitions.

Loud phonation of any given tone shifts its register mechanism toward the next lower register; for example, a crescendo falsetto tone grows into loud head voice. Conversely, soft intonation raises the mechanism to the next higher type, as when a loud head tone fades into soft falsetto. This phenomenon is the physiologic basis of *messa di voce*, the technique of swelling tones. Thus, the characteristic mechanism of each register represents a continuum of intralaryngeal adjustments. In the male voice, the gradual and overlapping transitions of phonic function may be aligned as follows: low chest tones, loud–soft; transition; middle register, loud–soft; transition; loud head voice—soft artistic falsetto–thin natural falsetto. X-ray studies can show the difference between the loud male head voice and the soft male falsetto. The former employs the midvoice mechanism, the latter the falsetto mechanism. In the female voice, the two lower registers behave similarly, while head voice can be only loud or soft and may be followed by a fourth register, the flageolet or whistle register of the highest coloratura sopranos. The Italian term falsetto simply means false soprano, as in a castrato (castrated) singer. Hence, the normal female cannot have a falsetto voice.

Studies of register differences. Studies devoted to the problem of voice register may be divided into two groups: observations of the visible laryngeal mechanism and studies of the audible register differences.

Studies of the visible laryngeal mechanism for the production of different registers began with the laryngoscope. Modern laryngostroboscopes employ the oscillating light of a high-power fluorescent light source that is monitored by the laryngeal vibrations through a throat microphone. Such devices, when they flash on and off at just the right rate, make the vocal cord movements appear much slower than they actually are, so that the observer perceives a slow-motion pattern. High-speed cinematography (moviemaking) has elucidated many details of vocal cord function for the various registers. Radioscopic (X-ray) methods were introduced only a few years after the discovery of X-rays in 1895. Among these, lateral (from the side) radioscopy of the larynx reveals the mechanism of vocal cord tension; frontal X-ray films demonstrate the typical configuration of the vocal cords for each register. Mechanical recordings of the respiratory movements of the chest, originally with rubber belts and lately with electronic strain gauges, disclose the breathing patterns for the various registers. Breath support (*appoggio*) of singing instruction can be demonstrated through such recordings, as well as by radiography of the chest. Aerodynamic measurements of pressure, flow rate, and volume of the air exhaled during specific phonic tasks have produced additional details. Electromyography (study of muscle currents) involving the insertion of needle electrodes into certain laryngeal muscles permits the isolated recording of finely coordinated muscular effort during the singing in various registers.

Differences in sound-wave patterns

A second group of investigations concerns audible register differences as an acoustic phenomenon. Electroacoustic analysis demonstrates the specific sound-wave patterns (harmonic spectra) of each register. In general, the full chest voice is rich in higher harmonics, whereas the thin falsetto voice is composed chiefly of sound-wave energy distribution near the vocal fundamental (the relatively narrow band of wave frequencies that characterizes any particular voice). The subjective impressions of singers during the production of an ascending scale reflect the voluntary techniques of vocal breath control, such as with respiratory support (*appoggio*). Positioning of the larynx, suitable shaping of the pharyngo-oral resonator (vocal tract), proper placement of the tongue, and the specific tension of the soft palate belong among the learned techniques of register equalization. Definite vibrations may be felt in the thorax, in the area of the hard palate, or above the nose. These subjectively felt resonances depend on bone conduction of the laryngeal sound. Very little has as yet been done regarding the subjective evaluation of voice registers by listening judges. These perceptual factors are still little understood, but it appears that multiple acoustic perceptions operate in voice-register judgment.

It is clear that the vocal registers represent a continuum of laryngeal adjustments in response to different respiratory-mechanical requirements necessary for the production of the individual frequency range. The poles of these adjustments at the opposites of chest voice and male falsetto voice illustrate the chief differences, as shown in Table 1; the midvoice occupies an intermediate position.

Vocal attributes. *Vocal frequency.* The voice has various attributes; these are chiefly frequency, harmonic structure, and intensity. The immediate result of vocal cord vibration is the fundamental tone of the voice, which determines its pitch. In physical terms, the frequency of vibration as the foremost vocal attribute corresponds to the number of air puffs per second, counted as cycles per

second (cps or Hz). This frequency is determined by both stable and variable factors. The stable determinants of the individual voice range depend on the laryngeal dimensions as related to sex, age, and body type. The smaller a larynx, the higher its pitch range. Within this individually fixed range, variables that influence the pitch of a given phonation include: tension of the cord, force of glottal closure indicated by the glottal resistance, and expiratory air pressure. Growing tension of the cricothyroid muscle (as the external vocal cord tensor) increases the vocal pitch, and vice-versa. Increased glottal closure and expiratory effort add to this tensing effect under certain circumstances. For example, 100 vibrations per second produce a low chest tone of a low male voice, while 1,000 are close to the "high C" of a female soprano. An average vocal range normally encompasses two musical octaves (*e.g.*, 100 to 400 vibrations per second); trained singers may reach three or more octaves.

Voice types. Musical practice for centuries has recognized six basic voice types: bass, baritone, and tenor in the male, in contrast to contralto, mezzo-soprano, and soprano in the female. Sex, therefore, is one of the first determinants of voice type in the two categories. Body type and general physical constitution represent the second determinant of the individual voice type because the laryngeal dimensions vary in fairly strict conformity to whether the body type is large or husky or frail or small. A tall, athletic male usually has a large, spacious larynx. Repeated observations show that short, dainty females tend to have a small and delicately built larynx. The intermediate voice types of the male baritone and the female mezzo-soprano usually represent the corresponding intermediate body types. The art of singing recognizes additional subdivisions. The voice of a basso profundo is extremely low and heavy. The lyric tenor possesses a high, light, and flexible voice. Still higher and lighter is the counter tenor (as used in singing oratorios) who is the male counterpart of the highest female voice found in the extra high and light coloratura soprano. The dramatic voices employed in the Wagnerian operas represent intermediate forms between a male tenor (or high baritone) and a heroically masculine body type. The female dramatic soprano is usually heavily built; her strong mezzo-soprano voice can produce the high soprano tones.

The relationship between registers and voice types

The registers are related to voice types. As a general rule, the low voices possess a large range of chest voice with a much smaller range of head voice. The reverse holds for the high voice types, while baritone and mezzo-soprano assume an intermediate position. In the normal individual and the well-trained singer in particular, the midvoice encompasses one musical octave. As a further rule of thumb, the traditional and optimal transition tones follow a fairly stable and general pattern. As summarized in Figure 3, the three female voice types usually show the first transition from chest to midvoice at the tones d^1, e^1, and f^1, above middle c^1, respectively. The second transition between midvoice and head register in the three female voice types is almost precisely one octave higher. An extra-low contralto voice may prefer to shift the two transitions at slightly lower frequencies, whereas a very high coloratura soprano may prefer the two shifts a semitone (halftone) higher. The two transition tones of the three male voice types are situated almost precisely one octave lower than the respective six female transition tones. It should not be overlooked that the specific features in male voices sound approximately one octave lower than in the female voices of corresponding type. This octave phenomenon stems from the larger dimension of the adult male larynx. (The musical custom of writing the tenor part on the soprano stave in contrast to the correct notation of bass and baritone in the bass clef is a misleading tradition that derives from an old custom of four-part writing, for the tenor always sounds one octave lower than the soprano.)

Vocal ranges. As shown in Figure 3, the individual ranges of the singing voice extend from about 80 cycles per second in the low bass to about 1,050 cycles per second in the "high C" of the soprano (all values are approximated). The lowest note of serious musical literature is a low D with 73 cycles per second at the end of Osmin's aria in Mozart's *Abduction from the Seraglio*, and the highest is a high f^3 with almost 1,400 cycles per second sung by the Queen of the Night in Mozart's *Magic Flute*. Exceptionally high soprano tones are no longer sung with vocal cord vibration but are produced in the flageolet (or whistle) register simply by whistling through the narrow eliptical slit between the overtensed and motionless vocal cords. When citing the exceptional vocalistic feats of singers from the classical bel canto era, it should not be overlooked that musical pitch has been rising markedly since those days. Concert pitch is presently standardized at 440 cycles per second for the international tuning tone a^1. In the last half of the 18th century, the reference tone was at least one semitone lower.

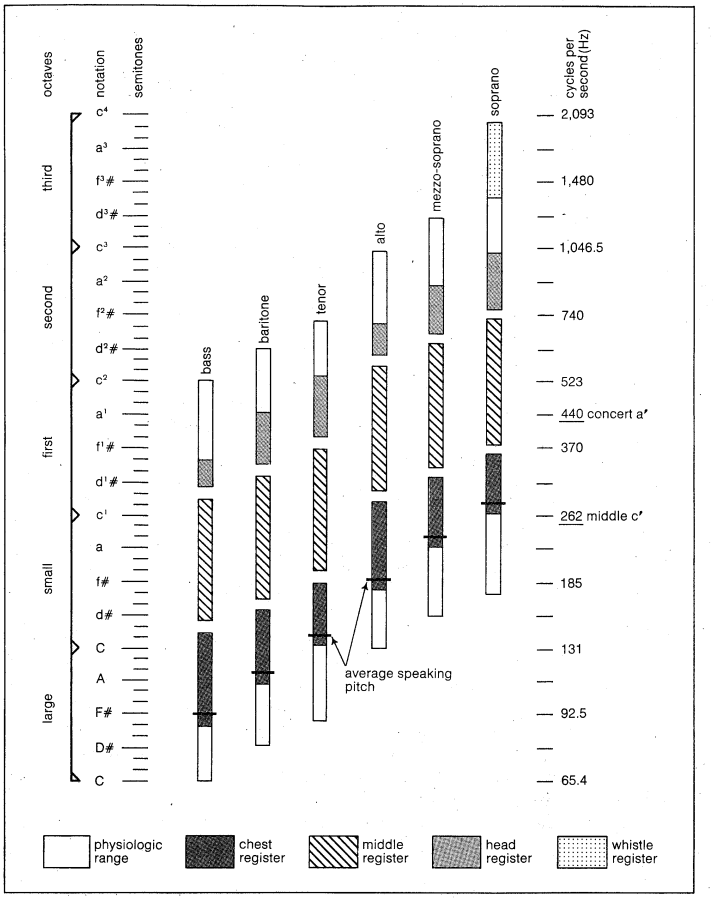

Figure 3: Relationships of registers, vocal range, average speaking pitch, and extreme tones of human voice. Octaves and notation according to von Helmholtz; frequencies based on standard concert a' = 440 Hz.

From *Archives of Otolaryngology*, vol. 62, p. 597; copyright 1955, American Medical Association

Harmonic structure. A second attribute of vocal sound, harmonic structure, depends on the wave form produced by the vibrating vocal cords. Like any musical instrument, the human voice is not a pure tone (as produced by a tuning fork); rather, it is composed of a fundamental tone (or frequency of vibration) and a series of higher frequencies called upper harmonics, usually corresponding to a simple mathematical ratio of harmonics, which is 1:2:3:4:5, etc. Thus, if a vocal fundamental has a frequency of 100 cycles per second, the second harmonic will be at 200, the third at 300, and so on. As long as the harmonics are precise multiples of the fundamental, the voice will sound clear and pleasant. If nonharmonic components are added (giving an irregular ratio), increasing degrees of roughness, harshness, or hoarseness will be perceived in relation to the intensity of the noise components in the frequency spectrum.

The primary laryngeal tone composed of its fundamental and harmonics is radiated into the supraglottic vocal tract (above the glottis). The cavities formed by the

Modulation of vocal tone

pharynx, nasopharynx, nose, and oral cavity represent resonators. Since they are variable in size and shape through the movements of the pharyngeal musculature, the palatal valve, and the tongue in particular, the individual sizes of the supraglottic resonating chambers can be varied in countless degrees. The shaping of the vocal tract thus determines the modulation of the voice through resonance and damping. As a general rule, a long and wide vocal tract enhances the lower harmonics, producing a full, dark, and resonant voice. Conversely, shortening and narrowing of the vocal tract leads to higher resonances with lightening of the voice and the perceptual attributes ranging from shrill and strident to constricted and guttural.

Vocal styles. These types of vocal resonance may be illustrated with a continual series of vocal practices that have been studied through physiologic and electroacoustic analysis. This perceptual series begins with the full, loud, and sonorous sound during the natural vocalizations for laughing, yawning, and yodelling. The rich higher harmonics responsible for the perceptual qualities of these vocalizations are produced by a maximally lowered larynx and greatly widened resonator. At the next step is the sonorous and full sound of so-called covered singing in the German opera style. Rich in higher harmonics (or overtones), this vocal style is performed with lowered larynx, elevated epiglottis, and widened throat cavity. A large group of open or uncovered singing styles lying in the centre of the series extends from the extremely uncovered, flat, and "white" openness of, for example, Spanish flamenco singing, over the flat style of popular singing, to the brightness of Italian bel canto. Approaching the other pole of the series, the large group of functional voice disorders results from constricted resonance of the vocal tract. It is typical of these hyperkinetic (overactive) vocal disorders that the voice is produced with marked laryngeal elevation, constriction of the laryngeal vestibule, and often with pronounced elementary sphincter action of the larynx. The extreme end of this functional series is characterized by the use of the larynx as a primitive sphincter organ as employed in ventriloquism. The maximally elevated and constricted larynx within a very narrow throat cavity produces the high-pitched, thin, muffled, and weak quality of ventriloquism, which is characterized by great reduction of the higher harmonics.

Use of the larynx in ventriloquism

Individual voice quality. Apart from the variable influences of the vocal tract on the momentary vocal resonance according to training and intention, the supraglottic resonator exerts a constant influence on the vocal quality by shaping its individual characteristics. Just as human faces differ in almost endless variations, the configuration of the supraglottic structures is also highly characteristic, having, in fact, been called the "inner face." The anatomical shape and the physiologic flexibility of the vocal tract serve to mold the individual vocal personality in at least two ways: by its inborn shape and by the learned behaviour of using it for communication. Any individual's mother tongue shapes his articulatory behaviour into certain patterns, which remain audible in all languages that he learns after puberty and constitute one aspect of the so-called foreign accent. It often is easy to recognize a speaker over the telephone after having listened to his voice a few times without necessarily having met him in person. The ability to recognize a given speaker solely by the quality and inflection of his voice is the basis of efforts to produce "voice prints" that should be as unmistakably identifying as fingerprints are.

Intensity. Vocal intensity, the third major vocal attribute, depends primarily on the amplitude of vocal cord vibrations and thus on the pressure of the subglottic airstream. The greater the expiratory effort, the greater the vocal volume. Another component of vocal intensity is the radiating efficiency of the sound generator and its superimposed resonator. The larynx has been compared to the physical shape of a horn. This construction is most efficient in acoustical practice, as seen in the shape of wind instruments, car horns, sirens, loudspeakers, etc. A well-shaped, wide, and flexible vocal tract enhances the projective potential of the voice. Conversely, a morphologically narrow, pathologically constricted, or emotionally tightened throat produces a muffled, constricted sound with poor carrying power.

Laughing and yawning

The inborn automatic reflexes of laughing and yawning illustrate the resonator action of the vocal organ. Together with a widely opened mouth, flat tongue, elevated palate, and maximally widened pharynx, the larynx assumes a lowered position with maximally elevated epiglottis. This configuration is ideal for the unimpeded radiation of the vocal cord vibrations so that the resulting sound is loud and bright, with a gaily ringing quality; it is the sound of happy laughter. The opposite is present with the painfully tight-throated, choked sobbing of someone crying in despair.

PRODUCTION OF SPEECH

As shown by physiologic, culturally learned, and pathologic examples, the vocal functions represent highly coordinated actions of all organs participating in phonation so that it is difficult to view each factor, attribute, or quality in isolation. This restriction is even more apparent in the study of speaking.

Singing and speaking. A major difference between singing and speaking is psychological in nature. Singing as a physiological performance is exhibited by the majority of human beings who have what seems to be an inborn musical sense that depends on appropriate development of their highest cortical (brain) centres for audition. Although the art of singing in a particular artistic style typically demands formal study, the untrained use of the voice for self-expression through singing develops spontaneously in late childhood and during the period following vocal maturation. Singing involves the use of inherited neural mechanisms that are regulated in part by deeper, subcortical (below the cortex) brain centres, particularly those related to emotional activity. Singing serves many as a way of emotional relief and is related to the social activities of human play. Although song among humans is not as intimately related to sexual propagation as it is in certain animals (*e.g.*, birds), people are still influenced by such sensual stimuli as love songs and madrigals, as well as ceremonial and religious performances.

The practice of spontaneous singing and of artistic song satisfies emotional needs, but it may not always communicate in a clear ideational sense. When a brain stroke causes aphasia (loss of language for communication), for example, the singing voice often remains normal or at least better preserved, so that some aphasics who cannot say a word can sing with good articulation. This observation has been used to explain that disorders causing aphasia may damage other brain areas than those used for singing. Another example is the severe stutterer who can sing or whisper with fluency. The same dichotomy of communicative speech and declamatory singing is often seen in cases of spastic dysphonia (a peculiar, grave voice disorder without demonstrable brain damage that causes a painfully choked and halting manner of speaking, while singing usually remains undisturbed).

Perceptual differences between speaking and singing

In the perceptual category, the principal differences between speaking and singing concern the rhythmic patterns. Speaking uses gliding vocal inflections with rapid pitch variations as well as frequent and abrupt intensity modifications for syllabic accentuation. The rhythmical pattern of stresses, unstressed syllables, and breathing pauses is dictated by the meaning of the sentence. The so-called prosodic features of speech (*i.e.*, its melodic inflections) follow the general, regional, and dialectal rules of a given language. In this sense, the essence of speaking is its continual flexibility, variability, and adaptability.

Singing differs from speaking in the following respects. The melody is followed in precise and discrete steps over customary musical intervals (*e.g.*, from the note f to the note "cee" on the piano), which commonly are not smaller than semitones in Western music, though quarter and eighth tones are frequently used in Oriental or African music. The vowels are prolonged because they carry the melody. The rhythm of the fixed tonal steps follows the

pattern prescribed by the composer and long notes may be sustained for special effects.

Exceptions to these general rules are found in the portamento, a gliding change between two pitch levels, of Western song, used sparingly as an embellishment. Parlando singing is a speaking type of song, used in the recitativo of Italian opera style. In these intentionally communicative preludes to formal arias—because they tell most of the story—the rhythm of the spoken word is incorporated into the melody, which, in turn, to a certain degree, follows the prosodic vocal inflection.

The melodic inflection of speech communicates considerable meaning in certain languages, such as in Africa and China. This problem of linguistic tonality or word melody requires the appropriate selection of various rising, sustained, or falling intervals to express the full meaning of a word. Chinese words are monosyllabic, and their multiple meanings cannot be understood without the appropriate prosodic inflection by the "tones" of the particular dialect. If Chinese is spoken without vocal inflection, such as when whispering, intelligibility is reduced by at least one-third.

Articulation and speech sounds. Voice alone has little communicative function, except as elementary exclamation. The chief function of voice in speech is as a carrier wave that is modulated into speech sounds by such articulating organs as the lips and tongue.

Phonetic classification. For many centuries, speech scientists have classified speech (phonetic) sounds into two categories: vowels and consonants. Vowels represent resonances of the suitably shaped vocal tract, while consonants are produced by total or partial occlusions within the various zones of articulation. Almost equally old is a phonetic classification of voiced sounds with simultaneous laryngeal tone and unvoiced sounds without laryngeal participation. Vowels are voiced in almost all languages, while the consonants are likely to occur in pairs, one voiced and one unvoiced (B–P, V–F, Z–S, etc.). In acoustic terms, the voiced consonants represent sound-noise mixtures, the unvoiced partners being complex noises. Additional distinguishing features of the consonants are their mechanisms of articulation. Explosion of a preceding occlusion (an obstruction of the breath by the tongue, for example) produces the plosives or stop consonants such as the sound for P. A friction noise within a narrow channel gives rise to the fricative sounds such as that for F.

Articulation zones

Moreover, the various types of speech sounds are produced in different articulation zones marking the place of articulation that is typical for each language. The labial zone (between both lips) and the labiodental zone (between lower lip and upper teeth) are relatively stable in most languages. The linguodental zone (between tongue tip and teeth) varies greatly in different languages. In the Latin and Slavic languages, dental articulation with the tongue is often low against the teeth without aspiration. When this low linguodental articulation is used in English, it is called dentalization, a dialectal error because English typically requires higher linguoalveolar articulation (touching the tongue to the front part of the palate) with marked aspiration. North German assumes an intermediate position. The palatal articulation zone is subdivided into several segments along the midline between tongue and palate. Pharyngeal articulation does not ordinarily exist in English but is normal in such languages as German (as in the word *ach*) and Arabic. Laryngeal articulation represents two phonemes (elements of speech sounds): the glottal stop produced by bursting firm glottal closure for the hard attack of vowels, such as in North German, and the production of a faint hissing noise between the incompletely closed and motionless vocal cords.

Finally, speech sounds are also grouped as oral sounds without nasal resonance and as nasal sounds with various degrees of nasalization. Oral sounds are produced by fairly tight occlusion through contraction and elevation of the soft palate against the constricted posterior pharyngeal wall. The nasal sounds are produced with relaxed and lowered velum (soft palate) so that part of the sounding air column can enter the nasopharynx and nose, thus eliciting the resonance of these spaces. Three nasal sounds ordinarily occur in English (those for M, N, and Ng). French and certain other Latin languages make much freer use of nasalized vowels, such as in the final syllable "tion."

Phonetic science still faces the problem of providing a clear definition of the differences between nasal resonance, nasalization, and nasality. In essence, these are differences of degree and linguistic context. It may be said that nasal resonance produces nasal sounds, nasalization is the addition of nasal resonance to vowels, while nasality is a pathological phenomenon meaning the admixture of nasal resonances and noises during the articulation of those speech sounds that should not be nasal. (More will be said later in connection with cleft palate.)

Phonemes and phonetic transcription

Phonetic science describes the numerous speech sounds of a given language as its phonemes, which correspond to the smaller number of written letters or graphemes of conventional printed or written language only in a loose fashion, especially in English. (Close transcription is feasible with a system called the International Phonetic Alphabet.) The next larger unit of speech is the syllable, which contains at least one vowel or one vowel and an adjacent consonant. The vowel is that part of a word with high acoustic energy (loudness), while the consonants vary greatly in intensity, depending on articulation. The description of words (morphemes) and sentences (grammemes) is a task of linguistics. These linguistic units often overlap. "I" is a phoneme, a diphthong (combination of two vowels), a syllable, a word, and can even be a sentence, such as in: Who is it?—I. Words consist of one or more syllables, and sentences consist of one or more words.

Acoustic analysis. Perceptual recognition of speech sounds depends on the fact that the vocal tract is shaped during their articulation in such a manner that the resulting resonances produce characteristic bands (of sound-wave frequency) within the total energy spectrum, the so-called formants. These frequency bands are demonstrated by electroacoustic sound analysis, with such devices as the sound spectrograph. A suitable arrangement of electric sound-wave filters with variable band widths permits the graphic display of speech sounds in a three-dimensional system. Time is depicted on the horizontal axis, frequency (often from 100 to 8,000 cycles per second) on the vertical axis, and intensity by graded blackening of the heat-sensitive recording paper, increasing darkness indicating greater intensity. During phonetic analysis, the recorded formants are labelled as F1, F2, F3, etc. Their position on the frequency scale reflects the perceptual impressions they give to the listener. On this formant scale, the vowel u contains the lowest formant, followed by o, a, and e, while i has the highest formant with the perceptual correlate of thin reediness. Vowels represent complex sounds with relatively pure harmonic structure. Nonharmonic noise admixtures detract from their clarity, giving the perceptual impression of hoarseness.

The physical correlates of nasality are difficult to explain. Modern research has shown that the essence of nasality is represented by several features: weakened lower formants through damping, the occurrence of abnormal resonances and antiresonances, and the appearance of a new formant in higher frequency regions.

Central regulation. The question of what the brain does to make the mouth speak or the hand write is still incompletely understood despite a rapidly growing number of studies by specialists in many sciences, including neurology, psychology, psycholinguistics, neurophysiology, aphasiology, speech pathology, cybernetics, and others. A basic understanding, however, has emerged from such study. In evolution, one of the oldest structures in the brain is the so-called limbic system, which evolved as part of the olfactory (smell) sense. It traverses both hemispheres in a front to back direction, connecting many vitally important brain centres as if it were a basic mainline for the distribution of energy and information. The limbic system involves the so-called reticular activating system (structures in the brain stem), which repre-

The limbic system

sents the chief brain mechanism of arousal, such as from sleep or from rest to activity. In man, all activities of thinking and moving (as expressed by speaking or writing) require the guidance of the brain cortex.

In contrast to animals, man possesses several language centres in the dominant brain hemisphere (on the left side in a clearly right-handed person). It was previously believed that left-handers had their dominant hemisphere on the right side, but recent findings tend to show that many left-handed persons have the language centres more equally developed in both hemispheres or that the left side of the brain is indeed dominant. The foot of the third frontal convolution of the brain cortex, called Broca's area, is involved with motor elaboration of all movements for expressive language. Its destruction through disease or injury causes expressive aphasia, the inability to speak or write (see Figure 4). The posterior third of

From N. Geschwind, *Science*, vol. 170, no. 3961, p. 941 (1970); Copyright 1970 by the American Association for the Advancement of Science

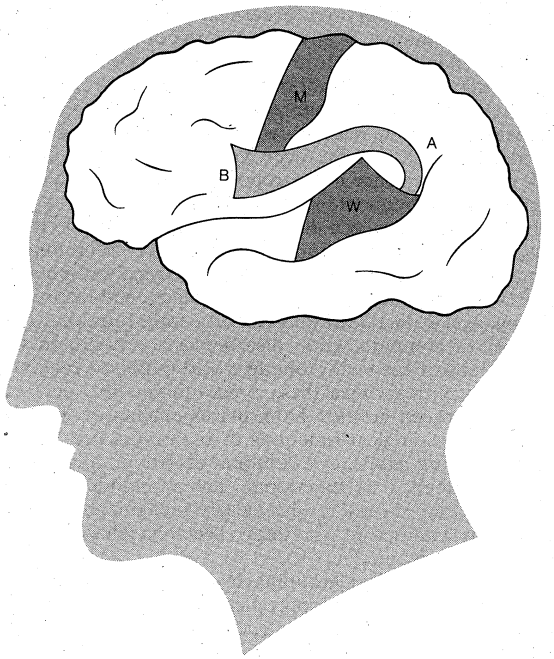

Figure 4: Lateral surface of left hemisphere of brain. B, Broca's area; M, motor cortex; W, Wernicke's area; A, arcuate fasciculus.

the upper temporal convolution represents Wernicke's area of receptive speech comprehension. Damage to this area produces receptive aphasia, the inability to understand what is spoken or written as if the patient had never known that language.

Broca's area surrounds and serves to regulate the function of other brain parts that initiate the complex patterns of bodily movement (somatomotor function) necessary for the performance of a given motor act. Swallowing is an inborn reflex (present at birth) in the somatomotor area for mouth, throat, and larynx. From these cells in the motor cortex of the brain emerge fibres that connect eventually with the cranial and spinal nerves that control the muscles of oral speech.

In the opposite direction, fibres from the inner ear have a first relay station in the so-called acoustic nuclei of the brain stem. From here the impulses from the ear ascend, via various regulating relay stations for the acoustic reflexes and directional hearing, to the cortical projection of the auditory fibres on the upper surface of the superior temporal convolution (on each side of the brain cortex). This is the cortical hearing centre where the effects of sound stimuli seem to become conscious and understandable. Surrounding this audito-sensory area of initial crude recognition, the inner and outer auditopsychic regions spread over the remainder of the temporal lobe of the brain, where sound signals of all kinds appear to be remembered, comprehended, and fully appreciated. Wernicke's area (the posterior part of the outer auditopsychic region) appears to be uniquely important for the comprehension of speech sounds.

The integrity of these language areas in the cortex seems insufficient for the smooth production and reception of language. The cortical centres are interconnected with various subcortical areas (deeper within the brain) such as those for emotional integration in the thalamus and for the coordination of movements in the cerebellum (hindbrain).

Feedback mechanisms. All creatures regulate their performance instantaneously comparing it with what it was intended to be through so-called feedback mechanisms involving the nervous system. Auditory feedback through the ear, for example, informs the speaker about the pitch, volume, and inflection of his voice, the accuracy of articulation, the selection of the appropriate words, and other audible features of his utterance. Another feedback system through the proprioceptive sense (represented by sensory structures within muscles, tendons, joints, and other moving parts) provides continual information on the position of these parts. Limitations of these systems curtail the quality of speech as observed in pathologic examples (deafness, paralysis, underdevelopment).

Substitutes for the larynx. A growing number of middle-aged or older patients have had their larynx removed (laryngectomy) because of cancer. Laryngectomy requires the suturing of the remaining trachea into a hole above the sternum (breastbone), creating a permanent tracheal stoma (or aperture) through which the air enters and leaves the lungs. The oral cavity is reconnected directly to the esophagus. Having lost his pulmonary activator (air from the lungs) and laryngeal sound generator, such an alaryngeal patient is without a voice (aphonic) and becomes effectively speechless; the faint smacking noises made by the remaining oral structures for articulation are practically unintelligible. This type of pseudo-whispering through buccal (mouth) speech is discouraged to help the patient later relearn useful speech on his own. A frequently successful method of rehabilitation for such alaryngeal aphonia is the development of what is called esophageal or belching voice.

Alaryngeal aphonia

Esophageal voice. Some European birds and other animals can produce a voice in which air is actively aspirated into the esophagus and then eructated (belched), as many people can do without practice. The sound generator is formed by the upper esophageal sphincter (the cricopharyngeus muscle in man). As a replacement for vocal cord function, the substitute esophageal voice is very low in pitch, usually about 60 cycles per second in humans. Training usually elevates this grunting pitch to about 80 or 100 cycles.

Esophageal voice in man has been reported in the literature since at least 1841 when such a case was presented before the Academy of Sciences in Paris. After the perfection of the laryngectomy procedure at the end of the 19th century, systematic instruction in esophageal (belching) phonation was elaborated, and the principles of this vicarious phonation were explored. Laryngectomized persons in many countries often congregate socially in "Lost Cord Clubs" and exchange solutions of problems stemming from the alaryngeal condition.

Artificial larynx. Approximately one-third of all laryngectomized persons are unable to learn esophageal phonation for various reasons, such as age, general health, hearing loss, illiteracy, linguistic barriers, rural residence, or other social reasons. These persons, however, can use an artificial larynx to substitute for the vocal carrier wave of articulation. Numerous mechanical and pneumatic models have been invented, but the modern electric larynx is most serviceable. It consists of a plastic case about the size of a flashlight, containing ordinary batteries, a buzzing sound source, and a vibrating head that is held against the throat to let the sound enter the pharynx through the skin. Ordinary articulation thus becomes easily audible and intelligible. Other models lead the sound waves through a tube into the mouth or are encased in a special upper dental plate. More recent

efforts aim at surgically inserting an electric sound source directly into the neck tissues to produce a more natural sound resembling that of normal speech.

Synthetic production of speech sounds. The essence of speech and its artificial re-creation has fascinated scientists for several centuries. Although some of the earlier speaking machines represented simple circus tricks or plain fraud, an Austrian amateur phonetician, in 1791, published a book describing a pneumomechanical device for the production of artificial speech sounds.

Speech synthesizers. Modern electronic speech synthesizers have been constructed in various phonetic laboratories for the past several decades. Some of these are named the "Coder," "Voder," and "Vocoder," abbreviations for longer names (*e.g.*, "Voder" standing for Voice Operation Demonstrator). In essence, they are electrical analogues of the human vocal tract. Appropriately arranged electric circuits produce a voicelike tone, a modulator of the harmonic components of this fundamental tone, and a hissing-noise generator to produce the sibilant and other unvoiced consonant sounds. Resonating circuits furnish the energy concentrations within certain frequency areas to simulate the characteristic formants of each speech sound. The resulting speechlike sounds are highly controllable and amazingly natural as long as they are produced as continuants. For example, it is possible to imitate the various subtypes of the hard U.S. sound for R (as in "car") by moving a few levers or knobs. Difficulties become greater when many other attributes of fluent speech are to be imitated, such as coarticulation of adjacent sounds, fluctuating nasalization, and other segment features and transients of connected articulation. Speech synthesizers have, nevertheless, made a contribution to the study of the various physical characteristics that contribute to the perception and recognition of speech sounds.

Speech recognizers

The counterpart of speech synthesizers is the speech recognizer, a device that receives speech signals through a microphone or phono-optical device, analyzes the acoustic components, and transforms the signals into graphic symbols by typing them on paper. Modern models may incorporate computers to store some of the information that permits the device directly to type from dictation. Early models had great difficulties with the correct spelling of homophonous words (those that sound alike but differ in spelling and meaning) such as "to, too, two" or "threw, through, thru." Human transcribers usually have no difficulty with these distinctions because they listen to major parts of the sentence to recognize each word from the context and general situation. The computerized machines developed in the 1970s, however, had to be programmed for each detailed aspect of speech recognition that people normally learn through many years of general schooling and specialized training.

Disorders of speech

THE STUDY OF SPEECH PATHOLOGY

Prevalence of speech disorders. A comprehensive evaluation of knowledge and research in speech and hearing, published in 1969 by a section of the U.S. Public Health Service, under the title *Human Communication and Its Disorders—An Overview*, reveals that approximately 9,000,000 Americans are reported to have hearing impairments of handicapping magnitude; another 2,000,000 are said to suffer from central processing disorders from neurologic disease; and 10,000,000 to have speech disorders. The cost of coping with these problems is about $500,000,000 per year, while the annual deficit in earning power among such impaired persons approximates nearly $2,000,000,000. The same report estimated the prevalence of various speech disorders in the United States as shown in Table 2. The disorders of articulation among young children continue to be numerically most frequent.

No data in similar detail are available from other countries; however, from experience in Germany, Austria, and other Central European countries, it may be said that the incidence and prevalence of speech disorders follow similar patterns among other Western nations. Certain deviations from these trends are equally typical. The incidence of cleft palate is very high among American Indians, such as in Montana, while it is much lower among Negroes than in Caucasians, such as in Jamaica. Stuttering is more frequent in northern countries, such as in Scandinavia, than it is in southern regions—*e.g.*, Italy. Similar trends have been noted in the Far East. Nonorganic, functional, or emotional disorders of voice and speech reflect psychological tensions exerted by the environment. For such reasons, vocal nodules (growths on the vocal cords), contact ulcer, vocal fatigue, etc., occur with greater incidence in metropolitan areas and are conspicuously less frequent in rural regions.

Table 2: Estimated Prevalence of Speech Defects in the United States

type of speech problem	ages 5–21 years		all ages	
	percent	number	percent	number
Functional articulatory	3.0	1,500,000	3.0	6,000,000
Stuttering	.7	350,000	.7	1,400,000
Voice	.2	100,000	.2	400,000
Cleft palate speech	.1	50,000	.1	200,000
Cerebral palsy speech	.2	100,000	.2	400,000
Retarded speech development	.3	150,000	.3	600,000
Impaired hearing (with speech defect)	.5	250,000	.5	1,000,000
Total	5.0	2,500,000	5.0	10,000,000

Classification of speech disorders. In accordance with physiological considerations, disorders of communication are first classified into disorders of voice and phonic respiration, disorders of articulated speech, and disorders of language. It has been known for a long time that the majority of communication disorders are not caused by local lesions of the teeth, tongue, vocal cords, or regulating brain centres. Since these predominant disorders of voice and speech develop from derangements of the underlying physiological functions of breathing, use of the voice, speaking habits, or emotional disorders, this group has been labelled as functional. The remainder of the communication disorders with clearly recognizable structural abnormalities in the total speech mechanism has been termed organic.

Interaction of functional and organic disorders

While this empirical grouping has certain implications for the selection of the appropriate treatment, it is not satisfactory because organic structure and living function can never be separated. Certain functional disorders of the voice caused by its habitual abuse may very well lead to secondary structural changes, such as the growths (polyps and nodules) of the vocal cords, which develop as a result of vocal abuse. On the other hand, all of the obviously organic and structural lesions, such as loss of the tongue from accident or surgery, almost inevitably will be followed by emotional and other psychological reactions. In this case, the functional components are of secondary nature but to a great extent will influence the total picture of disturbance, including the patient's ability to adjust to his limitation, to relearn a new mode of appropriate function, and to make the best of his condition.

Within these major groups, the various types of communication disorders have for a long time, and in most parts of the world, been described by the listener's perceptual impression. Most languages employ specific words for the various types of abnormal speech, such as stuttering, stammering, cluttering, mumbling, lisping, whispering, and many others. The problem with such subjective and symptomatic labels is the fact that they try to define the final, audible result, the recognizable phenomenon, and not by any means the underlying basis. This general human tendency to describe disorders of communication by what the listener hears is analogous to the attempts of early medicine to classify diseases by the patient's symptoms that the diagnosing physician could see or hear or feel or perhaps smell. Before the great discoveries of the 19th century had erected a logical basis for medical pathology, the various diseases were classified as numerous types of fevers, congestions, dyscrasias, etc. Thus, malaria was originally thought to be caused by the evil emanations (miasma) of the bad air (*mal aria*) near swamps

until it was recognized to be caused by a blood parasite transmitted by the mosquito.

The various approaches of medical, psychiatric, psychological, educational, behavioral, and other schools of speech pathology have made great advances in the recent past and better systems of classification continue to be proposed. They aim at grouping the observable symptoms of speech disorders according to the underlying origins instead of the listener's subjective impressions. While this is relatively easy in the case of language loss from, for example, a brain stroke because the destroyed brain areas can be identified at autopsy, it is more difficult in the case of the large group of so-called functional speech disorders for two reasons: first, they are definitely not caused by gross, easily visible organic lesions, and, second, many functional disorders are outgrown through maturation or appropriate learning (laboratory study of the involved tissues in such cases would reveal no detectable lesions). It is hoped that refined methods of study in the areas of both "functional" psychology and "organic" neurophysiology will eventually reveal the structural bases for the prevalent disorders of voice and speech.

Treatment and rehabilitation. The selection of methods in the medical treatment or educational rehabilitation of communication disorders depends primarily on the underlying basis for the disturbance. Any case of chronic hoarseness should be evaluated first by a laryngologist to establish a precise diagnosis. This is particularly important in the older age groups in which an incipient laryngeal cancer is often overlooked because the patient does not pay attention to his deteriorating voice. The prognosis of all cancers becomes rapidly poorer the longer the disease remains unrecognized. As soon as disease of the larynx is excluded as a cause of the vocal complaint, vocal rehabilitation by a competent speech pathologist should be considered.

Treatment by appropriate specialists

Malformations, diseases, or injuries of the peripheral speech mechanism are treated by appropriate specialists; the plastic surgeon repairs a cleft of the palate; the neurologist and internist treat the stroke patient until he has recovered sufficiently to be referred for re-education of his language abilities. The pediatrician treats the child with mental retardation, while the geneticist counsels the family regarding the possible inheritance of the disorder and its future avoidance. Deafness or severe hearing loss in early childhood is a typical cause for severe delay of language development and should be promptly recognized through appropriate examination by the ear surgeon (otologist) and hearing specialist (audiologist). Cases of childhood autism (withdrawal, severe eccentricities) or early schizophrenia are now being recognized with increasing frequency by speech pathologists, child psychiatrists, pediatricians, and clinical psychologists. This multitude of various professional interests in the recognition and rehabilitation of such exceptional children is well served by the coordination of these efforts in the modern team approach. But again, the largest group of disorders of voice and speech has causes other than these grossly organic lesions. They belong within the province of speech rehabilitation by experts in speech pathology and other functional practitioners.

Development of speech correction. That mankind has been troubled by speech afflictions since the beginning of recorded history can be gleaned from numerous remarks in the books of the Bible. Further, many scientific and medical writers from the time of antiquity to the Middle Ages reported observations of speech and voice disorders. The recommended remedies merely reflected the inadequacies of the philosophical or empirical notions of their times. Scientifically oriented speech pathology originated in Germany during the latter part of the 19th century, following closely the development of otolaryngology. Three names stand out in this respect: C.L. Merkel (*Anthropophonik*; 1857), Adolph Kussmaul (*The Disorders of Speech*; 1877), and Hermann Gutzmann, Sr., who became the first professor of speech pathology at the University of Berlin Medical School around 1900.

During the same time, the new science of experimental phonetics was developed by Jean-Pierre Rousselot in Paris, who promptly recognized the great contributions that experimental phonetics could make to the study of normal and disturbed speech. This close collaboration of medical speech pathology with experimental phonetics has remained typical for the European continent where speech correction is customarily carried out under the direction of physicians in the ear, nose, and throat departments of the university hospitals. The designation of speech and voice pathology as logopedics and phoniatrics with its medical orientation subsequently reached many other civilized nations, notably in Japan and on the South American continent. The national organizations in most of these areas are now represented in the International Association of Logopedics and Phoniatrics, which was founded in Vienna in 1924.

Experimental phonetics

The evolution of speech correction in the Anglo-Saxon countries followed a different trend. Although Great Britain has had a long tradition in general and experimental phonetics, its College of Speech Therapists was organized as an examining and supervisory body in 1945. Similar organizations followed in other areas of the British Commonwealth.

American speech pathology elected a different way. The American Speech and Hearing Association (ASHA), founded in 1925 in New York City, became the organizing, examining, and supervisory body for a rapidly growing membership, which surpassed 12,000 by 1970. More than 200 colleges and universities in the United States, many accredited by ASHA, offer degrees in speech pathology and audiology, some including work at the doctoral level. The large majority of ASHA members hold the master's degree and work as speech clinicians in the public school systems. A smaller number with master's degrees and a still smaller number with doctoral degrees staff the more than 300 clinics that deal with communication disorders and that are usually affiliated with hospitals, colleges, universities, and occasionally with civic organizations.

Soviet Russian speech correction originally followed the developments of European logopedics and phoniatrics and is now directed by the Department of Logopedics in the Government Institute of Defectology of the Academy of Pedagogical Sciences in Moscow. One facet of speech pathology in the U.S.S.R. is its emphasis on Pavlovian theory (conditioning and retraining) and intensive use of neuropsychiatric methods, including pharmacology, sleep therapy, and other intensive treatment programs during hospitalization. Similar trends operate in the eastern European countries under Russian influence, such as in Czechoslovakia, where the first independent medical department of logopedics and phoniatrics was organized at the Faculty of Medicine of Charles University in Prague.

MAJOR TYPES OF SPEECH DISORDERS

Voice disorders. In international terminology, disorders of the voice are described as dysphonia. Depending on the underlying cause, the various types of dysphonia are subdivided by the specifying adjective. Thus, a vocal disorder stemming from paralysis of the larynx is a paralytic dysphonia; injury (trauma) of the larynx may produce traumatic dysphonia; endocrine dysphonia reflects the voice changes resulting from disease of the various endocrine glands such as the pituitary. The various dysphonias of clearly organic origin from systemic disease (*e.g.*, muscular, nervous, or degenerative disease afflicting the entire body) or from local laryngeal changes differ in their visible symptomatology, as well as in the perceptual impression produced by the abnormal voice. Nevertheless, it has not yet been possible to define the acoustical alterations in the vocal spectrum that would allow a clear and objective differentiation among the subjective graduations of an abnormal voice as hoarse, harsh, husky, breathy, grating, gravelly, gritty, etc.

Because a large group of dysphonias have no visible laryngeal causes, they are grouped as nonorganic. Two main types of these so-called functional voice disorders may be distinguished: the habitual dysphonias that arise

Emotional causes

from faulty speaking habits and the psychogenic dysphonias that stem from emotional causes. Both of these types of dysphonia again occur in two basic subtypes, the hyperkinetic (overactive) and the hypokinetic (underactive) since emotional disorders interfere with voluntary vocal function by either causing excessive or depressed physiological activity. In the hyperkinetic disorders, the highly coordinated patterns of phonation regress to the primitive, forceful, and exaggerated sphincter action of the larynx as seen during gagging. The result is hyperkinetic dysphonia, the gratingly harsh vocal disorder due to excessive muscular action in a constricted larynx. In the second subtype, the movements for phonation regress even more deeply to the original function of respiration; the sluggish larynx remains more or less open, and the glottis is incompletely closed for phonation, leading to hypokinetic dysphonia with subdued, breathy huskiness.

Disorders of language development. The most frequent speech disorders are those that disturb the child's acquisition or learning of language. While those concerned with modern terminology are striving for an improved classification according to the etiologic (causative) factors, it is still customary to classify these disorders on the basis of the complaint: absence of speech, baby talk, poorly intelligible articulation, lisping, etc. Recent studies of large numbers of children with such developmental language disorders have shown that at least two chief classes of these disorders may be distinguished: general language disability from genetic factors with a familial (inherited) pattern chiefly from the paternal side, and acquired language disorders due to damage sustained before, during, or shortly after birth (*i.e.*, perinatally).

These latter perinatal damages encompass the gamut of toxic, infectious, traumatic, nutritional, hormonal, and other damages that may hurt the growing fetus or young infant. Major and minor birth injury is not an infrequent factor. Hereditary factors also encompass a great variety of genetically predetermined influences, including familial tendency to exhibit slow language development, lesser endowment in the brain area for language, inferior function in the highest brain areas of auditory performance without organic damage to the ears, slow maturation of motor function (including clumsiness and deviation from normal cerebral dominance), and other signs of delayed cerebral growth. Additional environmental causes include poor language patterns used by the family, parental neglect, emotional maladjustment, general weakness from prolonged disease, as well as various socioeconomic, cultural, and other psychological influences.

While some otherwise perfectly normal children, particularly boys, may not elect to begin talking until age three, making good progress in every respect from then on, the absence of speech after age two may be caused by any of the conditions mentioned thus far and would appear to merit prompt investigation. If an organic cause can be detected, the symptomatic description of delayed language development then yields to a specific etiologic (causal) diagnosis. Although it is best to describe the absence of speech in early childhood as simply delayed language development, some American investigators tend to refer to this condition as congenital (present at birth) aphasia, a term rejected by most European scholars who argue that there cannot be an inborn or early acquired aphasia before a language has been learned.

Many children encounter unusual difficulties in mastering the patterns of articulation of their mother tongue and are said to manifest articulatory immaturity (infantile dyslalia). If no organic cause can be found, the probable cause may be delayed maturation of psychomotor skills.

Marked delays of language development are often followed by a period of inability to learn the rules of grammar and syntax at the usual age (dysgrammatism). Though this is often a sign of inherited language disability, it may reflect mental retardation or other types of brain damage.

Some children who have suffered such laboured language development may then go through a period of retarded reading and writing disability, a condition often defined as dyslexia. Again, there are two chief varieties: the primary or developmental reading and writing disability due to constitutional (organic) and hereditary factors, and a large secondary group of symptomatic reading disorders acquired through any of the influences that retard language development in general, including troubles with vision. Practically all investigators agree that primary or developmental dyslexia shows a marked hereditary tendency (is familial) and is typically associated with other disorders of psychomotor development, deviation from the prevalent right handedness, and poor function in the auditory area in the brain, often associated with lack of musical talent. Primary dyslexia is significantly associated with other developmental speech disorders.

Reading and writing disability

Cluttering. Those who have followed large numbers of children with language disabilities for a long time are impressed by the fact that these various manifestations of an underlying developmental disorder often terminate in a peculiar impediment of speech that has been well known to European speech pathologists for many years but is not yet fully recognized in American speech literature: cluttering (or tachyphemia), the hasty, slóppy, erratic, stumbling, jerky, and poorly intelligible speech that may somewhat resemble stuttering (see below) but differs from it markedly in that the clutterer is usually unaware of it, remains unconcerned, and does not seem to fear speaking situations. Its association with other past or persistent signs of subnormal language development also differentiates congenital cluttering from emotional stuttering. Experts are strikingly unanimous in stressing the hereditary nature of cluttering.

Lisping. Although lisping belongs among the articulatory disorders and usually has the same causes as articulatory disorders (dyslalia) in general, it differs from other disorders of articulation in several respects. For one, lisping occurs in various varieties: with the tongue tip protruding between the front teeth, with a slurping noise in the cheek pouch, with the tongue too far back along the palatal midline, with excessive tongue pressure against the teeth; in several snorting and nasal subtypes, as well as through substitute hissing deep in the throat or even within the larynx, such as in cleft-palate speech. Moreover, the causes of lisping include a diverse group of particular conditions: abnormal number or position of teeth; imitation of other lispers; deficiency of palatal closure; slight hearing loss in the high frequencies; as well as several psychologic causes, such as effeminate affectation, infantile mannerisms, or mental disturbance. Lisping is less easily outgrown than the other infantile dyslalias and may persist into adult life if not corrected.

Causes of lisping

Stuttering. Academically known as dysphemia, what is called stuttering in the U.S. is usually named stammering in Great Britain. While everyone seems to know what stuttering sounds like, experts do not agree about what really causes it. In the age groups after puberty, stuttering is the most frequent and conspicuous type of disturbed speech encountered. This is one reason why among the studies dealing with speech pathology in the world literature those devoted to stuttering are the largest single group. Despite numerous and intensive studies of the problem, findings and conclusions are far from unanimous. A great number of theories have been proposed to explain the origin and nature of stuttering, which range from the premise that subtle physical disturbances in the nervous system (so-called neurogenic asynchronies) are responsible to the opinion that psychological maladjustment alone is to blame. The report issued by the U.S. Public Health Service (see above *Prevalence of Speech Pathology*) concludes that "stuttering remains an enigma while illustrating the type of disorder which does not have either a clean-cut organic cause or a clearly habitual basis."

Research findings indicate (as is the case with many developmental speech disorders, particularly language disability, articulatory disorders, reading disability, and cluttering) that trouble with stuttering affects the male sex at least four times more frequently than the female. Hereditary predisposition has been noted in many studies of large groups of stutterers, with evidence for an inherited tendency found among as many as 40 percent of the

stutterers studied. Some experts insist that stuttering is not a single disease entity but that it comprises several types of the disorder with different causes. According to such views, the familial occurrence of stuttering represents a combination of the stuttering symptom with a cluttering tendency that is inherited. Although imitation of another stutterer may form the basis for acquiring the habit, purely psychological explanations that stress parental attitudes in training their children fail to reveal why many stutterers have siblings (brothers or sisters) with perfectly normal speech.

Treatment of stuttering

The treatment of stuttering is difficult and often demands much skill and responsibility on the part of the therapist. The possibility of some specific medical cure seems remote at the present time. Even the most advanced methods of modern psychiatry have failed to produce superior results in treatment. For a time it was hoped that new psychopharmacological drugs (*e.g.*, tranquillizers) might facilitate and accelerate recovery from stuttering, but these efforts have been disappointing thus far. The typical program of management in this disorder is a strict program of psychotherapy (talking freely with a psychiatrist or psychologist so as to reduce emotional problems) supported by various applications of learning theory or behavioral theory (in retraining the stutterer) and other techniques depending on the therapist's position. It is widely agreed that the patient must acquire a better adjustment to the problems of his life and that he needs to develop a technique for controlling his symptoms and fears. Prognosis (predicted outcome of treatment) thus is held to depend greatly on the patient's motivation and perseverance. It is interesting to note that experienced investigators no longer aspire to a "cure" of stuttering through an etiologic (causal) approach. Instead of focussing on underlying causes, they aim at making the patient "symptom-free" via symptomatic therapy.

Prevention of stuttering may be aided through parent counselling. The normal, immature speech of many children is characterized by various nonfluencies; these include hesitations, syllable repetition, groping for the right word, and vocalizations between words such as "ah-ah." Some misguided parents castigate these normal signs of developing speech with various admonitions and, even worse, try to forbid the nonfluencies by mislabelling them as stuttering. In some children, this parental interference associates normal nonfluency with feelings of insecurity and fear, tending to make the child become a real stutterer. Much research has been devoted to this probable etiology for one type of stuttering; its elimination through parental guidance indeed has been reported to help in reducing the number of stutterers.

Dysphasia and aphasia. Dysphasia means the partial or total loss of language as a result of lesions in those parts of the brain that are directly related to language function. Stroke in elderly patients and head injury in younger ones are typical causes. Aphasia is seen most frequently when the left side of the brain is afflicted, as evidenced by paralysis of the right arm and leg. Evidence indicates that the left hemisphere is dominant in all right-handed individuals and in some left-handers as well. Some experts even believe that the left brain hemisphere is dominant for language in most individuals regardless of handedness and that dominance of the right brain is exceptional in some left-handers. According to other opinions, dominance for language is more evenly distributed in both hemispheres in left-handed persons. As explained before, two major brain areas are recognized as intimately associated with language function: Broca's area in the third frontal convolution and Wernicke's area in the posterior third of the upper temporal convolution. The angular gyrus at the junction of the temporal (side), parietal (top), and occipital (back) lobes of the brain is believed to be related to graphic language as used for reading and writing.

Aphasiology, the science of aphasic language loss, is studied by neurologists, neurosurgeons, some phoniatrists, certain speech pathologists, as well as some psychologists and linguists. This diversity of research background accounts, in part, for the great diversity in theoretical approaches to aphasia. Numerous classification schemes that have been proposed vary from simple groupings into a few main types of aphasia to complicated systems with many forms and subtypes of aphasic disturbances. Similar to research in stuttering, the literature on aphasia is exceptionally large and growing.

The phenomenon of aphasia

The essence of aphasia is the loss of memory for the meaning of language and its production. Thus, in the predominantly expressive or motor forms, the patient can no longer remember the intricate patterns for articulation; he can no longer form a word in speaking or writing, even though he may know what he wants to express. In the predominantly receptive or sensory forms, the patient can talk freely, sometimes excessively and incessantly (logorrhea), although with numerous errors and meaningless clichés, but he no longer comprehends what is said to him or what he tries to read. Those who recover from receptive forms of the disorder are likely to explain that during their aphasia spoken language sounded like an unintelligible, alien tongue. The degree to which there is combination of expressive and receptive symptoms varies greatly with the type and extent of brain lesion. There may be total loss of all language functions (global aphasia) to slight residual errors or misunderstandings when the brain damage is only slight or temporary. A major complication of aphasia is the frequent association with right hemiplegia, in which the paralyzed hand is no longer serviceable for writing. Retraining of the left hand for writing may then become necessary.

Management of aphasia has two goals: one, the physical recovery of the patient through treatment by the internist, neurologist, and possibly brain surgeon and two, the re-education of the brain functions that remain, the aim being to help the patient relearn some use of language under the guidance of the speech pathologist. The better the recovery from the brain lesion, the more chances there are of prompt and complete return of language. When the brain losses are permanent, the patient must relearn each word, sentence, and phrase like the young child, albeit in a more cumbersome manner, apparently using brain parts that still function. He is repeatedly shown the picture of an object along with its printed name; these words are spoken to him by his teacher over and over in the hope that he will learn to repeat the word or phrase until he can say it spontaneously. Words that are relevant to the patient's everyday life are emphasized first with due consideration for his interests and past occupation; later he may advance to the use of abstract concepts and of higher levels of language. Various types of automated training programs are available, including a simple play-back device that shows an inserted card with a picture on it, the name of the pictured object printed next to it, and the audible word recorded on a strip of magnetic tape. Devices of this type enable the patient to practice at his own pace.

Symptomatic speech disorders. Under this heading may be summarized various types of communication disorders that develop on the basis of known structural lesions or metabolic disturbances. Etiologic classifications group these impediments according to the types of organic diseases, as well as in respect to the afflicted effector organs (such as the tongue). Disturbed speech from lesions in the various parts of the nervous system is known as dysarthria. Mental retardation usually limits the development of linguistic ability to the same extent as it does intellectual capacity; this language disorder has been described as dyslogia. Mental disturbances can also manifest themselves in linguistic symptoms, such as in the peculiar (dysphrenic) mode of speech among sufferers of schizophrenia. Hearing loss dating from early childhood leads to a typical distortion of the speech pattern for which various names have been coined, such as audiogenic dyslalia. Visible defects in such oral articulators as the lips and teeth limit the mechanics of articulation and thus reduce the quality and intelligibility of speech; such speech problems are known collectively as dysglossia.

Dysarthria. Damage to those parts of the nervous system that regulate the actions of voice and speech cause distinctive alterations of the speech pattern. The most im-

portant disorder of this type is cerebral palsy from brain injury before, during, or soon after birth. The majority of cerebral palsy victims retain normal intelligence, but are handicapped by distortions of voluntary movements, including those for speaking. Just as walking may be stilted and jerky and arm movements crude and uncontrolled, the patterns of voice and speech will reflect the same distortions. Great advances in rehabilitation have been achieved in the recent past, such as with the well-known Bobath method, which is based on learned suppression of primitive reflexes.

Effects of cerebral palsy

Shaking palsy. Another type of dysarthria is observed in cases of Parkinson's disease. This affliction of the nervous system makes body movements either excessively rigid or tremulously repetitive, such as with the so-called "pill-rolling" sign of hand tremor. Voice and speech reflect the same patterns, sometimes appearing as the first obvious symptoms of the disease. Brain surgery is used in an attempt to improve these abnormal body movements, often with good general results, although speech may be little improved or even made worse. Neurologists also are collecting observations on promising drug treatments for Parkinson's disease, such as with L-Dopa.

When a neurologic disease damages the bulbar nuclei (in the brain stem) of the nerves innervating the organs for speech, the effect of bulbar dysarthria is heard. In severe cases, voice may be reduced to a faint grunting, while articulation deteriorates into mumbling or total muteness. Chorea, another neural disorder manifested in sudden jerky movements of the entire body, may be associated with bizarre, explosive disruptions of the speech flow. Cerebellar dysarthria results from disease of the brain part called the cerebellum (which regulates fine motor coordination), leading to various disorganizations of speech including a "drunken" (ataxic) quality.

Mental retardation. Major advances in the science of inheritance (genetics) and in biochemistry have clarified a number of inborn metabolic causes of many types of mental retardation (see HUMAN BEHAVIOUR, INNATE FACTORS IN). Some of these forms of retardation can be avoided through genetic counselling of prospective parents or prevented by prompt treatment following early diagnosis. (In some cases a change in diet is effective.) Improved prenatal care may reduce the size of another group of mentally retarded individuals whose problem stems from brain damage sustained during fetal life before birth. The number of unknown causes in other cases of retardation is still considerable, however.

Management of the mental retardate

The total management of the mentally retarded child concerns a large group of specialists: pediatrician, geneticist, clinical psychologist, audiologist and speech pathologist, and special educators in institutions for such children. Following classification on the basis of a level of educability, the child undergoes a composite training program geared to his capabilities. Intensive training in language usage not only tends to improve his communication skills but also forms a bridge to increased general learning. There has been recent stress on the not infrequent combination of mental retardation with hearing loss; in such cases, the audiologist prescribes a hearing aid and auditory training to improve the receptive aspects of communication.

Language and mental disorder. Expert analysis of the bizarre speech patterns associated with certain psychiatric disturbances is of primary diagnostic significance. If a mute child persists in stereotyped rituals and strange behaviour, a diagnosis of childhood autism is likely to be made. Some experts distinguish this from a similar disorder called childhood schizophrenia, in which previously good general and linguistic development falls apart in association with similarly bizarre behaviour. In adolescence, a sudden change of voice to a shrill falsetto or weird chanting may herald the outbreak of juvenile schizophrenic disease. Infantile lisping, strange distortions of articulation, and various eccentricities in verbal expression are other signs of schizophrasic speech in the adult schizophrenic. Linguistic study may help the psychiatrist in analyzing the patient's ways of thinking and to provide a measure of the sufferer's progress under therapy. Great therapeutic stress is placed on establishing contact with the autistic child by eliciting from him some sort of communication. Language is felt to be one of the best bridges to break open the closed inner world of such children.

Speech of the hard of hearing. Hearing loss that dates from childhood hinders the normal development of language because the most important sensory portal for speech learning remains deficient. Such children learn to say the sounds of speech as they hear them; that is, in a muffled, distorted, or even inaudible fashion. The articulatory disorder (audiogenic dyslalia) usually reflects the measured (audiometric) pattern of hearing loss. If sound waves at high frequencies cannot be heard, speech sounds with formants in that high-frequency region will be affected. The hissing sibilants contain the highest formants and are therefore most typically disturbed by high-frequency hearing loss. The lower frequencies that can still be heard limit the audible formants to this residual range, which transposes the normal formant patterns into the abnormally lowered frequency band. As a result, a sharp hissing S is spoken as a muted Sh, and the light vowels are transformed into their darker counterparts (for example, the word "set" may be pronounced as "shot" or "shöd" as if it were German).

The voice reflects analogous changes. In the case of conductive hearing loss (in which neural structures for hearing are intact), the patient hears himself well through the bones of his skull but cannot hear others. Because his bone conduction remains good, his voice will sound loud to him and he tends to keep it subdued. The opposite occurs with neural (or perceptive) hearing loss in which there is nerve dysfunction. In this case, the patient hears his own voice as poorly as that of others, and he tends to talk in an overloud and screeching voice.

Correction of audiogenic dyslalia may be possible through early fitting of a suitable hearing aid, intensive auditory training, and speech exercises aided by audiovisual playback devices (auditory trainers, tape recorders, visible speech devices, etc.).

Deaf-mutism

Profound or total deafness going back to early childhood without special training inevitably leads to deaf-mutism, the absence of language development as a direct result of deafness. Deaf-mute children have traditionally been educated in special schools for the deaf, where the oral method (showing how to shape the oral structures for each speech sound) of teaching speech has competed with the older manual method of allowing the deaf to communicate through their own gestural or finger spelling. Recent advances in training include the liberal use of amplification devices (*e.g.*, group hearing aids) in all school situations as well as the earliest possible fitting of hearing aids following definite diagnosis. This can be accomplished even when the patient cannot communicate that he hears (*e.g.*, in very young babies) through such methods as recording brain-wave patterns in response to measured sound stimulation (EEG response audiometry).

Speech impediments from defective articulators. Dysglossic (from defective oral structures) disorders in articulation have interested mankind for the longest time; the biblical and poetical interchange of the words for "tongue" and "speech" in many languages has kept alive the assumption that speech originates within the fleshy tongue. For the same reason, the popular term tongue-tied still persists to refer to an abnormally immobile tongue and some assumed resulting limitation of linguistic ability. Even the academic designation of the science of languages as "linguistic" is traditionally based on the Latin word *lingua* for tongue.

Tongue-tie. In practice, the condition of a true tongue-tie (ankyloglossia) occurs only rarely and is quite easily corrected through a simple operation. Even when the shortened band beneath the tongue tip is permitted to persist, very little speech disturbance, if any, is audible in such persons. The only limitation of articulation to be expected is the decreased ability to protrude the tongue tip between the teeth for the English Th and the trilling lingual R in southern German, Latin, and Slavic languages. In any event, a true tongue-tie never causes stut-

tering, lisping, or any other of the major speech disorders.

Loss of tongue. Major defects of the tongue from paralysis, injury, or surgery reduce the articulation of the lingual sounds to the same extent that the tongue's mobility is visibly limited. Spontaneous compensation is usually quite prompt, depending on the patient's general linguistic talent. One exception is complete bilateral (both sides) paralysis of the tongue, which causes a very severe disorder of chewing and swallowing as well as severe limitation of speech intelligibility. The total loss of the tongue (true aglossia) from injury or surgery is often amazingly well compensated. Patients can learn to use residual portions of a tongue stump as well as other oral structures to substitute for the missing tongue; indeed, some persons without a tongue have relearned to speak so well that the listener would not suspect its absence.

Nasal speech. Several types of nasal speech are not easily diagnosed; even specialized physicians are often not fully aware of the differences.

Increased nasal resonance leads to open nasality (hypernasal speech), affecting all oral speech sounds that should not be nasal. Organic causes impair the accuracy of palatal occlusion during emission of the nonnasal sounds. Among these are paralysis, congenital malformation, injury, or defects of the palate. The functional causes of palatal sluggishness include imitation, faulty speech habits, dialectal influences, hearing loss, mental retardation, or psychiatric disorders.

Decreased nasal resonance

Decreased nasal resonance produces closed nasality (hyponasal speech), which muffles the three nasal resonants (M, N, and Ng). The best known organic causes are an acute cold, hay fever, large adenoids, as well as all other nasal diseases that obstruct the airway. Functional causes are less frequent, in the form of a rare, faulty speech habit; occasionally the problem comes from mental retardation or from severe language disability.

Mixed nasality poses a serious problem; it stems from the combination of one cause of open nasality with another of closed nasality (one may be of organic type and the other functional, or both may be organic). A typical combination is the open nasality from paralysis (paresis) of the palate (or its congenital deficiency) combined with closed nasality from obstruction of the nasopharynx by adenoids. The resulting mixed nasality causes the nasal resonants to sound muffled and subdued, while careful testing reveals slight open nasality on all oral sounds.

Treatment of nasal speech is unlikely to be successful without prudent balancing of all factors involved. This responsibility rests primarily with the diagnosing otolaryngologist or phoniatrist. The complaint of "talking through the nose" should never warrant a tonsil and adenoid operation without complete evaluation. If this were done in the example cited just above, removal of the obstructing adenoids would alleviate only the closed nasality, while making the open component more severe with marked deterioration of the patient's speech. This dilemma is often present when adenoids cause chronic middle-ear disease with hearing loss, while the palate is incompetent, as from a slight congenital malformation or paresis. In such case, the patient's general health and his hearing must be weighed against the possibility of making his speech worse.

Cleft palate speech. This type of organic dysglossia has also been named rhinoglossia (Greek *rhin, rhis*: "nose") because it is an organic cause of excessively nasal speech. Clefts of the lip, upper jaw, and hard and soft palate occur in various types and combinations. Cleft palate is a congenital (present at birth) malformation that develops for various reasons during the early weeks of embryonic life. The causes may be grouped as follows: inheritance in some cases; embryonal damage from various environmental causes in others; while still other cases of cleft palate are part of a syndrome of general or multiple malformation, which may again be hereditary, the result of chromosomal aberrations, or of environmental origin. Genetic influences are inferred from evidence that North American Indians (Montana) show a high incidence of cleft palate, but Negroes (as on the island of Jamaica) show an unusually low incidence.

Hereditary influences

The speech disorder in cleft palate cases is complex. As a direct, mechanical result of the absent velopharyngeal (soft palate-pharynx) closure, voiced sounds assume an abnormal nasal quality from the unusual resonance of the nasal chambers. The influence of nasality on the perceptual and acoustic characteristics of the speech sounds has been discussed earlier. A second component is a mechanical limitation in articulating plosive sounds (*e.g.*, P) because the necessary intra-oral pressure cannot be achieved. For the same reason, the sibilant sounds (*e.g.*, S) are greatly distorted because the articulating air escapes through the nose before it can produce the characteristic hissing noise at one of the places of constriction. The child with an unrepaired cleft palate seems unconsciously to attempt to overcome these mechanical limitations in several ways. He tries to constrict the nostrils through facial grimaces, and he attempts to increase the expiratory air pressure. He also succumbs to the "law of centripetal regression of articulation"; that is, he shifts the articulation of the oral sounds below the point of deficient palatal occlusion, down into the pharynx or even the larynx. It is easy to demonstrate by X-ray fluoroscopy how the larynx becomes constricted during each plosive or sibilant sound in such cases.

Mechanism of cleft palate disorder

These mechanical limitations of articulation in cleft palate lead to secondary modifications of behaviour. Linguistic ability is retarded through general limitation of speech learning; emotional reactions to the handicap may complicate the clinical picture; a vicious circle is thus established, which in turn impedes the sufferer's general intellectual and special linguistic development.

Other coincidental disorders complicate the pattern of cleft-palate speech. Many cleft-palate patients also suffer from middle-ear infection, and the resulting hearing loss may add the component of audiogenic dyslalia. In other cases, the structural malformation may be complicated by mental retardation. Coincidental genetic factors may aggravate the speech problem when the syndrome of familial (neurally inherited) language disability is superimposed. In such cases, the mechanical speech disorder of rhinoglossia becomes complicated by the additional signs of delayed speech development, articulatory dyspraxia, dysgrammatism, reading and writing disability, etc. This combination is evident in some cases following the successful surgical correction of the palatal deficiency. Although the nasality is promptly alleviated in such cases, the various speech disorders from language disability may persist, since they have nothing directly to do with the previous cleft palate.

Treatment of cleft palate

Management of cleft palate is the task of a well-coordinated team. The plastic surgeon closes the palatal deficiency, the psychologist analyzes the intellectual endowment, the speech pathologist corrects the various components of disordered speech, the audiologist determines coincidental hearing loss, and the otolaryngologist cares for the health of nose and ears. Tonsils and adenoids may be diseased, leading to the frequent complication of middle-ear infection with hearing loss. This condition may require removal of tonsils and adenoids to preserve hearing. A dilemma is then created; removal of tonsils and adenoids is generally contra-indicated in cases of deficient palatal closure because this operation increases the degree of open nasality. The child's welfare then should be carefully considered in order to avoid any harm.

When surgical repair is not feasible, the palatal defect may be covered by a special prosthetic plate (obturator) similar to false dental appliances. This technique has been known for many centuries, and various models of obturators have been constructed in the course of time. Cleft-palate care therefore includes the services of a prosthodontist (who makes false teeth) for the optimal construction of such appliances. If worn by children, obturators should be regularly altered to maintain continuous fit as the patient grows.

Well-organized centres for the management of cleft palate are able to offer excellent care so that the speech impediment can be ideally or almost completely corrected in many cases. The problem of cleft palate thus demonstrates once more that human speech requires complex

detailed study of its normal functions and manifold approaches for the correction of its imperfections.

Spencer, Herbert

Herbert Spencer, an early upholder of the theory of evolution, maintained that every aspect of reality must be viewed in terms of a continuing development from lower to higher stages. He thus regarded human progress as "not an accident but a necessity." His naturalistic philosophy, a broad synthesis of knowledge buttressed by a detailed, scientific examination of a vast range of biological and social phenomena, significantly influenced the development of biology, psychology, anthropology, and sociology.

Life and works. Spencer was born in Derby on April 27, 1820. His father, William George Spencer, was a schoolmaster; and his parents' dissenting religious convictions inspired in him a nonconformity that continued active even after he had abandoned the Christian faith. Spencer declined an offer from his uncle, the Rev. Thomas Spencer, to send him to Cambridge, and in consequence his higher education was largely the result of his own reading, which was chiefly in the natural sciences. He was, for a few months, a schoolteacher and from 1837 to 1841 a railway civil engineer.

In 1842 he contributed some letters (republished later as a pamphlet, *The Proper Sphere of Government*, 1843) to *The Nonconformist*, in which he argued that it is the business of governments to uphold natural rights and that they do more harm than good when they go beyond this. After some association with progressive journalism through such papers as *The Zoist* (devoted to mesmerism and phrenology) and *The Pilot* (the organ of the Complete Suffrage Union), Spencer became in 1848 a subeditor of *The Economist*. In 1851 he published *Social Statics* (reissued in 1955), which contained in embryo most of his later views, including his argument in favour of an extreme form of economic and social laissez-faire. About 1850 Spencer became acquainted with Marian Evans (the novelist George Eliot), and his philosophical conversations with her led some of their friends to expect that they would marry; but in his *Autobiography* (1904) Spencer denies any such desire, much as he admired Miss Evans' intellectual powers. Other friends were G.H. Lewes, T.H. Huxley, and J.S. Mill. In 1853 Spencer, having received a legacy from his uncle, resigned his position with *The Economist*.

Having published the first part of *The Principles of Psychology* in 1855, Spencer in 1860 issued a prospectus

Spencer.
The Gernsheim Collection, the University of Texas at Austin

and accepted subscriptions for a comprehensive work, *The Synthetic Philosophy*, which was to include, besides the already published *Principles of Psychology*, volumes on first principles and on biology, sociology, and morality. *First Principles* was published in 1862, and between then and 1896, when the third volume of *The Principles of Sociology* appeared, the task was completed. In order to prepare the ground for *The Principles of Sociology*, Spencer started in 1873 a series of works called *Descriptive Sociology*, in which information was provided about the social institutions of various societies, both primitive and civilized. The series was interrupted in 1881 because of lack of public support. Spencer was a friend and adviser of Beatrice Potter, later Beatrice Webb, the social reformer, who frequently visited Spencer during his last illness and left a sympathetic and sad record of his last years in *My Apprenticeship* (1926). Spencer died on Dec. 8, 1903, at Brighton, leaving a will by which trustees were set up to complete the publication of the *Descriptive Sociology*. The series comprised 19 parts (1873–1934).

Writing of *The Synthetic Philosophy*

Spencer was one of the most argumentative and most discussed English thinkers of the Victorian period. His strongly scientific orientation led him to urge the importance of examining social phenomena in a scientific way. He believed that all aspects of his thought formed a coherent and closely ordered system. Science and philosophy, he held, gave support to and enhanced individualism and progress. Though it is natural to cite him as the great exponent of Victorian optimism, it is notable that he was by no means unaffected by the pessimism that from time to time clouded the Victorian confidence. Evolution, he taught, would be followed by dissolution, and individualism would come into its own only after an era of socialism and war.

The synthetic philosophy in outline. Spencer saw philosophy as a synthesis of the fundamental principles of the special sciences, a sort of scientific summa to replace the theological systems of the Middle Ages. He thought of unification in terms of development, and his whole scheme was in fact suggested to him by the evolution of biological species. In an article, "The Development Hypothesis" (1852), Spencer rejected the notion of special creation; and in "Progress: its Law and Cause" (1857), he applied the idea, borrowed from the Estonian naturalist, K.E. von Baer, that biological development in the individual is from the homogeneous to the heterogeneous to the evolution of the solar system; of animal species; of human society; and of industry, art, language, and science. It should be noticed that Spencer published his idea of the evolution of biological species before the views of Charles Darwin and the British naturalist Alfred Russel

From the homogeneous to the heterogeneous

Wallace were known; but Spencer at that time thought that evolution was caused by the inheritance of acquired characteristics, whereas Darwin and Wallace attributed it to natural selection. Spencer later accepted the theory that natural selection was one of the causes of biological evolution, and himself coined the phrase "survival of the fittest" (*Principles of Biology* [1864], vol. 1, p. 444). He did not, however, posit any of these causes as ultimate principles of evolution. In his view the principle of change from homogeneity to heterogeneity was more important and was itself a consequence of principles still more fundamental. In *First Principles* he argued that there is a fundamental law of matter, which he called the law of the persistence of force, from which it follows that nothing homogeneous can remain as such if it is acted upon, because any external force must affect some part of it differently from other parts and cause difference and variety to arise. From this, he continued, it would follow that any force that continues to act on what is homogeneous must bring about an increasing variety. This "law of the multiplication of effects," due to an unknown and unknowable absolute force, is in Spencer's view the clue to the understanding of all development, cosmic as well as biological.

Sociology and social philosophy. That Spencer first derived his general evolutionary scheme from reflection on human society is seen in *Social Statics,* in which social evolution is held to be a process of increasing "individuation." He saw human societies as evolving by means of increasing division of labour from undifferentiated hordes into complex civilizations. Spencer believed that the fundamental sociological classification was between military societies, in which cooperation was secured by force, and industrial societies, in which cooperation was voluntary and spontaneous.

Military versus industrial societies

Evolution is not the only biological conception that Spencer applied in his sociological theories. He made a detailed comparison between animal organisms and human societies. In both he found a regulative system (the central nervous system in the one, government in the other), a sustaining system (alimentation in the one case, industry in the other), and a distribution system, (veins and arteries in the first; roads, telegraphs, etc., in the second). The great difference between an animal and a social organism, he said, is that whereas in the former there is one consciousness relating to the whole, in the latter consciousness exists in each member only; society exists for the benefit of its members and not they for its benefit.

Liberal principle of variety

This individualism is the key to all of Spencer's work. His contrast between military and industrial societies is drawn between despotism, which is primitive and bad, and individualism, which is civilized and good. He believed that in industrial society the order achieved, though planned by no one, is delicately adjusted to the needs of all parties. In *The Man versus the State* (1884) he wrote that England's Tories generally favour a military and Liberals an industrial social order but that the Liberals of the latter half of the 19th century, with their legislation on hours of work, liquor licensing, sanitation, education, etc., were developing a "New Toryism" and preparing the way for a "coming slavery." "The function of liberalism in the past was that of putting a limit to the powers of kings. The function of true liberalism in the future will be that of putting a limit to the powers of parliaments."

Metaphysics. In his emphasis on variety and differentiation, Spencer was unwittingly repeating, in a 19th-century idiom, the metaphysics of liberalism that Spinoza and Leibniz had adumbrated in the 17th century. Spinoza had maintained that "God or Nature" has an infinity of attributes in which every possibility is actualized, and Leibniz had argued that the perfection of God is exhibited in the infinite variety of the universe. Though neither of them believed that time is an ultimate feature of reality, Spencer combined a belief in the reality of time with a belief in the eventual actualization of every possible variety of being. He thus gave metaphysical support to the liberal principle of variety, according to which a differentiated and developing society is preferable to a monotonous and static one.

Evaluation. Spencer's attempt to synthesize the sciences showed a sublime audacity that has not been repeated because the intellectual specialization he welcomed and predicted increased even beyond his expectations. His sociology, although it gave an impetus to the study of society, was superseded as a result of the development of social anthropology since his day and was much more concerned with providing a rationale for his social ideals than he himself appreciated. Primitive men, for example, are not the childlike emotional creatures that he thought them to be, nor is religion to be explained only in terms of the souls of ancestors. When T.H. Huxley said that Spencer's idea of a tragedy was "a deduction killed by a fact," he called attention to the system-building feature of Spencer's work that led him to look for what confirmed his theories and to ignore or to reinterpret what conflicted with them.

MAJOR WORKS

PHILOSOPHY AND RELIGION: *The Nature and Reality of Religion,* 1885 (withdrawn from publication). Spencer's series on *Synthetic Philosophy* comprises: *First Principles,* 1862; *The Principles of Biology,* 2 vol., 1864–67; *The Principles of Psychology,* 1855; *The Principles of Sociology,* 3 vol., 1876–96; *The Principles of Ethics,* 2 vol., 1892–93.

POLITICAL AND SOCIAL: *The Proper Sphere of Government,* 1843; *Social Statics,* 1851; *Education: Intellectual, Moral, Physical,* 1861; *The Study of Sociology,* 1872; *The Man versus the State,* 1884; *Facts and Comments,* 1902.

OTHER WORKS: *Essays: Scientific, Political, and Speculative,* 3 vol., 1891; *Autobiography,* 1904, an intellectual rather than a personal autobiography.

BIBLIOGRAPHY. A so-called official biography is that by DAVID DUNCAN, *Life and Letters of Herbert Spencer,* 2 vol. (1908). T.H. HUXLEY, in "Evolution and Ethics," in *Collected Essays,* vol. 9 (1894), accuses Spencer of "fanatical individualism" and "reasoned savagery." H. SIDGWICK, *Lectures on the Ethics of T.H. Green, Mr. Herbert Spencer and J. Martineau,* pp. 135–312 (1902); and G.E. MOORE, *Principia Ethica,* sect. 31–35 (1903, reprinted 1954), contain detailed criticisms of Spencer's ethical theory. See also J. RUMNEY, *Herbert Spencer's Sociology: A Study in the History of Social Theory* (1934); S. ANDRESKI (ed.), *Principles of Sociology,* abr. ed. (1969), which includes an analysis and assessment of Spencer's sociological theory; D. MACRAE (ed.), *The Man Versus the State: With Four Essays on Politics and Society* (1969), in which the introduction (pp. 7–54) deals with Spencer's views on society and politics; and J.Y.D. PEEL, *Herbert Spencer: The Evolution of a Sociologist* (1971).

Spenser, Edmund

A contemporary of William Shakespeare, Edmund Spenser was considered in his day to be the greatest of English poets, who had glorified England and her language by his long allegorical poem *The Faerie Queene,* just as Virgil had glorified Rome and the Latin tongue by his epic poem the *Aeneid.* Spenser had a strong influence upon his immediate successors, and the sensuous features of his style, as well as his nine-line stanza-form, were later admired and imitated by such poets as Byron and Shelley in the Romantic Period of the late 18th and early 19th centuries. He is widely studied today as one of the chief begetters of the English literary Renaissance, a golden age for poetry in English, and as a master who embodied in poetic myth a view of the virtuous life in a Christian universe.

Youth and education. He did all this in a life-span of about 46 years. Very little is certainly known about the man. He was born in London, most probably in 1552 or 1553. He was related to a noble Midlands family of Spencer, whose fortunes had been made through sheep raising, and to three of whom—Ladies Carey, Compton, and Strange—he dedicated poems. His own immediate family was not wealthy. He was entered as a "poor boy" in the Merchant Taylors' grammar school, headed by Richard Mulcaster, a teacher with advanced ideas and respect for English as a literary medium. Still, Spenser, in 45 hours of class per week, would have studied mainly Latin, with some Hebrew, Greek, and music.

In 1569, when he was about 16, his English versions of

Spenser, oil painting by an unknown artist. In the collection of Pembroke College, Cambridge.
By courtesy of the Master and Fellows, Pembroke College, Cambridge

poems by the 16th-century French poet Joachim du Bellay and his translation of a French version of a poem by the Italian poet Petrarch appeared at the beginning of an anti-Catholic prose tract, "The Theatre for Worldlings"; they were no doubt commissioned by its chief author, the wealthy Flemish expatriate Jan van der Noodt. (Some of these poems he later revised for his *Complaints* volume.)

Sizar at Cambridge

From May 1569 Spenser was a student in Pembroke Hall (now Pembroke College) of the University of Cambridge, where, along with perhaps a quarter of the students, he was classed as a sizar—a student who, out of financial necessity, performed various menial or semimenial duties. According to the Statutes of 1570 (which, like many such regulations, may have been an attempt to enforce what in part was unenforceable), his day would have run from 5 AM to 8 or 9 PM, with compulsory attendance at worship and lectures. For his bachelor of arts degree, which he received in 1573, he would have studied, in Latin, the ancient authorities on rhetoric, logic, and philosophy. For his master's degree he would have studied Greek language and literature, arithmetic, geometry, and the astronomy of the Ptolemaic system. Because of an epidemic he in fact left Cambridge in 1574 but received his master of arts degree in 1576.

His best known friend at Cambridge was the slightly older Gabriel Harvey, a fellow of Pembroke, who was learned, witty, and enthusiastic for ancient and modern literature but also pedantic, devious, and ambitious for the life of action and power at the same time that he was unaware of his own shortcomings for this role. There is no reason to believe that Spenser shared the most distasteful of these qualities, but, in the atmosphere of social mobility and among the new aristocracy of Tudor England, it is not surprising that Spenser hoped for preferment to higher position. He shows, at some points in his career, symptoms of frustration over the unresponsiveness of the powerful to his needs and wishes, but the evidence does not suggest that this frustration was obsessive.

His period at Cambridge was undoubtedly important for the acquisition of his very wide knowledge not only of the Latin and some of the Greek classics but also of Italian, French, and English literature of his own and earlier times. His knowledge of the traditional forms and themes of lyrical and narrative poetry provided foundations for him to build his own highly original compositions. Without the Roman epic poet Virgil's *Aeneid*, the 15th-century Italian Ludovico Ariosto's *Orlando Furioso*, and, later, Torquato Tasso's *Gerusalemme liberata* (1581), Spenser could not have written his heroic, or epic, poem *The Faerie Queene*; without Virgil's *Bucolics* and the later tradition of pastoral poetry in Italy and France, he could not have written *The Shepheardes Calender*; and without the Latin, Italian, and French examples of the highly traditional marriage ode and the sonnet and canzone forms of Petrarch and succeeding sonneteers, he could not have written his greatest lyric, *Epithalamion*, and its accompanying sonnets, *Amoretti*. The patterns of meaning in his poetry are often woven out of the traditional interpretations—developed through Classical times and his own—of pagan myth, divinities, and philosophies and out of an equally strong experience of the faith and doctrines of Christianity; these patterns he further enriched by the use of medieval and contemporary story, legend, and folklore.

Spenser's religious training was a most important part of his education. He could not have avoided some involvement in the bitter struggles that took place in his university over the path the new Church of England was to tread between Roman Catholicism and extreme Puritanism. Contrary to a former view, there is little reason to believe that he inclined toward the Puritanical side. His first known appointment (after a blank of several years, when he may have been in the north of England) was in 1578 as secretary to Bishop John Young of Rochester, formerly master of Spenser's college at Cambridge. His first important publication, *The Shepheardes Calender* (1579 or 1580), is more concerned with the bishops and affairs of the English Church than is any of his later work.

Early works. *The Shepheardes Calender* can be called the first work of the English literary Renaissance. Following the example of Virgil and of many later poets, Spenser was beginning his career with a series of eclogues (literally "selections," usually short poems in the form of pastoral dialogues), in which various characters, in the guise of innocent and simple shepherds, converse about life and love in a variety of elegantly managed verse forms, formulating weighty—often satirical—opinions on questions of the day. The paradoxical combination in pastoral poetry of the simple, isolated life of shepherds with the sophisticated social ambitions of the figures symbolized or discussed by these shepherds (and of their probable readership) has been of much interest in modern literary criticism. The *Calender* consists of 12 eclogues, one named after each month of the year. One of the shepherds, Colin Clout, who excels in poetry but is ruined by his hopeless love for one Rosalind, is Spenser himself. The eclogue "April" is in praise of the shepherdess Elisa, really the Queen (Elizabeth I) herself; "October" examines the various kinds of verse composition and suggests how discouraging it is for a modern poet to try for success in any of them. "November," a lament for a lady called Dido, may covertly express regret for what seemed in 1579 the Queen's intended French marriage, which was strongly opposed at home by Robert Dudley, earl of Leicester, Sir Philip Sidney, and others of Spenser's acquaintance. Most of the eclogues, however, concern good or bad shepherds—that is to say, pastors—of Christian congregations, including his own beloved "Roffy," Bishop Young. The *Calender* was well received in its day, and it is still a revelation of what could be done poetically in English after a long period of much mediocrity and provinciality. The archaic quality of its language, sometimes deplored, was partly motivated by a desire to continue older English poetic traditions, like that of Chaucer. Archaic vocabulary is not so marked a feature of his later work.

Initiator of the English literary Renaissance

The two years 1578–80 probably produced more changes in Spenser's life than did any other corresponding period. He appears by 1580 to have been serving the fascinating, highly placed, and unscrupulous Earl of Leicester and to have become a member of the literary circle led by Sir Philip Sidney, Leicester's nephew, to whom the *Calender* was dedicated and who praised it in his important critical work *The Defence of Poesie* (1595). Spenser remained permanently devoted to this brilliant writer and good nobleman, embodied him variously in his own poetry (for example, as the Sir Calidore of *The Faerie Queene*, Book VI), and mourned his early death in an elegy. By 1580 Spenser had also started work on *The Faerie Queene* and in the previous year had apparently married one Machabyas Chylde. It is an interesting sidelight on his personal character, of which next to

Relations with Sidney and Harvey in 1578–80

nothing is known, that at a meeting with Gabriel Harvey in London in 1578, Spenser gave his friend four English books of humorous tales with the proviso that if Harvey did not read them all by January 1, he should surrender to Spenser his four volumes in Greek of the amusing writer Lucian. From another of Harvey's notations it is known that Spenser gave him a little book recommending foreign travel, with practical hints and a description of Naples (though nothing is known of Spenser's ever having travelled abroad). Later notations suggest that by 1580 Spenser may have been living as a modish young man about town, with Italianate and French leanings. Latin verses by Spenser sent to Harvey in 1579 show him eager to undertake a contemplated (but apparently never completed) trip to France on Leicester's business but reluctant to leave behind someone in England with whom he was head over heels in love. He asserts that Harvey would never thus have allowed love to stand in the way of ambition. With the same letter went another one, also published, pointing out the danger to himself of dedicating a work to Sidney if Sidney might happen to consider it insufficiently meritorious. (Unless Harvey published these letters without Spenser's prior knowledge, it is difficult to understand how this latter observation was allowed to become public property.) The ironies in Harvey's and Spenser's exchange of letters are so intricate as to make it difficult to draw further conclusions from them about Spenser, except that he was young, ambitious, accomplished, and sincerely interested in the theory and practice of poetry. Finally, in 1580, at the end of this two-year period, he was made secretary to the new lord deputy of Ireland, Arthur Lord Grey, who was a friend of the Sidney family. Spenser's life was to lie mostly in Ireland for his remaining 19 years.

Career in Ireland. Sixteenth-century Ireland and the Irish were looked on by the English as a colony, although the supposed threat of an invasion by Spain, the Catholic enemy, and the conflict between an imposed English Church and the at first decadent Catholicism of the Irish, were further complicating factors. Irish chieftains and the Anglo-Irish nobility, dating from as far back as the Norman conquest, encouraged native resistance to newly arrived English officials and landowners. As Grey's secretary, Spenser accompanied the Lord Deputy on risky military campaigns as well as on more routine journeys.

Service in Ireland

But Ireland was certainly no exile for Spenser. He became deeply attached to the country, its people and its landscapes. He several times gives poetic form to romantic or idyllic reactions to the Irish scene (as in "Mutabilitie Cantos," VII, vi, 37–39; *Colin Clouts Come home againe*, 88–155), along with an equally strong dislike for its unproductive wildness and lawlessness (as in "Mutabilitie Cantos," VII, vi, 54–55). The conflict between Grey's direct, drastic governmental measures and the Queen's characteristic procrastinating and temporizing style soon led to his frustration and recall. But Spenser, like many others, admired Grey's methods; his later tract, *A View of the Present State of Ireland* (written 1595–96, published 1633), argues lucidly for a typically 16th-century theory of rule: firm measures, consistently applied, with gentleness only for completely submissive subject populations. At the point where Spenser, treating the virtue of Justice in *Faerie Queene*, Book V, embodies the injustice of another national state against his own, his hero Sir Artegall, in conquering Grantorto, becomes temporarily a projection of Grey in his victory over a small Spanish expeditionary force in Ireland.

For four or five years from about 1584, Spenser carried out the duties of a second important official position in Ireland, deputizing for his friend Lodowick Bryskett as clerk of the lords president (governors) of Munster, the southernmost Irish province. The fruits of his service in Ireland are plain. He was given a sinecure post and other favours, including the right to dispose of certain forfeited parcels of land (he no doubt indulged in profitable land speculation). For a time he leased the small property of New Abbey, County Kildare, and on this basis was first designated "gentleman." Finally, he obtained a much larger estate in Munster. One of the chief preoccupations of the presidents of this province, scarred as it was by war and starvation, was to repopulate it. To this end, large "plantations" were awarded to English "undertakers," who undertook to make them self-sustaining by occupying them with Englishmen of various trades. In 1588 or 1589 Spenser took over the 3,000-acre plantation of Kilcolman, about 25 miles to the north and a little to the west of Cork. No doubt he took there his son and daughter and his wife, if she was still alive (she is known to have died by 1594). By acquiring this estate, Spenser made his choice for the future: to rise into the privileged class of what was, to all intents, a colonial land of opportunity rather than to seek power and position on the more crowded ground of the homeland where he had made his poetic reputation (and where he was to increase it still further). In his new situation he, like other undertakers, had much conflict with the local representative of the older Anglo-Irish aristocracy, Maurice Lord Roche; further, they had very limited success in filling the plantations with English families. Even after the defeat of the Armada (1588), the danger of Spanish invasion was taken seriously, and the threat of an Irish uprising was to prove all too real ten years later. Nevertheless, no matter what may be thought about the justice or the viability of the English hegemony in Ireland, it was under these conditions that Spenser brought his greatest poetry to completion.

Spenser's congenial literary friend in Ireland was the older official Lodowick Bryskett, a man of cosmopolitan culture. The son of an Italian merchant who had settled in England, he had attended Cambridge and accompanied Sir Philip Sidney on extensive Continental travels. In a prose dialogue he shows us Spenser (no doubt partly fictionalized), proclaiming that his *Faerie Queene* is to be composed in several books, each devoted to a single virtue. The date pointed to seems to be 1582, but Bryskett's book was published long after Spenser had made the same point in his introductory letter to Raleigh, in the first edition of his great poem, which purported to explain what was to be the general scheme of the work.

"The Faerie Queene." In its present form, *The Faerie Queene* consists of six books and the fragment (known as the "Mutabilitie Cantos") of a seventh. According to the introductory letter, it was to contain 12 books each telling the adventure of one of Gloriana's knights (the origin of these adventures was to be explained in the last book, not extant). Like other poets, Spenser must have modified his general plan many times, yet this letter, inconsistent though it is with various plot details in the books which are extant, is probably a faithful mirror of his thinking at one stage. The stories actually published were those of Holiness (the Red Cross Knight), Temperance (Sir Guyon), Chastity (Britomart, a female knight), Friendship (ostensibly concerning Triamond and Cambello, although these play a very small part), Justice (Artegall), and Courtesy (Calidore). What is most characteristic of Spenser in this work is his serious view of the capacity of the romance form to act as a paradigm of human experience: the moral life as quest, pilgrimage, aspiration; as eternal war with an enemy, still to be known; as encounter, crisis, the moment of illumination—ethics with the added dimensions of mystery, terror, love, and victory and with all the generous virtues exalted. Modern impatience with the obscure allusions in the poem, with its political and ecclesiastical topicalities, is a failure to share the great conflict of Spenser's time between Protestant England and Catholic Spain—to him, the war between good and evil was here and now. As a setting, Spenser invented the land of Faerie and its queen, Gloriana. To express himself he invented a nine-line stanza, the first eight of five stresses and the last of six, whose rhyme pattern is ababbcbcc. Spenser proves himself a master: picture, music, metre, story—all are at one with the deeper significance of his poem, providing a moral heraldry of colours, emblems, legends, folklore, mythical allusion, all prompting deep, instinctive responses. Enjoyment of the poem's sensuous surface is itself to undergo an experience, an ascent in vision with the protagonists.

Presentation of *The Faerie Queene* to Elizabeth I

The poem was published with the help of Sir Walter Raleigh, who owned large lands to the east of Spenser's estate. He and the poet came together at Kilcolman in 1589 and became well acquainted with one another's poetry. Spenser implies that Raleigh persuaded Spenser to accompany him back to England to present the completed portion of *The Faerie Queene* to Queen Elizabeth herself. The history of this episode is charmingly evoked in *Colin Clouts Come home againe*, which is also one of Spenser's most effective pastoral embodiments of a provincial innocent up against the sophistications of a centre of power, with subsequent reflections on false, superficial love and the true love that finally animates a concordant universe.

Arriving thus in London with the support of the Queen's favourite, Spenser was well received—not least by Elizabeth herself. The first three books of *The Faerie Queene* were duly published in 1590, together with a dedication to her and commendatory sonnets to notables of the court. These included, as an afterthought, Lord Burghley, who was perhaps the most powerful figure there. Spenser saw the book through the press, made a hurried visit to Ireland, and returned speedily to London—presumably in the hope of preferment. At this time he supervised the printing of certain other of his poems in a collection called *Complaints*, many of which had probably been written earlier in his career and were now being published so as to profit from the great success of his new heroic poem. It is difficult to believe that the many titles of poems which have not survived but were mentioned earlier in his career (including "Dreames," "Dying Pelicane," and many more) were not published in revised form and under other titles in his known work; for *Complaints* suggests by its miscellaneous and uneven character that Spenser was hastily bringing to the light of day nearly every last shred that he had to offer: early translations, an elegy, and the delightful mock-heroic poem "Muiopotmos" are contained in it; another item, the beast fable "Prosopopoia, or Mother Hubberd's Tale," apparently caused the authorities to withdraw unsold copies of the volume (perhaps in 1592) because it contained a covert attack on Lord Burghley. Spenser seems to have believed that this lord's powerful influence was blocking his own and other worthy men's progress. Nevertheless, in 1591 the Queen gave Spenser a small pension for life.

Last years. Back in Ireland, Spenser pressed on with his writing, in spite of the burdens of his estate. In early 1595 he published *Amoretti* and *Epithalamion*, a sonnet sequence and a marriage ode celebrating Spenser's marriage to his second wife (Elizabeth Boyle) after what appears to have been an impassioned courtship in 1594. This group of poems is unique among Renaissance sonnet sequences in that it celebrated a successful love affair culminating in marriage. As in passages in *The Faerie Queene* (III, vi; VII, vii), Spenser develops in *Epithalamion* an aspect of Platonism (descending from the Greek philosopher's *Timaeus* but also much cultivated during the Middle Ages) according to which the changes wrought by time in our imperfect universe imitate the unchanging excellence of eternity through their cyclical character, continually restoring what they continually remove. Such are day and night, the circling year, the rebirth of plant and animal life, and the reproduction of man under the stimulus of sexual pleasure in marriage. Spenser conveys the unity of these cycles in his marriage ode, where he symbolizes the daily and annual cycles of the sun by giving the poem 24 stanzas (representing the hours) and a total of 365 pentameter and hexameter lines (representing the days).

Second marriage

Other kinds of Platonism, sometimes interwoven with other philosophical strands, appear in the *Amoretti* and in many other of Spenser's works. Platonic doctrines, so popular in Renaissance poetry (that true beauty is not material but is heaven-sent, bespeaking in principle an inner spiritual excellence; and that Love is, in one way, a god who leads men to such beauty and reduces warring chaos to harmony) appear in a number of Spenser's poems, especially in the *Fowre Hymnes* (1596), where Platonism is combined with Christianity. In that year Spenser may have again been busy in London supervising the publication of a number of works, including Books IV, V, and VI of *The Faerie Queene*.

This burst of publication was the last of his lifetime. His early death may have been precipitated by the penetration into Munster of the Irish uprising of 1598. The undertakers and other loyalists failed to make head against this. Kilcolman was burned, and Spenser, probably in despair despite the Privy Council's having just recommended his appointment to the important post of sheriff of Cork, carried official letters about the desperate state of affairs from the president to London. He died there on January 13, 1599, but the long-held belief that it was "for lack of bread" (as the poet Ben Jonson told William Drummond of Hawthornden in 1618) is incredible, considering his official status and patronage. He was, in fact, buried with ceremony in Westminster Abbey close by the grave of Geoffrey Chaucer.

MAJOR WORKS

POEMS: *The Shepheardes Calender* (1579); *The Faerie Queene*, Books I-III (1590); *Complaints* (1591); *Daphnaïda* (1591); *Amoretti* and *Epithalamion* (1595); *The Faerie Queene*, Books I-VI, 2 vol. (1596); *Fowre Hymnes* (1596); *Prothalamion* (1596); *The Faerie Queene*, Books I-VI with the fragment of Book VII known as "Mutabilitie Cantos" (1609).

TRANSLATIONS: "A Theatre, Wherein Be Represented the Miseries and Calamities That Follow the Voluptuous Worldlings," ed. by Jan van der Noodt, containing anonymous translations in verse by Spenser of poems from the French (1569).

PROSE: *Three Proper, and Wittie, Familiar Letters*, by Gabriel Harvey and Spenser (1580); *A View of the Present State of Ireland* (1633).

Speransky, Mikhail Mikhaylovich

Mikhail Mikhaylovich Speransky, a leading Russian statesman under the emperors Alexander I and Nicholas I, compiled the first complete collection of Russian law. He was born the son of the village priest at Cherkutino in central Russia on January 12 (January 1, old style),

1772. Known in his childhood simply as Misha, son of Mikhail the priest, he was sent at the age of 12 to the ecclesiastical seminary in Vladimir, the provincial capital. The deficiency of lacking a surname was overcome by an imaginative uncle, who dubbed him Speransky, a Russified form of the Latin word for hope. The boy soon distinguished himself by his ability to analyze problems and to express his thoughts with grace and clarity, but he already displayed an aloofness that emphasized his consciousness of his intellectual superiority yet cloaked his very real desire to feel the affection of those whom he respected, a quality that was to be a handicap in his later official career.

Novosti Press Agency

Speransky, portrait by an unknown artist.

As a priest's son, he was sent at government expense to the Main Seminary newly founded in St. Petersburg. On completion of the course, he should have returned to his native diocese as a teacher. But a practice sermon so pleased the Metropolitan of St. Petersburg that the Synod granted permission to retain Speransky as a teacher of mathematics in the Main Seminary. Speransky resisted the urging of the Metropolitan that he take monastic vows, a step that would have opened to him the possibility of rising to the highest offices in the Church. Despite his refusal, he was, in 1795, appointed instructor of philosophy and prefect of the seminary.

Secretary to Prince Kurakin

At this point, Speransky's future prospects were radically changed. Prince A.B. Kurakin took him into his household as secretary. Here he deepened his knowledge of the thought of the French Enlightenment and was introduced to the Idealist philosophy of Immanuel Kant. On the accession of Emperor Paul I (1796), Kurakin was appointed procurator general of the Senate, a post as close as possible in the Russian system of that time to that of prime minister. He was, thus, powerful enough to secure Speransky's release from his priestly status and thus enable him to enter government service. Speransky was pushed rapidly upward through the lower bureaucratic grades; by the end of 1798, still not 27 years old, he had already risen high enough in the Table of Ranks to be entitled to enjoy, on a hereditary basis, all the privileges of "the most ancient nobility."

In the same year, Speransky met an English girl whose widowed mother had come to Russia as a governess. He became so enamored of her that, although she knew no Russian and he understood no English, a courtship in fractured French led to their marriage. In the following year a daughter was born, but the mother, suffering from tuberculosis, died a few months later. Speransky, completely shattered, disappeared for a time. He never remarried but immersed himself wholly in his work. When Kurakin suddenly fell from favour, Speransky's tact, his evident ability, and his industry enabled him to continue his career. Under Paul's successor, Alexander I, he was assigned to ever more responsible positions, at first in the new Ministry of the Interior, where he gained invaluable experience in drafting legislation and was the prime mover in founding *Severnaya pochta* or *Novaya Sankt-Petersburgskaya gazeta*, Russia's first official newspaper. In 1807 he became intimately associated with the Emperor himself, as his administrative secretary and assistant. In 1808 he accompanied Alexander to his meeting with Napoleon, who described him as "the only clear head in Russia." Though he proved to be not yet able to cope successfully with the task of codifying the country's laws, he reorganized the seminaries and secured the establishment of the first Russian lycée (state secondary school).

Secretary to the Emperor

In 1809 he laid the basis for his own downfall by two measures that outraged the bureaucratic nobility: one required that holders of court titles perform actual service to the state; the other required that all officials must pass examinations in order to be promoted at various stages of their careers. The angry nobles began to refer contemptuously to him as the *popovich* ("priest's son"). It was in this year, also, that Speransky proposed his new "constitution" (the Plan of 1809). Well aware that Alexander wanted no tampering with the essence of the autocracy or with its basis in serfdom, Speransky prepared complicated plans for dividing the population into three classes with varying degrees of political and civil rights and for creation of elective assemblies, the dumas, and an appointive State Council. The latter was set up on January 1, 1810, but the dumas, innocuous though they would have been, remained on paper. In these years (1807–12) when he had the Emperor's confidence, Speransky was responsible for a number of financial and administrative reforms designed not to change the essence of the state structure but to improve its functioning. His obvious pro-French leanings, however, added to the hostility of the nobles, whose pocketbooks had suffered by Russian participation in the Continental System, the systematic economic warfare employed by Napoleon against England.

Speransky's aloof personality and his continued association with persons inferior to him in social standing had prevented him from making friends among men with political prestige. He was thus left defenseless against his high-placed enemies at court, including the emperor's sister, Catharine of Oldenburg. In 1811 the renowned historian N.M. Karamzin attacked him in his well-known memoir, *Of Old and New Russia*. In March 1812, Speransky was summarily dismissed. Returning to his home at midnight, he found a police carriage waiting at his door. Without even taking leave of his daughter, the fallen minister started on the long journey to exile in Nizhny-Novgorod, whence he was soon transferred to the even more distant Perm, in the Urals.

Exile

Two years later he was permitted to return to his estate near Novgorod, but it was not until 1816 and only after he had stooped to appeal to his successor in Alexander's favour, Count A.A. Arakcheyev (whom the poet Pushkin contrasted with Speransky as Alexander's "evil genius"), that he was permitted to re-enter state service—though only as provincial governor in remote Penza. In 1819, however, he was promoted to be governor general of Siberia, where he effected significant administrative reforms. In 1821 he was summoned to St. Petersburg and appointed a member of the State Council, in which he was too prudent to advocate further reforms, lest he again irritate his master.

Under Alexander's successor, Nicholas I, Speransky's great talents were again utilized, first as a member of the special tribunal that tried and sentenced the Decembrists, a group of officers who staged a liberal revolt on Nicholas' accession in December 1825. Here he again demonstrated his ability to read an emperor's mind; it was he who drafted the letter to the court that secured a significant reduction of the sentences the tribunal had imposed. In the same year he became, in effect, the head of the Second Division of the Emperor's personal chancellery. Still an efficient workhorse, he took part in the labours

Work for Nicholas I

of Nicholas' secret committees for study of the peasant problem. His major achievement, however, was the publication, in 1830, of the first *Complete Collection of the Laws of the Russian Empire* (*Polnoye sobraniye zakonov Rossiyskoy imperii*), 45 volumes. On the basis of this compilation, which began with the *Code* (*Sobornoye ulozheniye*) of 1649, he supervised preparation of a *Digest of the Laws* (*Svod zakonov Rossiyskoy imperii*), 15 volumes (1832–39). In 1837 he was awarded the high Russian decoration, the highest grade of the Order of Andrew the First-Called, and, in January 1839, was accorded the title of count. He died a few weeks later, on February 23 (February 11, O.S.), in St. Petersburg.

BIBLIOGRAPHY. The best biography of Speransky is the excellent work of MARC RAEFF, *Michael Speransky: Statesman of Imperial Russia, 1772–1839* (1957). See also his *Siberia and the Reforms of 1822* (1956). For Speransky's own early writings (to 1809), see *M.M. Speranskii: Proiekty i zapiski*, ed. by S.N. VALKA (1961).

Sphenisciformes

The penguins are a group of flightless seabirds constituting a particularly distinct and homogeneous order, Sphenisciformes; the one family, Spheniscidae, is limited in distribution to the Southern Hemisphere. Although a few penguins inhabit temperate regions and one, the Galapagos penguin (*Spheniscus mendiculus*), lives at the Equator, the majority of the 18 species breed on islands in subantarctic waters.

Drawing by Christian D. Olsen

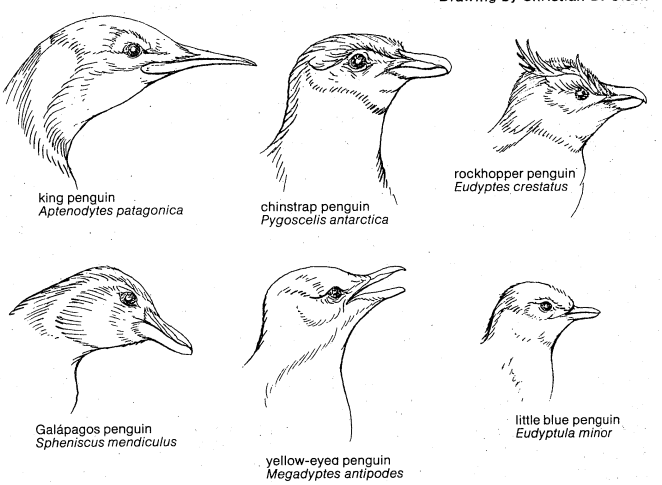

Figure 1: Heads of representative sphenisciformes.

The stocky, short-legged appearance of penguins has endeared them to the popular mind. They range from about 35 centimetres (14 inches) in height and approximately one kilogram (about two pounds) in weight, in the little blue, or fairy, penguin (*Eudyptula minor*), to 115 centimetres (45 inches) and 25 to 40 kilograms (55 to 90 pounds) in the emperor penguin (*Aptenodytes forsteri*). Most are black on the back and white below, often with lines of black across the upper breast or spots of white on the head. Colour is rare, being limited to red or yellow irises of the eye in some species; red beaks or feet in a few; yellow brow tufts in the three species of *Eudyptes*; and orange and yellow on the head, neck, and breast in the two species of *Aptenodytes*.

The total populations of some species, such as the emperor penguin, are estimated in hundreds of thousands, but those of most species of smaller penguins certainly run to several millions. The largest breeding colonies are on the islands between 50° south latitude and Antarctica. These immense colonies, some of which contain hundreds of thousands of individuals, represent a large potential food resource, but the economic importance of penguins is negligible. Nineteenth-century whalers and seal hunters visited some colonies for meat and eggs, and a penguin oil industry once took large numbers of birds; by the early 20th century, however, this exploitation was no longer profitable, and most colonies were left alone or actively protected. Some species are now increasing in numbers, apparently as a result of the drastic reduction of Antarctic whales, which compete with penguins for the krill (minute crustaceans) on which both feed.

Natural history. *Reproduction.* Many features of the life cycle vary with the body size of the species and its geographical distribution; the chronology of breeding may also vary within a species in relation to latitude. Certain species, such as the Cape or jackass penguin (*Spheniscus demersus*), probably other members of this genus, and the little penguin, breed twice a year, but the majority of species breed only once each year and the king penguin (*Aptenodytes patagonica*) twice in three years. One egg is laid by the emperor and king penguins, and two, or occasionally three, by all others. Most penguins begin breeding in the austral spring or summer; king penguins are on a 14- to 18-month cycle, and the timing of an individual pair depends on the success or failure of the previous breeding attempt. Some populations of the gentoo penguin (*Pygoscelis papua*) also breed in winter. The breeding of the emperor penguin begins in autumn, apparently timed so that the long developmental period will produce the young in midsummer, when their chances of survival are greatest.

The gentoo, which has a circumpolar distribution, is notable for the lack of synchrony among populations, but otherwise its breeding schedule is essentially typical of most penguins. In the Crozet Islands, off southern Africa, for example, egg laying takes place in July. The two eggs are incubated for 35 or 36 days, and the rearing of the chick takes two months. The last immature birds go to sea in January, leaving the adults to molt in February.

Many types of visual and vocal displays are employed between the arrival of the birds at the colony and their departure. Courtship calls are used during pairing and to a lesser degree during the succeeding phases of breeding. There is marked vocal dimorphism between sexes in the emperor penguin and the king penguin, and less marked dimorphism in some other species. Upon arrival at the colony each bird returns to the nest that it left the previous year and generally rejoins its mate of the previous year, unless the death of the latter forces it to choose another partner. This applies even to the emperor penguin, which is capable of finding its mate despite the absence of a nest and the large size of the colony.

Types of display

The displays that occur with the reassembly of the colony and the finding of mates, as well as those preceding copulation, are quite similar among the majority of species, but the accompanying vocalizations are more diverse. Various species have been described as braying, trumpeting, croaking, cackling, and cooing. The behaviour of experienced older birds is more elaborate and more effective than that of younger individuals. Adélie penguins (*Pygoscelis adeliae*) may return to the reproductive colony from their third year onward but do not breed successfully until their fifth or sixth year.

Incubation of eggs is performed by both sexes in all species except the emperor penguin, in which it is done by the male alone. It begins immediately following the laying of the single egg in the emperor and king penguins and after the laying of the second egg in other penguins. With the advent of incubation, the bustle and myriad cries that characterized mating give way to quiet and inactivity. Faulty incubation behaviour by inexperienced birds frequently results in the abandonment or breakage of eggs. The mortality (eggs and chicks) is very important at the egg stage, varying from year to year depending on climatic conditions, the percentage of young birds in the reproductive population, and the pressure of predation. In general, the mortality (eggs and chicks) is from 40 to 80 percent of the eggs laid. In coastal colonies predators include, in order of importance: skuas (*Catharacta*); sheathbills (*Chionis*); and the giant petrel (*Macronectes giganteus*). On the Australian, African, and South American continents, the nocturnal habits of certain penguins and the fact that they nest in burrows substantially limit predation, which is mostly by gulls and man.

Following egg laying, the female usually departs for the sea to feed, returning to relieve her mate after about ten to 20 days, depending on the species; thereafter, they alternate in periods of a week or two. The female emperor penguin, however, must often walk 80 to 160 kilometres (50 to 100 miles) from colony to the sea and does not return until the end of the incubation period. During the 64-day incubation period, which extends through the height of the Antarctic winter, the male emperor penguin incubates the egg, holding it on his feet and living on stored fat reserves. During violent winter storms, members of the colony gather for mutual protection from wind and cold in tightly packed crowds called huddles.

Emergence from the shell takes 24 to 48 hours, during which the brooding parent is particularly irritable. The chick shows feeding behaviour immediately on hatching, receiving a regurgitated "soup" of crustaceans or fish by inserting its bill into the open mouth of the parent. During its early days the young bird is sheltered under the body of one of its parents, who take turns foraging and brooding. Growing larger, the young bird remains at a parent's side, although able to maintain its body heat and move about alone. In surface-nesting species, following the individual rearing phase in the nest or (in the emperor and king penguins) on the feet of the parent, the chick joins 100 or more of its contemporaries in a nursery

Jean Prevost

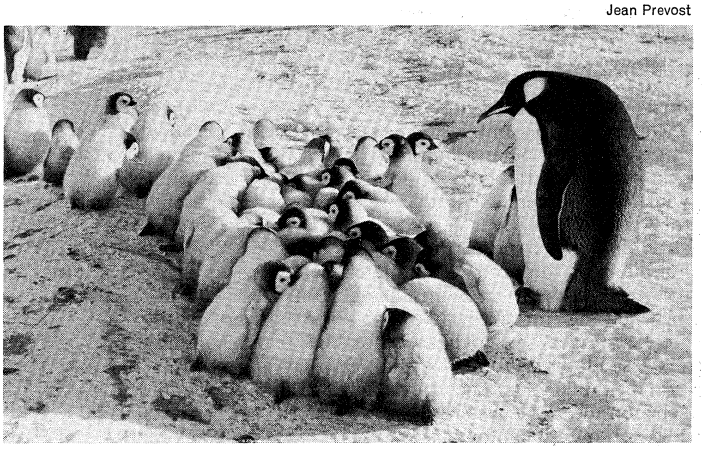

Figure 2: *Crèche of emperor penguins (Aptenodytes forsteri).* To guard against predators, the young are herded into groups attended by adults while the parents fish for food.

Crèche behaviour

group, or crèche, sometimes guarded by a few adults, while both its parents forage at sea. Upon returning with food, the parent calls its chick from the crèche and is able to distinguish it from other chicks (which frequently also respond) by voice and appearance. During the breeding season the number of "unemployed" adults in the colony increases with the addition of those who have lost eggs or chicks. In emperor penguin colonies, these unemployed birds often interfere with parents that have young and cause increased mortality. During the crèche stage the fuzzy down that has covered the chick since hatching is replaced by a coat of short stiff feathers, like those of the adult but usually somewhat different in colour. Once this molt is complete, the juvenile leaves the colony to seek its own food at sea.

The period of growth of the young bird from hatching to complete independence varies from two months, in the smallest species of the genus *Eudyptula*, to 5½ months in the emperor and 12 to 14 months in the king penguin.

Molt. Adult penguins molt all of their feathers once a year, following the breeding period. While in molt the bird is unable to enter the water and instead withdraws to a communal molting site usually situated in a sheltered area away from the colony. The duration of the molt varies from about two weeks in small species to more than a month in the larger ones.

Locomotion and orientation. Penguins are adapted for rapid locomotion in water, in which the wings, or flippers, are used for propulsion; the birds "fly" under water. When moving at high speed they frequently leave the water in leaps that may carry them a metre or more through the air; during this time they breathe.

On land, penguins are much more awkward, and their rocking walk is highly amusing to watch. Despite their short legs, however, penguins can run with surprising speed. Some species, such as the rockhopper (*Eudyptes chrysocome*) and Adélie penguins, move among rocks with agility, using the flippers for balance. When moving rapidly on snow or ice, many penguins "toboggan," sliding on the belly as they propel themselves by the feet and flippers. The flippers, along with the beak, are the prime weapons in defense and attack.

"Tobogganing"

Scientists have long wondered how penguins are able to find their way back to their colonies from far out at sea, where currents may have carried them great distances, and how they are able to direct themselves correctly on land, in the absence of clear-cut landmarks. Recent studies have shown that penguins transported into the interior of Antarctica are able to find their way back to the ocean by using the sun as a directional aid. It is probable that the same means of orientation is used at sea, and that upon approaching the coast they are able to recognize features of the shoreline and the ocean bottom.

Food habits. The type of food utilized varies with the species, the geographical region, and the time of year. Most of the smaller southern penguins feed primarily upon krill (crustaceans of the family Euphausidae), which attain high densities in the rich, well oxygenated Antarctic waters. Cephalopods (squid and cuttlefish) and small fishes may form substantial fractions of the food and, in a few, such as the Cape penguin, comprise the basic elements of the diet. The total weight (biomass) of food consumed by a large penguin colony is prodigious, often exceeding several tons per day.

Natural enemies. The principal enemies of penguins at sea are the leopard seal, or sea leopard (*Hydrurga leptonyx*), and the killer whale or grampus (*Orcinus orca*). The eared seals (*Otariidae*) of the genera *Arctocephalus* and *Neophoca* also take penguins in the Australian–New Zealand and subantarctic regions.

Form and function. The penguins are highly specialized for their flightless aquatic existence. The feet are located much farther back than those of other birds, with the result that the bird carries itself mostly upright; its walk can thus be described as plantigrade (*i.e.*, on the soles). It rests on the ground on a sole, comprising the whole foot, instead of one formed of the toes, as in other birds. The most notable character of the group is the transformation of the forelimb into a swimming member, accompanied by a body morphology particularly adapted

From R.W. Storer, "Diving Birds," International Ornithological Congress (1958)

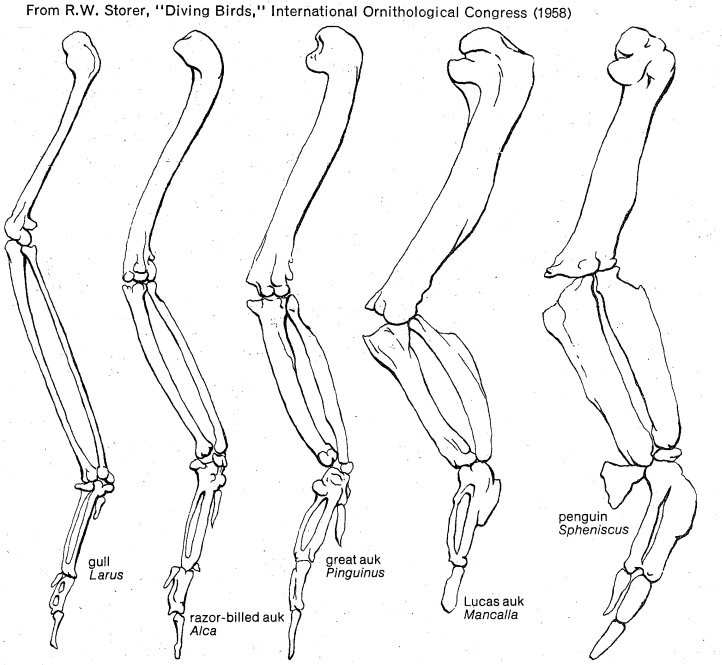

Figure 3: Evolution of the wing in diving birds.

to movement in a liquid medium. The thoracic (rib) cage is well developed, and the sternum bears a pronounced keel for the attachment of the pectoral muscles, which move the flippers. The flipper has the same skeletal base as the wing of flying birds but with its elements shortened and flattened, producing a relatively rigid paddle-like limb covered with very short feathers, which makes an ideal organ for rapid propulsion. The body plumage likewise consists of very short feathers, which minimize friction and turbulence; by their density and the layer of air which they retain, the feathers provide almost ideal insulation of the body.

Structure of the forelimb, or flipper

The insulation of the bird's body is particularly important for Antarctic species that move in water that is always below 0° C (32° F). The cooling power of seawater at −1.9° C (28.6° F) is equal to that of a temperature of −20° C (−4° F) with a wind of 110 kilometres (70 miles) per hour. The velocity of movement of the birds in the water serves to increase this heat loss. In fact, the skin is insulated by a layer of air trapped under the plumage, and the only bare skin in direct contact with the water is that of the feet. In the case of the emperor penguin on land in winter, the feet may also be in close and permanent contact with ice. The skin temperature is then in the neighbourhood of 0° C, and snow does not melt upon contact. This low temperature is made possible by remarkable anatomical arrangements in the lower limb, in which closely adjacent arteries and veins form a system of heat exchange between opposing flows; in the upper member a remarkable heat-exchange network permits the cooled returning blood to absorb heat from the outflowing blood, providing maximum economy of heat consistent with the functioning and survival of the foot.

Like the petrels, the penguins have supraorbital glands or salt glands, which permit the ingestion of hyperosmotic substances (*i.e.*, with more salt than the body tissues); excess chloride is excreted in the form of a solution the concentration of which is greater than that of seawater. These glands are functional in the young penguin chick, which consumes food of marine origin from its first day of life.

Recent research has shown that the species most isolated geographically, such as the emperor penguin, can be subject to viral diseases of the psittacosis–*Lymphogranuloma* type. Some, such as the Adélie penguin, carry in their bodies trace amounts of pesticides such as DDT, albeit in lower quantities than are found in many birds that live closer to man.

Evolution and classification. *Fossil record.* Evidence from paleontology indicates that the penguins and tubinares (Procellariiformes: albatrosses, shearwaters, and petrels) had a common origin. Both groups are represented by well-defined fossils from the Eocene (about 50,000,000 years ago). During the Tertiary Period (from about 25,000,000 to 65,000,000 years ago) the sphenisciform line produced a number of distinctive side branches, all recognizably penguins. From the taxonomic point of view the radiation (evolutionary differentiation) had reached the level of the subfamily in the Miocene (between 7,000,000 and 26,000,000 years ago), and the diverse subfamilies of that epoch have been replaced in the present-day group by one in which the radiation has reached the level of genera. All of the fossil remains of penguins have been collected within the zone of the present-day distribution of the Sphenisciformes. Some apparently lived in warmer regions than do most of today's penguins. Certain species, such as *Palaeospheniscus patagonicus*, had a height intermediate between the large and the medium-sized modern species; others, such as *Pachydypees*, *Anthropornis*, and *Palaeeudyptes*, reached heights of between 120 to 160 centimetres (about 50 to 60 inches).

Classification. One authority has divided the *Spheniscidae*, fossil and modern, into five subfamilies: *Palaeospheniscinae* and *Paraptenodytinae* of the Patagonian Miocene; *Anthropornithinae* of New Zealand, Patagonia, and Antarctica; *Palaeeudyptinae* of New Zealand and Australia; and finally *Spheniscinae*, which includes all the present-day genera.

BIBLIOGRAPHY. JOHN SPARKS and TONY SOPER, *Penguins* (1967); and BERNARD STONEHOUSE, *Penguins* (1968), are well-illustrated popular books. R.C. MURPHY, *Oceanic Birds of South America*, 2 vol. (1936), is a classic work with extensive information on ten species of penguins. J.T. EMLEN and R.L. PENNEY, "Distance Navigation in the Adélie Penguin," *Ibis*, 106:417–431 (1964), is a short technical paper concerned with long-range movements. R.L. PENNEY, "Territorial and Social Behaviour in the Adélie Penguin," the "Antarctic Research Series," vol. 12, *Antarctic Bird Studies*, pp. 83–131 (1968), reviews many studies of the behaviour of this species. JEAN PREVOST, *Écologie du Manchot empereur, Aptenodytes forsteri Gray* (1961), is a detailed study, in French, of the largest penguin species. Also of interest is L.E. RICHDALE, *Sexual Behavior in Penguins* (1951). G.G. SIMPSON, "Fossil Penguins," *Bull. Am. Mus. Nat. Hist.*, 87:1–99 (1946), is a basic work on the evolution of penguins.

(J.Pr.)

Sphenopsida

The Sphenopsida is generally considered to constitute a class of primitive, spore-bearing, vascular plants. The sole living genus, *Equisetum*, the horsetails or scouring rushes, comprises about 30 species of herbaceous plants and constitutes the order Equisetales. Extinct members, some of which appeared as early as the Devonian Period (beginning 395,000,000 years ago), include many herbaceous plants of the Equisetales, shrubby Hyeniales, vine-like Sphenophyllales, and trees of the order Calamitales.

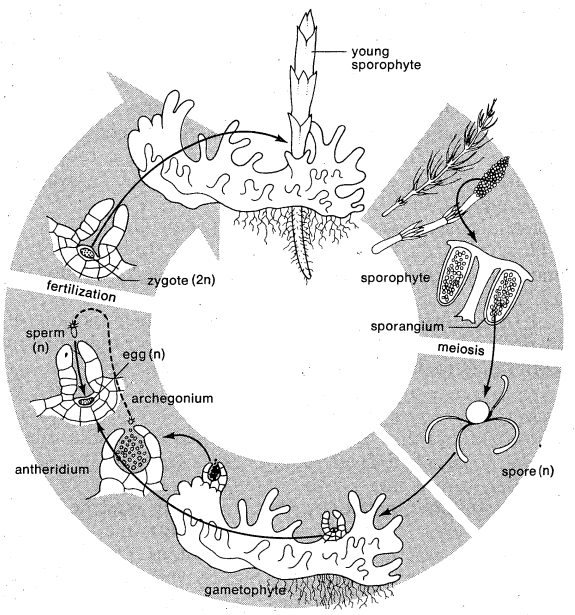
General features. Sphenopsids, fossil and living, characteristically have whorled leaves and conspicuously jointed stems, which in many cases are also ribbed. When branches occur in *Equisetum*, they alternate with the leaves in position on the stem, an arrangement not known to occur in any other group of living plants. The buds in seed plants usually arise in the angle that the leaf makes with the main stem. Reproductive structures are present in the form of greatly compressed stems called cones, or strobili, which form at the ends of branches. The giant horsetails of the order Calamitales were trees up to one metre (three feet) in diameter and 30 metres (100 feet) in height. Their leaves—like those of extant horsetails—were arranged in spokelike whorls at regular intervals (nodes) along the jointed stems.

Size range

In the Sphenophyllales, an extinct order of climbing sphenopsids, the leaves were wedge shaped, with a repeatedly forking (dichotomous) venation system. The order Hyeniales included shrublike plants with inconspicuous leaves arranged in rather indistinct whorls.

Of the living species of *Equisetum*, most are less than one metre (three feet) tall; they are widely distributed in the Northern Hemisphere. There are reports of specimens of *E. giganteum*, from the American tropics, that attain a height of about ten metres (30 feet), with a stem diameter of only two centimetres (less than an inch); they are apparently supported by tall grasses in their environment. The majority of *Equisetum* species are found in wet or damp habitats, often in shaded locations along streams, ditches, and canals; some species, however, have become adapted to drier and sunnier conditions.

The extant sphenopsids have had little economic importance. The extinct giant forms contributed to the coal beds of the Carboniferous Period (345,000,000–280,000,000 years ago). Living horsetails have been used as scouring agents, their cleaning value being attributed to the abrasive action of the silica-laden walls of certain of their cells. Silica is only one of several minerals that horsetails selectively accumulate in their bodies. Gold is another—up to 4½ ounces per ton of plants—not economically feasible to mine but a certain indication of the availability of such ore deposits in the soil. Horses foraging on stands of *Equisetum* have been known to die from severe intestinal inflammation.



Life cycle. Horsetails, like other vascular plants, display an alternation of generations: an asexual phase, represented by a sporophyte (the horsetail plant); and a sexual phase, the gametophyte, an inconspicuous, delicate, green plant. Each year thousands of gametophytes are probably initiated from spores, but very few survive in nature. Horsetails apparently survived as a small group of very ancient plants mainly by vegetative reproduction

Fragility of gametophytes

rather than by a regular dependence on an alternation of sexual and asexual generations. It is assumed that fossil members had an alternation of generations, although only sporophytes have been described for them.

Some horsetails have terminal cones (strobili) on green aerial branches. Other species, however, have separate, upright, aerial branches for vegetative and for reproductive shoots. In the latter, the strobilate branches appear first, and, after the spores are shed, the green, vegetative shoots develop. The component fertile appendages of the strobilus are called sporangiophores; each consists of a stalk bearing a flattened disk at its apex, on the lower edge of which is found a circle of sporangia, each opening and shedding spores by a longitudinal slit on its inner side. (The Carboniferous, treelike horsetails and their smaller allies are believed to have possessed the most elaborate reproductive strobili known among the vascular plants.)

The spores have four bands (elaters); these elaters, which coil and uncoil in response to changes in moisture content of the air, assist in the dispersal of the spores. Under low light intensity and high humidity, the spores grow into small, flattened, green prothallia (early gametophytes). After a period of development these gametophytes come to resemble miniature green pincushions, being up to three centimetres (slightly over an inch) in diameter. Eggs are produced in structures called archegonia, at the bases of the upright lobes on the small gametophytes, and sperm are produced in structures called antheridia, present on the lobes. The egg is fertilized in the archegonium by a sperm; then the zygote, by continued divisions, forms an embryo within the archegonium. The embryo (young sporophyte) is nourished by the gametophyte until it develops its own shoot and roots. One gametophyte may support two or more young sporopyhtes before it ultimately dies and decays.

Life cycle of *Equisetum*.

Form and function. The shoot system of the sporophyte consists of an underground stem (rhizome) and an aerial stem, both of which show the same basic organization.

The slender, herbaceous stems of *Equisetum* have hollow internodes. The whorled leaves are greatly reduced and are united laterally at each node to form a toothed sheath around the stem. Each leaf has a single, unbranched midvein. Secondary growth, during which girth increases annually, was characteristic of the extinct Calamitales and Sphenophyllales. In *Equisetum* the vascular strands are organized into a cylinder surrounding a large pith cavity. In the majority of species, the cell walls of the outer cell layer (epidermis) are thick and contain silica deposits. Roots arise at nodes of the rhizome. Branch buds also are initiated at nodes, but their subsequent growth is dependent on the growth characteristics of the particular species. In relatively unbranched species, the potential buds remain inhibited.

The sporophyte consists of stem, leaves, and roots. Spores are produced in spore cases (sporangia), which are borne on sporangiophores. The latter are organized into strobili associated with sterile bracts (much reduced leaves)—as in Sphenophyllales and Calamitales—or without them (Hyeniales, Equisetales). Each sporangiophore in *Equisetum* has five to ten sporangia. The entire sporangiophore appears to be a condensed, dichotomous branch system (*i.e.*, dividing into two parts), each sporangium occupying the end of a branch but lying parallel to the stalk of the sporangiophore.

Evolution and classification. Certain Sphenopsida flourished as trees (for example, *Calamites* species) during the coal-forming Carboniferous Period, but the earliest sphenopsids appeared as early as the Devonian. In its fossil history the class is believed to have constituted a larger portion of the flora of the Earth than at the present time.

Equisetum, which may have been present also during the Carboniferous, may be one of the oldest living genera of vascular plants. The evolutionary tendency in this genus has not been noticeably radical. The more primitive species, which now range in South America, Cuba, and Mexico, have perennial, green shoots with green, pointed cones. The advanced species, northward to the Arctic, have annual, green, branched, vegetative shoots and nongreen, unbranched, fertile shoots with brownish cones. Intermediate combinations of these features occur in many species.

The evolutionary trend

Annotated classification. Some botanists recognize five or six different orders in the class; others restrict the class to four orders. There is only one order, Equisetales, that has both living and extinct species; all others comprise extinct sphenopsids. The latter are indicated by a dagger (†) in the listing below.

CLASS SPHENOPSIDA (OR ARTICULATAE)
Extinct and living primitive, seedless, vascular plants with jointed, ribbed stems and whorls of leaves at regular intervals along the stem.

† Order Hyeniales (Protoarticulatae)
Extinct, shrublike plants, with short, forked leaves in whorls. One family: Hyeniaceae.

† Order Pseudoborniales
One family, Pseudoborniaceae, with a single extinct species, *Pseudobornia ursina.*

† Order Sphenophyllales
Extinct, vinelike sphenopsids, with small, wedge-shaped leaves. Two families: Sphenophyllaceae and Cheirostrobaceae.

† Order Calamitales
Extinct tree horsetails in two families: Asterocalamitaceae and Calamitaceae.

Order Equisetales
Herbaceous horsetails and fossil allies with needlelike leaves in whorls along the stem. About 30 extant species in the genus *Equisetum* and several extinct species in the genus *Equisetites*. *Equisetum* is distributed predominantly in the Northern Hemisphere.

Critical appraisal. Whereas the dominant opinion is that the Sphenopsida is a class, also called Articulatae, in reference to the jointed, or articulated, stems, some authorities raise the group to the level of a division, Arthrophyta or Sphenophyta, or a subdivision, retaining the term Sphenopsida. These differences in viewpoint reflect a lack of information basic to the erection of a stable classification. Additional paleobotanical evidence is needed to establish a classification acceptable to most botanists.

Spices, Herbs, and Flavourings

Spices and herbs are dried parts of various plants cultivated for their aromatic, pungent, or otherwise desirable substances. They consist of rhizomes, bulbs, barks, flower buds, stigmas, fruits, seeds, and leaves. They are commonly spoken of loosely as spices, spice seeds, and herbs. Spices are the highly esteemed, fragrant or pungent plant products of tropical and subtropical regions, the dominant species of the trade including cardamom, cinnamon, cloves, ginger, and pepper. Spice seeds are the tiny aromatic fruits and oily seeds of herbaceous plants including anise, caraway, cumin, fennel, poppy, and sesame. Herbs are the fragrant leaves of such plants as marjoram, mint, rosemary, and thyme.

Spices, spice seeds, and herbs are employed as adjuncts to impart flavour and aroma or piquancy to foods. In the small quantities used to prepare culinary dishes they have little or no nutritive value, but they stimulate the appetite, add zest to food, enhance the taste, and delight the gourmet. For individual spices and herbs see RELATED ENTRIES under SPICES, HERBS, AND FLAVOURINGS in the *Ready Reference and Index*.

HISTORY OF THE SPICE TRADE

The role of spices and herbs in shaping the course of history is a long and romantic story.

The spice trade is one of the oldest known to man. Overland trade routes across Asia antecede recorded history, and merchandise moved over coastal sea routes in both directions between Arabia and southern Cathay (China) in very early times. Cinnamon, cassia, cardamom, ginger, and turmeric were known and employed by Eastern peoples thousands of years ago, and they became important items of commerce early in the evolutionary course of trade.

Ancient spice trade routes

Cinnamon and cassia found their way to the Middle East at least 2,000 years before the Christian Era. There are many references to spices in the Bible, including four to cinnamon and three to cassia. The spice trade in those days was extensive and profitable. Part of the immense yearly income of King Solomon came from "the traffic of the spice merchants" (1 Kings 10:15).

From time immemorial, southern Arabia (Arabia Felix of antiquity) had been a trading centre for frankincense, myrrh, and other fragrant resins and gums. It is logical to conclude that her merchants would seek to add to their store of aromatics and doubtless it was the Arabs who first brought the highly esteemed cinnamon and cassia to the Middle East. Shrewd traders as they were, they artfully withheld the true source of these spices. To satisfy the curious, to protect their market, and to discourage likely competitors, they spread abroad fantastic tales to the effect that cassia grew in shallow lakes guarded by winged animals, that cinnamon grew in deep glens infested with poisonous snakes, and that, in consequence, they obtained these spices only at great risk. Pliny the Elder (AD 23–79) ridicules these stories of "fabulous antiquity" and boldly declares that "all these tales, however, have been evidently invented for the purpose of enhancing the price of these commodities." Strabo (*c.* 64 BC–AD 20) in his *Geography* speaks of the extensive trade in spices carried on by the Arabians, of the wealth of the Arabian spice merchants, and observes that even a camel driver "might attain to some sort of wealth" by trading in spices.

Whatever part the overland trade routes across Asia played, it was mainly by sea that the spice trade grew. By rudimentary navigational skill, and aided by the winds called monsoons, Arabians were making direct sailings before the Christian Era. In the Far East, parallel in time and not less skilled, the Chinese were moving through the waters of the Malay Archipelago and trading in the Spice Islands. Ceylon was a central trading point.

With the advent of the Ptolemies, Egyptian trade with India began and was developed by the Romans who succeeded them. From its early, hesitant start this trade was well developed by the time of Strabo, who says that on a visit to Syene he found that about 120 ships sailed regularly from the Red Sea port of Myos-Hormos to India.

Under the Ptolemies, Alexandria, founded in 332 BC, had become a great seaport and centre of trade. Its revenues from port dues were already enormous when Ptolemy Alexander bequeathed this ancient city to the Romans in 80 BC. Under the Romans Alexandria became the greatest commercial centre of the world and the emporium for the aromatic and pungent spices of India that found their way to the markets of Greece and the Roman Empire.

Roman trade with India was extensive for over three centuries and then began to decline. It had, no doubt, weakened but not broken the Arabian hold on the spice trade. The Roman trade revived in the 5th century but dwindled in the 6th, whereas the Arabian trade endured into and through the Middle Ages.

By the 6th century Ceylon had become a notable trading centre to which came, according to Cosmas Indicopleustes of Alexandria, the "richest merchandise of the Indies, and all sorts of perfumes and spices."

At about the same time, Venice came into existence. By the 10th century it was beginning to prosper in the trade of the Levant; by the early part of the 13th century it enjoyed a monopoly of the trade of the Near East; and by the 15th century it was a formidable power in Europe. Part of Venice's great wealth came from trading in the spices of India, Ceylon, the East Indies, and Cathay, which it obtained in Alexandria and sold to northern and western European buyer-distributors at exorbitant prices.

Role of spices in the voyages of discovery

The Europeans knew full well the origin of the spices reaching Alexandria and, unable to break the hold of Venice, determined in the last third of the 15th century to build ships and venture abroad in search of a route to the spice-producing countries. So began the famed voyages of discovery. The Portuguese were first in the race, and the first to bring spices from India to Europe by way of the Cape of Good Hope.

Bartholomeu Dias doubled the Cape of Good Hope in 1488; Vasco da Gama reached Calicut, India, in 1498; and Pedro Álvares Cabral brought spices to Lisbon in 1501.

In 1492 Christopher Columbus sailed under the flag of Spain, and in 1497 John Cabot sailed for England; but both failed to find the fabulous spice lands.

Columbus had read, probably, that Eratosthenes of Cyrene (about 250 BC) had calculated the circumference of the world and that Strabo had observed that India might easily be reached from Spain, "still keeping the same parallel were it not for the extent of the Atlantic." Columbus thought, no doubt, that by sailing west he might reach the East before the Portuguese. But the first land he reached was not that of the fabulous Orient but a small island, which he named San Salvador. He thought he had arrived in the Indies "where the spices grow" (hence the name West Indies for the Caribbean islands he discovered). His four voyages resulted in no significant contribution to spices beyond his finding that the natives used capsicums, which they called *aji*, to season their food.

John Cabot fetched up on the barren coast of Cape Breton Island and took possession of the land in the name of Henry VII. He, too, thought he had arrived in the land where the spices grow, but he found none at all.

Ferdinand Magellan took up the quest for Spain in 1519. He discovered the straits that bear his name, and although he was killed in the Philippines en route, he is credited with the first circumnavigation of the world. Of the five vessels that set out from San Lucar under his command only one, "Victoria," returned to Spain, but triumphantly, laden as she was with the cloves of Tidore.

In 1577 Sir Francis Drake began his adventurous voy-

age around the world by way of Magellan's straits and the Spice Islands and brought the "Golden Hind" heavily laden with the cloves of Ternate and other treasures into Plymouth harbour in 1580.

For Holland, a fleet under the command of Cornelis de Houtman sailed for the Spice Islands in 1595; another, commanded by Jacob van Neck, put to sea in 1598; and their ships returned home with rich cargoes of cloves, mace, nutmegs, and pepper.

The market in Europe for spices was considerable; the prices were high and the profits great. The early success of the Dutch gave them a temporary monopoly on pepper, forcing the price of that spice in England to rise from two shillings and eightpence to eight shillings per pound in 1599. The London merchants acted quickly, and on the formation of the East India Company under charter of Queen Elizabeth, December 31, 1600, Capt. James Lancaster, later Sir James, sailed for the East Indies. His ships returned to England in September 1603 with 1,000,000 pounds of pepper, which had cost him less than sixpence a pound in Sumatra.

East India Company

In 1608 a cargo of cloves bought in the Spice Islands for £2,948 realized £36,287 in England.

In 1602 the Dutch East India Company came into existence by authority of the Estates-General of the Netherlands. In 1664 the French East India Company was organized by state authorization under Louis XIV. Other European nations granted charters to East India companies with varying success.

From the time in the latter part of the 15th century when the Portuguese put to sea in search of a southern route to India, European powers vied with one another in the quest for Eastern spices. Numerous vessels set out in search of spice cargoes. There followed struggles and conquests to gain advantage and monopolistic control of the trade. For over 100 years Portugal was the dominant power, then yielding to English and Dutch enterprise and conquest, and this to end in the 19th century with British interests firmly rooted in India and Ceylon and the Dutch in control over the greater part of the East Indies.

For mariners it was an age of adventure, risk, hardship, disease, and death; for nations an age of struggle, defeat, or conquest; an age of acquisition of new, near-primitive lands and of colonizing and gaining dominion over civilized foreign territories. For European commercial interests it was an age of rewarding success, which broke the monopoly of Venice, overcame the Muslim domination of the spice trade that extended from the Red Sea and the Persian Gulf to the China Sea, created a voluminous trade in a great variety of merchandise between Europe and the Far East, and opened up a New World.

The United States entered the spice trade at the close of the 18th century. Capt. Jonathan Carnes is credited with founding the pepper trade with the East Indies. Financed by Salem interests, he put to sea in the brigantine "Rajah," July 20, 1795, and returned in the following year with a cargo of 158,544 pounds of pepper, which sold at 37 cents per pound and brought a handsome profit of 700 percent.

This historic voyage began a lucrative pepper trade with Sumatra that flourished for 69 years, bringing pepper to Salem, Boston, and New York. It is recorded that between 1795 and 1845 some 200 merchantmen laden with the pepper of the East Indies entered Salem harbour.

By the 20th century the world had come to know an orderly and stable pattern of trade in spices, and London had become its centre. Today, New York has taken the place of London.

USES, ANCIENT AND MODERN

The most notable uses of spices and herbs in very early times were in medicine, in the making of holy oils and unguents, and as aphrodisiacs. Priests employed them in worship, incantations, magical rites, and rituals.

Beliefs in the healing powers of spices

Ancient herbals, including those of Cathay, Sumer, Assyria, Egypt, Greece, and Rome, testify to the use of spices and herbs in the treatment of disease. Hippocrates, Galen, and Pedanius Dioscorides, among others, employed them. In the first century of the Christian Era Pliny the Elder, in his *Natural History*, extols at length the efficacy and healing powers of spices and herbs in the treatment of just about every ailment known in his day. Such virtues, tempered and moderated, filtered down into the Middle Ages and early modern times.

It is not known when man first used spices and herbs in food. Sesame seems to have been known and employed as food, for making wine, and for its oil from time immemorial. Garlic and onions were employed as part of the diet in very early times. Certainly by the time of the ancient Greeks and Romans many spices and herbs had come into use to flavour food and beverages.

Herodotus (*c.* 484–*c.* 425 BC) describes the food of peoples he had met or heard about and relates that some ate fish and meats raw, sun-dried, salted, or pickled. Dried, salted, and pickled meats were staple items of food in many lands centuries after his time, and it requires no effort to imagine the welcome change the gratifying flavour of spices and herbs brought to foods, not only to opulent Greeks and Romans but to the affluent of society everywhere long after them.

Only the wealthy could indulge the use of imported aromatic spices and this was true, apparently, all over the world. Marco Polo observed, in 13th-century Cathay, that the higher class people ate meat that had been preserved in several of their spices, but the poor had to be content with meat steeped in garlic juice.

In Europe, in the course of time, knowledge slowly spread of the use of spices and herbs to aid in the preservation of food by retarding or preventing rancidity or other deterioration caused by oxidation and to flavour dishes. By medieval times large quantities of culinary herbs were in use. Eastern spices were beyond the purse of the greater number of people, but with the ascendency of the western European nations in the Oriental spice trade these conditions gradually changed, and the aromatic and pungent spices finally came into general use by rich and poor alike.

Modern uses of spices, spice seeds, and herbs are legion. There are few culinary recipes that do not include them, and their judicious use brings a delectable, distinctive aroma and taste to a host of dishes (see Table 1).

In the food industry they are employed in the preparation of numerous products including processed meats, fancy sausages, sauces and vinegars, prepared mustard, pickles, chutneys, preserves, mayonnaise, salad dressings, biscuits, cookies, cakes, confections, and beverages.

Their essential oils and oleoresins are the basis of a number of spice flavourings and seasonings employed in food manufacturing, where oil spices are preferred to the whole or ground spices for the preparation of certain products.

Spice and herb liqueurs

Spices and herbs, or their oils where processing temperature permits, go into the preparation of a number of liqueurs including absinthe, anisette, benedictine, crème de menthe, curaçao, and kümmel.

Their essential oils are the flavouring components of a number of extracts; and they are employed in perfumery, cosmetics, toilet preparations, hair oils, toothpastes, toilet soaps, and tobacco.

In medicine the spices and herbs have not entirely lost their reputation. In India and other Asiatic countries their curative virtues enjoy respect. They still have a place, though limited, in Western medicine. Present-day herbalists extol the efficacies of some of the spices, spice seeds, and herbs in the treatment of certain ailments.

MODERN TRADE AND PRODUCTION

In the passage of time, by intentional transplanting and seeding, and by natural dissemination, many of the plants from which we obtain spices, spice seeds, or herbs have become established in lands near to, or far from, their natural habitat. Ginger, native to southeastern Asia, is now cultivated in many countries across the world from East to West; capsicum spices, native to Central America, enjoy almost universal production; pepper, native to and an export spice of southern India, is also cultivated for export in Indonesia, Cambodia, Sri Lanka (Ceylon), Malagasy Republic, Malaysia, Thailand, and Brazil; carda-

mom and sesame, products of the Old World, now flourish in the New World. Today spices, spice seeds, and herbs come from many parts of the world (see Table 2). This has led to increased production, but not overproduction; the consumption of spices and herbs throughout the world is considerable.

Variations of quality have resulted because of differences in altitude, temperature, soil composition, precipitation, and other environmental factors and because of differences in methods of harvesting, drying, processing, and storing in the various regions.

Spices, spice seeds, and herbs are purchased directly from producers or, more commonly, through brokers specializing in the trade and operating, usually, in major seaports such as New York, London, Hamburg, and Amsterdam.

Organizations or associations exist to promote, facilitate, and regulate trading: the Spices Export Promotion Council, India; Fachverband der Gewürzindustrie c.V., West Germany; and the American Spice Trade Association, United States.

Importation and sale. Spices and herbs destined for ports overseas are transported in general cargo vessels. On arrival at their destination, these products are subject to examination for adulteration and contamination by port health authorities acting under the imported food laws of their respective countries. For example, spices, spice seeds, and herbs imported into the United States are subject to sampling and examination by the Food and Drug Administration; spice lots found to be contaminated are reconditioned under their supervision.

Inspection at ports of entry

Following inspection, spices and herbs imported for or by merchants and manufacturers located in the port of entry are cleared through customs on payment of duty, if any (a procedure usually carried out by customs brokers), and picked up at the pier. Those en route to other areas are shipped in bond to their destination, where they are similarly cleared and then picked up at the bonded warehouse by the merchants concerned.

Spices, spice seeds, and herbs are usually imported whole, some to be sold whole, most to be further processed by grinding. Spice grinding is a specialized business requiring ability to identify the various spices, spice seeds, and herbs; to assess their quality; and to know their structure and principal chemical components.

Bark and root (rhizome) spices must be reduced to a size suitable for introduction into the grinding machine. This is usually accomplished with the aid of a knife-cutter comminuting machine.

Grinding machines commonly in use in the United States include pulverizers, roller mills, hammer mills, and comminuters.

The ground and sifted spices are mixed to uniformity usually in a ribbon blender or mixer. This machine also prepares spice and herb mixtures (see below *Blends*).

Excessive heat must be avoided in the grinding process, as it will cause a loss of valuable volatile oil.

Spices, spice seeds, and herbs are sold whole or ground, in small containers for the retail trade, or in bulk quantities. Bulk buyers include meat packers, fancy sausage specialists, pickle manufacturers, producers of condiments, commercial bakers, confectioners, and the catering industry.

The United Nations and the Organization for Economic Co-operation and Development provide statistics of imports and exports reported by several but not all countries. Many countries provide only a partial report; world totals would be greater if all information were included. The international category 075.0 covers a limited number of spice items (see Table 3).

Production. Spices in general, after harvesting and collection, are cleansed of extraneous matter, cured if necessary, dried in the sun or by artificial heat or both, sorted, and graded. Spice seeds are obtained by threshing

*Mostly mustard seed. †Estimated. ‡075.0 includes aniseed, allspice, capsicum spices, caraway, cardamom, cassia, cassia buds, cinnamon, cloves, clove stems, coriander, cumin, curry powder, fennel, ginger, laurel (bay) leaves, mace, nutmeg, pepper, saffron, star anise, thyme, vanilla beans. §No record. All data 1968.

the harvested plants after they have been stacked in the field to mature and dry. Herbs are harvested, suspended, or stacked in the open to dry, and the dried leaves rubbed from the stalks; or following harvesting they are dried by exposure to controlled artificial heat and then processed mechanically to produce herbs of good colour, full flavour, and desired fragment size. Consumer demand at retail differs the world over because cuisine differs.

Blends. Ground mixtures of spices, some long established and some newly introduced, are available.

Meat tenderizers. Meat tenderizers may be seasoned or unseasoned. The seasoned tenderizers contain appropriate ground spices. Both types usually contain salt and dextrose, some contain monosodium glutamate, but the principal tenderizing substance in all of them is papain. Papain is derived from the latex or the unripe fruit of the papaya, or papaw, tree, *Carica papaya*, native to tropical America. Papain is a proteolytic enzyme that acts as a protein digestive.

Peels. Peels such as lemon and orange produced by spice manufacturers consist of the dried and finely comminuted peels blended, respectively, with lemon oil and orange oil.

Condiments. Condiments (Latin *condire*, "preserve") are, loosely, any kind of relish or seasoning added to prepared food dishes. In this sense pepper could be classified as a condiment, but the term usually includes such preparations as chutneys, catsup, tabasco sauce, Worcestershire sauce, barbecue sauce, soya sauce, mayonnaise, salad dressing, prepared mustard, etc. The last mentioned item is more closely allied to spices; the others contain spices among a number of ingredients. The major ingredient of prepared mustard is mustard flour (ground mustard seed), although other spices are present as well as vinegar, salt, and sugar or dextrose. Prepared mustard with horseradish added is also available.

Essential oils. Essential oils are so called because they contain the aroma and flavour of the plants. They are also called volatile oils because they evaporate when exposed to air.

In addition to the principal flavour component or components of the oils, lesser amounts of other natural organic chemical constituents present in the essential oil contribute to the full flavour of the spice, seed, or herb.

Oleoresins. Oleoresins, as their name implies, are natural combinations of essential oils and resins, more or less liquid in consistency. Resins are complex natural oxidation products of essential oils. Oleoresins occur naturally in capsicums, ginger, laurel (bay) leaves, pepper, star anise, and turmeric.

Commercially, an oleoresin is prepared from a spice or herb by extraction with a selected volatile, organic solvent. This process yields a mixture of the essential oil, soluble resins, and related substances present in the spice or herb depending on the kind of solvent employed. These mixtures contain the flavouring principles present in the original spice or herb.

By combining essential oils and oleoresins in various processes, products are obtained that replace the natural spice or herb and can be used in the manufacture of soluble spice flavourings, stable flavourings for use by commercial bakeries, and complete flavourings for all types of processed meats and fancy sausages.

Soluble spice flavourings are made by distributing the oleoresin product on a dry, soluble, edible substance such as salt or dextrose. When other substances such as ground spices are added, the complete mixture is known commercially as a dry soluble seasoning.

Maintenance of quality. *Quality control.* All bulk spices, whole and ground, are stored in dry, clean, sanitary, rodent-proof, cool premises. Temperature and humidity are controlled to inhibit mold growth and discourage insect infestation in the interest of consumer protection, and to avoid loss to the manufacturer.

Whole spices and herbs intended for grinding should not be stored too long. A slow deterioration of essential oil

Table 4: Mixed Seasonings and Flavour Enhancers

blend	typical ingredients
Apple pie spice	cinnamon, allspice or cloves, ginger, nutmeg or mace
Barbecue spice	cayenne or red pepper, cumin, cloves or allspice, garlic
Celery pepper	ground celery seed, black pepper
Celery salt	ground celery seed, free-running salt
Chili powder	capsicums
Cinnamon sugar	cinnamon, sugar
Curry powder	turmeric, cumin, fennel, coriander, fenugreek, cayenne or red pepper, black or white pepper, with or without ginger, allspice, cloves, cardamom (depending on quality); curry powder is "Hot" or "Mild" and formulae, accordingly, include or omit the more pungent spices
Garlic pepper	garlic powder, black or white pepper
Garlic salt	garlic powder, free-running salt, minced garlic
Herbs, fine	sweet marjoram, sweet basil, rosemary, thyme
Hamburger seasoning	allspice or cloves, celery, onion powder, white pepper, sage
Italian seasoning	sweet basil, sweet marjoram, origanum (oregano), rosemary, savory
Mincemeat spice	cinnamon, allspice or cloves, nutmeg, mace
Onion pepper	onion powder, black or white pepper
Pastry spice	cinnamon, allspice or cloves, nutmeg or mace, cardamom, anise, sugar
Poultry seasoning	white pepper, sage, origanum (oregano), savory, thyme, allspice or cloves, onion powder
Pumpkin pie spice	cinnamon, allspice or cloves, nutmeg, mace, ginger
Pickling spice	allspice, cracked bay leaves, cardamom seed, cracked cassia, whole small chilies, cloves, cracked ginger, broken mace, mustard seed, black pepper
Flavour enhancers	
Salad seasoning	a mixture of spices including onion and garlic powder, sesame and celery, salt, and monosodium glutamate
Seasoned pepper	a mixture of spices including garlic and onion powder, black pepper, and monosodium glutamate
Seasoned salt	a mixture of salt, spices, spice extractives, and monosodium glutamate
Monosodium glutamate	$HOOCCH(NH_2)CH_2CH_2COONa$, white crystalline powder, very soluble in water, employed to impart a meat flavour to foods; very little is required to give the desired effect

may occur with the passage of time although the cellular structure is intact. Spices and herbs with oil glands on or near the surface are more vulnerable than those with oil secretion cells deeply seated in the tissues.

Ground spices should not be left exposed to the air but kept in tightly closed containers while awaiting packaging. Grinding fractures and tears apart the tissues and cell walls, and loss of volatile constituents will occur in direct ratio to surrounding air temperature unless the products are properly contained.

All retail packages and containers should afford full protection against this kind of loss.

Laboratory tests

Laboratory quality-control checks can be made by sampling and routine analysis. For this purpose the spice is ground fine enough to pass through a sieve with circular openings one millimetre in diameter. The sample should be thoroughly representative of the lot.

The procedure usually involves the following determinations: (1) moisture, (2) total ash, (3) ash insoluble in hydrochloric acid, (4) volatile oil, (5) nonvolatile ether extract, (6) crude fibre, (7) starch.

In North America, spices and herbs offered for sale to the public are subject to spot sampling and analysis by government agencies responsible under the food laws.

Shelf life. The shelf life of spices depends largely upon the form of the spice and the material used for packaging. The shelf life from the date of manufacture varies as follows: flaked items in tins, 12 months; whole spices in cartons, 18 months; ground spices in tins, 24 months; and spices packed in glass containers, 36 months.

Standards. Standards of identity are promulgated by governments to regulate the industry and protect the public. Minimum and maximum limits for physical and chemical properties insure against inferiority or adulteration. These requirements must be met by foreign exporters and by importers at home.

Not all countries have standards relative to spices, spice seeds, and herbs, but there is universal recognition of the value of such standards to exporters, importers, and manufacturers, and of their necessity in the interests of consumer protection. A trend to the promulgation of standards by more nations is now evident.

FLAVOURINGS

Flavouring extracts, essences, and flavours are liquids added to foods to enhance taste and aroma. They are prepared from essential oils, such as almond and lemon; from vanilla; from fresh fruits by expression; from ginger by extraction; from mixtures of essential oils and synthetic organic chemicals; or entirely from synthetic chemicals, with alcohol, glycerol, propylene glycol, alone or in combination, as solvents. Water is added and sometimes certified food colour.

Extracts, essences, and flavours employing only natural flavouring agents are called pure; those employing synthetics (in part or entirely) are called imitation or artificial flavourings.

Essential oils, complex substances derived from plants, consist of a number of organic chemical components including alcohols, aldehydes, ethers, esters, hydrocarbons (terpenes, sesquiterpenes, etc.), ketones, lactones, phenols, and phenol ethers. Nearly all of these organic chemicals have been synthesized, and it is these synthetics that are employed in the manufacture of imitation flavourings.

Essential oil extracts. These extracts are prepared by dissolving an essential oil in alcohol of the proper strength, adding water and, where desirable and permitted by law, a small amount of certified food colour. They include almond, anise, celery, cassia or cinnamon, clove, lemon, nutmeg, orange, rosemary, savory, basil, sweet marjoram, thyme, and wintergreen.

Nonalcoholic flavouring extracts. Nonalcoholic flavouring extracts are prepared by employing glycerol or propylene glycol or a combination of these to bring the essential oil into solution, with added water, and sometimes food colour.

True fruit flavours. True fruit flavours are obtained by expression, concentration, or distillation of fresh fruits. The alcoholic content of the finished product is usually between 18 and 22 percent to prevent fermentation.

Imitation, artificial extracts, essences, flavours. Imitation, artificial extracts, essences, and flavours are prepared by bringing into solution with alcohol, glycerol, or propylene glycol various synthetic flavouring agents to formulate an extract, essence, or flavour with the likeness of the flavour of the fruit, spirit, or liqueur for which it is named. These preparations cover a wide range of flavourings including vanilla, lemon, lime, banana, cherry, butterscotch, brandy, and rum.

Some contain few ingredients, others many. Imitation vanilla extract may be prepared with synthetic vanillin, coumarin (this ingredient is now prohibited in the United States and Canada), heliotropin, glycerol, water, and caramel colouring.

Imitation strawberry flavour may contain 10, 12, or more synthetic organic chemicals including aldehyde C16, aldehyde C14, benzyl acetate, methyl anthranilate, amyl acetate, amyl butyrate, and ethyl propionate, with solvents and added colour, according to the particular manufacturer's art, skill, and experience in bringing out the fullest and most realistic flavour.

Imitation brandy flavour may contain, with other organic chemicals, ethyl oenanthate, methyl succinate, ethyl acetate, and ethyl propionate.

Certain synthetic organic chemicals lend a distinctive note to imitation flavourings—for example, allyl caproate and ethyl butyrate to pineapple, benzaldehyde to almond, benzyl butyrate to raspberry, and citral to lemon.

Imitation extracts, essences, and flavours must be labelled accordingly.

Quality control and analysis. In the United States the industry is presided over by the Flavor and Extract Manufacturers' Association, FEMA, incorporated in 1909. The association assisted in the framing of federal laws to ensure quality of product and continues in this work in the interests of the industry and for the protection of the consumer. FEMA played an important part in arriving at an efficient method of analysis for vanilla, the most widely employed flavouring product, including such modern techniques as paper and column chromatography.

The International Organization of Flavour Industries,

International Organization of Flavour Industries

IOFI, with headquarters in Brussels, was recently incorporated under the laws of Belgium. Its main purpose is the continuing evaluation of flavour ingredients for safety, and its aim is directed toward the establishment of a universal code of flavour laws. The Flavor and Extract Manufacturers' Association is a member of IOFI.

For analytical procedures relevant to flavouring extracts consult "Official Methods of Analysis" of the Association of Official Analytical Chemists, 10th ed. (1965), pages 286-305, or other standard analytical texts.

BIBLIOGRAPHY. General works on spices and herbs include: J.W. PARRY, *Spices*, vol. 1, *The Story of Spices and the Spices Described* (1969), a history of spices, with descriptions of individual spices, spice seeds, and herbs (illustrated); F. ROSENGARTEN, JR., *The Book of Spices* (1969), a comprehensive and illustrated work including a history of spices, a description of individual spices and herbs, and a number of culinary recipes using them; and AMERICAN SPICE TRADE ASSOCIATION, *A Glossary of Spices* (1966), an illustrated booklet describing and suggesting uses for various spices, spice seeds, herbs, and blends.

Food flavourings are treated in J. MERORY, *Food Flavourings: Composition, Manufacture, and Use* (1960), a guide to the manufacture of such flavouring extracts as vanilla, fruit flavours, and others; and the *Organic Chemicals Handbook* (1963), a booklet issued by Fritzsche Brothers, Inc. (New York) listing various aromatic organic chemicals and describing their colour, appearance, volatility, and application. More technical treatment is offered in J.W. PARRY, *Spices*, vol. 2, *Morphology, Histology, and Chemistry* (1969). *The Oleoresin Handbook* (n.d.), an illustrated booklet issued by Fritzsche Brothers, Inc. (New York) treating the commercial production of oleoresins, also covers various spices, spice seeds, herbs, and vanilla extract, and includes an appendix on U.S. Federal specifications. The *Official Analytical Methods of the American Spice Trade Association* (1965) treats accepted analytical methods of the U.S. industry; the *Official Methods of Analysis of the Association of Official Agricultural Chemists* (1965) treats accepted analytical methods for this organization.

Legislation, regulation, and standards of identity issued by various governments are treated in a number of official publications, such as the UNITED STATES DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE, *The Federal Food, Drug, and Cosmetic Act*, as amended (1968); and the CANADIAN DEPARTMENT OF NATIONAL HEALTH AND WELFARE, *The Food and Drugs Act and Regulations* (1969).

(J.W.P.)

Spinoza, Benedict de

Benedict de Spinoza (Despinoza) was a 17th-century Rationalist, author of one of the most consummate systems of metaphysics in the history of philosophy. Convinced that every feature of reality is necessary and that every logically coherent possibility must exist, Spinoza set out to deduce the nature of reality, taking Euclid's geometry as a model, from a set of primitive definitions and axioms. Spinoza's significance thus lies not as much in the particular merits of the system itself (which was pantheistic) as in the fact that it comprises a specific sample of a thoroughgoing metaphysical system, which scholars can examine in order to evaluate the validity and promise (or their opposites) of the metaphysical enterprise in general.

Early life and career. Spinoza was born of Jewish parents in Amsterdam on November 24, 1632. His Hebrew name was Baruch (meaning blessed), which by custom was rendered into its Latin equivalent, Benedictus.

Spinoza's grandfather and father were Portuguese and had been crypto-Jews after the Spanish Inquisition had compelled them to embrace Christianity. Later, after Holland's successful revolt against Spain and the granting of religious freedom, they found refuge in Amsterdam. His mother, who also came from Portugal, died when Benedict was barely six years old.

The Spinozas were prosperous merchants and respected members of the Jewish community, and it may be assumed that Spinoza attended the school for Jewish boys founded in Amsterdam about 1638. Its curriculum included the traditional Hebrew subjects: the Old Testament, the Talmud, the Hebrew codes, and the works of Ibn Ezra, Maimonides, Crescas, and others. Outside school hours the boys had private lessons in secular subjects. Spinoza was taught Latin by a German scholar, who may also have taught him German; and he knew to some extent all of the other significant continental languages. When he learned mathematics and physics is not known.

Spinoza, oil painting by an unknown artist, c. 1665. In the Herzog-August Bibliothek, Wolfenbüttel.

In March 1654 Benedict's father died. There was some litigation over the estate, with Benedict's only surviving stepsister claiming it all. Benedict won the lawsuit but allowed her to retain nearly everything.

His studies so far had been mainly Jewish, but he was an independent thinker and had found more than enough in his Jewish studies to wean him from orthodox doctrines and interpretations of Scripture; moreover, the tendency to revolt against mere tradition and authority was very much in the air in the 17th century. But the Jewish religious leaders in Amsterdam were fearful that heresies (which were no less anti-Christian than anti-Jewish) might give offense in a country that did not yet regard the Jews as citizens.

Difficulties with Jewish authorities

Spinoza soon incurred the disapproval of the synagogue authorities. In conversations with other students, he had held that there is nothing in the Bible to support the views that God had no body, that angels really exist, or that the soul is immortal; and he had also expressed his belief that the author of the Pentateuch (the opening books of the Bible) was no wiser in physics or even in theology than were they, the students. The Jewish authorities, after trying vainly to silence Spinoza with bribes and threats, excommunicated him in July 1656, and he was banished from Amsterdam for a short period by the civil authorities. There is no evidence that he had really wanted to break away from the Jewish community, and indeed the scanty knowledge available would suggest the opposite. On December 5, 1655, for example, he had attended the synagogue and made an offering that, in view of his poverty, must have been a rare event for him; and, about the time of his excommunication, he had addressed a defense of his views to the synagogue.

Among Spinoza's Christian acquaintances was Francis van den Enden, who was a former Jesuit, an ardent classical scholar, and something of a poet and dramatist and who had opened a school in Amsterdam. For a time, Spinoza stayed with him, helping with the teaching of the schoolchildren and receiving aid in his own further education. In this way he improved his knowledge of Latin, learned some Greek, and was introduced to the Neoscholastic philosophy of such writers as Franco Burgersdijck and Adrianus Heereboord. It may have also been through van den Enden's school that Spinoza became acquainted with the "new philosophy" of René Descartes, later acknowledged to be the father of modern philosophy. Spinoza's other Christian acquaintances were mostly of the Collegiants, a brotherhood that later merged with the

Mennonites; they were especially interested in Cartesianism, the dualistic philosophy of Descartes and his followers (see below).

At the same time, he was becoming expert at making lenses, supporting himself partly by grinding and polishing lenses for spectacles, telescopes, and microscopes; he also did tutoring. One of Spinoza's friends at this period was Simon Joosten de Vries, whose admiration for him was so great that he pressed him to accept a gift of 2,000 florins and wanted to make him his sole heir. This Spinoza refused, and, when he was bequeathed an annuity of 500 florins, he would accept only 300. A kind of reading and discussion circle for the study of religious and philosophical problems came into being under the guidance of Spinoza. In order to collect his thoughts, however, and reduce them to a system, he withdrew in 1660 to Rijnsburg, a quiet village on the Rhine, near Leiden.

It was in 1661, during his stay at Rijnsburg, that Spinoza met Heinrich Oldenburg, soon to become one of the two first secretaries of the Royal Society in London, with whom Spinoza was later to conduct the most important part of his correspondence. Rijnsburg was the headquarters of the Collegiants, and Spinoza's lodgings there were with a surgeon named Hermann Homan. In Homan's cottage Spinoza wrote *Korte Verhandeling van God, de Mensch en deszelfs Welstand* (written *c.* 1662; *Spinoza's Short Treatise on God, Man, and His Well-Being*, 1910) and *Tractatus de Intellectus Emendatione* ("Treatise on the Correction of the Understanding"), both of which were ready by April 1662. He also completed the greater part of his geometrical version of Descartes's *Principia Philosophiae* (with the appendix of "Cogitata Metaphysica" ["Metaphysical Thoughts"]) and the first book of his *Ethica*. Spinoza's attitude in these works already showed a departure from Cartesianism. Part of the *Korte Verhandeling*, it is conjectured, was based on notes that he had prepared in connection with the Amsterdam study circle, to which he seems also to have sent periodically the various parts of the *Intellectus Emendatione* and other works for study and discussion.

Early works in Rijnsburg

Influence of Descartes and the geometrical method. His version of Descartes's *Principia* (which covered at first only its second part) was prepared while Spinoza was giving instruction in the philosophy of Descartes to a private pupil. When he showed this work to his Cartesian friends in 1663, they persuaded him to do the same with the first part, which he then did in a fortnight. These two parts, together with its appendix, "Cogitata Metaphysica," were accordingly published by his friends under the title *Renati des Cartes Principiorum Philosophiae Pars I et II, More Geometrico Demonstratae, per Benedictum de Spinoza* (1663), with an introduction explaining that Spinoza did not share the views expressed in the book. This was the only book published in Spinoza's lifetime with his name on the title page.

The philosophy of Spinoza may thus be regarded as a development from and a reaction to that of his contemporary Descartes (1596-1650). Though it has been argued that Spinoza was also much influenced by medieval philosophy (especially Jewish), he seems to have been much more conscious of the Cartesian influence, and his most striking doctrines are most easily understood as solutions of Cartesian difficulties. Clearly, he had studied Descartes in detail. He accepted Descartes's physics in general, though he did express some dissatisfaction with it toward the end of his life. As for the Cartesian metaphysics, he found three very unsatisfactory features, viz., the transcendence of God, the substantial dualism of mind and body, and the ascription of free will both to God and to human beings. In Spinoza's eyes, those doctrines made the world unintelligible. It was impossible to explain the relation between God and the world or between mind and body or to account for events occasioned by free will.

The publication of Spinoza's version of Descartes's *Principia* had been intended to prepare the way for that of his own philosophy, for he had both to secure the patronage of influential men (as a shield against the hostility of the Calvinists) and to show the more philosophically minded that his rejection of Cartesianism was not out of ignorance.

Spinoza became dissatisfied with the informal method of exposition that he had adopted in the *Korte Verhandeling* and the *De Intellectus Emendatione* and turned instead to the geometrical method in the manner of Euclid's *Elements*. He assumed without question that it is possible to construct a system of metaphysics (*i.e.*, an account of the world as a whole) that will render it completely intelligible. It is therefore possible, in his view, to present metaphysics deductively—that is, as a series of theorems derived by necessary steps from self-evident premises expressed in terms that are either self-explanatory or defined with unquestionable correctness. His masterpiece, the *Ethica*, was set out in this manner—*Ordine Geometrico Demonstrata*, according to the reading of its subtitle. Its first part, "De Deo" ("Concerning God"), was finished and in the hands of his friends early in 1663. Initially the work was intended to have three parts only, but it eventually appeared (in 1677) in five parts. Spinoza's desire for an impersonal presentation was probably his chief motive for adopting the geometrical method, appreciating that the method guarantees true conclusions only if the axioms are true and the definitions correct. Spinoza, like his contemporaries, held that definitions are not arbitrary but that there is a sense in which they may be correct or incorrect.

Adoption of the geometrical method

The question was discussed at length in his unfinished *Tractatus de Intellectus Emendatione*. A sound definition, he held, should make clear the possibility or the necessity, as the case may be, of the existence of the object defined. Because the *Ethica* begins with the definition of "substance," the necessary existent, the entire system is vulnerable to anyone disputing that definition, however cogent the subsequent reasoning may be. In fact, as Gottfried Wilhelm Leibniz, a Rationalist philosopher and mathematician, pointed out, though the system is closely knit, its demonstrations do not proceed with mathematical rigour.

Period of the "Ethica." In June 1663 Spinoza moved to Voorburg, near The Hague, and it appears that by June 1665 he was nearing the completion of the *Ethica*. During the next few years, however, he was at work on his *Tractatus Theologico-Politicus*, which was published anonymously at Amsterdam in 1670. This work aroused great interest and was to go through five editions in as many years. It was intended "to show that not only is liberty to philosophize compatible with devout piety and with the peace of the state, but that to take away such liberty is to destroy the public peace and even piety itself." As this work shows, Spinoza was far ahead of his time in advocating the application of the historical method to the interpretation of the biblical sources. He argued that the inspiration of the prophets of the Old Testament extended only to their moral and practical doctrines and that their factual beliefs were merely those appropriate to their time and are not philosophically significant. Complete freedom of scientific and metaphysical speculation is therefore consistent with all that is important in the Bible. Miracles are explained as natural events misinterpreted and stressed for their moral effect.

Critico-historical treatment of the Bible

Spinoza also told his friend Oldenburg that he wanted to clear himself of the charge of atheism. Apparently, with the completion of the *Ethica* in sight, Spinoza was considering the question of its publication but found it impracticable in view of the contemporary state of public opinion; he therefore set himself to show that the Bible, properly understood, gives no support to ecclesiastical intolerance or to clerical interference in civil and political affairs.

In May 1670 Spinoza moved to The Hague, where he remained until his death. He began to compose a Hebrew grammar, *Compendium Grammatices Linguae Hebraeae*, but did not finish it; instead, he returned to the *Ethica*, although the prospect of its publication became increasingly remote. There were many denunciations of his *Tractatus Theologico-Politicus* as an instrument "forged in hell by a renegade Jew and the devil, and issued with the knowledge of Mr. Jan de Witt" (a promi-

nent but controversial Dutch statesman, who had shown sympathy for Spinoza). De Witt's murder by a Dutch mob in 1672 during a war with France provoked the philosopher to plan to post placards decrying "the very lowest of barbarians" responsible for the murder—an act that might have cost him his life had he not been forcibly prevented from carrying it out by his landlord. Further, Spinoza's political situation in The Hague was compromised in May 1673, when he went to Utrecht (then under French occupation) with a view to possible negotiations for peace. On his return several weeks later, he was badly received by the suspicious populace of The Hague. When the *Ethica* was finally completed in 1675, Spinoza had to abandon the idea of publishing it, though manuscript copies were circulated among his intimate friends.

Substance, attributes, and modes of the *Ethica*

The Ethica begins by distinguishing substance, attributes, and modes. Substance is that which can be conceived as existing in complete independence. Because it cannot be explained by anything else, it must be its own cause, or necessarily existent. There can be only one such substance, and this is quickly identified with God and with the whole of Nature. Spinoza thus arrives at a pantheism. The most shocking feature of his philosophy was his denial not only of the transcendence of God but also of God's personality, providence, free will, and purposes. The good man, although he loves God, will not expect God to love him in return.

Substance, in Spinoza's view, has an infinity of attributes. By an "attribute" is understood "that which the intellect perceives of substance, as constituting its essence." Of these attributes, only thought and extension are known to man. Thus, the universe is a spatial whole that is conscious throughout, and "All things . . . ," as he says, "are alive"—a position known as panpsychism. The theory of infinite attributes, however, poses difficulties. Since all attributes characterize substance throughout its extent, it seems to follow that, underlying every attribute (not merely mind and matter), there should be some entity related to the human mind in the same way that the body is related to it. But, if this were so, one would expect that all of the attributes would be known to man—as is the extension of body—though, in fact, they are not. This difficulty has led some commentators to view Spinoza as saying that the attributes are simply the infinitely many possible ways in which substance could be conceived. It seems clear, however, from Spinoza's 66th letter that he thought of the attributes as objective.

Substance is also diversified into an infinity of finite modes, best understood as "parts"—which cannot, however, be separated from the whole. Human beings and other commonsense objects, which are typically modes, are parts of nature; and Spinoza once referred to the human mind as part of the infinite intellect of God. There is a one-to-one correspondence between modes under the several attributes. There are also infinite modes, both immediate and mediate. The immediate infinite mode under the attribute extension is motion and rest, and the mediate infinite mode is the "aspect of the whole universe"; this last may be a reference to the conservation of motion in the total universe. The immediate infinite mode under thought is said to be the "absolutely infinite intellect"; by this Spinoza may refer to the sum total of consciousness of knowledge.

The whole scheme is completely deterministic. Since the nature of God cannot be other than it is, the whole system of modes, which follows from or expresses the nature of God, must necessarily be as it is. A mode under one attribute cannot be caused by a mode under another attribute, for they have no property in common. Any modal happening under one attribute has its explanation entirely in terms of the general laws that govern modal happenings under that same attribute.

Spinoza's views of body, knowledge, will, emotion

In applying his metaphysical scheme to human beings, Spinoza argued that man's body is a mode under extension, a complex mode owing its unity to the maintenance of a constant pattern of relations between changing parts. The human mind is likewise a system maintaining the same pattern of relation through change of parts. Spinoza sometimes spoke of the mind and body as one and the same thing, conceived now under thought and now under extension. Although there is no causal connection between mind and body, there is a mental correlate for every physical event and vice versa. Thus, for Spinoza, every change in the human body is associated with some change of awareness, however dim and vague it may be, in the human mind; and a human being can know external physical objects only insofar as they affect his own body.

Spinoza held that all sense experience and all unscientific generalization from it is inadequate. No object can be isolated from the rest of nature; hence, no one can state the whole truth about it, since this would involve the whole of nature. Knowledge of this kind—the first of three different grades—was called by Spinoza opinion or imagination. If, however, the consciousness is directed solely toward those properties that all objects have in common, there is no distortion such as occurs in sense experience. This second kind of knowledge is called reason. In this way Spinoza accounted for the possibility of a priori knowledge in geometry, general physics, and general psychology. The third kind of knowledge, intuition, seems to be the adequate knowledge of individual objects. It is possible through intuition, he held, to state of any individual thing that it depends on God as its complete, immanent cause. Perhaps by the term intuition Spinoza referred to a kind of mystical experience, the insight—accompanied by a strong emotion that he called "the intellectual love of God"—into the dependence of all things, including the human being himself, on the whole of nature.

Though the distinction between truth and falsehood about particular things occasioned Spinoza great difficulty, it is at least clear that a man's understanding of an individual thing or event will be adequate in proportion as he can explain its features in terms of general laws, which are the concern of reason, or it will be adequate insofar as he can make correct causal statements about it.

Spinoza maintained that, though deliberately chosen action indeed occurs, it does not involve free will in the ordinary sense. Willing is primarily *thinking* of the course of action to be followed, and, when there are no hindering factors, the action in question inevitably follows. The illusion of undetermined choice arises from one's ignorance of the preceding causes of thought and action. Spinoza's alternative account of freedom is to be found in his distinction between the active and the passive emotions. In human beings, conatus (appetite and desire) is one of the primary emotions. The only other primary emotions are joy, the psychic accompaniment of enhanced power, and grief, that of enfeebled power. Insofar as men are able to understand themselves and their environment, they can control events rather than be controlled by them; they then experience desire and joy in their active forms. A man is free insofar as his emotions are active rather than passive and in proportion as he is able to think clearly and to preserve himself for the maximum time in an active state. Spinoza was the first to emphasize that the complete understanding of emotions and of their causation deprives them of their overmastering quality.

Moral and political philosophy

Spinoza's moral philosophy, as he presented it in the *Ethica,* defines "the good" in largely subjective terms: the good for different species (*e.g.*, for man and for horse) is different. Thus, for God the distinction between good and evil would be meaningless, as it is essentially relative to the purposes of finite creatures. Human beings, however, have enough in common to suggest what is really good for them, however different their views may be. Thus, "good" may be said to have an objective significance for human beings, especially as reflecting the "knowledge of God." Spinoza's ethics are essentially egoistic, but the conduct that he enjoined is that which would be commended by an altruistic Utilitarian: he tried to prove, for example, that hatred may be overcome by love. His ideal man is in many respects comparable to the Stoic sage, for his aim is the maximum self-sufficiency; but Spinoza had a stronger realization of the necessity for cooperation and friendship between rational men in a civil society.

Last years and posthumous influence. After Spinoza had completed the *Ethica*, he concentrated his attention on political problems and began his *Tractatus Politicus*, which he did not live to finish. During the post-*Ethica* period, he was visited by several important people, among them Ehrenfried Walter von Tschirnhaus (in 1675), a scientist and philosopher, and Gottfried Wilhelm Leibniz (in 1676), like Spinoza, one of the foremost Rationalists of the time. Leibniz, having heard of Spinoza as an authority on optics, had sent him an optical tract and had then received from Spinoza a copy of the *Tractatus Theologico-Politicus*, which deeply interested him. According to Leibniz' own account, he "conversed with him often and at great length." Spinoza, however, was now in an advanced stage of consumption, aggravated by the inhaling of glass dust from the polishing of lenses in his shop. On February 21, 1677, he died and was buried four days later in the New Church on the Spui. He was unmarried and left no heir, and his few possessions were sold by auction. These included about 160 books, the catalog of which has been preserved.

In accordance with Spinoza's previous instructions, several of his friends prepared his manuscripts secretly for the press, and they were sent to a publisher in Amsterdam. The *Opera Posthuma* (Dutch version: *Nagelate Schriften*), which was published before the end of 1677, comprised the *Ethica, Tractatus Politicus,* and *Tractatus de Intellectus Emendatione*, as well as letters and the Hebrew grammar. His *Stelkonstige reeckening van den regenboog* ("On the Rainbow") and his *Reeckening van kanssen* ("On the Calculation of Chances") were printed together in 1687. The *Korte Verhandeling* was lost to the world until E. Boehmer's publication of it in 1852.

Spinoza's place in Western intellectual history

Spinoza has an assured place in the intellectual history of the Western world, though his direct influence on technical philosophy has not been great. Throughout the 18th century he was almost universally decried as an atheist—or sometimes used as a cover for the detailing of atheist ideas. The tone had been set by Pierre Bayle, a Skeptical philosopher and encyclopaedist, in whose *Dictionnaire historique et critique* Spinozism was described as "the most monstrous hypothesis imaginable, the most absurd"; and even David Hume, a Scottish Skeptic and historian, felt obliged to speak of the "hideous hypothesis" of Spinoza.

Spinoza was rendered intellectually respectable by the efforts of literary critics, especially of the Germans Lessing and Goethe and the English poet Coleridge, who admired the man and found austere excitement in his works, which they saw as the expression of an intensely religious attitude entirely divorced from dogma. Spinoza has also been much studied by professional philosophers since the beginning of the 19th century. Both absolute Idealists and Marxists have read their own doctrines into his work, and Empiricist philosophers, while rejecting his metaphysical approach, have developed certain detailed suggestions from his theory of knowledge and psychology.

MAJOR WORKS

Korte Verhandeling van God, de Mensch, en deszelf's Welstand (written *c.* 1662, first pub. as *Tractatus de Deo et Homine Ejusque Felicitate*, 1852; *Short Treatise on God, Man, and His Well-Being*, trans. by A. Wolf, 1910); *Tractatus de Intellectus Emendatione* (written 1662, first pub. 1677; trans. by W.H. White, 1899); *Renati des Cartes Principiorum Philosophiae Pars I et II, More Geometrico Demonstratae, per Benedictum de Spinoza* (1663; *Principles of Cartesian Philosophy*, trans. by H.E. Wedeck, 1961); *Ethica in Ordine Geometrico Demonstrata* (written 1662–75, pub. 1677; *Ethics*, trans. by W.H. WHITE and A. STIRLING, 1894); *Tractatus Theologico-Politicus* (written 1665–70, pub. 1670; trans. by R.H.M. ELWES, 1889); *Tractatus Politicus* (unfinished, written from 1665 onward, first pub. 1677; trans. by A.G. Wernham in *The Political Works*, 1958).

BIBLIOGRAPHY. The best critical edition of Spinoza's work, known as the "Heidelberg edition," is by CARL GEBHARDT, 4 vol. (1924); there is also a good edition of the text by J. VAN VLOTEN and J.P.N. LAND, 3rd ed., 4 vol. (1914). For English versions, see *Spinoza's Chief Works*, ed. by R.H.M. ELWES, 2 vol. (1883–84); *Ethics*, trans. by W. HALE WHITE and A.H. STIRLING, 4th ed. rev. (1910); *Spinoza's Short Treatise on God, Man and His Well-Being*, trans. by A. WOLF (1910, reprinted 1963); and *The Correspondence of Spinoza*, trans. by A. WOLF (1928, reprinted 1966). For general works, see the short biography by FREDERICK POLLOCK, *Spinoza: His Life and Philosophy*, 3rd ed. (1912); and JACOB FREUDENTHAL, *Spinoza, Leben und Lehre*, ed. by CARL GEBHARDT, 2 pt. (1927). For biography, see STANISLAUS DUNIN-BORKOWSKI, *Der Junge de Spinoza* (1910); LEON BRUNSCHVICG, *Spinoza et ses contemporains*, 3rd ed. rev. (1923); and the detailed biography by A. WOLF in the introduction to his *Spinoza's Short Treatise . . .* (above). The original materials for a biography are contained in CARL GEBHARDT, *Spinoza: Lebensbeschreibung und Gespräche* (1914). The Jewish background of his thought is explored in LEON ROTH, *Spinoza, Descartes, and Maimonides* (1924, reprinted 1963) and *Spinoza* (1929), a more introductory work. See also RICHARD MCKEON, *The Philosophy of Spinoza* (1928); HARRY A. WOLFSON, *The Philosophy of Spinoza*, 2 vol. (1934, reprinted 1969), who argues that Spinoza was the last of the medievals and places him in the context of medieval Jewish and Scholastic thought. A Hegelian approach is presented in HAROLD H. JOACHIM, *Spinoza's Tractatus de Intellectus Emendatione: A Commentary* (1940) and *A Study of the Ethics of Spinoza* (1901, reprinted 1964). See also GABRIEL HUAN, *Le Dieu de Spinoza* (1914); HAROLD F. HALLETT, *Benedict de Spinoza: The Elements of His Philosophy* (1957); PAUL SIWEK, *Spinoza et le panthéisme religieux*, new ed. (1950) and *Au Coeur du spinozisme* (1952); and AUGUSTO GUZZO, *Il pensiero di Spinoza*, 2nd ed. (1964). His views on method, truth, and knowledge are given in G.H.R. PARKINSON, *Spinoza's Theory of Knowledge* (1954). STUART HAMPSHIRE, *Spinoza* (1956), discusses Spinoza from the standpoint of Analytic philosophy. The following collections of articles on Spinoza contain useful material: *Spinoza*, ed. by MARJORIE GRENE (1972); *Studies in Spinoza*, ed. by P. KASHAP (1972); and *Spinoza: Essays in Interpretation*, ed. by E. FREEMAN and M. MANDELBAUM (forthcoming). Of various bibliographies of Spinoza, mention may be made of ADOLPH S. OKO, *The Spinoza Bibliography* (1964); and JON WETLESEN, *A Spinoza Bibliography* (1968).

Spiritualist Groups

A Spiritualist is a person who believes that communication with those who have "passed into the higher life" (have died) is possible and makes such communication the centre of his religion. This article deals with the spiritualist religion, not with psychic research, which is a study on what are believed to be scientific lines of communication with the dead, telepathy, precognition, and kindred subjects.

The important terms in spiritualism are defined in the following ways. *Spirit* is the essential part of man. After the death of the body the spirit lives on. The *spirit world* is the world of disembodied spirits. A *medium* is a person on earth who is sensitive to vibrations from the spirit world and is able to convey messages between that world and this one and to produce other Spiritualist phenomena. A *control* is a disembodied spirit who gives messages to a medium who in turn gives them to men and women on earth. A *séance* is a meeting (usually small) around a medium to seek messages from the spirits. *Telepathy* is the communication of ideas through other than physical means. *Clairvoyance* is the power of seeing through means other than the physical eye. *Clairaudience* is the power of hearing through means other than the physical ear. *Levitation* is the lifting of an object by other than physical means. *Materialization* is the appearance of a spirit in matter. *Apport* is the production of objects without physical means or the passing of objects through objects (*e.g.*, walls) which have no openings.

HISTORY

Spiritualists believe that throughout human existence spirits have communicated with mortals. The Bible, they claim, is an outstanding record of Spiritualist phenomena. Well-known examples from the Bible are King Saul's clandestine visit to the woman at Endor, through whose mediumship Samuel, in the spirit, spoke to Saul, and Paul's vision of Jesus on the road to Damascus. Spiritualism, it is believed, furnishes the key that unlocks the biblical mysteries. The Transfiguration and the Resurrection are examples of materialization; Jesus walking on the water is an example of levitation; Pentecost was "the greatest séance in history."

During medieval times, the church acknowledged the reality of witches and wizards and forbade commerce with them. It was in the 19th century that Spiritualism as a self-conscious, organized religion began. In 1848 two girls, Margaret and Kate Fox, in Hydesville, a village in western New York, heard strange knockings in the cottage where they lived. They spoke to the spirit who produced the knockings, suggested a code, and began to receive messages. In the years just before these events, another resident of New York state, Andrew Jackson Davis, had written a book he called *The Principles of Nature, Her Divine Revelations*, based on his experiences with the spirits. The Fox sisters and Davis provided the impetus that brought Spiritualism into organized form.

In the years following, many persons both in America and abroad discovered their mediumistic powers and became centres around which groups formed. These groups grew into local churches, and the churches grew into over a dozen congregationally organized regional and national bodies. The *Yearbook of American Churches* lists three: the National Spiritualist Association of Churches founded in 1893 (the NSAC), the International General Assembly of Spiritualists, and the National Spiritual Alliance of the U.S.A. Most of the organizations are small and of short duration; moreover, they keep poor records. The *Yearbook*, whose figures are based on reports by the organizations themselves, shows somewhat less than 200,000 members in the United States in 1956, a figure that is probably much too high for actual formal membership and much too low for the number of persons interested in spiritualism.

Spiritualist organizations

Spiritualists claim that Spiritualist organizations have been formed in over 40 nations. Many of these national groups have joined to form the English based International Spiritualist Federation. Founded in 1923, it reports 38 affiliated societies in 29 countries; 9 of these countries have 2 affiliated societies, and Japan has 3.

Individuals who are members of the more traditional denominations and who have Spiritualist interests and yet do not wish to change their religious affiliation have formed the Spiritual Frontiers Fellowship (American) and the Churches' Fellowship for Psychical and Spiritual Study (British).

The interest in spiritist phenomena also took another organized form. In 1882 the Society for Psychical Research was founded in England. Its purpose was objective investigation, not worship or the giving of spiritual solace. Membership in the society did not, and does not, imply a necessary acceptance of the Spiritualist explanation for psychic phenomena. Among its members have been found such notable figures as Sir William Crookes, Sir Arthur Conan Doyle, F.W.H. Myers, and Sir Oliver Lodge. A parallel organization, the American Society for Psychic Research, was founded in 1885. Some of its well-known members have been William James, J.H. Hyslop, J.B. Rhine, and Gardner Murphy. In France, Camille Flammarion, Henri Bergson, and Gabriel Marcel were notable for their interest in psychic phenomena. Famous mediums whose manifestations have received serious investigation include D.D. Home, Mrs. Leonore E. Piper, Mrs. Gladys Osborne Leonard, and Mrs. Eileen Garrett.

BELIEFS, WORSHIP, ORGANIZATION

Beliefs. The NSAC, with its publication *Spiritualist Manual*, is the best organized of the Spiritualist bodies; the *Manual* is revised periodically. The NSAC encourages freedom of belief and also emphasizes its "Declaration of Principles."

In many of their emphases, these principles are similar to beliefs held by most religious persons in the West. Leaders in the NSAC, without depreciating in any way the importance of the teachings about the next life, urge that the member churches emphasize cultivation of the moral and spiritual virtues that enrich this life. Outside observers often note, however, that the major concern of the average Spiritualist seems to be contact with the spirits and the reception of messages from them.

Man has three elements, according to Spiritualist views: spirit, soul, and body. The body encases the soul and the spirit. The soul encases the spirit. At death the body dies, but the soul and the spirit live on. The soul apparently is made up of elements more refined than those of the body, and it serves the spirit in the next life as the body and soul serve the spirit in this life. Animals are believed to have souls but not spirits.

Spiritualists believe that the human spirit exists eternally as a part of the Universal Spirit and thus antedates the creation of the body and the soul. The NSAC holds that the soul enters the body at conception; some other Spiritualists hold that this entry happens a few months after conception. The soul, like the body, is said to be manufactured out of material elements, such as food, water, and air, but these are more refined than the bodily elements. The soul is the duplicate of the body in structure. At death the soul and the spirit are believed to go to one of the seven spheres that surround the earth. The lowest sphere is occupied by men who on earth were wicked, barbaric, and dominated by material desires. At the death of the body, most men go to the Third Sphere, often called the Summerland. There the life is very like the life of earth, except that it is made "finer" and the evils and sorrows are gone. The spirits in the Summerland are said to wear clothing, live in houses, have animals for pets. Each spirit finds and marries his soul mate (to whom he had been joined before his earthly birth), but the nature of the marriage relationship in the heavenly spheres is wholly platonic.

Beyond the seven earth spheres are higher and more universal spheres; they surround planets, suns, and even solar systems. Farther still are spheres still more tremendous. God, defined as Infinite Intelligence, is at the centre of the universe.

The souls of children who have died are believed to assume adulthood over a period of time. Persons in the lower spheres eventually attain higher spheres, where life is much happier than anything known on earth. Thus Spiritualists are universalists; that is, they believe in salvation for all. There is no hell in the traditional sense, though persons who have lived essentially evil lives must suffer before they can progress to the higher spheres. The law of progression applies to all. Whatever sphere a person is in, he is working to go higher. But he moves higher only through his own efforts, with of course the counsel of spirits wiser than himself.

These propositions are statements of fact, the Spiritualists assert. They claim "indubitable proof" that man lives after death. Their evidence comes from the spirits through mediums. Every human being, according to the theory, is a medium, but most are undeveloped. The simpler mediumistic powers can be cultivated if a person will centre his thoughts on spiritual concerns. *Mental phenomena* are thus said to be within the reach of many people; that is, spiritualists believe that people can and do receive ideas and information from their departed loved ones. Mental phenomena include the dramatic messages that come when a medium goes into trance. Through mediums in trance, prophecies have been made, books written, instructions given to surgeons on how to perform difficult operations, and intricate experiments proposed for proving the non-earthly source of the communications.

The function of mediums

Physical phenomena also are said to be produced by mediums. Apports are reported to occur; for example, when Jesus after the Resurrection stood among his disciples, "the doors being shut" (John 20:19). It is claimed that voices sometimes speak independently of the medium's voice, often magnified by a trumpet. Healings are said to be consummated—healings of physical as well as of psychosomatic illness. It is alleged that objects are levitated and float in the air without physical support. Spirits are said to materialize and thus can be seen with the physical eye; the appearances of angels recorded in the Bible are claimed as examples.

From the bodies of mediums a substance called ectoplasm is said to exude. It is believed to be a rarefied form of matter that the spirits can use to effect physical phenomena. Ectoplasmic hands may, for example, cause levitation and apports.

God is thought to be an impersonal being, the infinite,

eternal, distant Oversoul. Yet the possibility of intimate personal fellowship with superhuman powers is by no means absent from Spiritualism; what other faiths would call the "nearness of God" is for Spiritualists the nearness of our spirit guides, of souls who have gone on ahead of us and who are much concerned for our comfort, health, and safety.

Jesus is not thought to be God nor the second person of the Trinity, nor did he give his life as a ransom for mankind. Jesus was a man like all the rest of us. He was divine as are all men. But he did differ from us in his attainments. According to Spiritualists, he was the greatest medium who ever lived.

The doctrine of reincarnation is held by a minority but is not approved by the majority. The existence of poltergeists (boisterous ghosts) is considered so real that "few physical phenomena [are] better established." The possibility of "spirit possession" (of a low spirit entering the body of a living person) is also considered to be real. Possession is by ignorant and undeveloped spirits. But they are not evil; no being is basically evil. Each person can choose what spirits he will associate with, and they can harm him only in the sense that "unfitting companions" can harm him.

Spiritual healing is a strong emphasis. The value of drugs and surgery is freely acknowledged; but since man is so much more than just the body, the seat of disease is to be found largely in wrong mental and spiritual action.

Mediumship is not considered to be a supernatural gift, nor are spirits considered to be supernatural beings. There are no miracles. Everything happens according to natural law, both on earth and in the world to come. Throughout eternity man must strive to discover nature's laws, which are immutable, and to attune his life harmoniously with them.

Spirit messages are not thought to be infallible. No one should expect them to be infallible in view of their origin and the complex nature of the line of communication that they follow to reach the séance room. They originate with a spirit, who of course is not infallible. Then, in getting a message to earth, a spirit must contact a medium, or more probably first a medium's control. Neither the control nor the medium is thought to be infallible. Thus, the average message has several chances of being in error. Most of the messages deal with moral and spiritual concerns, and they conform to principles that are well known both on earth and in the spirit world. Spiritualists believe that messages that deal with "worldly affairs" are more likely to prove disappointing and misleading.

The conduct of séances

Worship. Séances and church services are the customary forms of worship for Spiritualists. Séances form around mediums, and the number of persons attending varies from one to a score, seldom more. The setting is usually a living room, the medium may or may not go into trance, and the room is usually darkened. Nonbelievers often criticize Spiritualists for conducting most of their séances in the dark. Spiritualists reply that the spirits find it easier to work in the dark than in the light, a fact considered no more remarkable than the greater strength of radio messages at night than in the daytime. Spiritualists believe that in the séance room the persons attending can communicate with the spirits simply by speaking to them. The spirits in turn, it is alleged, use different methods depending on the powers of the medium, such as rappings, table tippings, the voice of the medium, independent voices, automatic writings, the ouija board.

Church services are patterned after Protestant worship. They include prayers, hymns, musical selections, readings, collections, sermons, spirit messages, and benedictions. The readings make little use of the Bible; they are chiefly recent compositions dealing with spiritual subjects. The spirit messages, given by a message bearer (medium), are of the mental type of phenomena, and the bearer receives them in an undarkened room. The sermons often deal with the moral and spiritual concerns that are shared by most religious persons in the West.

Faith in the spirit origin of the communications seems to be largely confined to persons who have themselves served as mediums or else have received messages through mediums whom they trust. Some Spiritualist leaders acknowledge that fraud in the séance room is a recurring problem for the movement.

The Spiritualist, though he does not claim infallibility, believes that he is dealing with facts; he insists that his faith is constructed to conform to the facts, as contrasted with a change of facts to conform to faith.

BIBLIOGRAPHY. Books and pamphlets issued by the National Spiritualist Association of Churches include the *Spiritualist Manual* (rev. 1967); and the *Spiritualist Lyceum Manual* (rev. 1962), designed for youth. Publications of the Stow Memorial Foundation (an NSAC agency) include: B.F. AUSTIN, *The A.B.C. of Spiritualism* (1920); A. CAMPBELL HOLMES, *The Fundamental Facts of Spiritualism* (n.d.); and B. MORSE, *The "Whys" of Spiritualism* (1933).

Books by non-Spiritualists: G. LAWTON, *The Drama of Life After Death* (1932), is the best book-length study, definitive to its date. C.S. BRADEN, *These Also Believe* (1949), and J. STILLSON JUDAH, *The History and Philosophy of the Metaphysical Movements in America* (1967), contain excellent chapters. The latter describes some of the Spiritualist groups.

Books attempting to appraise Spiritualist and psychic phenomena: C.E.M. HANSEL, *ESP: A Scientific Evaluation*, with an introduction by E.G. BORING (1966), contains a chapter on Spiritualism. Hansel finds Spiritualist phenomena to be largely fraudulent. G. MURPHY, *Challenge of Psychical Research: A Primer of Parapsychology* (1961), does not accept the survival hypothesis, but acknowledges the existence of unexplained phenomena that have the appearance of communication with the dead. H.N. HART, *The Enigma of Survival: The Case For and Against an After Life* (1959), is a closely reasoned review of the evidence. The author reaches a conclusion favourable to survival. H. WESTWOOD, *There Is a Psychic World* (1949), is written by a clergyman who reaches conclusions favourable to the reality of spiritist phenomena.

(J.P.W.)

Sports, Amateur and Professional

A long-standing distinction in sports has been that between the professional and the amateur, and controversies over amateurism and professionalism, by no means new, have been growing in pace with growth of interest in sports as evinced by the increasing numbers of participants and spectators. Contributing factors in the controversies include the desires of manufacturers of sporting goods and accessories to promote their products; of promoters of sporting events to ensure the participation of topflight competitors; and of professional teams or sponsors to obtain the services of outstanding amateurs. Complicating factors include the application of different standards in different sports, and differences of standards and of interpretations of general standards among various countries. Questions of amateurism as they apply to the Olympic Games are dealt with in ATHLETIC GAMES AND CONTESTS. Pertinent information in relation to particular sports in which professionalism is or has been an issue will be found in the articles on those sports; *e.g.*, BASKETBALL; GOLF; TENNIS AND ALLIED COURT GAMES; and ASSOCIATION FOOTBALL (SOCCER).

The conflict between amateur and professional sports has often been compared to the distinction between love and money. The word amateur derives from the Latin *amator*, or "lover," and the amateur athlete by simplistic definition is one who competes for love of sport alone, while the professional competes for money. The problem with these definitions, as athletes have been discovering for centuries, is that it is hard to do the first without the second.

History. The burdens of pure amateurism were evident not long after the founding of the Olympic Games (about 776 BC). At first, when the city-states of ancient Greece sent only their aristocrats to the games, the Olympics were conducted in a spirit of amateurism. The aristocrats possessed both the money and leisure time to practice for their strenuous events. But as the influence of the merchant class began to pervade the games, the city-states took to subsidizing their best athletes. Money, food, homes, tax exemptions, and even army deferments were the awards athletes sought for winning their events (the original Olympians received only laurel wreaths).

The spirit of amateurism

Ultimately, the principles of amateurism were stretched

to intolerable limits. One Eupolus of Thessaly was convicted of bribing three boxing opponents in the 98th Olympiad. When the Romans conquered the Greeks, the Olympics fell into disrepute. The emperor Nero introduced such events as music for his own pleasure and managed to intimidate opponents wherever he chose to compete. Once, though he fell off a chariot, he was still declared winner of the race. When the Olympics were discontinued in AD 394, there were few cries of alarm.

Origins of concepts. The word *amator* was revived in 1788 and given the anglicized spelling "amateur" to separate "Gentleman Jack" Jackson, an aristocrat and a boxer, from the heavyweight bareknuckle fighters, who competed in Great Britain for side bets or small purses.

The word "professional" was first applied in the modern era to English jockeys who rode other men's horses for a fee. The nobles themselves had begun racing for awards in 1512, but soon hired hands were competing in their place.

First professionals

The concept of an amateur as a cultivated man of leisure and the professional as a money-seeking ruffian was standardized in 19th-century England. Beginning in 1812, an annual sports day was held at the Royal Military Academy in Sandhurst. Sports soon found their way into the curriculums of Rugby and other British schools, universities, and officer training schools. In 1866 the Amateur Athletic Club was founded

> . . . to afford as completely as possible to all classes of gentlemen amateurs the means of practising and competing against one another, without being compelled to mix with professional runners.

There came to be three categories of athlete: the professional, the gentleman amateur, and the amateur, who was distinguished from the gentleman amateur because he worked for a living. Democracy was introduced into the world of the gentleman amateur in the mid-1870s when W.J. Morgan, a walking champion and wage earner, had his entry accepted for a meeting organized by the prestigious London Athletic Club—over the objections of numerous members.

In spite of historical differences, the United States followed a similar concept of amateurism. As in England, the first amateur athletes were gentlemen learning their skills at New England boarding schools and Ivy League colleges. A professional might instruct a gentleman's son, but he left by the servant's door. Amateurs were rarely labelled as such, and many people, in fact, had no idea of the meaning of the word. Rather, professionals were defined as men who engaged in such sports as boxing, horseback riding, and sprinting for wages and cash prizes. Participants in such sports as lawn bowling and sailing were not paid and therefore were assumed to be amateurs. The first time the question of amateurism was raised in America was in 1872, when about half the oarsmen entered in a regatta on the Schuylkill River near Philadelphia were banned because they were "not amateurs." The nominations committee explained that anyone who competed for money or hoped to benefit financially through racing was not an amateur. The definition of an amateur as one who competes for pleasure and the professional as one who competes for money was accepted at a general meeting of rowing clubs in 1873.

The masses did take up sports on both sides of the Atlantic, but at first as second-class citizens. A late victim of the gentleman's code was a 1920 U.S. Olympic champion rower, John Kelly, who was banned from the Henley regatta because he was a bricklayer, not a gentleman.

When Baron Pierre de Coubertin revived the Olympics in 1896, he re-affirmed the traditional Olympic values. "The most important thing in the Olympic Games," he wrote, "is not to win but to take part, just as the most important thing in life is not the triumph but the struggle."

Amateur codes. An example of the general tenor of amateur codes is rule 26 of the Olympic regulations that defines an amateur as:

> one who participates and always has participated in sports solely for pleasure and for the physical, mental or social benefits he derives therefrom, and to whom participation in sport is nothing more than recreation without gain of any kind, direct or indirect. In addition he must comply with the rules of the International Federation concerned.

Differences between countries. The last sentence defines the major problem in the continuing conflict between amateurism and professionalism. The International Amateur Athletic Federation allows each country's national Olympic committee to define amateurism for its own athletes, resulting in widely diverging interpretations of the concept from country to country. The Soviet Union and other Communist nations, for instance, introduced a new category, the state amateur. Top amateurs are, in effect, subsidized by the state. There are no professionals as such, but leading amateurs are given jobs that allow them to train and travel at will. Many American athletes are also subsidized—at least insofar as they may receive full scholarships to college based primarily on their ability in a given sport. German athletes are aided by their Olympic association and French athletes by their government. An African Olympian may be a police lieutenant who spends most of his time training. Australian athletes on tour may be paid the same salaries they would be receiving at their regular jobs. This is known as "broken-time pay" a bone of contention over which the Rugby Football League in Great Britain broke away from the Rugby Football Union in the 1890s. In short, despite the restrictions of amateurism, most countries are able to send their leading athletes to international events.

The state amateur

Given the various interpretations of amateurism, it is not surprising that there have been disputes over alleged professionalism. At times, unmistakable professionalism has intervened. During the 1968 Olympics, for example, some athletes were paid, or offered payment, by track shoe manufacturers to wear their products.

Nationalism in the Olympics. To its defenders, amateurism connotes a state of mind as well as a condition. The Greek Olympics were originally conducted in a spirit of cooperation and brotherhood that crossed the political boundaries of the city-states. If professionalism erased that ideal in the original Olympics, the modern Olympics has never been able to avoid the nationalism that has affected competition. Point scores are unofficial (the contests are between individuals and teams, not nations), but the public, press, officials, and politicians follow them zealously. Since World War II the Olympics have been treated as an extension of the cold war between the United States and the Soviet Union. Before the 1968 Olympics Vice President Hubert H. Humphrey stressed the importance of American athletes winning more medals than the Russians.

Differences between sports. Just as amateurism has varied from country to country, amateurism has varied from sport to sport. Tennis amateurs are allowed to receive expenses but golfers are not. Yet amateur golfers are allowed to compete against professionals, while tennis players until recently were not. In track, there are at present practically no designated professionals. Track athletes receive expenses to compete in meets away from home, but under-the-table payments may often amount to something more like a living wage. A number of European ski amateurs have been suspended for instructing at clinics and accepting payment. "The only amateur I know," said one skier, "is the Agha Khan."

Critics and defenders. Critics of the amateur code contend somewhat facetiously that the only difference between amateurs and professionals is that amateurs demand payment in cash. The concept of a "gentleman amateur" is obsolete, they argue, when a modern athlete is nurtured under the belief that he will progress as far as his ability, not social origin, can take him; but the athlete who is not rich cannot progress without subsidization. Critics also contend that the amateur code is inconsistent and hypocritical. They wonder, for instance, if the famous American Indian Olympian Jim Thorpe, who lost his gold medals because he had played baseball for a reported $60 a month, was any more of a professional than the subsidized college amateur.

Defenders of the code maintain that without controls the differences between amateurs and professionals will

cease to exist. They point out that expensive catering to leading amateurs has weakened sport at the participant level. Frequently heard in many countries is the refrain, "We have become a nation of spectators." The traditionalists, who believe passionately in the original spirit of the ancient Olympics, contend moreover that the desired position of sports as a respite from the problems of mankind has been mitigated by professionalism and nationalism. "The ancient Greeks used to stop fighting to stage the games," a former president of the International Olympic Committee, Avery Brundage, once said. "Now we stop the games to stage our wars."

Signs of change. A number of developments, however, indicate that amateurism will continue to evolve from its roots. John Kelly, Jr., the son of the bricklaying rower and in 1971 the president of the Amateur Athletic Union (AAU) of the United States, took office saying,

> The old concept of only the gentry being allowed to compete and not the average citizen has to go. We are very hypocritical in this country.

Kelly also made peaceful overtures to the rival National Collegiate Athletic Association (NCAA). Agreement could yield a liberalized amateur code in America.

Athletes themselves have begun protesting restrictions, occasionally with success. Many European skiers have threatened to boycott the winter Olympics if amateur rules are not revised. Track athletes have asked permission to capitalize on their names in their professions and have suggested that track clubs be allowed to negotiate with private sponsors for financial backing. In international tennis, "open" competition between amateurs and professionals has been instituted, led by the British. Open tennis appears to be a sign of a similar trend in other sports. In golf, where amateurs are forbidden to accept expense money, changes that would allow for some expense money and free equipment have been suggested, especially since a United States amateur champion was suspended for three months in 1969 for accepting six dozen golf balls from a manufacturer.

De Coubertin himself saw the need to pay amateurs. In his memoirs, he contended that it was as unwise to declare an athlete a professional for accepting money as to call a sexton an infidel for being paid to take care of a church.

As a result of spiralling costs and insufficient income, many colleges in the United States are cutting back on athletic scholarships (or granting them solely on the basis of need, as other scholarships are granted). Some schools have relinquished athletic scholarships altogether and reverted to club sports, which have returned these colleges' programs to a level that is strictly amateur, both in finance and performance.

It appears that on one level the serious and talented amateur may be granted greater flexibility. On another level, the subsidized athlete of marginal ability may some day be eliminated. And on a third level, those of ordinary ability will continue to play sports for fun.

Problems of professionals. The professionals have not been spared their crises, either. Once regarded as a pastime, in which owners were considered kindly patriarchs and athletes willing gladiators, professional sport, for all practical purposes, existed outside the scope of the law.

Unions of athletes

Since World War II, professional sport has been regarded as a business; athletes have unionized and management has been taken to court for alleged antitrust violations; and labour laws in some countries—in Mexico, for example—have been enacted or revised to cover sports.

Expansion. Like many businesses, professional sport has undergone expansion most rapidly during the 1960s. In the United States and Canada, baseball, which once consisted of 2 leagues with 8 teams apiece, expanded into 4 divisions with 24 teams; the National Basketball Association expanded from 2 divisions of 4 teams apiece to 4 divisions with 17 teams, and a rival league, the American Basketball Association, was formed; ice hockey, too, expanded, from its once comfortable American-Canadian format of a single 6-team league to two 7-team divisions; and professional football merged its two competing associations and opened the 1970s with two 3-division associations under the control of the National Football League. There is also professional football in Canada.

At the same time, sports once regarded as minor are achieving national and international recognition at the professional level, thanks to widespread interest among fans and sponsors. Tennis, for the first time, has a regular series of tournaments—almost yearlong and touching down in such places as Iran, Italy, and Australia. Women's tennis has experienced similar growth. Purses are larger than ever in automobile racing, which continues its Grand Prix competition at the international level. Association football, or soccer, is finally recognized for what it always was—the world's most popular sport. The World Cup matches every four years attract widespread international attention. Even the only major sport with exclusively American roots—basketball—now has professional teams in Europe.

Manufacturers and sponsors. One reason professional sports have been able to expand has been the influence of manufacturers and sponsors. In golf and tennis, for instance, corporations finance the costs of and sometimes even assume the names of tournaments (Kemper Open golf, Virginia Slims tennis in the U.S.; Dunlop golf in Australia). Sponsored skiing competitions include the Evian World Cup. Auto races and racers are financed by automobile, tire, oil, and additive companies. Similarly, motorboat companies finance motorboat racers. Individual sponsors are prominent too, as in golf.

Television. But nothing has affected sports more dramatically than the ubiquitous eye of television. Television has sustained whole leagues, created franchise shifts, crippled some sports, sustained others, and even affected the rules of the games themselves. Television helped create expansion, too. In the United States, for example, there were only 42 professional sports franchises in 1960, mostly in the northeast quadrant of the country. Television exposure created instant interest elsewhere, and by 1970 there were 87 franchises throughout the nation.

Thanks to television exposure, athletes have become as marketable as the sports they play. Now some players, Brazil's Pele perhaps being the prime example, make as much money through promotions and business income as they do playing games.

The games themselves are affected by commercial timeouts, which have the potential to affect "momentum"—and scores. Once universally condemned, the commercials are now widely ignored. Even the formats of important sports events have been altered to suit the convenience of television. Games have been played at unusual hours to accommodate prime-time broadcasting. The U.S. Professional Golfers Association tournament was switched from its long tradition of man-to-man play to 72-hole medal competition in part because the latter format better suited television. Tie breakers for tennis sets have been adopted for the same reasons.

Television's impact on sports has not been entirely beneficial. Overexposure almost killed professional boxing. Minor league baseball in the U.S. dried up when television and major league expansion usurped its crowds and income.

Conclusions. Analysis of the available evidence indicates that professional sports will continue to grow; it is likely that recompense to athletes of national- and world-class calibre will be liberalized; and continuing and perhaps increased efforts may be required on the part of those interested in amateur sports for the masses—*i.e.*, those who may enjoy and benefit from taking part in sports as a leisure-time activity.

BIBLIOGRAPHY. LEONARD SHECTER, *The Jocks* (1969), raises some interesting points on the abuses of amateurism; PAUL WEISS, *Sport: A Philosophic Inquiry* (1969), discusses the ambiguities of amateurism and professionalism under their traditional definitions. See also F.G. MENKE (ed.), *The Encyclopedia of Sports*, 4th rev. ed. (1969), esp. the chapter, "The Amateur Athlete"; H.W. MORTON, *Soviet Sport* (1963); MELVYN WATMAN, *History of British Athletics* (1968); and WILLIAM JOHNSON, "TV Made It All a New Game," *Sports Illustrated*, 5 pt. (Dec. 22, 1969–Jan. 26, 1970), on the influence of television on sports.

(J.L.K.)

Springs and Wells

Springs and wells are generally openings for discharge of water from underground sources. A spring is a natural discharge with a perceptible current at the land surface or in the bed of a stream, lake, or sea; water that emerges at the surface without a perceptible current is called a seep. Springs and seeps represent water reappearing from the groundwater phase of the hydrologic, or water, cycle. A well, on the other hand, is a man-made hole excavated in the earth either to bring water or other fluids to the surface or to store fluids underground. From ancient times people have dug wells or pits to gain access to shallow groundwater, and in many places they have constructed wells from which water flows at the surface as from a spring.

Excavations for wells have attained depths exceeding two kilometres (1.2 miles) for water and to seven kilometres (4.4 miles) for oil and gas. Wells are also used for the extraction of valuable products such as oil, tar, sulfur, or soluble minerals; for the temporary storage of gas or other fluids or the permanent disposal of fluid wastes underground; and for the artificial replenishment of groundwater. Although wells have been constructed for a variety of purposes, the wells most numerous and widely distributed are those that yield water for use in homes, agriculture, and industry. Springs and seeps are widely distributed over the continents and some islands. Most wells withdraw water that has percolated down into groundwater reservoirs called aquifers, or water-bearers.

PHYSICAL CHARACTERISTICS

Water supply. Water in springs and wells generally originates as precipitation from the atmosphere. In humid regions the average annual precipitation exceeds the loss by evaporation from soil and vegetation and the surplus flows away as surface water or sinks as groundwater or both. In arid regions the loss to the atmosphere may exceed the average precipitation, and the surface water and groundwater are less abundant.

Some of the water from rain or snow becomes groundwater when the conditions of climate and geology are favourable. Rocks and soils that absorb water from storms faster than the soil can retain it are favourable for groundwater replenishment. Less favourable are soils that absorb water but retain most of it for subsequent evaporation or use by vegetation. Least favourable are land surfaces so impermeable that all rain either runs off immediately or collects in shallow pools and evaporates rapidly.

Technically, only water that percolates downward to reach a zone in which all rock pores are saturated is called groundwater. Throughout the saturated zone, the movement of goundwater is directed by geological conditions of the ground layers. Some saturated rock layers, or beds, are permeable enough to transmit water readily to springs and wells. The best of these aquifers are composed of gravel, sand, limestone, sandstone, or basalt. While other types of rocks may yield some water to wells and springs under favourable conditions, most of them are not good water-bearers. Some are too dense to allow water flow, and others have pores so small that little water can move through them. In regions having good aquifers, denser materials, such as clay or shale, may serve to confine water in the aquifers. In some places water so confined is under pressure sufficient to rise through an overlying layer to the land surface to form an artesian spring or artesian well.

The best water-bearing layers

Waterflow and temperatures. The aquifers that receive and discharge the largest quantities of groundwater are the unconsolidated materials (including gravel and sand) that nearly everywhere mantle the surface of the earth. The natural discharge of groundwater from such materials is partly by springs and largely by evaporation and seepage. The great majority of wells obtain their water from gravel and sand aquifers, especially those underlying valleys, lowlands, and plains.

Limestone and dolomite are sedimentary rocks composed predominantly of calcium and magnesium carbonates, which are soluble in water. Some of these layers are dense, others permeable; the permeability of many layers has been increased by the dissolving and subsequent removal of some of the original rock, leaving caverns and channels through which water may flow. The natural discharge from carbonate rocks forms many springs, including some of the largest on earth. The limestone spring area with greatest reported discharge is the Ra's al 'Ayn, a cape along the Khābūr River. A tributary of the Euphrates, its surface flows begin in Turkey and Syria and have a combined discharge averaging 42 cubic metres, or about 11,000 gallons, per second. (In the U.S., flow is generally given in gallons per minute, which would be 60 times the gallon per second figure, used throughout this article for consistency with metric units.)

In some limestone rock formations, rainwater disappears rapidly into holes or other openings and drainage is chiefly by subterranean channels. Some springs are actually underground rivers. One of these, the Trebišnica River in Yugoslavia, emerges five times in an otherwise subterranean course of 100 kilometres (about 60 miles). Such springs undergo marked increases in discharge and, perhaps, turbidity in response to rainstorms. The Fontaine-de-Vaucluse, the largest limestone spring in France, ranges from eight to 150 cubic metres, or about 2,100 to 39,600 gallons, per second, averaging 23 cubic metres, or about 6,100 gallons, per second. Submarine springs occur in several seas, generally issuing from limestone aquifers.

Aquifers in volcanic rock

Basalt, a volcanic rock that may form extensive plains, has about the same range of permeability as limestone. It is derived from lava flows, some of which are quite dense, in which solidification and subsequent weathering have produced very permeable aquifers. Several large springs rise in basalt along both flanks of the Cascade Range in the northwestern United States, and rivers draining these mountains have spring-fed tributaries with remarkably uniform flow. Large and spectacular springs discharge from the basalt aquifer underlying the Snake River plain in southern Idaho, which is exceptionally permeable and noted for wells of large yield.

The active volcanoes of Hawaii—Mauna Loa and Kilauea—are made up of basalt so permeable that even in the heaviest rainfall there is little water runoff. Impermeable materials hold fresh water in subterranean reservoirs on most of the Hawaiian Islands. Along the southern coast of Oahu, for example, a layer of clay and limestone rests above the basalt and confines freshwater under artesian pressure. For decades wells southeast of Oahu have withdrawn more than ten cubic metres, or about 2,600 gallons, per second from this aquifer, and nearly four cubic metres, or about 1,000 gallons, per second is discharged naturally by springs above sea level in the Pearl Harbor area.

Sandstone aquifers, which are sources of water in many springs and wells, give rise to very large springs only under exceptional conditions. A buried channel and prominent jointing are factors in discharges averaging 18 cubic metres, or about 4,750 gallons, per second of the Giant Springs along the Missouri River in Montana, called the largest fountain in the United States. The Lewistown Big Springs, whose four-cubic-metre-, or about 1,000-gallon-, per-second discharge provides the water supply of Lewistown, Montana, issue from sandstone that was dammed by a fault, or earth fold.

Springs, in fact, can be classified on the basis of their rate of flow from first magnitude, average discharge exceeding 100 cubic feet per second (2.83 cubic metres), or about 750 gallons, per second, down to eighth magnitude, emitting less than a pint a minute. At most, there are only a few hundred first-magnitude springs in the world, and the great majority of them flow from limestone or lava, mostly from cavern-like openings. Free and direct communication exists between the points of intake and of discharge, and the water has generally not reached depths greater than a few hundred metres (or yards) below the surface.

Springs are often classified on the basis of their water temperature. A thermal spring has a temperature significantly higher than the average air temperature of its surface surroundings. Among the largest thermal springs

are Warm Springs in Montana and Ana River Springs at Summer Lake, Oregon, both of which are first-magnitude springs that discharge water at about 20° C (68° F), significantly warmer than the air. Thermal springs are common in areas where there was volcanic activity in prehistoric times and in areas where rock layers have been broken and folded in geologically recent time. A cold spring has a temperature below the average for the region, as exemplified by Clear Lake in Oregon, where one spring discharges five cubic metres per second at 4° C (1,300 gallons per second at 39° F), which is 6° below the air temperature.

Quality of groundwater. Factors that determine the quality of water yielded by a spring or well include: the type of aquifer, or host rock, that yields the water, as well as the rock materials through which the water has passed; the temperatures along the route of subterranean travel; and the volume of water circulating, past and present.

Contributions of the aquifer

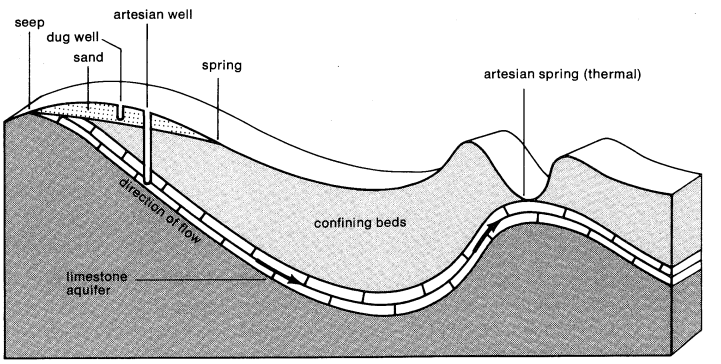
Water from precipitation is least modified underground where it travels for only short distances, shallowly and through permeable materials depleted of soluble minerals by previous water flow. For this reason, many gravel and sand aquifers, particularly in humid regions, yield water of excellent quality. In arid regions, on the other hand, spring and seepage areas may accumulate undesirable mineral residues as water evaporates. Shallow groundwater is especially vulnerable to degradation by chemical fertilizers and detergents, salt used in snow removal, waste from septic tanks, refuse from garbage dumps and land fills, and waste from industrial pits and ponds.

The quality of water in sedimentary rocks, most of which are of marine origin, depends upon the extent of freshwater flushing through such rocks. After the seawater has been washed away, many carbonate rocks and sandstones yield freshwater of good quality, though it may be hard because of its calcium and magnesium content. Many sedimentary rocks, however, are buried too deeply—and most shales are too impermeable—to be reached by freshwater from precipitation, and these still contain seawater. Of the numerous springs yielding saltwater from sedimentary rocks, one of the largest is Salt Springs in Florida, which discharges five cubic metres, or about 1,300 gallons, per second, containing about 5,400 milligrams of dissolved salt per litre (0.2 ounce per quart), chiefly sodium chloride, or common table salt (compare with seawater, at 35,000 milligrams per litre).

Many spring waters issuing from deep sedimentary rocks are mineralized: some are only slightly salty, whereas others are several times as saline as seawater.

In deep wells and mines the temperature generally increases 1° C for each 30 to 60 metres (100 to 200 feet) of depth. In the Australian Great Artesian Basin, however, the temperature rises about 1° per 20 metres (65 feet) of depth; wells 1,400 metres deep (about 4,600 feet) yield water at nearly 100° C (212° F), which must be cooled to be used for watering stock. The water has about 1,400 milligrams per litre of dissolved solids, chiefly the so-called black alkali, sodium bicarbonate, undesirable for irrigation. The natural discharge from this basin was by springs that built up large mounds of calcareous deposits.

Thermal springs are common in nonvolcanic regions where there has been faulting or intense folding of the rocks. One of the largest such hot springs in the world, the Big Horn Hot Springs at Thermopolis, Wyoming, discharges one cubic metre (265 gallons) per second of water at 56° C (135° F), and with 2,600 milligrams per litre dissolved solids, chiefly calcium bicarbonate, it forms quite beautiful and extensive travertine deposits. At the edge of the Sahara, springs at Nefta and Tozeur, in Tunisia, are of equal magnitude, but the temperature is less than 30° C (86° F), and the water, with less than 400 milligrams per litre dissolved solids, is excellent for irrigation.



Volcanic hot springs

Most thermal springs, however, are in volcanic regions where molten rock is near enough to the surface to be a formidable source of heat. Thousands of such springs occur in Iceland. The largest volcanic spring in the world, at Deildartunguhver, Iceland, is a third-magnitude spring that discharges 250 litres, or about 65 gallons, per second. The combined discharge of thermal waters in Yellowstone Park, Wyoming, is about three cubic metres, or almost 800 gallons, per second, barely enough, if concentrated in one outlet, to form a first-magnitude spring.

Volcanic eruptions commonly generate steam and more than 90 percent of the gases expelled from surface fissures or holes is water vapour. These gases presumably come from molten rock, as indicated by high temperatures at the surface, up to 700° C (about 1,300° F), and high geothermal gradients to considerable depths. In near-boiling springs, carbon dioxide is dominant, and hydrogen sulfide and nitrogen are common among dissolved gases. A porous siliceous crust is a common deposit at the surface. The spring waters also include dissolved compounds of boron, fluorine, lithium, and arsenic, probably from molten rock material within the earth. Spring gases, high surface temperature, and geothermal gradient are all conducive to development of geysers, of which there are about 200 in Yellowstone Park, 30 in Iceland, and others in Alaska, Kamchatka, and New Zealand. The waters in geyser areas are generally alkaline and rich in sodium chloride; in other volcanic areas they are acidic and rich in sulfates. Some hot springs are radioactive with radon, stinking with hydrogen sulfide, or poisonous with arsenic.

Most of the thermal water discharged at the surface in volcanic regions is probably derived from groundwater from local rainfall, the contribution of water from the molten rocks being no more than 5 percent. Many springs in volcanic regions are potable and usable for irrigation. The El Gato Spring, south of San Luis Potosí in Mexico, flows about five cubic metres (about 1,300 gallons) per second of radioactive water, at 41° C (106° F), with 500 milligrams per litre dissolved minerals. Other waters from volcanic rocks are far more mineralized: in Israel the springs along the shore of the Sea of Galilee, which served the Roman baths at Emmaus, flow from basalt at 60° C (140° F) and contain 28,000 milligrams per litre of dissolved solids, chiefly sodium and calcium chlorides; and in Turkey near the Mediterranean Sea, the Gayzer suyu wells up from volcanic rock at 100° C (212° F) with 63,000 milligrams per litre of dissolved solids, chiefly sodium chloride.

Groundwaters of highest salinity are associated with salt deposits. Some saline thermal springs discharge water that has passed through salt deposits at considerable depth, exemplified by the Glenwood Springs in the canyon of the Colorado River in Colorado, which flow 200 litres, or about 50 gallons, per second of sodium chloride brine at 52° C (126° F). The Aqua Salada de Timban in Argentina yields tepid water with 317,000 milligrams per litre of dissolved salts. Wells in several countries obtain brines of similar concentration. (H.E.T.)

Ground water flow to springs and wells.
Dug wells tap unconfined water and artesian wells tap confined water. Springs occur at the contact of aquifer and less permeable rocks. This artesian spring is thermal because of the water depth. A seep is groundwater that appears at the surface.

LIFE IN SPRINGS

The environmental setting. Compared to other surface waters, springs offer a remarkably uniform habitat. The temperature varies only a few degrees between summer

Constancy of conditions

and winter, and the chemical composition and volume of flow are almost constant. Springs arising from deep layers exhibit the greatest uniformity. Seasonal change in light intensity is the greatest single factor influencing spring communities.

Many spring organisms are restricted to a small area at or just downstream from the point of emergence of the water, where conditions are most constant. Farther downstream the water increasingly resembles that of drainage streams. Except for hot springs, many springs are at the average temperature of the region in which they occur; spring water is colder than normal surface waters in summer but warmer in winter. The emerging groundwater of many springs is often deficient in oxygen but rich in carbon dioxide and other gases until aerated at the surface. If the oxygen-deficient water contains iron in solution, ferric hydroxide (ochre) will form as the water becomes oxygenated and filamentous bacteria build the sheaths that contain the iron precipitates.

The physical and chemical zonation in springs is accompanied by a corresponding zonation of plants, which, in turn, determines the animal life of the spring. Depending on the flow and the local climate, typical spring–brook communities extend from 10 to 500 metres (33 to 1,640 feet) downstream. Thus, springs are important ecological study areas because of their relative constancy near the source and their downstream gradation.

The biotic component. Spring communities typically have few species but many individuals. Three kinds of springs can be distinguished on the basis of the type of water emergence: rheocrenes, in which the water flows rapidly away from the source; limnocrenes, in which the water issues at the bottom of a pool before overflowing as a spring brook; and helocrenes, in which water seeps slowly from the ground. Rheocrenes resemble mountain brooks; they have rocky bottoms, and their organisms are adapted to living in swiftly moving water. Limnocrenes and helocrenes contain organic-rich deposits of mud or sand in which plants thrive; their communities resemble those of ponds or stream pools. The animal life of springs is continuous with that of the groundwater runoff. In limestone areas, cave animals frequently appear in springs; most such occurrences are accidental following flooding, but some animals regularly migrate between the two habitats.

Springs vary in biological productivity. Large mineral-rich springs are usually very productive; they are termed autotrophic, which means they support autotrophs, or producers, such as algae and rooted plants, which, in turn, become food for many small aquatic animals. Small soft-water springs are generally of low productivity; they are called heterotrophic because they support primarily heterotrophs, organisms that derive their energy by consuming other organisms; in this case, they subsist on leaves and other terrestrial material that falls into the spring. In hot springs, only heterotrophic bacteria occur above about 75° C (167° F); below 75° C, autotrophic blue-green algae form conspicuous mats that support bacteria and, below about 50° C (122° F), a few specialized animals.

Spring organisms characteristically are small. Even in wide-ranging species, individuals inhabiting springs are smaller than members of their species in other habitats. Size reduction in spring organisms may be a response to limited food and space. Spring representatives of cave species have degenerate eyes, loss of pigment, and well-developed tactile organs. Cave animals that occur in springs include flatworms, annelid worms, snails, isopods, amphipods, crayfishes, and fishes.

The spring as sanctuary

Springs often provide refuge for aquatic organisms following climatic changes. When extensive lakes have evaporated, isolated populations of fishes and other organisms have often managed to survive in their springs. Isolation gave rise to unique species such as a minnow represented by only a few hundred individuals in a single spring hole in Death Valley, California.

Hot-spring organisms are able to withstand both high temperatures and severe chemical conditions. The most conspicuous representatives are species of blue-green algae, whose slimy or matted growth is often tinted orange or yellow when exposed to high light intensities in the shallow outflow channels. The algal mats can accumulate because of the scarcity of decomposer bacteria and the total absence of grazing organisms in waters hotter than 45° C (113° F).

Although periods of growth and reproduction are extended in the uniform spring environment, biological activity often responds to seasonal changes in light. In Icelandic hot springs, for example, the low light intensity in winter inhibits algal growth even though water temperatures remain favourable. In the constant flow of Silver Springs, Florida, some of the most abundant invertebrates and fishes exhibit breeding cycles that are regulated by seasonal changes in daily light duration. In the spring, photosynthetic production is two to three times greater than in winter because of light differences.

While many organisms can tolerate the constant high temperatures of hot springs for varying periods, only a few can carry on an active life. The highest temperatures at which growth has been demonstrated for representative hot spring organisms is: bacteria, 95° C (203° F); blue-green algae, 74° C (165° F); protozoa, 50° to 58° C (122° to 136° F); insects, 50° C; fish, 50° C.

As already indicated, communities in autotrophic springs depend on the photosynthetic production of aquatic plants and algae. In contrast, the communities of heterotrophic springs depend on photosynthetic production of the surrounding terrestrial vegetation. Many springs, like the large limestone springs, are in a natural balance, with rapid growth of organisms and rapid consumption, resulting in a constant standing crop. Silver Springs, Florida, for example, is one of the most productive ecosystems known, its rate of total primary production by plants comparing with that of estuaries, coral reefs, moist forests, and intensive agriculture. It greatly exceeds the productivity of lakes, the oceans, coastal seas, and ordinary cultivated crops.

The high productivity of autotrophic springs is based on a constant favourable temperature, continuous supply of nutrients and removal of wastes, and the extreme clarity of water, which allows maximum light penetration. The small number of species, and consequent lack of diversity however, make spring communities especially vulnerable to disruption by introduced exotic species. (K.V.S.)

UTILIZATION

In order to obtain the benefits of a continuous flow of potable water, many human settlements have developed within easy access of springs. Many other locations remote from springs, streams, or lakes are underlain by aquifers that yield potable water to wells.

Historical uses. Springs and wells are especially valued in arid regions, and from ancient times life in deserts has centred about such watering places, or oases. Al-Khārijah, in the western desert of Egypt, probably the City of Oasis mentioned by Herodotus, was occupied by Stone Age peoples drawn there by the springs; now it has spring mounds but no longer any springs, and artesian wells provide water for the present inhabitants and their crops. In most of the so-called Fertile Crescent, between the Mediterranean Sea and Tigris River, water supplies are variable and precarious, but several localities have long had a consistent supply from springs. One of these is Damascus, Syria, reputed to be one of the oldest cities.

The tapping of springs

From ancient times cities have constructed long aqueducts from springs to meet their needs. Between 312 BC and AD 226, Rome completed 11 aqueducts, mostly underground but partly on arches, from spring sources 15 to 90 kilometres (9 to 56 miles) from the city; these water lines had a combined capacity of nearly ten cubic metres, or 2,640 gallons, per second. In North Africa during the 2nd century, Emperor Hadrian constructed a 70-kilometre (44-mile) aqueduct from the Zaghouan Springs to Carthage; the same springs now furnish part of the municipal supply of modern Tunis, Tunisia. After AD 330, rain-filled cisterns and local streams in Constantinople became inadequate for the city's increasing population; aqueducts were completed in 368 and 396 to deliver wa-

ter from springs in the Belgrade Forest, and others were constructed centuries later. Some of these aqueducts are still in use, but the city of Istanbul, as it is now called, currently relies also on surface reservoirs and wells.

Contemporary uses. Until 1930 Tehrān, the capital of Iran, obtained its entire water supply from 12 wells or *qanāt*s, which discharged 800 litres, or about 212 gallons, per second for its 200,000 inhabitants; reservoirs now serve the city. A *qanāt*, or karez, consists of a shaft dug to the water table, perhaps as much as 100 metres (330 feet) deep, in an upland area, and a tunnel with gradient sufficient for water to flow and long enough (commonly several kilometres) to bring the water to the surface on lower land. More than 2,400 years ago Darius encouraged the construction of *qanāt*s by exempting from tax for five generations the revenue produced by new *qanāt*s. Currently an estimated 40,000 *qanāt*s in Iran discharge about 600 to 700 cubic metres, or 158,000 to 185,000 gallons, per second, chiefly for irrigation.

Millions of wells supply water for drinking and domestic use, particularly in sparsely populated areas. Individual farms, villages, and towns depend chiefly on wells for water supplies. Even some cities, with populations ranging from 300,000 to 500,000 inhabitants, rely upon wells.

Most of the water pumped from wells is used for irrigation, especially in arid regions where evaporation leaves seasonal or year-round deficiencies in soil moisture and a short supply of surface water. Irrigation permits spacing of wells to distribute water over much of the area underlain by a productive aquifer. Drilled wells with power-operated pumps commonly yield 20 to 300 litres, or about five to 80 gallons, per second.

Some wells and springs are utilized as sources of energy in plants that utilize the flow from springs to generate electricity. The water from hot springs and wells in many resort areas is used for heating buildings. Geothermal heat supplies only a minor fraction of present world need for heat energy.

The value of dissolved matter

Some springs contain dissolved products of economic value. Radioactivity and mineral content contribute to the alleged therapeutic properties of some hot springs, and elaborate systems of storing and using the water are often built for such purposes. Other thermal springs are related to ore deposits. Some mercury and manganese deposits are clearly of hot-spring origin, and several ore deposits have been formed by solutions related to volcanism. Many wells have been drilled to obtain mineral products including common salt and potassium chloride. Sulfur also is mined by utilizing wells to inject water hot enough to melt the sulfur and force it to the surface.

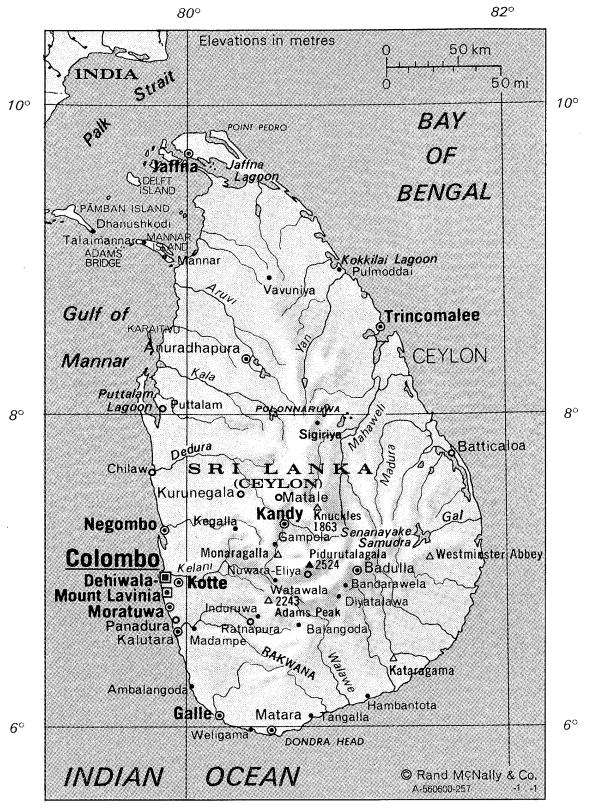
Sri Lanka (Ceylon)

Sri Lanka (known as Ceylon until 1972) is an independent island state in the Indian Ocean lying off the southeast coast of peninsular India. The Republic of Sri Lanka (Ceylon) has a parliamentary form of government and is a republic within the Commonwealth of Nations. The island is pear-shaped, with a maximum length of about 272 miles and a maximum width of about 140 miles; it has an area of 25,332 square miles (65,610 square kilometres). A shallow sea, Palk Strait, separates Sri Lanka from India; Talaimannar, on Sri Lanka's Mannar Island, is only 22 miles away from Dhanushkodi on India's Pāmban Island. A line of shoals, or sandbanks, called Adams Bridge, runs between Sri Lanka and India immediately south of this point. The capital of Sri Lanka is the port city of Colombo.

Since gaining independence from the United Kingdom in 1948, Sri Lanka has been striving to secure economic stability—a problem accentuated by a rapid population growth. The population has doubled in the past 25 years to its present total of about 13,000,000 and is increasing. This population explosion is the cause of a severe food shortage (nearly one-third of the food consumed has to be imported) as well as of unemployment and social unrest. The economy is overwhelmingly dependent upon the export of tea (which represents more than 65 percent of all Sri Lanka's foreign exchange earnings), rubber, and coconut products and is thus subject to the price fluctuations that characterize the world commodity markets.

The Sinhalese and Tamil linguistic groups

Sri Lanka is inhabited by a varied mixture of peoples who have immigrated to the island at intervals since remote times. The population, while consisting of nationals of Sri Lanka, is divided into several groups. The two principal linguistic groups are the Sinhalese, who generally are Buddhists and number over 9,000,000, and the Tamils, who generally are Hindus, numbering more than 2,500,000. Muslims (misnamed Moors), who number over 850,000, also speak Tamil. Relations between Sinhalese and Tamils have deteriorated in recent years, more as a result of current economic maladies than for historic reasons. Linguistic and religious groups—as well as the caste groups into which both Sinhalese and Tamils are divided—vie with one another to secure economic and political advantage, using pseudo-historic race myths and concepts in their struggles. Sri Lanka's ethnic and linguistic plurality is reflected in the design of its flag, which shows a yellow lion—symbolizing the legendary origin of the Sinhalese from a lion—on a red background, with a saffron stripe added to represent the Tamils and a green stripe to represent the Muslim minority.



Sri Lanka is a country of great beauty, with scenery varying from the palm-fringed beaches of its coasts to the highlands of the interior, where the famous Buddhist Temple of the Tooth is located at Kandy, once the capital of an independent kingdom. Sri Lanka has also been traditionally associated with elephants, but their numbers have decreased substantially in recent years. The name Ceylon is an English word derived from the Sanskrit Siṃhaladvīpa, meaning "Island of the Sinhalese." The Sinhalese name for the country is Laka, the Pāli name is Laṅkā and the prefix Sri is an honorific. The Tamil name is Īḻam or Ilaṅkai. (See CEYLON, HISTORY OF for historical aspects; for more detailed information on cultural aspects, see SOUTH ASIAN PEOPLES, ARTS OF; see also the city article COLOMBO.)

THE LANDSCAPE

The natural landscape. *Relief.* Like peninsular India, of which it forms a continuation, Sri Lanka is a fragment of an ancient southern continent called Gondwanaland by geologists.

Both peninsular India and Sri Lanka stand on the same continental shelf, the edge of which does not extend beyond 12 miles from Sri Lanka's coastline. This shelf is shallow, lying at a depth of between 30 and 40 feet in the Palk Strait, and attaining a maximum depth of only about 210 feet. Beyond the edge of the continental shelf the depth increases to about 3,000 feet within two miles.

The relief of the island is dominated by a highland massif (mountainous mass) situated in the southern central part of the island. This is surrounded by an inter-

mediate zone consisting of upland ridges and valleys, which are separated from the massif by well-defined scarps. The intermediate zone, in turn, is surrounded by an outer or lower coastal lowland zone, except in the southwest, where the land abuts directly onto the sea in the form of cliffs. Elsewhere there is a coastal fringe consisting of a series of lagoons, sandbars, peninsulas, dunes, and marshes. Five-sixths of the country lies at an altitude of less than 1,000 feet.

The four physiographic regions

For convenience Sri Lanka may be divided into four regions—the central highlands, the southwest, the east, and the northern lowlands. The central highlands, which were formed by faulting, have some fine scenery. The highest point is Pidurutalagala, a rounded peak 8,281 feet (2,524 metres) high; more renowned, however, is the pyramidical Adams Peak, 7,360 feet (2,243 metres) high, which lies to the southwest of Pidurutalagala and is a centre for pilgrimages by Buddhists, Hindus, Muslims, and even Christians.

The southern edge of the central massif consists of a rim of steep scarp running east to west and curving southward in the centre; at one point, called the World's End, the scarp wall forms an almost sheer drop of about 5,000 feet. To the north of the central highlands lies Knuckles Mountain, which is separated from the highlands by the valley of the eastward-flowing Mahaweli Ganga, Sri Lanka's largest river.

The southwest region is also mountainous and includes the Rakwana, or Bulutota, Range, a continuation of the central massif. Its topography consists of elongated ridges, parallel valleys, and a trellis (crisscross) drainage pattern.

The east consists of an undulating plain, dotted with isolated hills or inselbergs (steep-sided hills that remained after the remainder of the landscape had been scoured by erosion). Among these hills are Westminster Abbey (named for its shape), Monaragalla, and Kataragama.

The northern lowlands region consists of rolling countryside intersected by rivers and marked by occasional ridges and isolated hills. In the extreme north, the Jaffna Peninsula, which is made of limestone, is underlain by a coral reef. Several offshore islands have the same formation.

Drainage. The rivers of Sri Lanka are noted for their number rather than for their size. They radiate from the central highlands like the spokes of a wheel, except for the upper course of the Mahaweli Ganga, which has developed different characteristics from the fault movements that have shaped the terrain. Most of the rivers, however, tumble down in a series of waterfalls and cascades before reaching the plain. The Mahaweli Ganga is only 206 miles long and Aruvi Aru 104 miles long; the other rivers, of which there are more than 100, are all less than 100 miles in length. The mouths of the rivers are choked with sand.

The rivers

Geology. Forming part of a very old landmass, Sri Lanka has experienced a long series of geological events, including folding movements as well as uplifting movements that have resulted in the fracturing and faulting of rocks. These movements, in addition to providing differences in rock composition, account for the scarps that separate the different elevation levels. Climate has also exerted an influence upon the sculpturing of the land surface.

Nearly nine-tenths of the island is floored by rocks of Precambrian age (570,000,000 to 4,600,000,000 years old), consisting of schists (rocks changed by heat and pressure at depth and having a banded and foliated structure) and gneisses (imperfectly foliated rocks changed by heat and pressure, with alternating light and dark bands differing in mineral composition, and more coarsely grained than schists), overlain by sediments changed by heat and pressure. Among the sedimentary rocks, only a few outcrops of shale and sandstone of Jurassic age (from 136,000,000 to 190,000,000 years old) are to be found. These occur in the Tabbowa and Andigama areas; some coal has been found in them. The north and northwest areas are floored by sedimentary limestone of Miocene age (from 7,000,000 to 26,000,000 years old). Gravel deposits adjoining this sedimentary limestone belt may have been laid down in periods when the area lay under a shallow sea during the last 2,500,000 years. Sand dunes and alluvium are commonly deposited in

coastal areas. Some coral formations occur at Mathagal in the north and in the Madampe-Ambalangoda area in the southwest.

Climate. Sri Lanka lies between 6° and 10° north of the Equator, and consequently might be expected to experience an equatorial type of climate. Its position in relation to the Indian subcontinent and to the neighbouring seas, however, has resulted in modification of the climate, with a regime of monsoons (rain-bearing winds) being superimposed upon the equatorial regime. Further modifications are caused by relief.

Rainfall is the most important element in the climate. Although Sri Lanka is a small island, the distribution of rainfall is not uniform, varying from more than 200 inches to less than 40 inches a year in different parts. Further climatic variations in different places are the result of the seasonal incidence of rainfall. Because of elevation and aspect, the central and southwestern parts receive the most rain. Some strips along the extreme northwest and southeast coasts are described as arid because they receive less than 50 inches of rainfall a year; while this is a relatively large amount, much of the moisture is lost through evaporation, in addition to which there are several rainless months. Much of the rain is also lost because it runs off the surface. Cultivation in these areas is restricted to the short rainy season, except when irrigation is resorted to.

The southwest monsoon blows from May to October, and from December to March the northeast trade winds —locally known as the northeast monsoon—prevail. The monsoons are often irregular, beginning or ending earlier or later than expected, thus adding to the hazards of agriculture. Between the monsoons—from approximately October to December and again from March to May—normal equatorial conditions prevail.

The five climatic zones

While the north and east of the island are generally drier, and the south and west wetter, five climatic zones may be distinguished in terms of rainfall: the wet lowlands and the wet highlands in the west; the dry lowlands and the dry highlands in the east; and the arid zones, which, as already mentioned, are in the extreme northwest and southeast. At Colombo in the wet lowlands, annual rainfall amounts to 90 inches, and the average annual temperature is 81° F (27° C); at Watawala in the wet highlands, the annual rainfall amounts to 218 inches, and the average temperature is 65° F (18° C); at Trincomalee in the dry lowlands, annual rainfall averages 64 inches, and the temperature 82° F (28° C); at Mannar, on the island of Mannar in the arid zone, rainfall averages 40 inches a year, and the temperature averages 82° F (28° C). Nuwara Eliya in the wet highlands experiences some night frost but no snow. In Sri Lanka in general, temperatures vary little at different seasons; the annual and diurnal (daily) temperature variation does not exceed about 8° F (4° C). Most places in Sri Lanka have a high relative humidity.

Soils. In the wet zone, climate is the dominant factor in the formation and characterization of soils. Lateritic loams (reddish leached iron-bearing soils, composed of a mixture of clay, silt, sand, and organic matter) are the most common. They are generally well-drained, friable when dry, but poor. In the dry zones, the same types of rocks result in semilateritic and nonlateritic earths. In the sedimentary limestone areas, thin mantles of red loams, rich in lime, are common. Along the lower courses of the rivers, and on their floodplains, rich rice soils occur. Sandy soils are prevalent on the coastal dunes and sandbars.

Vegetation and animal life. As Sri Lanka has been occupied by man for many centuries, the natural vegetation cover has been altered by cultivation. The open, rolling grasslands, known as *patanas*, in the eastern highlands of the Uva region are said to have resulted from the destruction of the forests that previously grew there.

Nearly 70 percent of the island, however, is still covered with forest, natural grassland, and wasteland. The best developed evergreen forests are to be found in the wet zone; the larger part of the dry zone forests are of poor composition.

Animal life, once abundant, is now becoming depleted. The elephant population has dwindled to a few hundred. The common forest animals are deer, leopards, bears, jackals, monkeys, wild boars, cheetahs, and wild buffalo.

Traditional regions. The present-day pattern of population distribution bears little resemblance to that of the period before the advent of the Europeans, which ended with the arrival of the Portuguese in 1505. Earlier Sinhalese and Tamil settlements were confined to the dry lowlands of the north and were focussed on Anuradhapura. This environment resembled that of the settlers' original homelands in South India, where rice cultivation was based on irrigation from water tanks. The forested wet zone of southern Sri Lanka remained almost uninhabited until plantation agriculture was introduced by the British in the early 19th century.

The landscape under human settlement. *Rural settlement.* Individual villages are surrounded with cultivated plots and orchards, from which vegetables, fruits, and spices are obtained. Elsewhere, temporary (shifting) cultivation is practiced; after being used for from three to five years, the fields are allowed to revert to forest again.

Urban settlement. In 1971, nearly one-fourth of the total population was urban, and nearly half this number lived in towns in the Colombo region alone; the population of the city of Colombo is over 562,000. The urban population in other districts in relatively small. In the Kalutara district, to the south of Colombo, it is 161,000; in Galle, in the extreme southwest, it is 158,000; in Jaffna, in the extreme north, it is 236,000; at Matara, in the extreme south, it is 66,000; and at Batticaloa, in the east, south of Trincomalee, it is 71,000. It is less than 55,000 in each of the other 16 districts.

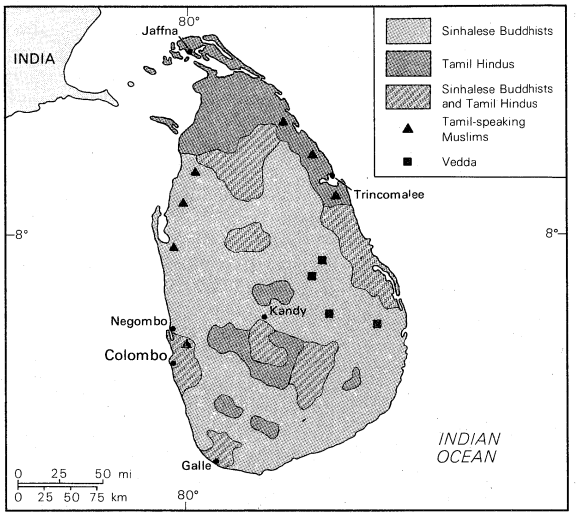
The urban population

PEOPLE AND POPULATION

Groups historically associated with the contemporary country. *Ethnic and linguistic groups.* As already mentioned, the two principal linguistic groups in Sri Lanka are the Sinhalese and the Tamils. The Sinhalese number over 9,000,000, of which over 5,000,000 are low-country Sinhalese and about 4,000,000 up-country, or Kandyan, Sinhalese. The Tamils number more than 2,500,000; they are divided about equally into Sri Lanka Tamils and Tamils of Indian origin. The Muslims, who as mentioned are sometimes miscalled Moors, are partly descended from Arab seafarers; they number over 850,000, and their mother tongue is Tamil. Other groups are the Burghers, who are of mixed Dutch and Eurasian origin, and Eurasians, who together number about 44,000; Malays, who number about 42,000; and a few small groups, numbering about 14,000 altogether, of Europeans who have adopted Sri Lanka nationality, Indians, and others. The Veddas, who are believed to be the aboriginal inhabitants of the island, are very few in number and are now practically indistinguishable from other groups, with whom they have intermarried. The Tamils of Indian origin are treated as stateless and have no civil rights. By the terms of an agreement with the Indian government in 1964, more than 500,000 of them are to be repatriated to India within 15 years, while 300,000 of them will be allowed to apply for citizenship in Sri Lanka.

Religious groups. The Sinhalese are generally Buddhists and the Tamils usually Hindus. Christians of all denominations number almost 987,000, while Muslims number approximately 910,000.

Archaeology. Geographically and culturally Sri Lanka is closely related to India, with which its sequences of prehistoric culture have much in common. Artifacts, probably relating to Middle Paleolithic times, have been found in different parts of the country, although their authentication must await discovery in well-stratified contexts. Data on later cultures are most numerous.



The outstanding feature of this culture is its highly developed stone industry, which shows traces of a Middle Stone Age tradition, such as is found on the mainland of India, combined with Late Stone Age techniques.

In the topmost layer of many sites, iron tools and pottery are found. Their exact age has yet to be determined,
